Pancreatic Ductal Adenocarcinoma (PDAC) is the 3rd leading cause of cancer-related deaths in the US, with a five-year survival rate of 12%. Barriers to treatment include the highly fibrotic tumor microenvironment (TME), the high interstitial pressure which acts to collapse the blood vessels, and the influx of immunosuppressive immune cells. Within this immune milieu, we find that the most abundant are tumor-associated macrophages (TAMs). These TAMs display a phenotype similar to anti-inflammatory (M2-like) macrophages. Despite TAMs exerting an immunosuppressive function within the TME, there is not a complete overlap with the characteristics associated with M2 macrophages. Interestingly, TAMs still display many markers associated with the pro-inflammatory (M1-like) macrophages. This dichotomy suggests there may be a level of plasticity within the macrophage compartment that can be exploited to lead to better tumor control. Previous studies have shown a connection between arginine metabolism and macrophage effector function along the M1/M2 axis. In macrophages, arginine can be broken down in two ways: via iNOS into nitric oxide, which aids in effector function, or via Arginase 1 (Arg1) into ornithine and later proline, which is an essential component of the extracellular matrix (ECM). This study seeks to elucidate how metabolic perturbations influence macrophage function and phenotype. Here we observed that changes in oxygen availability and glucose abundance shifted macrophage expression of iNOS and Arg1. In vivo we found that conditionally knocking out Arg1 in the myeloid compartment leads to lower fibrosis when inducing inflammation in the pancreas. Furthermore, macrophages polarized with PDAC cancer-conditioned media display a sharp increase in Arg1 expression as compared to unpolarized macrophages, as well as increased resistance to both glycolytic inhibitors and mitochondrial inhibitors. This preliminary data demonstrates an important link between macrophage metabolism and function in the context of pancreatic disease.

#1600 Interception of pro-tumorigenic glycan signaling in pancreatic cancer.

Jasper Hsu, Hyemin Song, Kristina Peck, Chelsea Bottomley, McKenna Stamp, Shira Okhovat, Dannielle D. Engle

Salk Institute, La Jolla, CA

Pancreatic cancer is a deadly malignancy. We have setup a pipeline to interrogate cancer cell intrinsic and extrinsic mechanisms contributing to treatment response. Using a combination of mouse and human organoids models together with *in vivo* investigation, we have systematically dissected key signaling hubs driving pro-tumorigenic cancer cell intrinsic features as well as remodeling of the tumor microenvironment (TME). We found that the glycan epitope, CA19-9, drives pancreatic inflammation, cancer, and metastasis. CA19-9 drives pro-tumorigenic intrinsic features in part through CA19-9 modification of the secreted glycoprotein Fibulin 3. We have also discovered direct and indirect mechanisms through which CA19-9 causes remodeling of the TME. Specifically, CA19-9 elevation causes expansion of all cancer associated fibroblast (CAF) subtypes, including an increase in antigen presenting CAFs and resulting increase in regulatory T cells. Further, there are dramatic increases in tumor associated macrophages (TAMs) derived from both inflammatory monocytes as well as tissue resident macrophages. To delineate the mechanisms by which these TME changes are mediated, we use novel co-culture model incorporating macrophages, organoids, and fibroblasts (MOrF). Blocking CA19-9 signaling *in vitro* and *in vivo* reverses these TME alterations. These changes to the TME are mediated through indirect effectors as well as previously unknown CA19-9 modified proteins. Overall, we elucidate previously unexplored mechanisms driving pancreatic tumorigenesis while also uncovered vulnerabilities for therapeutic exploitation.

#1601 The role of complement in pancreatic cancer cachexia.

A. C. D'Lugos, C. Callaway, S. M. Judge, **A. R. Judge**;
University of Florida, Gainesville, FL

Cancer cachexia is a multifactorial condition characterized by skeletal muscle atrophy and dysfunction that impairs longevity and quality of life for the vast majority of cancer patients. Recently, we discovered through unbiased proteomic analyses that the complement system is activated in the skeletal muscle of cachectic pancreatic cancer patients. Therefore, the purpose of this study was to investigate the role of complement in pancreatic cancer cachexia. To accomplish this, we obtained genetically modified, C57Bl6/J congenic mice lacking the central regulator of complement, C3 ($C3^{-/-}$ mice). Wild-type (C57Bl6/J, WT, n=12) and $C3^{-/-}$ mice (n=11) (male, 12 weeks old) received orthotopic injections of mouse pancreatic cancer cells (KPC) into the pancreas, and as non-cancer controls, WT (n=8) and $C3^{-/-}$ (n=4) mice received injections of PBS into the pancreas. Mice were monitored daily and euthanized at IACUC-mandated tumor endpoint (body condition score ≤ 2; range: 14-15 days). *In-vivo* diaphragm function was assessed immediately prior to euthanasia via M-mode ultrasound. Skeletal muscles (soleus, SOL; *tibialis anterior*, TA; diaphragm, DIA) were harvested and *ex-vivo* contractile function was assessed on strips of costal diaphragm. Diaphragmatic excursion and respiratory rate were reduced with KPC tumor burden in WT mice, but preserved in $C3^{-/-}$ mice. Deletion of C3 did not influence the KPC-induced reduction of body mass or KPC tumor growth. Atrophy of limb muscle mass (SOL, TA) and fiber size (TA) during KPC tumor burden was attenuated in $C3^{-/-}$ mice. Maximal specific force of DIA was greater in $C3^{-/-}$ versus WT KPC-bearing mice. KPC tumor burden increased collagen content in the DIA of WT mice, but not $C3^{-/-}$ mice. Diaphragm fiber size was reduced in WT KPC-bearing mice, but preserved in $C3^{-/-}$ mice. KPC tumor burden induced significant increases in immune cell (CD45+) infiltration and fibroadipogenic progenitor cell (PDGFRa+) abundance in the DIA of WT tumor-bearing mice, but to a lesser extent in $C3^{-/-}$ mice. These findings suggest complement activation is causative in pancreatic cancer-induced skeletal muscle wasting and dysfunction. Inhibition of complement during cancer cachexia may possess therapeutic potential for the preservation of skeletal muscle mass and function.

#1602 Leukemia inhibitory factor (LIF)-factor XIIIA mediated macrophage-stromal crosstalk in pancreatic cancer.

N. Jaferi[1], S. Mehra[2], V. Krishnamoorthy[2], S. Jinka[2], A. Bianchi[2], V. T. Garrido[2], L. A. Nivelo[2], B. Yuguang[2], N. S. Nagathihalli[2];
[1]Yale College, New Haven, CT, [2]University of Miami, Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy marked by a highly immunosuppressive tumor microenvironment (TME). Macrophages are known to promote immunosuppression and exhibit a profibrotic transcriptional profile with potential involvement in extracellular matrix (ECM) remodeling. Previously, we identified hyperactivation of cancer cell intrinsic cyclic AMP response element binding protein 1 (CREB) regulates leukemia inhibitory factor (LIF) to mediate macrophage infiltration and polarization within the TME of PDAC. Subsequently, we observed that disrupting LIF-LIF receptor (LIFR) signaling therapeutically not only diminishes the infiltration of tumor-associated macrophages (TAMs) but also results in a decrease in ECM deposition. This study delves into the potential regulatory pathway through which LIF induces remodeling of the ECM within the PDAC TME.

Methods: We targeted LIF-induced macrophage-stromal crosstalk using the LIFR antagonist (EC359) in an orthotopically tumor implanted LSL-$Kras^{G12D/+}$; $Trp53^{R172H/+}$; $Pdx1^{Cre/+}$ (KPC) mice model of PDAC. Sirius red staining in tumor sections was performed to assess ECM (collagen) deposition. Moreover, we performed RNA transcriptomics-based analysis of recombinant (rLIF) induced bone marrow derived macrophages harvested from syngeneic C57BL/6 mice. The Cancer Genome Atlas (TCGA) pancreatic cancer (PAAD) data set along with single-cell RNA sequencing (scRNA seq) were employed to assess the expression of major downstream targets of LIF. To validate the RNA-seq results, we conducted immunohistochemical analysis (IHC) on mouse PDAC tissue sections and quantitative polymerase (qPCR) analysis on RAW 264 macrophage cell line treated with rLIF or KPC $CREB^{WT}$ PDAC tumor cells conditioned media.

Results: We observed a drastic decrease in both TAM infiltration and, of note, ECM deposition in orthotopically implanted KPC pancreas tumor mice tissue treated with EC359 as compared to vehicle. Mechanistically, our RNA-seq analysis unveiled a significant upregulation of *Factor XIIIA* (FXIIIa), a major downstream target of LIF. Notably, TCGA data revealed that *FXIIIa* mRNA expression is upregulated across PDAC tumors marked by poor survival outcomes. Moreover, scRNA seq and IHC established that TAMs highly express FXIIIa in the PDAC TME. In exploring the effect of LIF-LIFR signaling in the ECM, mouse RAW 264.7 macrophage lines incubated in high LIF conditions confirmed transcriptional upregulation of ECM-associated proteins such as *FXIIIa* as well as fibronectin.

Conclusion: Our investigation provides valuable insights into the possible mechanism by which LIF triggers ECM remodeling, thereby contributing to the desmoplastic stroma. Significantly, our findings propose that LIF-regulated FXIIIa signaling in macrophages serves as a plausible mediator of the LIF-induced ECM remodeling in PDAC.

#1603 Intra-pancreatic fat promotes the progression of PDAC by activating thermogenesis.

X. Yin, Y. Chen, R. Xu, C. Hu, **C. Wang**, Y. Zhao;
Peking Union Medical College Hospital (PUMCH), Beijing, China

Background: The presence of minimal intra-pancreatic fat deposition (IPFD) in the healthy human pancreas has been demonstrated in numerous studies. But excess IPFD, or fatty pancreas disease, leads to a wide array of diseases, including but not limited to diabetes, pancreatitis, and pancreatic ductal adenocarcinoma (PDAC). Remarkably, PDAC patients with excessive intra-pancreatic fat accumulation are commonly associated with a poor prognosis compared to those with minimal deposition. However, the interaction between tumor and intra-pancreatic adipose tissue remains elusive. Here, we evaluated the pancreatic fat infiltration in normal people and patients with PDAC respectively, and explored the mechanism of how intra-pancreatic fat affects the progression of PDAC.

Methods: Magnetic resonance imaging (MRI) and clinical biopsy specimens were used to assess the degree of pancreatic fat infiltration in PDAC patients and healthy control individuals. The C57BL/6J mice injected orthotopically with KPC cells and adipocytes, high-fat diet (HFD)-induced obesity *KC (Pdx1-Cre; $Kras^{LSL\text{-}G12D/WT}$)* mice, and *KC; ob/ob* mice were established to dynamically observe how adipocytes affect tumor progression in vivo. The snRNA-seq of tumor samples and proteomics of conditional medium of PDAC cell lines were performed to identify the mechanism of interaction between cancer cells and adipocytes.

Results: We found that patients with PDAC presented excess intra-pancreatic fat deposition more frequently than healthy individuals, and the degree of fat infiltration was positively correlated with the tumor burden of PDAC patients. HFD-induced obesity *KC* mice and *KC; ob/ob* mice showed a higher degree of IPFD, which contributed to tumor growth and low survival rates of mice. Additionally, the expression of uncoupling protein 1 was upregulated in PDAC patients and *KPC (Pdx1-Cre; $Kras^{LSL\text{-}G12D/WT}$; $p53^{LSL\text{-}R172H/WT}$)* mice compared to normal controls. Constantly, the snRNA-seq of PDAC samples demonstrated the increase in thermogenic signature. In vitro, C3H10T1/2 cells treated with conditional medium from pancreatic cancer cell lines or co-cultured with pancreatic cancer cell lines showed increased expression of browning markers and elevated oxygen consumption rate. Specifically, combined analysis of the proteomic of T3M4 and CFPAC-1 conditional medium and the snRNA-seq revealed that pancreatic cancer cells secreted integrin β4 (ITGB4) to improve the thermogenesis of intra-pancreatic adipocytes (IPA), which in turn promoted cancer cell progression.

Conclusion: Parts of PDAC patients present excess intra-pancreatic fat accumulation, a process associated with tumor growth and poor prognosis. Mechanistically, pancreatic cancer cells activate the thermogenesis of IPA by secreting ITGB4, and then the thermogenetic adipocytes fuel the progression of the tumor in response.

#1604 Cancer-associated fibroblasts modulate T cell killing activity & phenotype in PDAC.

F. Zayou[1], H. Pearce[1], S. Nicol[1], S. Margielewska-Davies[1], S. Powell-Brett[2], R. Brown[2], J. Zuo[1], K. Roberts[2], H. M. McGettrick[1], P. Moss[1];
[1]College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom, [2]Queen Elizabeth Hospital Birmingham, University Hospital Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Background: Pancreatic ductal adenocarcinoma (PDAC) is highly aggressive malignancy characterised by its abundant extracellular matrix and diverse stromal cell components such as cancer associated fibroblasts (CAFs). CAFs play a pivotal role in shaping the tumour microenvironment and influencing the behaviour of immune cells, particularly T cells, through various mechanisms. The impact of CAFs on T cells is multifaceted as they can exert both pro- and anti-tumoral effects, influencing the delicate balance between immunosurveillance and immune evasion. In this study, we examined the phenotype and function of T cells when co-cultured with CAFs and Adjacent-normal fibroblasts (ANF) isolated from primary PDAC tissue following surgical resection.
Methods: Tumour and juxta-tumoral tissue from patients underwent digestion into a single cell suspension. Subsequently, the isolated fibroblasts were cultured and stained with a 22-plex antibody panel designed for flow cytometry. Additional functional assays involved co-culture of CAFs and ANFs with unstimulated or anti-CD3/CD28 stimulated allogeneic T cells. Cell proliferation rates were quantified through the CFSE assay, while the T cells were simultaneously stained to distinguish CD4+ and CD8+ T cells subpopulations. Additionally, the expression of key co-stimulatory molecules: CD69, NKG2D and DNAM-1 and the co-inhibitory molecule: PD-1 were assessed, providing a thorough examination of the immune dynamics within the tumour microenvironment.
Results: Flow Cytometry analysis revealed a distinct expression profile in CAFs compared to ANFs, with CAFs expressing higher levels of FAP and CD29. The CFSE assay further revealed that CAFs induced T cell proliferation of resting T cells with no significant increase in stimulated T cells. Notably, this co-culture led to a highly differentiated phenotype in both unstimulated and stimulated CD4+ and CD8+ T cells, characterised by elevated expression of activating markers (CD69 and NKG2D) and the inhibitory molecule PD-1. These findings suggest a dynamic interplay between fibroblasts and T cells in the tumour microenvironment, influencing both the proliferation and phenotypic aspects of T cell behaviour.

#1605 Oncolytic hsv-1(vc2) gm-csf regulates the proinflammatory profile suggestive of an immunomodulatory effect in PDAC cells.

N. Chintala Ramulu, S. Thota, B. Stanfield, K. Kousoulas, J. Francis;
Louisiana State University, Baton Rouge, LA

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive disease that is projected to be the second leading cause of cancer-associated deaths by 2030. Owing to its intrinsic immune evasive tumor microenvironment (TME), PDAC is regarded as an immunologically “cold” tumor with a significant therapeutic challenge. Although 5-fluorouracil or gemcitabine-based chemotherapy is considered as standard of care, harnessing immunological pathways may potentially convert PDAC to a “hot” tumor, thereby providing survival advantage to patients. Lately, the use of oncolytic virus has proven to be an alternative strategy to activate the innate immune response within the TME coupled with its cytotoxic effect against the cancer cells. The FDA approval of T-VEC for the treatment of stage IIIB/IV melanoma validates the preceding argument. In this study, we have investigated the effect of herpes simplex virus type-1 (HSV-1) (VC2) overexpressing granulocyte-macrophage colony-stimulating factor (GMCSF), HSV-1VC2GM-CSF in the murine KRAS, p53, and Cre (KPC), and human MIA PaCa-2 pancreatic carcinoma cells. Following a 24h infection of the KPC and MIA PaCa-2 cells with the HSV-1VC2GM-CSF, the observed cytopathic effects (CPE) included cell rounding, detachment, and aggregation as compared to the wild-type HSV-1VC2 treated or the uninfected control cells. The CPE effect of HSV-1VC2GM-CSF was proven to be a more direct and dynamic response against these cells. In the next steps, the viral titers were determined to be 9.6E7 pfu/ml, 1.26E7 pfu/ml for HSV-1VC2 and VC2GM-CSF respectively. The infection of VC2GM-CSF 0.1, 1.0 and 10 MOI in KPC cells resulted in a significant increase in the expression of proinflammatory markers including interleukin 10 (IL-10), cyclooxygenase -2 (COX-2) and iNOS at the gene level in contrast to the uninfected controls. This was coupled with an increase in the expression of Fas ligand (FasL) in the treated cells. Intriguingly, the treated cells showed a significant upregulation of programmed death ligand (PD-L1). Interestingly, in a 3D-coculture of KPC and RAW264.7 cells the expression of PD-L1 was significantly upregulated. Based on the evidence presented here, it is speculated that VC2GM-CSF-induced proinflammatory profile in KPC and Mia PaCa-2 cells converts to an immunomodulatory one characterized by the regulation of FasL and PD-L1. The effect of VC2GM-CSF in a PDAC organoid model to understand the interplay between the tumor and the stromal cells in response to the virus is currently underway.

TUMOR BIOLOGY: Tumor Evolution in Space and Time
Poster Session

#1609 Inferring the T cell repertoire dynamics in non-small cell lung cancer metastases.

C. Richard[1], S. Hessey[1], C. Naceur-Lombardelli[1], S. Veeriah[1], G. Nageswaran[2], C. Hiley[1], S. Quezada[1], B. Chain[2], TRACERx and PEACE Consortia, C. Swanton[3], M. Jamal-Hanjani[1];
[1]University College London (UCL) Cancer Institute, London, United Kingdom, [2]University College London (UCL) Division of Infection and Immunity, London, United Kingdom, [3]The Francis Crick Institute, London, United Kingdom

Non-small cell lung cancer (NSCLC) is a highly complex disease, characterized by extensive genomic heterogeneity and dynamic evolution under therapeutic pressure. This evolution can lead to alterations in the antigens expressed by cancer cells, thereby influencing the T cell repertoire (TCR) as T cells expand in response to foreign antigens. Despite the central role of TCR in cancer progression and treatment response, only few studies have investigated the temporal and spatial changes in the TCR repertoire. In this study, we delve into the role of the TCR repertoire in metastatic progression in NSCLC. We conducted TCR sequencing of multiregion primary tumors, normal-adjacent tissues, and post-mortem metastases sampled from a cohort of 22 patients enrolled in the TRACERx and PEACE studies. Our findings reveal that primary tumor regions and normal-adjacent tissues exhibit similar fractions of expanded clonotypes. However, a higher proportion of expanded intratumoral TCRs were privately expanded in the tumor samples, suggesting a unique TCR landscape within the tumor microenvironment. The TCR repertoire across multiregion primary tumor samples was largely homogenous, with most expanded clonotypes shared across at least two regions. However, only a small fraction of these clonotypes were tracked in metastases, indicating a significant shift in the TCR repertoire during metastatic progression. Notably, the expanded clonotypes that persisted over time from early to late stage disease were significantly enriched for clonotypes ubiquitously expanded in the primary tumor across all regions. This was not shown to be associated with an increased likelihood of generation via VDJ recombination, suggesting a tumor-specific immune response. The expanded TCR repertoire in the postmortem metastases clustered mainly by anatomical site, suggesting an immune response driven by tissue-resident T cells. Moreover, we found a significant positive correlation between repertoire dissimilarity and genomic distance, suggesting that T cell clones track with tumor clones across spatial sites within patients. Our study demonstrates the significant spatiotemporal dynamics of the TCR repertoire during the metastatic progression of NSCLC, orchestrated by both tissue-resident T cells and the genomic evolutionary trajectory of tumors. Such an exploration could provide valuable insights to inform future strategies for immunotherapy treatments and enhance clinical monitoring of patients.

#1610 Elucidating tumor evolution and heterogeneity in metastatic bladder cancer from rapid autopsies.

P. Itagi[1], S. Arora[1], T. Persse[1], M. Yang[1], P. Galipeau[1], Y. Lin[2], F. Vakar-Lopez[3], J. K. Lee[4], P. Grivas[3], R. B. Montgomery[3], J. L. Wright[3], H.-M. Lam[3], A. Hsieh[1], G. Ha[1];

[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]Aarhus University, Aarhus, Denmark, [3]University of Washington, Seattle, WA, [4]David Geffen School of Medicine at UCLA, Los Angeles, CA

Background: Bladder Cancer is a highly prevalent cancer with staggering mortality of about 20%. Metastatic BLCA (mBLCA) with variant histologies are aggressive and have a poor prognosis. The extent and impact of tumor heterogeneity in these variant subtypes are not fully understood. This work explores the intricate characterization of intra-patient and inter-patient tumor heterogeneity through genomic and transcriptomic analyses, drawing insights from a unique rapid autopsy cohort comprising 20 patients. The resulting revelations provide critical perspectives on heterogeneity and clonal evolution in mBLCA, underscoring the essential role of understanding these dynamics for the development of personalized treatment strategies.

Approach: Our research focuses on the genetic and molecular characteristics of these tumors, including the vast landscape of tumor heterogeneity, clonal evolution, genomic alterations, mutational signatures, and structural variants. Within the tumor microenvironment, we identified diverse cell populations with distinct genetic profiles. A detailed examination of mutational signatures sheds light on the specific processes underlying genetic alterations, while the investigation of structural variants elucidates their consequential role in cancer development and progression. Advanced bioinformatics tools are deployed to process and interpret the vast genomic and transcriptomic datasets, facilitating the identification of clonal populations, their genetic features, and the trajectory of clonal evolution. Furthermore, statistical models are employed to discern correlations between mutational signatures, treatment responses, and clinical outcomes.

Summary: The study unveils substantial inter-patient heterogeneity and discernible differences in mutational signatures, revealing intriguing correlations with treatment responses. These variations are intricately connected to underlying genomic alterations, copy number alterations, and gene expression patterns, offer a detailed perspective on the molecular landscape of mBLCA.

Conclusion: This multi-omics exploration stands as the most extensive study of its kind, leveraging rapid autopsy samples of metastatic variant histology BLCA. The research provides unprecedented resolution of genomic alterations and intra- and inter-patient tumor heterogeneity. The exploration of clonal evolution enhances our appreciation of the temporal dynamics of tumor progression, establishing a robust foundation for future therapeutic interventions precisely targeting evolving tumor clones. As we advance into an era of personalized medicine, these findings pave the way for tailored therapeutic strategies in the challenging landscape of metastatic variant histology Bladder Cancer.

#1611 DNA methylation co-operates with genomic alterations during non-small cell lung cancer evolution.

F. Gimeno-Valiente[1], C. Castignani[2], E. L. Cadieux[2], N. E. Mensah[2], O. Chervova[3], M. Jamal-Hanjani[1], N. McGranahan[1], S. Beck[3], J. Demeulemeester[4], M. Tanic[1], C. Swanton[3], P. Van Loo[2], **N. Kanu**[1];

[1]University College London (UCL), London, United Kingdom, [2]The Francis Crick Institute, London, United Kingdom, [3]University College London, London, United Kingdom, [4]VIB - KU Leuven Center for Cancer Biology,, Leuven, Belgium

Aberrant DNA methylation patterns have been described in nearly all human cancers, yet their interplay with genomic alterations during tumor evolution is poorly understood. To explore this crosstalk, we performed reduced representation bisulfite sequencing on 217 tumor regions from 59 patients from the TRACERx study, all with matched adjacent normal tissue, to deconvolve tumor methylation rates. We combined two new metrics for integrative evolutionary analysis with DNA and RNA sequencing data. I-TMD (intra-tumoral methylation distance) quantifies intra-tumor DNA methylation heterogeneity. MR/MN classifies genes based on the rate of hypermethylation at regulatory (MR) versus non-regulatory (MN) CpGs, to identify driver genes exhibiting recurrent functional hypermethylation. We observed early DNA methylation of VIPR2 and ZNF714 co-occurring with driver mutations in CDKN2A and STK11, respectively. Finally, we found DNA methylation-linked dosage compensation of essential genes co-amplified with neighboring oncogenes. Our identification of hypermethylated driver genes under positive selection may open new avenues for therapeutic stratification of patients with non-small cell lung cancer.

#1612 Timing ecDNA acquisition across cancer.

A. R. Lynch, P. Van Loo;
UT MD Anderson Cancer Center, Houston, TX

Extrachromosomal DNA (ecDNA) are acentric, circular DNA fragments which form after DNA double strand breaks. They segregate randomly during mitosis, promoting high-level amplifications of positively selected oncogenes such as *EGFR* and *MYC*. The prevalence of ecDNA across several cancer types, such as glioblastoma and sarcoma, has made promising therapeutic targets. However, while DNA damage is a hallmark of nearly all cancers, the formation of ecDNA is not, and the determinants for ecDNA acquisition are unclear. Furthermore, whether the timing of tumors' acquisition of ecDNA (i.e., early or late clonal or sub-clonal) affects patient survival and drug resistance is unclear. Here, we leverage orthoganol information from ecDNA amplicons, such as mutation allele frequency and sequence synteny, to develop computational methods for elucidating the evolutionary history of ecDNA. Applying these to several cancer subtypes in TCGA, we find that most ecDNAs arise early in tumor evolution. We expect these results will help identify determinants of ecDNA acquisition and its temporal influence on patient survival.

#1613 Evolution of mutations in the antigen presentation machinery across cancers.

W. Chen[1], T. Baker[2], Z. Zhang[1], P. Van Loo[1], **S. S. Gu**[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]The Francis Crick Institute, London, United Kingdom

Immune escape is a critical hallmark of cancer progression. Under immunosurveillance, a subset of cancer-associated antigens or neoantigens are presented to the cancer cell surface via the antigen presentation machinery (APM) for recognition by antigen-specific T cells. During clonal evolution, cancer cells can evade such immunosurveillance by suppressing or ablating the APM. The defects in APM can further cause resistance to cancer immunotherapies and is associated with worse prognosis. Understanding how the defects in APM emerge and further shape the evolution of cancers is critical for devising strategies to overcome such immune escape mechanisms. However, it is not known when mutations in the APM occur along the history of cancer clonal evolution. We utilized a molecular archeology of cancer approach to reconstruct the evolution history of mutations in APM across 38 cancer types using whole-genome sequencing data from PCAWG. Genetic alterations in the APM occur in nearly 30% of patients, with varying frequencies and associations with immune infiltration across cancer types. Employing a League model to compare the timing of genetic events, we found that APM mutations can be early clonal, late clonal, or subclonal along cancer development. Further examination of individual tumors identified driver mutations that can happen before or after APM mutations along cancer development. Our study reveals the evolution of APM mutations in different cancers in a genetic context-aware manner. This information can contribute to optimizing personalized immunotherapy.

#1614 Macroscopic clonal expansion with driver mutations in normal human endometrium.

K. Watanabe[1], N. Kakiuchi[1], K. Ieiri[1], H. Maeda[1], T. Hirano[1], S. Kitamura[1], M. Taki[1], K. Yamanoi[1], R. Murakami[1], K. Yamaguchi[1], J. Hamanishi[1], H. Tanaka[2], S. Miyano[2], M. Mandai[1], S. Ogawa[1];

[1]Kyoto University, Kyoto, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan

Introduction: The epithelial cells of the endometrium undergo rapid proliferation and shedding each month under the influence of estrogen and progesterone. Recent studies have demonstrated pervasive driver mutations in the endometrium with ageing. However, previous observations have been limited to the microscopic scale, and it is still unclear how clonal expansion occurs over the entire endometrium and what driver mutations are responsible therein. To address these issues, we performed multisampling of the endometrium with extensive spatial mapping.

Methods: We collected multiple endometrial glands from normal endometrium in a 5mm lattice in 19 patients aged 30 to 85 years who underwent hysterectomy (3-31 samples per case), followed by DNA extraction, detected somatic mutations by whole exome sequencing, to identify large clones that spread across samples based on shared mutations.

Results: In total, 213 bulk endometrial glands were analyzed. The number of detected somatic mutations per sample ranged from 4 to 81 (mean±SD: 32.5±14.1), with at least one known driver gene mutation detected in 204 of 213 samples (mean±SD: 3.03±1.78). The mutational signature analysis revealed the predominance of the age-related SBS1 and SBS5 signatures. dN/dS analysis identified 20 genes that were positively selected in normal endometrium, including *PIK3CA, PIK3R1, KRAS, PPP2R1A, ARHGAP35,* and *FBXW7*, most of which are also known as driver genes for endometrial cancer. The number of mutations and their frequency for each driver gene did not differ by background diseases: endometriosis, endometriosis-associated ovarian cancer and other non-endometrial related diseases. In contrast to the high frequency of driver gene mutations, copy-number alterations were found in only 3 samples, such as +1q, +7, +10 and +12. We found clones showing a large expansion involving multiple samples in 8 cases, most of which harbored one or more driver mutations, such as *PIK3CA* and *KRAS*. The size of the largest clone carrying a *KRAS* mutation, which was found in a 32-year-old woman with cervical cancer, spanned as long as 10 mm in diameter. This suggests that clonal expansion in the endometrium could be very rapid even in healthy women, which contrasts to the observations that clonal expansion in other organs is usually seen in aged individuals.

Conclusion: We confirmed the high frequency of driver mutations in the normal endometrium, most of which overlapped to those found in endometrial cancers, suggesting that these driver genes
are involved in the early phase of the development in the endometrial cancer. Some of the driver-mutated clones expanded in macroscopic size. Our findings provide an interesting insight into the clonal structure and underlying genetic variation in the normal endometrium.

#1615 Balanced molecular feature selection unveils universally tumor-lineage informative methylation sites in colorectal cancer.

X. C. Li[1], Y. Liu[1], A. A. Schaffer[1], S. M. Mount[2], S. C. Sahinalp[1];
[1]National Cancer Institute, Bethesda, MD, [2]University of Maryland, College Park, MD

In the era of precision medicine, performing comparative analysis over diverse patient populations is a fundamental step toward tailoring healthcare interventions. However, the critical aspect of equitably selecting molecular features across multiple patients is often overlooked. To address this challenge, we introduce FALAFL (FAir muLti-sAmple Feature seLection), a novel algorithmic approach based on integer linear programming. FALAFL is designed to bridge the gap between molecular feature selection and algorithmic fairness, ensuring a balanced selection of molecular features across different patient samples.
We have applied FALAFL to the problem of selecting lineage-informative CpG sites within a cohort of 9 colorectal cancer patients subjected to low-coverage single-cell methylation sequencing. Our results demonstrate that FALAFL excels at rapidly determining the optimal set of CpG sites, which are well covered by cells across the vast majority of the patients, while ensuring that each patient contributes a similar number of sites to the final selection. An analysis of the FALAFL-selected CpG sites reveals that their lineage informativeness exhibits a strong association across diverse patient profiles, suggesting the non-stochasticity and universality of methylation changes in tumor evolution. Furthermore, these universally lineage-informative sites exhibit subclonal level alterations in the colorectal cancer primary tumors and are strongly associated with lineage-specific gene expression patterns.
By integrating equity considerations into the molecular feature selection process, FALAFL is poised to propel equitable healthcare data science practices and advance our understanding of cancer and other complex diseases.

#1617 Tumor evolution during therapy in ovarian cancer.

S. K. Hautaniemi[1], J. Oikkonen[1], A. Lahtinen[1], M. Nguyen[1], G. Marchi[1], K. Lavikka[1], A. Rajavuori[2], S. Hietanen[2], A. Virtanen[3], J. Hynninen[2];
[1]University of Helsinki, Helsinki, Finland, [2]University of Turku and Turku University Hospital, Turku, Finland, [3]University of Helsinki and HUS Diagnostic Center, Helsinki, Finland

The evolution of tumors from diagnosis to relapse in ovarian high-grade serous carcinoma (HGSC) patients is poorly understood. Consequently, it is unknown whether diagnostic samples are representative enough to guide treatment directions at relapse, or whether acquired changes during therapy provide targets in patients with relapses. To answer these questions and characterize tumor evolution during treatment, we used data from >700 tissue and plasma samples from 200 HGSC patients belonging to the observational, longitudinal DECIDER trial (NCT04846933).
Mutations from whole-genome sequencing data from tissue samples (2-12 per patient) were used to construct phylogenetic trees. The trees were corrected by the copy-number alterations and curated to integrate circulating tumor DNA (ctDNA) exome- and targeted-sequencing data from plasma samples. Evolutionary states presenting within and between sample heterogeneity were evaluated through clonal complexity and divergence. Additionally, genetic differences between persistent and non-persistent subclones were studied to identify features affecting treatment resistance.
Our results indicate that the majority of subclones survive chemotherapy treatment and major subclonal replacement takes place in only a few patients. Within-sample heterogeneity was higher in plasma samples than in ascites, highlighting the importance of ctDNA samples to estimate persistent subclones.
Additionally, our recently reported evolutionary states (Lahtinen et al. Cancer Cell 2023) were often altered by the treatment induced selection pressure. At late relapses, subclone compositions typical of maintaining evolutionary state tumors were less common, and a higher number of acquired subclones were detected, suggesting further evolution of the persisting clones.
In summary, chemotherapy does not suppress heterogeneity in HGSC tumors. Interestingly, patients with the worst prognosis have a stable composition of multiple clones in their tumors, and tumors with low heterogeneity responded better to primary treatment. Relapse samples show lower within-sample heterogeneity and further evolution. Furthermore, we detected several evolutionary trajectories from stable, persistent cancer subclone populations to highly dynamic subclone structures. This renders diagnostic samples suitable to guide relapse treatment decisions in a subset of patients with HGSC but not for all.
Our characterization of the dynamics of tumor clonal heterogeneity during treatment allows to define better therapeutic interventions for HGSC patients with relapsed disease.

#1618 Highly populated phylogenetic reconstruction in patients with hormone receptor positive - HER2 non-amplified metastatic breast cancer.

F. Richard[1], T. Geukens[1], M. De Schepper[1], A. Mahdami[1], K. Van Baelen[1], M. Maetens[1], G. Zels[1], H.-L. Nguyen[1], A. Pabba[1], S. Leduc[1], E. Isnaldi[1], J. Van Cauwenberge[1], K. Borremans[1], H. Izci[1], I. Bachir[2], S. Hatse[1], P. Vermeulen[3], E. Vanderheyden[1], B. Boeckx[1], D. Lambrechts[1], A. Smeets[4], I. Nevelsteen[4], K. Punie[3], P. Neven[4], H. Wildiers[4], W. Van Den Bogaert[4], J. Demeulemeester[1], E. Biganzoli[5], G. Floris[4], C. Desmedt[1];

[1]KU Leuven, Leuven, Belgium, [2]Bordet Institute, Brussels, Belgium, [3]GZA Hospitals, Antwerp, Belgium, [4]UZ Leuven, Leuven, Belgium, [5]University of Milan, Milan, Italy

Background: Tumor progression still needs to be further elucidated in hormone receptor positive (HR+) breast cancer, the most common subtype of breast cancer. Here, leveraging the extensive sampling approach of our postmortem rapid tissue donation program UPTIDER (NCT04531696), we used phylogenic reconstruction to analyze disease progression.

Patients and Methods: Thirteen patients with HR+/HER2 non-amplified primary breast cancer, recruited in UPTIDER between 12/2020 and 05/2022, were considered. Shallow whole-genome sequencing was performed on 495 solid samples including a matched germline DNA and archived primary tumor sample for each patient. Log2 coverage ratios were computed with CNVkit and profiles with median absolute pairwise deviation < 0.35 were co-segmented per patient using the copynumber R package. Purity and ploidy were assessed by ABSOLUTE and manually reviewed. Samples with purity > 30% were kept for downstream analysis. Phylogenetic reconstruction was performed using MEDICC2 for each patient. Metrics derived from the trees were: (i) tree length, (ii) trunk length, (iii) trunk ratio as trunk length/tree length*100. Overall survival (OS) was defined as time between primary diagnosis and death. Comparison was done using Wilcoxon test, time to event analysis using cox regression. Endocrine resistance was defined as per the ESMO guidelines (PMID:34678411).

Results: 81% (399/495) of the samples passed QC. Phylogenies included a median of 28 samples per patient (range: 9-59) and 10/13 phylogenies included primary samples at diagnosis. Multi-seeding from the primary tumor was observed in 7 patients, suspected in 1, and a single seeding was observed in 2 patients. Median OS was 8.0 years. Higher trunk ratios tended to associate with poorer OS (Hazard ratio: 1.08 per 1% increase, 95% confidence interval: 0.99-1.16, p=0.06). In organs where multiple metastatic lesions were sampled (n= 73 organs, median of 3 samples/organ, range: 2-18 and median of 5 organs per patient, range: 1-10) seeding from at least 2 organs was detected in 48% (35/73) of the organs. Phylogenies from patients with secondary endocrine resistance (7 patients) tended to have a shorter trunk compared to patients with primary endocrine resistance (5 patients, median of 18 and 48 alterations respectively, p=0.15).

Conclusion: Branching evolution from the primary tumor was more frequently observed than linear evolution. Phylogenies revealed extensive tumor heterogeneity, questioning treatment decisions based on a single biopsy. Additionally, evaluation of multiple metastatic samples per organ showed seeding from multiple organs in 48% of organs evaluated, indicating greater disease heterogeneity than previously thought. Phylogenetic differences were also noted according to the type of endocrine resistance (primary versus secondary).

#1620 Multiregion spatial sequencing of early-stage head and neck squamous cell carcinoma revealed theranostic intratumor heterogeneity.

G. Marret[1], S. Vacher[1], **C. Lamy**[1], L. Ahmanache[1], L. Courtois[1], C. Kamoun[2], M. Halladjian[1], Z. El Beaino[1], J. Klijanienko[1], C. Martinat[1], E. Jeannot[1], J. Martin[1], G. Rougier[1], N. Badois[1], M. Lesnik[1], A. Dubray-Vautrin[1], O. Choussy[1], W. Ghanem[3], R. Taouachi[3], J. Masliah Planchon[1], N. Servant[2], M. Kamal[1], I. Bieche[1], C. Le Tourneau[1];

[1]Institut Curie, Paris, France, [2]INSERM U900, Paris, France, [3]Institut Curie, Saint-Cloud, France

Introduction: Head and neck squamous cell carcinoma (HNSCC) is characterized by substantial intratumor heterogeneity (ITH) at the molecular level that may foster tumor evolution, adaptation, and therapeutic failure. Personalized-medicine strategies mostly rely on single tumor-biopsy samples which might not capture the mutational burden of heterogeneous tumors. We investigated genetic ITH portrayed from multiregion spatial sequencing in early-stage HNSCC patients.
Patients and Method: Seventy-eight early-stage HNSCC patients treated with upfront curative-intent surgery in the prospective biobanking SCANDARE study (NCT03017573) were included. We developed a pathological measure of ITH, based on the relative contribution of multiple poorly and well-differentiated intratumor regions (n = 199) in resected tumor samples. To characterize genetic ITH, we performed targeted next-generation sequencing on multiple spatially separated intratumor regions by using a custom panel of 571 genes (named DRAGON), in combination with 3'-Tag RNA sequencing and pathway enrichment analysis.
Results: Fifty-nine patients displaying a minimum of two sequenced intratumor regions (total, n = 180) were analyzed. We observed genetic ITH in 22/59 patients (37%), of whom 6/22 (27%) based on theranostic molecular alterations. Three of the six patients exhibited molecular alterations in *PIK3CA* (n = 2) and *TSC2* (n = 1) that have supporting clinical evidence of actionability in some cancer types (OncoKB level 1) and three patients exhibited actionable molecular alterations in *PTEN* (n = 2) and *CDKN2A/B* (n = 1) supported by substantial research evidence (OncoKB level 4). Two patients exhibited molecular alterations in *SMARCA4* that is likely oncogenic, albeit not yet annotated by OncoKB. The pathological measure of ITH accounted for a significant source of variation in gene expression. Notably, we identified 346 differentially expressed genes imposing p-values ≤ 0.05 and |log fold-change| ≥ 1 involved in several Reactome's signaling pathways, including the cell junction organization (R-HSA-446728) and the tight junction interaction (R-HSA-420029) pathways.
Conclusions: We reported clinically relevant genetic ITH in early-stage HNSCC, which can lead to underestimation of the mutational landscape portrayed from single tumor biopsy and may present major challenges to precision medicine. Our findings uncovered the biology behind ITH and may have translational implications for biomarkers discovery in HNSCC.

#1621 Integrated analysis of genetic, transcriptional and TME evolution of ccRCC: TRACERx Renal.

A. Fernandez Sanroman[1], L. Au[1], B. Jek Yang Tan[1], **C. Spencer**[1], A.-L. Catin[1], I. Lobon[1], H. Pallikonda[1], K. Litchfield[2], F. Byrne[1], J. Larkin[3], A. Fendler[1], S. Turajlic[1];

[1]The Francis Crick Institute, London, United Kingdom, [2]UCL Cancer Institute, London, United Kingdom, [3]The Royal Marsden Institute, London, United Kingdom

Background: Genetic evolution of clear cell renal cell carcinoma (ccRCC) follows distinct trajectories, with varying levels of intratumor heterogeneity (ITH) and chromosomal complexity (WGII). While these patterns associate with clinical outcomes, it remains unknown whether they fully reconcile tumor behavior and how genetic and transcriptional features co-evolve in relation to the tumor microenvironment (TME).

Methods: To analyze the patterns of transcriptional and TME heterogeneity, we performed bulk whole-transcriptome sequencing on 244 samples, including 22 metastatic and 12 tumor-adjacent normal samples, from 79 ccRCC patients recruited to the TRACERx Renal study. We integrated transcriptional data with previously published genetic, phylogenetic, spatial and clinical information.

Results: Transcriptional distances between paired samples from the same primary tumor mirrored but were not fully determined by genetic distance (p-value < 0.001); and increased from primary-primary to primary-metastasis and primary-normal pairs. Within primary-metastasis pairs, metastasis-seeding primary tumor regions were transcriptionally closest to their matched metastasis (p-value < 0.001), suggesting that an important fraction of metastatic transcriptional traits were acquired in the primary tumor. Regarding the tumor clonal structure, transcriptional evolution followed a conserved path through increasing cell proliferation and oxidative phosphorylation and downregulating DNA repair from earlier to later clones. Further, within tumors with increasing WGII we observed upregulation and downregulation of repressors and downstream effectors, respectively, of the canonical cGAS-STING pathway. Combining the presence of this transcriptional pattern with WGII predicted shorter PFS in TRACERx Renal (p-value < 0.001) and in TCGA-KIRC (p-value < 0.001).

Clonal evolution was also linked to changes in TME, with each of the previously defined genetic evolutionary trajectories associated to a specific TME (p-value < 0.001). For example, ccRCCs on a PBRM1-SETD2 trajectory demonstrated increased infiltration of cytotoxic immune cells. TME ITH was pervasive and associated with shorter PFS (p-value = 0.03). A recurrent trend from earlier to later clones was progressive T cell depletion (p-value < 0.001). The evolution of the TCR repertoire mirrored the tumor clonal structure (p-value = 0.002), suggesting the thus far elusive antigenic source in ccRCC is heritable. Accordingly, the TCR repertoire in metastasis-seeding primary tumor regions resembled the closest the TCR repertoire of matched metastasis (p-value = 0.06).

Conclusion: Integrated analysis of genetic and transcriptional data in TRACERx Renal showed i) transcriptional and TME ITH not fully recapitulated by genetic ITH, ii) conserved paths of transcriptional and TME evolution and iii) a heritable nature of part of the ccRCC antigen source.

#1622 Characterization of the phylogenetic relationships in bilateral breast angiosarcoma.

M. Kim[1], J. Youk[2], S. Kim[1], M. Kim[2], B. Keam[2], T. Kim[2], D.-W. Kim[2], M. Song[3], J. Koh[4], J. Bae[4], H.-G. Moon[2], S.-A. Im[2];

[1]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of, [3]Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of, [4]Department of Pathology, Seoul National University Hospital, Seoul, Korea, Republic of

Background: Breast angiosarcoma represents around 20% of all angiosarcomas, and often spread to lung, liver, and bones. Driver mutations of angiosarcoma, specifically *PTPRB*, and *PLCG1*, are well-known as reported previously. Notably, contralateral breast is another metastatic site of the breast angiosarcoma, where an unusual location for other soft tissue sarcomas. However, it remains uncertain whether the contralateral disease originates from the primary tumor or emerges independently. Here, we present a 75-year-old woman with bilateral breast angiosarcomas to investigate the genetic relationship between the tumors.
Methods: Irregular and heterogeneous masses were synchronously detected through breast sonography. Whole genome sequencing (WGS) was conducted at 60X coverage using bilateral total mastectomies, along with a matched normal blood sample (n=1). Single nucleotide variants (SNVs) and small indels were identified using Strelka2 and Varscan2. Subsequent filtering was performed using custom Python scripts to establish high-confidence variants. A phylogenetic tree was then reconstructed based on SNVs to trace clonal evolution and distinguish between de novo primary and metastasis. Following this, COSMIC mutational signatures were analyzed to characterize the genomic profile.
Results: For the left breast angiosarcoma, we found 1,086 SNVs and 101 indels, while the right breast angiosarcoma had 921 SNVs and 92 indels. Despite their small size (<1.0 cm) and low FNCLCC grade (G1), these two cancers shared 600 SNVs and 135 indels as “truncal events”, indicating that one side metastasized from the other. According to the phylogenetic tree and the molecular clock of the two angiosarcomas, we estimated that the metastasis occurred during the middle stages of cancer evolution. Additionally, we identified 7 nonsynonymous SNVs (*ADAMTS7, RPS15, CYP2A6, OR1S2, ARHGAP23, GNAQ, UGT2B7*), five of which were shared. Remarkably, the GNAQ driver mutation exhibited a mutation at codon 209, a hotspot mutation not previously reported in breast angiosarcoma. The dominant Cosmic mutational signatures were SBS1/5 and ID1/2, all of which were associated with aging.
Conclusion: Our findings demonstrate that bilateral breast angiosarcomas metastasized from one side to the other, as evidenced by the WGS data. This study underscores that the capability of WGS to distinguish between oligometastatic disease and multiple primary cancers, which has implications for predicting patients’ prognosis.

#1626 Clonal expansion in bile duct associated with chronic inflammation.

H. Maeda[1], N. Kakiuchi[1], T. Ito[1], E. Ogawa[1], M. Shiokawa[1], N. Uza[1], H. Tanaka[2], Y. Nannya[3], H. Makishima[1], Y. Kodama[4], E. Hatano[1], S. Miyano[2], S. Ogawa[1];

[1]Kyoto University, Kyoto, Japan, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]The University of Tokyo, Tokyo, Japan, [4]Kobe University, Kobe, Japan

Introduction: Chronic inflammation has been implicated in cancer development in many tissues and has recently been associated with promoted clonal expansion in non-cancer tissues. Primary sclerosing cholangitis (PSC) is a chronic progressive disease of unknown etiology affecting the bile ducts and has been associated with a substantially increased risk of cholangiocarcinoma. Clonal dynamics in the normal bile duct and PSC epithelium remains poorly understood because of the limited accessibility to normal/inflamed bile ducts. In this study, we established a method to detect somatic mutations accumulated in the bile duct epithelium and investigated a mutation rate in normal bile duct cells and clonal expansion in PSC epithelium.

Methods: We established single cell-derived organoids from bile, which were subjected to whole genome sequencing to measure the age-related mutation rate in normal epithelial cell in the bile ducts. We next established organoids from multiple sites in perihilar bile ducts and collected epithelial samples from intrahepatic bile ducts obtained by laser-capture microdissection (LCM) from patients with PSC who underwent total hepatectomy for liver transplantation, for which we performed whole exome sequencing to investigate clonal expansion in PSC-involved bile ducts.

Results: In total, 14 single cell-derived organoid lines were established from 2 patients with PSC and 3 control individuals. Based on the whole genome sequencing of those organoids, the number of mutations found in non-PSC bile duct epithelium increases with age at an annual mutation rate of 34.3 mutations per genome per year, which did not substantially differ from the rate in the PSC epithelium, suggesting that the inflammatory process in PSC hardly affected the mutations in PSC epithelium. To further investigate clonal expansion in the PSC epithelium, a total of 120 bulk organoid samples from perihilar bile ducts in 3 PSC patients and 111 LCM samples from intrahepatic bile ducts in 4 PSC patients were analyzed. In perihilar bile duct-derived organoids, we detected a median of 13 [1-30] somatic mutations per exome in samples derived from perihilar bile ducts and 20 [5-41] mutations per exome in those from intrahepatic LCM samples. Most mutations were detected in a single sample but some mutation clusters were shared by adjacent samples, which expanded in an area as large as 13 mm in length. Expanded clones harbored mutations in known cancer-driver genes, such as *ARID1A* and *KRAS*, which were enriched in segmental bile ducts, suggesting their role in the clonal expansion.

Conclusions: Here, we established the method to detect somatic mutations accumulated in the normal/inflamed bile duct epithelium using an organoid-based analysis of clonal somatic mutations. Our results revealed clonal expansion existing in PSC epithelium and open up a way to the better understanding of carcinogenesis in the bile duct.

#1627 Persistence and dynamics of mutation, selection, and epistasis during the somatic evolution of low-risk, high-risk, and metastatic prostate cancer.

M. Rajaei[1], A. Yang[1], C. N. Cross[1], J. N. Fisk[2], E. B. Perry[1], J. D. Mandell[1], S. G. Gaffney[1], T. N. Yamaguchi[3], J. Livingstone[3], V. L. Cannataro[4], P. Humphrey[1], J. Costa[1], P. C. Boutros[3], J. P. Townsend[1],

[1]Yale University, New Haven, CT, [2]University of Rhode Island, Kingston, RI, [3]University of California Los Angeles, Los Angeles, CA, [4]Emmanuel College, Boston, MA

Driver genes and mutations responsible for prostate cancer tumorigenesis have been identified, but research has not previously quantified the effects of prostate cancer driver mutations, or how the magnitude of those effects vary with cancer stage and epistatic interactions among genes. Using 2699 prostate cancer tumor exomes, genomes, and panel sequences (1648 primary tumors and 1051 metastatic samples), we calculated the cancer effect size (CES)—the each mutation confers to lower-risk (Grade Group 1/2) and higher-risk (Grade Group 3/4/5) tumorigenesis and metastasis. The lower-risk, higher-risk, and metastatic tumors exhibited similar neutral rates at which mutations were introduced into DNA, with these underlying gene mutation rates generally increasing from lower-risk to higher risk to metastatic tumors. However, lower risk, higher risk, and metastatic tumors noticeably differed in the genes and specific somatic variants that were most highly selected for within each group. Therefore, to assess whether differences in natural selection that we observed among low-risk, high-risk, and metastatic tumor types were at least partly due to epistatic interactions, we applied a model of pairwise epistasis that quantified the effect of the presence or absence of a mutation in one gene on the selection for mutations in another gene. We found significant evidence of epistatic effects among driver genes. Our results indicate a very early role for SPOP in the development of prostate cancer: strength of selection for SPOP mutations is tightly associated with the degree to which the mutation ablates contact with the BRD3, and these disruptive mutations in turn increase the selection for mutations in several other tumor suppressors and oncogenes such as RHOA. Previously identified gene-gene interactions such as that between SPOP and PIK3CA were supported by this analysis, and we also identified novel gene-gene interactions such as those between AR and MUC16 occurring during metastasis. In conclusion, we have demonstrated that rates of mutation and strengths of selection on these driver mutations vary dynamically along the trajectories to lower-risk, higher-risk, and metastatic prostate cancer, and that powerful selective epistasis among driver genes provides an explanation for these differences. Because precision therapeutic targeting of somatic variant genes is fundamentally targeting the selective benefit obtained from that variant at the time of treatment, understanding these changes in stage-specific and somatic genotype-specific selective strengths will enable better therapeutic targeting in translational and clinical science.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Cell Cycle, DNA Repair, and Telomere Biology
Poster Session

#1631 A homogeneous assay system for discernment of proliferative, antiproliferative, and cytotoxic effects in culture.
D. F. Lazar, K. R. Kupcho, A. L. Niles, J. J. Cali;
Promega, Madison, WI

We describe a novel homogeneous cell-based assay developed for the quantitative detection of Ki-67 protein, a recognized marker of cell proliferation, utilizing Lumit™ immunoassay technology. This luminescent assay has been effectively multiplexed with a fluorescent measure of cell death, employing a cell-impermeant fluorogenic DNA dye. This multiplex allows for the clear distinction between antiproliferative activity and overt cytotoxicity in cell culture models. Through varying lytic conditions, we demonstrated effective cell lysis and detection of nuclear Ki-67 protein. Specifically, Lumit™ Lysis Buffer II provided efficient recovery of Ki-67 protein without compromising assay performance, including the requisite binding of labeled antibodies to the target protein. This assay exhibited excellent signal-to-background (up to 40-fold) and signal linearity ($R^2 = 0.99$) in wildtype HeLa cells (~1000 to 80,000/well), while the signal in Ki-67 knockout HeLa cells was comparable to the no-cell background, indicating excellent specificity for Ki-67 protein. Due to the unavailability of recombinant full-length Ki-67 protein, two different recombinant Ki-67 protein fragments were used to corroborate assay sensitivity of <1 pM Ki-67 protein. The assay's suitability for human Ki-67 protein detection, not mouse, was observed through further cell-based testing. The proliferation/cytotoxicity assay multiplex was validated in both suspension and adherent cell lines, as well as primary cell culture, detecting antiproliferative and proliferative responses. CDK4/6 inhibitors are a class of antiproliferative agents of significant interest for their potential in treating cancer. In Jurkat cells, treatment with the CDK4/6 inhibitor palbociclib led to a dose-dependent reduction in Ki-67 protein expression with an EC_{50} of 88 nM, and total Ki-67 elimination at 2 µM compound concentration. Notably, there was no cytotoxicity detected at the tested doses and treatment duration (up to 48 h), but a significant reduction in viable cell number at maximal palbociclib concentrations, aligning with an antiproliferative mechanism. This work establishes a rapid, simple, luminescent assay for determining Ki-67 levels that can be paired with a fluorogenic readout of cell death, facilitating efficient and quantitative discernment of altered proliferation in mammalian cell culture using standard microplate readers.

#1632 Dissecting AMBRA1-cyclin D axis deregulation in embryonal tumors of the central nervous system.

G. Milletti[1], G. Cadeddu[2], A. Adelantado Rubio[1], C. Ferraina[3], A. Maya-Mendoza[1], F. Cecconi[1];

[1]Danish Cancer Society Research Center, Copenhagen, Denmark, [2]Universita degli studi di Tor Vergata, Roma, Denmark, [3]Ospedale Pediatrico Bambino Gesu, Roma, Italy

Dissecting AMBRA1-cyclin D axis deregulation in embryonal tumors of the centralnervous systemEmbryonal tumors of the central nervous system (CNS) are malignant growths originating from embryonic neural stem cells, primarily affecting pediatric patients. These tumors pose a significant threat to children's health, leading to high morbidity and mortality rates. To improve survival rates and reduce morbidity, there is a critical need for advanced molecular diagnostics and innovative therapies. Among these tumors are medulloblastomas (MB) and other embryonal tumors, previously classified as primitive neuroectodermal tumors (CNS-PNET). These malignancies are characterized by uncontrolled cell proliferation, primarily driven by abnormalities in cell cycle proteins. Consequently, targeting cell cycle regulators has emerged as a promising approach for their treatment. Two key signaling pathways, namely the MYC and the cyclin D-CDK-RB pathway, govern the decision-making process related to genome replication. Mutations in both MYC and the CDK4/6/cyclin D pathway, leading to the functional inactivation of RB, have been identified as relevant factors in the development of CNS-PNET and medulloblastomas. Our seminal research has highlighted the crucial role of AMBRA1, an upstream master regulator orchestrating the transition from G1 to S phase (Maiani & Milletti et al., 2021). Specifically, AMBRA1 modulates the abundance of D-type cyclins and MYC by facilitating their proteasomal degradation, thereby ensuring genomic stability during DNA replication.Based on these discoveries, we propose that AMBRA1 functions as a multifaceted tumor suppressor across various cancer types. An unbiased Sleeping Beauty analysis identified AMBRA1 as a genetic driver of CNS-PNET, providing a strong foundation for investigating its role further (Beckmann et al., 2019). We hypothesize that the simultaneous deletion of AMBRA1 and p53 in an inducible knockout mouse model can lead to the spontaneous development of CNS-PNET or medulloblastoma, contingent on the specific targeted cell lineage. Additionally, our research demonstrates that AMBRA1 deficiency confers resistance to CDK4/6 inhibitors while creating a synthetic lethality with CHK1 inhibitors. Consequently, we propose that a comparative analysis of AMBRA1, D-type cyclins, and Myc family expression levels could serve as a diagnostic marker. This marker could facilitate patient-based stratification for CHK1 inhibitor treatment efficacy, enabling the differentiation of non- responsive cases to CDK4/6 chemotherapy.

#1633 A phenotype risk score to define patients with a 'long-telomeropathy' and at risk for a novel cancer-like syndrome.

s. hebbring, P. Alaire;
Marshfield Clinic, Marshfield, WI

Introduction: In human populations, telomere length (TL) displays a large inter-individual variability. At the population level, the most predictive variable for TL is age. Rare loss-of-function mutations in telomere maintenance genes are known to cause telomeropathies, a group of deadly diseases triggered by critically short telomeres. Over the last few decades, GWASs have uncovered many common variants associated with TL. More recently, a small number of PheWASs have suggested short-TL is associated with risk for a wide spectrum of phenotypes whereas long-TL is primarily associated with increased risk for several different neoplasms. We hypothesized that genetic variation contributing to long-TL may cause a unique and heritable telomeropathy, distinguishable from classical telomeropathies, that we refer to as a long-telomeropathy resulting in a cancer-like syndrome. To test this hypothesis, we studied telomere genetics in two large independent cohorts linking genomics with electronic health records data.
Methods: Discovery cohort consisted of approximately 70,398 individuals from the All of Us (AoU) Research Program. Marshfield Clinic's PMRP Biobank of 19,443 individuals served as a replication set. Previously published GWAS results (161 common variant) were utilized to produce a weighted polygenic risk score for TL (TL-PRS). A PheWAS of TL-PRS in AoU identified 19 significant phenotypes that passed a Bonferroni-adjusted p-value threshold (P<2.71E-5). Notably, risk for all 19 phenotypes were associated with long-TL and were categorized as neoplasm or neoplasm-like phenotypes. PheWAS results were used to generate a phenotype risk score for long-telomeropathy (longTL-PheRS), and this model was replicated in PMRP.
Results: The validated longTL-PheRS was used to screen rare variants that may contribute to increased risk for a telomere dependent cancer-like syndrome. When focusing on 293 telomere related genes in AoU, SKAT identified *ATM* (P=8.8E-7) and *DCLRE1B* (P<1E-10) as statistically significant risk genes. Whereas *ATM* has been previously implicated in multiple cancer types, *DCLRE1B* has not. SKAT results were influenced largely by a single missense variant in each gene [P=2.43E-15 (*ATM,* p.Leu2307Phe) and =1.78E-12 (*DCLRE1B,* p.Asn510Tyr)]. Neither variant was previously reported as pathogenic.
Conclusion: Many decades of research in telomere biology has demonstrated the health consequences associated with telomere shortening. This study builds on a growing body of evidence that long telomeres also have significant negative health implications. Individuals who have a genetic predisposition to long telomeres influenced by both common and rare variants may be at risk for a spectrum of tumors. These findings may lead to new diagnostic or preventative measures for individuals at risk for a long-telomeropathy and a cancer-like syndrome.

#1634 Cyclin D1 induces Akt1 activity in RB deficient prostate cancer.

X. Jiao[1], A. W. Ashton[2], Z. Li[1], R. Harish[1], D. Li[1], G. Robertson[3], D. Shen[4], X. Ju[5], K. Chen[5], W. Zhang[6], S. Archilefu[7], K. A. Iczkowski[8], H. Rui[5], B. Knudsen[6], P. Timpson[9], M. Nobis[9], **R. G. Pestell**[1];

[1]Baruch S. Blumberg Institute, Wynnewood, PA, [2]Lankenau Institute for Medical Research, Wynnewood, PA, [3]BC Cancer Agency, Vancouver, BC, Canada, [4]Washington University, St. Louis, MO, [5]Thomas Jefferson University, Philadelphia, PA, [6]University of Utah, Salt Lake City, UT, [7]University of Texas Southwestern Medical Center, Dallas, TX, [8]UC Davis Health, Sacramento, CA, [9]Garvan Institute of Medical Research & The Kinghorn Cancer Centre, Sidney, Australia

Background: Prostate cancer (PCa), the second leading cause of death in American men, is a genetically heterogeneous disease. The aberrant activation of AKT is one of the most frequent alterations in human cancers, and an elevated level of phosphorylated AKT at Ser473 site (pSer473) is associated with metastatic cancers (1). In prostate cancer (PCa), PI3K/AKT activation induces tumorigenesis (2), androgen receptor (AR)-mediated signaling, enzalutamide resistance and stemness, synergizing with other pathways including the notch intracellular domain (NICD). The *cyclin D1* gene (*CCND1*), which is overexpressed in PCa, conveys canonical function by encoding the regulatory subunit of a holoenzyme that phosphorylates the retinoblastoma gene (RB) product, and non-canonical functions through phosphorylating other substrates and transcriptional activities. Cyclin D1 expression augments growth of some castrate-resistant PCa (CRPC) and clinical trials are targeting the cyclin D1 related CDK kinase activity in pRB^{+} PCa. Several Rb-independent mechanisms of action have been described (3). In recent studies the effect of CDK inhibitors was similar in patients with Rb^{+} vs. Rb^{-} PCa (4). Whether Rb expression is required for the antiproliferative effects of CKD4/6 inhibition in PCa remains to be established.

Methods: The kinetics of Akt1 induction by mitogens was assessed using the phosphorylation of the dichromic fluorescent (DCF) dye substrate LS456. We used cyclin D1 shRNA to show endogenous cyclin D1 augmented AKT1 signaling in response to mitogens.

Results: Cyclin D1 reintroduction into cyclin $D1^{-/-}$ cells augmented Akt1 phosphorylation, requiring the cyclin D1 K112 residue. CDK inhibitors reduced Akt activity in RB^{+} and RB^{-} human prostate cancer cell lines. Prostate-specific epithelial cell deletion of cyclin D1 (probasin-CRE-cyclin-$D1^{fl/fl}$) reduced prostate epithelial cell Akt1 activity assessed by immunohistochemical (IHC) staining. $pAkt^{Ser473}$ was reduced in cell nuclei and the cytoplasm of both epithelial cells and stromal fibroblasts without a significant change in the abundance of Akt1. The downstream targets of Akt signaling ($pTSC2^{Ser939}$, and $pFKHR^{Ser319}$) and $AR^{Ser213P}$ were reduced in both epithelial cells and stromal fibroblasts. Genetic deletion of both epithelial cell and stromal cyclin D1 further reduced Akt1 activity, prostate epithelial cell proliferation, and markers of cancer stem cells. Proteomic analysis of cyclin D1-expressing stroma identified heterotypic chemokine signals that augment PCa AKT activity.

Conclusions: Cyclin D1 induces Akt1 activity in both RB^{+} and RB^{-} PCa cells which may contribute to tumor progression and therapy resistance.

#1635 Inhibition of FANCA Suppresses Breast Cancer Development by Regulating Cell Cycle Progression.

L. Luo, W. Liu, F. Yuan, F. Li, A. Palovcak, D. Calkins, K. Briegel, Y. Li, C. Mason, Z.-J. Liu, S. Daunert, Y. Zhang;
University of Miami Miller School of Medicine, Miami, FL

FANCA is one of the 22 known Fanconi anemia (FA) pathway genes that are involved in interstrand crosslink (ICL) repair. We have also shown that and FANCA plays a role in double strand break repair by promoting strand annealing and exchange. In this report, we describe that FANCA expression in breast cancer is significantly elevated within TCGA databases and in patient tumors-derived sections on both transcription and translation levels and this elevation is associated with poor outcomes of the breast cancer patients. Importantly, we have found that overexpressing FANCA in breast cancer cell line MDA-MB-231 promotes tumor growth both *in vitro* and *in vivo*. We have also demonstrated that FANCA inactivation by knocking out or knocking down inhibits growth of MDA-MB-231 *in vitro* and *in vivo* by causing cell cycle arrest at G1 phase resulting from hypophosphorylation of Rb protein. Our RNA-seq data has indicated that E2F targets are also downregulated in FANCA knockout (KO) cells compared to the wildtype (WT) MDA-MB-231 cells, which is consistent with the G1/S cell cycle arrest and Rb hypophosphorylation. Intriguingly, heterozygous FANCA KO in a breast cancer mouse model MMTV-PyMT model has shown reduction of breast tumor formation and volume. Our goal is to elucidate the role of FANCA in breast cancer development and to evaluate the potential of FANCA as a target for breast cancer treatment.

#1637 EPHB4 is a key regulator of G1/S transition in hepatocellular carcinoma.

A. Husain, E. Y. T. Chiu, H.-T. Ma, D. W. H. Ho, K. M. F. Sze, L.-K. Chan, I. O. L. Ng;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, Hong Kong

Effective therapeutic regimens against advanced hepatocellular carcinoma (HCCs) have recently improved but it remains very limited. Targeting receptor tyrosine kinases (RTKs) has proven to one of the main ways of achieving better survival outcome in HCC patients, yet the precise mechanism for this success remains to be elusive. We have systematically investigated the expression profiles of RTKs transcriptomic datasets i.e. The Cancer Genome Atlas - Liver hepatocellular carcinoma (TCGA-LIHC) (n=371) and our in-house cohort of paired i.e. HKU-QMH (n=41), and identified EPHB4 as one of the most abundantly expressed and frequently mutated RTKs in human HCCs. EPHB4 expression was found to be significantly correlated with Alpha Fetoprotein (AFP) expression, a factor commonly used in the diagnosis of HCCs. Furthermore, EphB4 has been demonstrated to play a regulatory role in VEGF/VEGFR-mediated angiogenesis, critical targets for current successful drugs. We confirmed abundant membrane EphB4 expression in HCC clinical specimens and human HCC cell line models using immunohistochemistry. Clinicopathological correlation analysis of EPHB4 mRNA expression revealed that its overexpression is associated with aggressive tumor features including presence of tumor microsatellite, liver invasion, venous invasion, and absence of tumor encapsulation. Functionally, stably knocking down EPHB4 (shEPHB4) resulted in a strong reduction of proliferation and self-renewal rates of multiple HCC cell lines *in vitro*. It significantly reduced tumor growth rates in subcutaneous and liver orthotopic models *in vivo*. Furthermore, limiting dilution assay showed EPHB4 plays a role in tumor initiation property of HCC cells. Mechanistically, we performed Gene Set Enrichment Analysis (GSEA) of transcriptome profiles for shEPHB4 with respective controls and found that knocking down EPHB4 causes HCC cells undergo drastic changes in several cell cycle checkpoints including G1/S transition. Using thymidine blockade, we further confirmed that knockdown of significantly hinders the transition of HCC cells from G1 to S phase of cell cycle. Our data suggests a strong link between EphB4 and cell cycle. Conclusion: We found EphB4 plays a functional role in regulating G1/S transition in human HCCs and understanding regulatory role of EphB4 on cell cycle progression may provide mechanistic insights into the how to effectively target HCC in the clinic.

#1638 Regulation of spindle pole integrity by the MASTL-ENSA-aurora a pathway during mitosis.

S. Kim, K. Jun, Y.-H. Kim, **J. Kim**;
Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of

The preservation of spindle pole integrity is crucial for proper spindle assembly and chromosome segregation in mitosis, yet the precise mechanisms governing spindle pole integrity remain elusive. During mitosis, phosphorylated Ensa (p-ENSA) localizes to spindle poles, and the inhibition of ENSA leads to a range of mitotic defects, including misaligned chromosomes, multipolar spindles, asymmetric bipolar spindles, and centrosome aberrations, resulting in a delayed mitotic progression. Remarkably, the mitotic delay induced by ENSA inhibition is alleviated upon depletion of PP2A-B55α, but spindle pole defects persist. Significantly, we have observed an interaction between ENSA and Aurora A during mitosis, and the inhibition of ENSA diminishes Aurora A expression at the mitotic spindle poles. Intriguingly, the injection of MKI-2-sensitized tumors is associated with heightened chromosomal instability and downregulation of the MASTL-ENSA-Aurora A pathway in an orthotopic breast cancer mouse model. These findings offer new insights into the regulation of spindle pole integrity through the MASTL-ENSA-Aurora A pathway during mitosis, emphasizing the pivotal role of ENSA in recruiting Aurora A to the spindle pole, independently of PP2A-B55α.

#1639 Telomere dynamics in aging and cancer by nanopore long-read sequencing.

T. T. Schmidt[1], C. Tyer[2], P. Rughani[2], C. Haggblom[1], J. Jones[1], X. Dai[2], K. A. Frazer[3], F. H. Gage[1], S. Juul[2], S. Hickey[2], J. Karlseder[1];
[1]Salk Institute For Biological Studies, La Jolla, CA, [2]Oxford Nanopore Technologies, Inc., New York, NY, [3]University of California San Diego, La Jolla, CA

Telomeres are the protective, nucleoprotein structure at the ends of linear eukaryotic chromosomes. The accurate measurement of both telomeric length and composition of individual telomeres in mammalian cells has been challenged by the length and repetitive nature of telomeres. With the advent of third generation sequencing technologies, it is now technically possible to sequence entire telomeres and map them to individual chromosome arms. Here, we report a reliable method to enrich, sequence and analyze human telomeres using Oxford Nanopore Technologies long-read sequencing. To enrich for telomeric sequences we combine the ligation of adapters complementary to the telomeric G-overhang with restriction enzyme digest to sequence the telomeric C-strand and part of the adjacent subtelomere. The subtelomeric information is harvested to map individual telomeric reads to specific chromosome arms and even alleles. We have measured bulk, chromosome-arm-specific telomere length dynamics during cellular aging of cultured primary cells and in a patient-derived aging cohort. To address the impact of the telomere maintenance mechanism on telomere length and composition, we have sequenced matched pairs of fibroblasts and induced pluripotent stem cells, as well as five well-established telomerase- and ALT-positive cancer cell lines. Our results suggest that based on nanopore telomere long-read sequencing ALT-positive cells can be easily discriminated from normal and telomerase-positive cancer cells. Further, telomere sequencing allows to evaluate the methylation status of the subtelomeric CpG islands adjacent to telomeres.
In summary, nanopore telomere long-read sequencing allows to measure the length and composition of individual telomeres and their mapping to specific chromosome arms. Telomere long read sequencing methods will be valuable tools to study telomere biology during aging and cancer.

#1640 The role of CDC20 in the progression of colorectal cancer.

Nouran Abualsaud, Nada Gazzaz, Amal Alhamid, Deemah Alenizy, Bahauddeen M. Alrfaei, Mana Alshehri

Blood and Cancer Research, King Abdullah International Medical Research Center, Riyadh, Saudi Arabia

Colorectal cancer (CRC) is the one of most common cancers and a major leading cause of cancer-related death worldwide. CDC20 is a key cell cycle regulator required during mitosis. Pathologically, CDC20 has been found to be overexpressed in cancer cells of various malignancies including breast, lung, brain and hepatic cancers and high level of CDC20 expression is associated with poor prognosis and disease progression in these cancers. Although it has been reported that CDC20 is associated with CRC progression and metastasis, it is still largely unknown how CDC20 regulates CRC cancer progression. Thus, the goal of this study is to identify the role of CDC20 in the progression of colorectal cancer. Our gene expression analysis revealed that CDC20 is highly expressed in colon cancer tissues compared to their adjacent normal colon in a cohort of CRC patients, suggesting the involvement of CDC20 in the CRC progression. To further understand the role of CDC20 in CRC progression, we experimentally targeted CDC20 genetically and pharmacologically. To perform CDC20 Loss of function studies, we screened various CRC cell lines for CDC20 protein levels and CDC20 highly expressing cell lines were utilized to establish CDC20-knockdown cells using shRNA targeting CDC20 and scrambled shRNA as controls. CDC20 Down-regulation levels were confirmed using both western blot and RT-PCR analysis. The effect of CDC20 knockdown/CRC cells on CRC cell proliferation was investigated using xCELLigence real-time cell analysis instrument and colony formation assay. Our results revealed that CDC20 knockdown CRC cells have lower proliferation capacity compared to the control, suggesting involvement of CDC20 in regulating tumorigenic phenotypes of CRC cells. Pharmacologically, we targeted CDC20 using a specific molecular inhibitor, Apcin and we assessed the Apcin treatment effect on cell viability and migration of CRC cells. Our results showed that Apcin significantly reduced CRC cell viability and migration in a dose-dependent manner. Taken together, our results suggest that CDC20 is a key regulator in the tumorigenic behavior of CRC and is considered a potential therapeutic target for treating patients with CRC.

#1641 Clobetasol differentially effects the vulvar cancer cell line, UMSCV-4, causing both increases in apoptosis while maintaining a subpopulation in quiescence.

J. E. Lewis, M. Ogden, G. Minnuto, K. Haering, L. North;
SUNY Geneseo, Geneseo, NY

Vulvar cancer is a rare but aggressive form of cancer that remains understudied. Our results show that treatment of the vulvar cancer cell line, UMSCV-4, with the glucocorticoid, clobetasol, increases apoptosis. Clobetasol is often used to treat a common inflammatory disease of the vulva known as vulvar lichen sclerosus (VLS) and up to 65% of vulvar carcinomas arise in the background of VLS. This would indicate clobetasol may also decrease the progression of vulvar cancer, if our observations reflect what is happening in vivo. However, our studies also show that apoptosis is not universal for the clobetasol treated UMSCV-4 cells. A subpopulation appears to enter a state of quiescence as evidenced by the return of some of the cells to normal cell proliferation upon removal of clobetasol. We previously showed that $p27^{Kip1}$ is upregulated in the clobetasol treated cells. Cells that were incubated in clobetasol for three months and then removed from clobetasol (UMSCV-4 LT), allowing them to reenter the cell cycle, no longer expressed high levels of $p27^{Kip1}$ upon re-exposure to clobetasol. We are now examining the differential phosphorylation states of $p27^{Kip1}$ in the untreated and treated cells as well as identifying other genes important to clobetasol induced quiescence using RNAseq.

#1642 NuMA exclusive post-translational modification in epithelial cancer cells is a novel target for cell eradication.

M. Cohen-Armon;
Tel Aviv University, Tel Aviv, Israel

The post-translational modification of proteins implicated in mitosis in healthy and in cancer epithelial cells was measured by 2-D gels analysis. The post-translational modifications of NuMA in a variety of human epithelial cancer cells was prevented by treatment with a small phenanthridine, PJ34, while not impaired in similarly treated healthy epithelial cells. NuMA in the cancer cells was phosphorylated by pim1 kinase, and was polyADP-ribosylated by Tankyrase1. These post-translational modifications are inhibited by PJ34. Tankyrase1 is not expressed in healthy epithelial cells, and pim1 kinase was hardly expressed in these cells. Preventing the post-translational modification of NuMA in the epithelial cancer cells also suppressed the protein binding capacity of NuMA. NuMA clustering in the mitotic spindle poles, which stabilizes the mitotic spindle, and is required for the alignment of chromosomes in the spindle mid-zone was impaired. In epithelial cancer cells treated with PJ34, the mitotic spindle poles were distorted, extra-centrosomes were not clustered in multi-centrosomal cancer cells, and chromosomes were dispersed. Chromosomes dispersion violated mitosis termination. Mitosis arrested in the anaphase led to mitotic catastrophe cell death. PJ34 treated epithelial cancer cells were eradicated during 72-96 hours, regardless of their mutations, while treated healthy epithelial cells were not affected, and continued to proliferate.

#1643 Relative telomere length analysis in breast cancer patients with *TP53* p.R337H and *XAF1* p.E134* germline variants.

Larissa M. Okano[1], Stefanne M. J. Bortoletto[1], Mariana Paraizo[1], Aline S. Fonseca[1], Bonald C. Figueiredo[1], Enilze M F. S. Ribeiro[2], Ariana Centa[1], Luciane R. Cavalli[1]

[1]Faculdades Pequeno Principe, Research Institute Pele Pequeno Principe, Curitiba, Brazil,[2]Genetics Department, Universidade Federal do Parana, Curitiba, Brazil

Background: Telomere deregulation is one of the forms of genomic instability, an enabling characteristic of the cancer hallmarks. The *TP53* gene plays a fundamental role in genome integrity maintenance by controlling cell cycle, apoptosis, senescence, and DNA repair. The germline variant *TP53* p.R337H, a low penetrance variant, has been described in several types of cancer, including sporadic and familial breast cancer. The *XAF1* p.E134*, a germline variant of the tumor-suppressor gene X-linked inhibitor of apoptosis (XIAP)-associated factor 1 (*XAF1*), is a genetic modifier of p53 function and was found to co-segregate with *TP53* p.R337H variant on the 17p13 region. The main objective of this study was to determine the impact of the *TP53* p.R337H and *XAF1* p.E134* germline variants on the relative telomere length (RTL) in breast cancer patients.

Materials and methods: Peripheral blood samples from three distinct groups of patients were collected: patients with breast cancer (BC; n=56) (test group), patients with other types of cancer (non-BC; n=59), and individuals without cancer and cancer family history (non-CA; n=100) (control groups). The samples were genotyped for the *TP53* p.R337H and *XAF1* p.E134* variants. The RTL analysis was performed by RT-qPCR, using primers for the TEL gene (T) and *36B4* gene (S) (reference) and calculated based on the T/S ratio.

Results: BC cases with *TP53* p.R337H variant exhibited higher RTL compared to cases without the variant. No RTL differences were observed for the *XAF1*p.E134* variant or for the concomitant presence of these variants. However, in the non-BC cases higher RTL were observed in all the cases positive for the variants compared to the negative cases. The same was observed for the BC and non-BC cancer cases combined (CA cases). In the non-CA cases no difference in the RTL was observed in relation to the variants. The stratification of the cases by age (≤ or >45 years old), showed that the *TP53* p.R337H variant was significantly associated to longer telomeres in the BC and CA patients across all ages. *XAF1* p.E134* showed age-dependent effects, with longer telomeres in BC and CA patients ≤ 45 years. Non-BC cases had similar results.

Conclusion: This study indicates that *TP53* p.R337H significantly impacts telomere length in BC cases, while *XAF1* p.E134* shows age-dependent effects. Despite the observed variability, these findings highlight an association between these germline variants and telomere length regulation. Further research is needed to elucidate the functional impact and underlying mechanisms of these variants, particularly in the context of breast cancer.

#1644 Exploring the role of a *TERT* intronic tandem repeat in regulating cell proliferative responses to environmental factors and cancer risk.

M. Ho[1], O. Florez-Vargas[1], M. Hogshead[1], B. Papenberg[1], C. Lee[1], C. Zhang[1], K. Forsythe[1], W. Yan[1], R. Chari[2], L. Prokunina-Olsson[1];
[1]National Cancer Institute, Rockville, MD, [2]Frederick National Laboratory for Cancer Research, Frederick, MD

The chr 5p15.33 genomic locus encoding telomerase reverse transcriptase (*TERT*) is structurally complex, with several highly polymorphic intronic variable number tandem repeats (VNTRs). A germline VNTR located in *TERT* intron 6 (VNTR6-1, 38 bp repeat unit) has previously been associated with *TERT* alternative splicing but its potential role in regulating cellular functions and disease risk is unclear. To functionally characterize VNTR6-1, we deleted this region (1-2 kb) using CRISPR/Cas9 in UMUC3 (bladder cancer cell line). Cell count growth tracking of parental and VNTR6-1 knockout (VNTR6-1 KO) cells via automated live-cell monitoring revealed different relative growth rates under serum starvation vs. normal conditions, suggesting that VNTR6-1 might be sensitive to growth factors present in culture media. Evaluation of growth in media with full vs. charcoal-stripped (CS) serum, showed significant differences, with higher cell counts in parental vs. VNTR6-1 KO in CS-serum (P=4.1e-3), parental vs. parental in full (P=1.57e-4) or CS-serum (P=4.76e-2), but not in parental vs. VNTR6-1 KO in full serum (P=0.378). After 5-6 days of growth, cells in CS-serum also rapidly began outgrowing cells in full serum. We observed that VNTR6-1 KO dampened the outgrowth response in cells lacking growth factors in CS-serum. Proliferation-specific growth assays tracking the dilution of an incorporated dye in cells by flow cytometry further showed that VNTR6-1 KO leads to more pronounced proliferation differences due to the presence or absence of serum-supplied factors. Overall, cell growth patterns appear to be sensitive to serum in interaction with VNTR6-1, suggesting a potential VNTR6-1-dependent response to extracellular signaling. In human populations, we have identified two VNTR6-1 groups: Short (24-27 copies) and Long (40.5-66.5 copies). In the PLCO dataset (n=100,445 cancer cases and controls), logistic regression showed that VNTR6-1-Long group was associated with a decreased risk in male-prevalent cancers such as bladder and prostate, but an increased risk in female-prevalent cancers such as breast, endometrial and ovarian. These results support a link between the *TERT* region, and potentially VNTR6-1, with hormone signaling and cancer risk. Motif analysis within VNTR6-1 predicted binding sites for several transcription factors, including those associated with development and cell growth. Together, these results suggest that VNTR6-1 may be involved in regulating cell growth, potentially by facilitating responses to extracellular signaling pathways. Additionally, given the location of VNTR6-1 within a multi-cancer GWAS region, our findings provide functional context for the role of this polymorphic repeat in differential risk and outcomes in certain cancers.

#1645 Telomere-related genes associated with clinical-pathological in pancreatic ductal adenocarcinoma.

E. Curiel Gomez, Sr.[1], V. Maldonado Lagunas[2], J. Melendez Zajgla[2];

[1]Universidad Nacional Autonoma de Mexico (UNAM), Mexico City, Mexico, [2]Instituto Nacional de Medicina Genomica, Mexico City, Mexico

Pancreatic ductal adenocarcinoma (PDAC) stands as one of the leading causes of cancer deaths worldwide. Studies have suggested that telomeres shortening is linked to genetic instability, higher risk of developing pancreatic cancer and pancreatic tumorigenesis. However, previous research has predominantly focused on either telomere length or specific telomere-related genes in pancreatic cancer. Therefore, it is essential to elucidate the association between telomere-related genes and pancreatic cancer to identify novel therapeutic strategies and establish prognostic biomarkers. Telomere-relevant genes were downloaded from the TelNet database. Expression data from primary tumour of The Cancer Genome Atlas-PAAD (TCGA-PAAD) cohort, the Genome Sequence Archive CRA001160 dataset and the GTEx database were obtained for screen for differentially expressed genes (DEGs). Gene set enrichment analisis was performed using the Enrichr software. The gene essentiality queried from the gene dependency database of the Achilles-DepMap project was also assessed. Finally, data of The Cancer Genome Atlas-PanCancer CaPa cohort and healthy pancreas from the GTEx database, obtained from the UCSC Xena project, were used to correlate gene expression with stemness signatures and clinical-pathological variables. We identified 300 telomere-associated DEGs, Of these, 73 genes were common to studies and they were to be enriched in biological processes related to the cell cycle and telomere homeostasis. The differentially expresed of ASS1, S100P, IGF2BP2, MET, ABCC3 and RAC1 genes were significantly associated with overall survival and recurrence-free survival, conferring them prognostic value. Furthermore, the expression profiles of these genes are significantly associated with the histological grade of the disease, as well as with tumour T-N classification, the presence of residual tumour, the degree of response to treatment and stemness signatures. Among these, three genes of particular interest (KLF3, RAC1 and ABI1) were identified and shown to be highly essential in pancreatic cancer cell lines. In summary, we have identified a telomere gene-related signature for pancreatic cancer, highlighting the prognostic value of KLF3, RAC1, and ABI1 genes. This signature is significantly associated with clinical-pathological variables of the disease, potentially offering new insights for individualized therapy.

#1646 IL-23R is a regulator of the mitotic spindle and is critical for cell viability in AML.

N. Duong[1], D. H. Khan[1], G. E. Thomas[1], R. Hurren[1], J. Lee[2], J. St-Germain[1], L. Drimmer[1], Y. Yan[1], N. Maclean[1], M. Gronda[1], V. Rondeau[1], B. D. Brown[3], C. L. Jones[1], H. Chang[2], A. Arruda[1], M. D. Minden[1], L. Zhang[2], S. M. Kornblau[3], B. Raught[1], V. Spadavecchio[4], A. D. Schimmer[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]UHN Toronto General Hospital, Toronto, ON, Canada, [3]MD Anderson Cancer Center, Houston, TX, [4]Interlinked Therapeutics LLC, Portland, OR

To identify novel biological vulnerabilities in AML, we searched for gene ontologies that were upregulated in AML compared to normal hematopoietic cells. Of the upregulated processes, the mitotic spindle ontology was a top hit. Unexpectedly, expression of the IL-23 receptor (IL-23R) showed a strong positive correlation with the mitotic spindle ontology. IL-23R is a cell surface cytokine receptor that is canonically expressed on T cells, but not known to have a role in AML. In 7 of 7 tested AML cell lines and 15 of 20 primary AML patient samples, IL-23R protein was expressed >2 fold higher compared to mean IL-23R in normal mononuclear hematopoietic cells (n=5) and CD34+ cells (n=3). IL-23R is classically a T cell surface receptor and we confirmed localization to the cell surface in T cells. However, only small amounts of IL-23R were present on the cell surface of AML cell lines and primary AML samples. Rather, in AML cells, primary AML samples, and AML stem cells, IL-23R was located intracellularly as determined by 4 different modalities and 4 different antibodies directed against 4 different epitopes of the receptor. Of note, only the full-length IL-23R protein was detected by immunoblotting. We also detected IL-23R's heterodimeric partner, IL12Rβ1, in AML cells. To understand the function of intracellular IL-23R, we used BioID mass spectrometry to identify proteins that interacted with IL-23R. Pathway analysis of interacting proteins identified mitotic spindle formation as the top pathway. Using Proximity Ligation Assays, we validated interactions with mitotic spindle proteins, and BioID hits, NUMA, TMEM201, TACC1, and BAG6 in AML cells. By confocal microscopy, we demonstrated that IL-23R colocalized with the mitotic spindle and centrosomes in AML cells and primary AML samples. IL-23R interacted with the mitotic spindle via its (S/T)x(I/L)P motif (amino acids 588-591). IL-12Rβ1 was also found in complex with IL-23R at the mitotic spindle in AML cells. Additionally, it was discovered that the cytokine, IL-23, promoted translocation of IL-23R to the mitotic spindle through clathrin-mediated endocytosis. Knockdown and knockout of IL-23R in AML cells led to dysregulation of the mitotic spindle with multipolarity, lagging chromosomes, and other spindle defects. Knockdown of IL-23R also reduced proliferation, clonogenic growth, and marrow engraftment of AML cells and primary AML samples. In contrast, knockdown of IL-23R in normal CD34+ cells did not impair engraftment. Likewise, constitutive homozygote IL-23R knockout mice had no difference in complete blood counts and stem cell number/function compared to wild type. In summary, IL-23R interacts with the mitotic spindle and centrosome where it regulates mitotic spindle formation and is critical for AML cell viability. Thus, we discover a novel function for IL-23R and a potential therapeutic target for this disease.

#1647 Plk4 phosphorylates the distal tip complex to promote centriole growth.

A. Amoiroglou, J. M. Ryniawec, D. W. Buster, G. C. Rogers;
University of Arizona, Tucson, AZ

The centrosome is the major microtubule-organizing center of the cell with a key role in forming the mitotic spindle. The centrosome consists of two core duplicating elements, the centrioles, surrounded by pericentriolar material, a cloud of proteins that nucleates microtubules. Centrioles are barrel-like structures composed of microtubule bundles and are essential to maintain centrosome number. Therefore, centriole duplication and growth are tightly regulated to ensure proper centrosome number throughout the cell cycle. Alterations in centrosome number lead to an abnormally shaped mitotic spindle that often mis-segregate chromosomes, thereby causing chromosomal instability, a hallmark of cancer. Defects in centriole growth, such as over-elongation, can increase centrosome numbers (known as 'centriole amplification', an overproduction of centrioles frequently observed in cancer cells). For example, over-elongation of the centriolar barrel can cause multiple ectopic daughter centrioles to assemble or simply fragment, producing multiple smaller (but functional) centrioles. Thus, understanding how centrioles grow and define length is a major question in the field. Centrioles elongate at their distal ends and, in *Drosophila*, elongation is regulated by a group of proteins, Cep97, CP110 and Klp10A. Elongation is negatively regulated by Cep97 and CP110 which cap centrioles at their distal end to maintain centriole length, by counteracting the microtubule depolymerizing kinesin, Klp10A. Recently, we identified a new centriole regulator, Cep104, that also localizes to the centriole distal tip. We discovered that Cep104 promotes centriole elongation through its microtubule-binding TOG domain. Additionally, Cep104 localization to the centriole distal ends is dependent on Cep97. Furthermore, Cep97, CP110, Cep104 and Klp10A form a complex and we have mapped their sites of interaction. Collectively, we refer to this as the Distal Tip Complex (DTC). Although the DTC is first recruited to new daughter centrioles during G1/S-phase, the majority of centriole elongation occurs during mitosis. Here, we explore the mechanisms that regulate the DTC to promote centriole growth during mitosis. We hypothesize that Polo-like kinase 4 (Plk4), the master regulator of centriole duplication, phosphorylates and inhibits the DTC to promote elongation of nascent centrioles. Notably, we found that centrioles are longer in cells overexpressing Plk4. Using tandem mass spectrometry, we identified multiple sites that Plk4 phosphorylates on each DTC protein. Analysis of DTC phosphomutants revealed that the phosphorylation state of Klp10A, Cep97 and CP110 affect centriole number. We are currently investigating how Plk4 phosphorylation regulates the activities of these conserved centriole length factors.

#1648 RB represses cohesin-dependent loop formation and activates E2F-independent transcription.

H. Lee[1], I.-M. Gkotinakou[1], B. Krishnan[2], N. J. Dyson[1], M. S. Lawrence[1], I. Sanidas[1];
[1]Massachusetts General Hospital, Charlestown, MA, [2]Whitehead Institute for Biomedical Research, Cambridge, MA

The retinoblastoma protein (RB) suppresses the activity of the E2F transcription factor family, controlling cellular proliferation. Recent studies, however, indicate that RB's role in chromatin organization, which is not yet fully understood, might be distinct from this E2F-dependent regulation. Employing chromosome conformation capture at a single nucleosome resolution, we identified RB as a cell cycle-regulated repressor of cohesin-dependent loop formation at topologically associating domain (TAD) boundaries. RB depletion increased the number and size of cohesin-dependent loops and strengthened topologically associating domains (TADs). This phenomenon was specific to the G1 phase and was not observed in the S phase, indicating that this novel RB function is regulated by the cell cycle. Mechanistically, RB showed extensive colocalization with cohesin in the human genome, and it impacted cohesin's distribution on the chromatin. Active RB reduced cohesin from RB-bound TAD boundaries and decreased cohesin activity therein, as assessed by the increased K105/106 acetylation of the cohesin subunit SMC3. This led to reduced insulation in chromosome conformation capture assays. Importantly, by weakening the insulation activity of the adjacent insulators, RB non-canonically enhanced the expression of non-E2F target genes salient for cell adhesion and extracellular matrix organization. When RB was lost, cells showed a more rapid cellular detachment rate and an elevated migration rate, indicating that this novel RB function controls specific transcriptional programs rather than arbitrary genes to regulate the process of cell adhesion and migration. Overall, we conclude that RB has a central role in the interplay between cell cycle and chromatin organization, by repressing the cohesin-dependent loop formation at TAD boundaries. This RB function safeguards E2F-independent transcriptional programs driven by active enhancers and helps maintain cellular adhesion to the extracellular matrix.

#1649 Large scale multi-omics concordance study of cyclin E1 identifies high expressing tumors lacking CCNE1 gene alterations across multiple tumor indications.

[1]University of Cambridge, Cambridge, United Kingdom,[2]AstraZeneca, Cambridge, United Kingdom,[3]AstraZeneca, Waltham, MA

Cyclin E1 is a key regulator of the G1/S transition and is thought to cause excessive entry into the cell cycle. *CCNE1* is amplified in a range of tumor indications, and its amplification is associated with poorer prognosis and resistance to chemotherapy. Cyclin E1 is also being investigated as a potential biomarker for inhibitors targeting the replication stress response. Understanding the best way to quantify cyclin E1 overexpression is fundamental to support patient selection approaches for these inhibitors. In many cases, gene amplification correlates with increased cyclin E1 protein expression; however, there are a proportion of high-grade serous ovarian cancer and basal-like breast cancer cases where cyclin E1 protein overexpression does not correlate with gene amplification. In this study, we investigate if this phenomenon is observed in other cancers and some of the potential mechanisms causing cyclin E1 overexpression. We used a multi-omics approach to assess cyclin E1 expression in 1417 formalin-fixed paraffin-embedded (FFPE) patient tumor resections across 6 indications (SCCHN, Bladder, NSCLC, TNBC, Ovarian & SCLC). We used copy number variation (CNV) determined by next generation sequencing (NGS), NanoString nCounter RNA analysis and protein expression by immunohistochemistry (IHC). 830 were evaluable for all 3 methods and demonstrated *CCNE1* gene amplification by NGS (CNV normalized log2 ratio ≥1.5) in 3.3% cases. Using a threshold of mRNA z-score >2, 17% cases had high *CCNE1* mRNA and 29% had high cyclin E1 protein (H-score ≥100). 15.7% (130/830) cases had high protein expression without gene amplification or gain, crucially this was found across all 6 indications (n=20/102 SCCHN, n=29/166 Bladder, n=34/232 NSCLC, n=15/76 SCLC, n=15/143 TNBC & n=17/118 Ovarian). Impaired protein degradation has been proposed as a mechanism that may result in high Cyclin E1 expression. From a panel of 1600 genes, we assessed the relationship between cyclin E1 and mRNA expression of 57 genes involved in the ubiquitin-proteasome pathway in 1239 samples across the 6 indications. We assessed mutations which could impair ubiquitination in 915 samples across the 6 indications. We also assessed the methylation status of 893 genes associated with ubiquitin ligases or deubiquitinases in a cohort of 170 TNBC samples. Further investigation into other mechanisms causing cyclin E1 overexpression is required. IHC provides an ideal platform to build our understanding of cyclin E1 expression spatially. Our results indicate that assessing Cyclin E1 protein overexpression instead of *CCNE1* gene amplification could greatly broaden the population of patients who could benefit from replication stress response kinase inhibitors, as cyclin E1 overexpression correlates with genomic instability and replication stress.

#1650 Characterization of nucleolar biological functions via Auxin inducible degron-mediated acute depletion in triple negative breast cancer cells.
N. Samadi Rad, J. Mills, A. Tessari, D. Sunil Kumar, V. Anastas, S. Lamba, A. Reers, I. Cosentini, Z. Zhu, T. Magliery, E. Cocucci, L. Rizzotto, D. Palmieri; The Ohio State University, Columbus, OH

Nucleoli are large nuclear sub-compartments where vital cellular processes, such as rRNA production and ribosome assembly, take place. Aggressive tumor types, such as Triple Negative Breast Cancer (TNBC), require increased ribosome biogenesis to support their enhanced proliferation. Therefore, it has been suggested that the nucleolus could be a valid anti-neoplastic target. However, we still have a limited understanding of the cancer-specific functions of the nucleolar components, preventing the effective development of therapeutic agents. The characterization of nucleolar proteins is technically challenging. Several nucleolar proteins are essential, and their complete abrogation cannot be achieved through conventional RNAi or CRISPR-KO approaches. Additionally, many nucleolar proteins display peculiar biophysical properties, and their functions are connected to their abundance. Therefore, artificial overexpression systems might not fully recapitulate their endogenous biological functions. To overcome these challenges, we implemented an Auxin Inducible Degron (AID) system to acutely abrogate endogenous nucleolin, one of the most abundant nucleolar proteins, and asses its impact on the proliferation of TNBC cell lines. We used CRISPR/Cas9 editing in TNBC cell lines to modify the endogenous NCL gene, fusing it with an AID tag. Then, we stably transduced the cells with a modified Oryza Sativa TIR1 (OsTIR1-F74G) E3 ubiquitin ligase. In response to the synthetic phytohormone phenyl-auxin, OsTIR1 leads to the proteasomal degradation of AID-containing endogenous nucleolin in less than 6h, sparing any other human protein. RNA sequencing analysis showed that nucleolin degradation significantly alters the expression of genes involved in cell cycle progression. Accordingly, nucleolin degradation reduces cancer cell proliferation in vitro, associated with increased propidium iodide staining, suggestive of a G2/M cell cycle arrest. However, immunofluorescence analyses revealed that nucleolin abrogation leads to the accumulation of bi-nucleated cells with actin patches. These findings are indicative of potential cytokinesis defects due to altered spindle tension during mitosis. Notably, nucleolin abrogation increased the efficacy of chemical inhibitors of the Anaphase Promoting Complex on suppression of cell proliferation. To the best of our knowledge, this study is the first reporting the acute abrogation of an endogenous, highly abundant nucleolar protein, using the AID system. This approach allowed the characterization of nucleolin biological functions with unprecedented temporal resolution, shedding light on new biological functions in the regulation of cell division. Finally, our results suggest that nucleolin inhibition could enhance the therapeutic activities of drugs affecting cell cycle progression in TNBC.

#1651 Targeting intermediates of the PRMT5/BRG1 axis as a combination therapy.

A. Shaykevich, I. Silverman, A. Siegman, R. Maitra;
Yeshiva University, New York, NY

Over 40% of colorectal cancer (CRC) patients harbor a mutation in the *KRAS* gene, leading to a worse prognosis. PRMT5 and BRG1 are proteins considered potential therapeutic targets for cancer. Our lab has previously reported that both PRMT5 and BRG1 are overexpressed in *KRAS* mutant CRC when compared to *KRAS* wild-type CRC. It is therefore proposed that the PRMT5-BRG1 axis may be a strong therapeutic target for CRC. In this study, several key proteins that potentially mediate crosstalk between the PRMT5-BRG1 axis and *KRAS* were investigated.A literature review was first conducted to determine how the PRMT5-BRG1 axis acts in cancers. Additionally, pathways that may be involved in mediating the potential crosstalk between BRG1 and *KRAS* were discussed. Initial findings indicated that the PRMT5-BRG1 axis facilitates cancer oncogenesis. At the same time, the axis suppresses Myc/Max/Mad expression, leading to a dual role of the PRMT5-BRG1 axis depending on the tumor status. BRG1 was also found to work alongside mutant *KRAS* to affect tumor levels, with the effect differing by tumor type. The STRING database to determine the connection between the PRMT5-BRG1 axis and *KRAS*. It was determined that PRMT5, BRG1, and *KRAS* all interact with *PBRM1*, *SMARCB1*, *ARID1A*, and *ARID2*, with a combined interaction score >0.5. The UCSC Xena software was then used to analyze the mRNA data of CRC patients from The Cancer Genome Atlas (TCGA) database. Xena was utilized to determine which proteins are over expressed in CRC patient tumor samples compared to non-cancerous colon and rectum patient samples. Levels of *PBRM1* and *ARID1A* were observed to significantly decrease in CRC patients as compared to non-cancerous samples by approximately 15% (adjp < 0.0001 and 0.05, respectively). However, *SMARCB1* expression increased by 12% (adjp < 0.05). The Gene Expression Profiling Interactive Analysis (GEPIA) software was then used to analyze the correlation between the intermediary genes and PRMT5, BRG1, and *KRAS* in CRC patient tumor samples. *PBRM1*, *SMARCB1*, *ARID1A*, and *ARID2* all demonstrated positive correlation with PRMT5, SMARCA4, and *KRAS* (R greater than 0.75 for nearly all correlations and p =0) in CRC patient tumor samples. Our study thus showcases the possible disrepair of the PRMT5/BRG1 axis in relation to *KRAS*. Key downstream proteins are decreased in CRC and may lower the potential crosstalk between PRMT5, BRG1, and *KRAS*. These findings are significant, and these key intermediate proteins may be strong therapeutic targets via inducing expression. Further research is currently in progress to outline the molecular processes behind the therapeutic role of revitalizing the SMARCA4/BRG1 axis when the downstream proteins are induced.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Cell Signaling Components as Therapeutic Targets
Poster Session

#1654 Anti-tumor activity of orally-available cyclic peptide LUNA18 through direct RAS inhibition in RAS-altered tumors.

H. Sase[1], S. Michisaka[2], Y. Tachibana[2], M. Hasegawa[2], T. Fujii[2], K. Takei[2], T. Kanei[2], N. Murao[2], S. Kuramoto[2], N. Shibahara[2], A. Ohta[2], M. Tanada[2], T. Shiraishi[2], H. Iikura[2], T. Kitazawa[2], H. Tanaka[2];

[1]Chugai Pharmaceutical Co., Ltd., Chuo-ku, Tokyo, Japan, [2]Chugai Pharmaceutical Co., Ltd., Yokohama, Kanagawa, Japan

RAS is the one of the most frequently altered genes in human cancer and contributes to the growth of tumors. Recently, KRAS G12C inhibitors were approved as the first molecular targeting agents for RAS, but there are still huge unmet medical needs in RAS-mutated cancers because drugs targeting non-KRAS G12C tumors have not yet been approved and efficacy by even approved KRAS G12C inhibitors is not satisfactory. LUNA18 is the cyclic peptide that binds to RAS mutants and wildtype, including KRAS, NRAS and HRAS, thereby inhibiting protein-protein interaction (PPI) between the inactive form of RAS and GEFs (guanine nucleotide exchange factors). LUNA18 decreased the active form of KRAS and phosphorylated ERK and AKT, and cell proliferation in RAS-mutated cancer cells with nM order of cellular IC50s irrespective of tumor types and amino acid substitutions except for Q61 mutants. On the other hand, LUNA18 did not inhibit proliferation of cells with active mutations downstream of RAS (BRAF and MEK), suggesting LUNA18 selectively inhibited growth of RAS-dependent cells. Consistent with in vitro cellular activity, oral administration of LUNA18 showed durable RAS signal inhibition up to 24-48 hours and tumor regression in RAS-mutated xenograft models. In addition to KRAS-mutated cells, LUNA18 also showed in vitro and in vivo robust efficacy in KRAS-amplified cells. These data indicated LUNA18 is the versatile compound that selectively suppressed cellular signaling from RAS G12/G13 mutants as well as RAS wildtype amplification through inhibition of PPI between the inactive form of RAS and GEFs, and it can be applicable to a wide range of RAS-altered tumors. Rebound of the MAPK pathway is reported to be the one of the cause for attenuating efficacy of KRAS G12C inhibitors. We also observed the rebound of ERK activation 24-72 hours after the treatment with a KRAS G12C inhibitor in cells with the KRAS G12C mutation though suppression of KRAS activity was maintained. On the other hand, LUNA18 persistently suppressed ERK activity as well as KRAS activity up to 72 hours. The combination of the KRAS G12C inhibitor with siRNA for RAS wildtype showed durable inhibition of ERK activity, suggesting that RAS wildtype plays a key role for the rebound of ERK activity and inhibitory activity to RAS wildtype by LUNA18 contribute to the persistent inhibition of RAS signaling by LUNA18. We orally administered LUNA18 and a KRAS G12C inhibitor to a xenograft model, which showed temporal response and then acquired resistance to a KRAS G12C inhibitor, and found that LUNA18 significantly suppressed emergence of resistance to a KRAS G12C inhibitor. These results supported that the combination of the KRAS G12C inhibitor with LUNA18 could be a promising option to patients with KRAS G12C mutation by suppressing resistance to a KRAS G12C inhibitor through the suppression of rebound of the MAPK pathway.

#1655 Targeting lipid metabolism disrupts KRAS oncogenesis in pancreatic cancer.

Neha Arora[1], Hong Liang[1], Alex Reed[2], Jeffrey T. Chang[1], Benjamin F. Cravatt[2], Yong Zhou[1]

[1]Integrative Biology and Pharmacology, McGovern Medical School at UTHealth Houston, Houston, TX,[2]Department of Chemistry, The Scripps Research Institute, La Jolla, San Diego, CA

Background: KRAS mutations are chief genetic event in pancreatic cancer. Recently approved inhibitors, sotorasib and adagrasib specifically target $KRAS^{G12C}$, a minor mutation in pancreatic cancer. Further, patients developed acquired resistance by generating secondary KRAS mutations, posing an added obstacle for allele specific inhibitors, warranting alternative strategies to tackle KRAS-dependent cancers. KRAS forms proteolipid signaling platforms on plasma membrane (PM) termed nanoclusters. We have shown mutant KRAS nanoclusters selectively enrich phosphatidylserine (PS) lipid, being particularly receptive to unsaturated PS, suggesting lipid acyl chain metabolism is crucial for KRAS function. In cells, lysophosphatidylcholine acyltransferases 3 (LPCAT3) preferentially catalyzes synthesis of unsaturated PS. We tested the hypothesis that inhibition of LPCAT3 depletes unsaturated PS in the PM, perturbs the PS-dependent PM interactions and oncogenic functions of KRAS.

Methods: LPCAT3 knockdown (KD) mediated by siRNA in doxycycline (Dox) inducible $KRAS^{G12D}$ murine cells (iKRAS) and CRISPR-Cas9 in human pancreatic tumor line (MiaPaCa-2). LPCAT3 inhibition achieved using small molecule inhibitors (SMIs): HTS3 and HTS4. Shotgun lipidomics characterized re-modeling of PS lipidomes. PM distribution and nanoclustering of KRAS was evaluated by super-resolution electron microscopy (EM). Anti-tumor effect of LPCAT3 inhibition was examined *in vitro* by proliferation, colony formation and soft agar assays and cellular signaling by western blot.

Results: LPCAT3KD decreased polyunsaturated PS levels in MiaPaCa-2 and mislocalized mutant $KRAS^{G12V}$ on the PM with a 4-fold reduction in KRAS PM distribution ($p<0.0013$) and disrupted KRAS nanoclustering, without affecting that of $HRAS^{G12V}$ in transformed MiaPaCa-2. LPCAT3KD reduced colony formation ability in MiaPaCa-2. LPCAT3 siRNA reduced KRAS-dependent MAPK signaling, and significantly reduced colony formation only upon Dox-induced expression of $KRAS^{G12D}$, while having no effect in uninduced iKRAS. An integrated knowledgebase tool canSAR.ai generated a druggability score of 77% suggesting LPCAT3 is highly druggable by chemistry-based assessment. Indeed, recently discovered LPCAT3 inhibitors, significantly reduced MAPK signaling, proliferation and colony formation in mutant KRAS-dependent tumor cells while having no significant effect in WT KRAS cells corroborating mutant KRAS specificity of LPCAT3.

Conclusion: We demonstrate targeting unsaturated PS lipid metabolism by inhibiting LPCAT3 disrupts KRAS signaling platform and perturbs its oncogenic functions in pancreatic cancer cells. Since various KRAS mutants require unsaturated PS to propagate signaling, our approach targets diverse KRAS mutants, uniquely addressing drug resistance issue. Further, we will optimize the LPCAT3 inhibitors and study their efficacy in xenograft mouse models.

#1656 ISM6331, a novel and potent pan-TEAD inhibitor, exhibits strong anti-tumor activity in preclinical models of Hippo pathway-dysregulated cancers.

Q. Li[1], J. Wan[1], J. Liu[1], J. Shang[1], J. Yu[1], W. Zhu[1], C.-J. Chen[1], J. Qiao[1], L. Wang[1], M. Zhang[1], X. Ding[1], S. Bavadekar[2], **S. Rao**[2], F. Ren[1], A. Zhavoronkov[2]; [1]Insilico Medicine, Shanghai, China, [2]Insilico Medicine, New York, NY

The Hippo-YAP/TAZ-TEAD signaling pathway plays critical roles in tumorigenesis and tumor progression. Genetic alterations of Hippo pathway regulators, such as NF2 or LATS1/2, have been shown to induce YAP/TAZ-TEAD transcriptional activity, promoting initiation and progression of many solid tumors. In addition, many studies have shown that YAP/TAZ-TEAD activation mediates resistance to multiple targeted therapies, particularly EGFR-KRas-MAPK pathway inhibitors. The TEAD family of transcription factors (TEAD1/2/3/4) share structural similarity and have overlapping functions in tumor development and TEAD auto-palmitoylation is critical for its interaction with YAP/TAZ and its transcriptional function. Therefore, blocking TEAD palmitoylation and allosterically disrupting YAP/TAZ-TEAD-mediated transcriptional regulation, is emerging as a promising approach for the treatment of tumors with Hippo pathway dysregulation.
In this work, ISM6331, a novel and potent TEAD inhibitor with excellent inhibition against TEAD1/2/3/4 was identified leveraging an AI generative model. ISM6331 reversibly binds to the TEAD palmitoylation site and significantly suppresses TEAD transcriptional activity. ISM6331 potently and selectively inhibited the growth of many Hippo pathway-dysregulated tumor cells and dose-dependently suppressed the expression of TEAD target genes *in vitro*. In NF2-deficient or LATS1/2-mutant *in vivo* mesothelioma models, ISM6331 exhibited promising anti-tumor efficacy as monotherapy in a dose-dependent manner from 3 to 30mg/kg. ISM6331 also showed synergism with EGFR or KRasG12C inhibitors in inhibiting tumor cell growth and overcame drug resistance in *in vitro* and *in vivo* models. In addition, ISM6331 showed excellent pharmacokinetic properties in multiple preclinical species and was well-tolerated in GLP-toxicity studies. In summary, ISM6331 has promising potential to treat Hippo pathway-dysregulated tumors as monotherapy as well as in combination with targeted therapies.

#1657 Microfluidics-based screening platform identifies a novel therapeutic approach to targeting EML4-ALK driven cancers.

R. C. Centore[1], M. Watson[2], J. Doh[1], J. Cattin[2], C. Sgambato[2], A. Alex[2], J. Sawant[1], P. Radhakrishnan[1], J. Cornish[2], A. Howarth[2], N. Bharatham[2], W. E. Arter[2], S. Qamar[2], K. L. Saar[2], D. Williamson[2], A. Seeber[1], N. Groenewegen[2], M. Czekalska[2], T. Kartanas[2], N. Ermann[2], A. Taher[2], T. Knowles[2], S. Arora[1]; [1]Transition Bio, Inc., Watertown, MA, [2]Transition Bio, Inc., Cambridge, United Kingdom

To achieve proliferative dysregulation, a hallmark of cancer, tumor cells utilize a variety of mechanisms to maintain constitutive oncogenic signaling in the absence of extracellular cues. One such mechanism occurs in cells expressing the EML4-ALK fusion protein. This fusion, found in about 4% of non-small cell lung cancer (NSCLC), is a result of an inversion within chromosome 2, placing the 3' end of the *ALK* (anaplastic lymphoma kinase) gene downstream of the 5' end of the *EML4* (echinoderm microtubule associated protein-like 4) gene. The resulting fusion protein contains the oligomerization domain and additional disordered sequence elements of EML4 upstream of a functional ALK kinase domain. EML4-ALK is a critical driver for these tumors, promoting aberrant ALK-dependent oncogenic signaling. While tumors harboring the EML4-ALK fusion initially respond to ALK tyrosine kinase inhibitors (TKIs), resistance remains a significant clinical challenge requiring new therapeutic approaches. Recently, it has come to be understood that rather than responding through extracellular proliferative cues, the EML4-ALK fusion protein elicits constitutive ALK signaling through the formation of cytoplasmic biomolecular condensates. These condensates are the result of phase separation and have been shown to be causal for disease phenotypes in cell and animal models driven by EML4-ALK, establishing condensate modulation as a novel means by which to treat TKI-resistant tumors. Here, we have developed a novel proprietary microfluidics-based high throughput screening platform (termed PhaseScan™) to identify small-molecule modulators of EML4-ALK condensates. Using this technology, we identified compounds that disrupt EML4-ALK condensates *in vitro* and in cells through a novel mechanism, distinct from that of known ALK TKIs, providing utility in both TKI-resistant as well as TKI-naïve tumors. Further profiling of the mechanism of action (MoA) revealed specific modification within the disordered region of EML4, disruption of EML4 oligomerization, and defective ALK signaling in cancer cells. Thus, our PhaseScan™ methodology enabled the identification of novel, functionally active chemical matter that would have otherwise been challenging to identify utilizing any conventional hit identification methodology.

#1658 CFT1946, a potent, selective BRAF V600X mutant-specific degrader demonstrates superior activity as a single agent to clinically approved BRAF inhibitors and standard of care combinations in preclinical models of BRAF V600X melanoma, CRC, NSCLC, and brain metastasis.

B. Kreger, J. R. Stephenson, M. E. Sowa, S. A. Perino, L. L. Poling, E. Hurh, M. J. Thomenius, Y. Liang, S. L. Fisher, R. M. Pollock;
C4 Therapeutics, Watertown, MA

Activating mutations in BRAF at residue V600 (typically V600E) lead to dysregulation of the MAPK pathway and occur in approximately 8% of all human cancers including 60% of melanoma, up to 12% of colorectal cancer (CRC), and 4% of NSCLC. Currently approved BRAF inhibitors (BRAFi) are selective for BRAF V600X mutant proteins and are typically used in combination with MEK inhibitors (MEKi) in melanoma and NSCLC, or anti-EGFR antibodies such as cetuximab in CRC. However, their activity is limited by primary or acquired resistance often mediated by RAF dimer-inducing mechanisms. Furthermore, progression of BRAF V600X melanoma after BRAFi/MEKi treatment frequently involves brain metastasis, and currently approved BRAFi have relatively poor brain penetration. CFT1946 is a potent, orally bioavailable, cereblon-based BiDAC^{TM} degrader that selectively degrades BRAF V600X mutant protein and is currently under investigation in a Phase I clinical trial. CFT1946 has the potential to overcome limitations of clinically approved BRAFi, as degradation of BRAF V600X should abrogate RAF dimer-driven resistance and paradoxical activation. Indeed, we have previously demonstrated that CFT1946 is efficacious in an A375 BRAF V600E/NRAS Q61K xenograft model of BRAFi resistant melanoma. Here we substantially expand our preclinical characterization of CFT1946 across multiple models of BRAF V600X-driven cancers including BRAF V600X-driven CRC and NSCLC, additional BRAFi-resistant melanoma models, and a brain metastatic melanoma model. Single agent CFT1946 outperformed the SOC encorafenib + cetuximab combination in a panel of BRAF-V600X CRC xenograft models. Pathway analysis in BRAF V600X CRC models revealed that CFT1946 suppresses EGFR-mediated MAPK pathway reactivation, a mechanism known to diminish the impact of approved BRAF inhibitors in this indication. CFT1946 also demonstrated regression in a BRAF-V600X NSCLC PDX model where the SOC dabrafenib + trametinib showed only modest tumor growth inhibition. Consistent with our previous results in the A375 melanoma model, single agent CFT1946 showed superior activity versus the SOC dabrafenib + trametinib combination in all additional melanoma models tested, with complete regression achieved using a CFT1946 + trametinib combination in a PDX model bearing a BRAF-V600E kinase duplication that showed minimal response to dabrafenib + trametinib. Finally, using an A375 intracranial model, treatment with CFT1946 gave robust, dose dependent efficacy and survival advantage over encorafenib. The promising activity of CFT1946 in a broad range of BRAF V600X preclinical models supports its ongoing clinical investigation in BRAF V600 mutant solid tumors (NCT05668585).

#1659 Phosphorylation of cell cycle and apoptosis regulatory protein (CARP)-1 by stress-activated protein kinase P38γ is a novel mechanism of apoptosis signaling by genotoxic chemotherapy.

J. Venkatesh[1], M. Muthu[1], V. T. Cheriyan[1], S. C. Sekhar[1], N. C. P. Acharige[2], E. Levi[3], H. Assad[1], M. K. H. Pflum[2], **A. K. Rishi[1]**;
[1]Barbara Ann Karmanos Cancer Institute, Detroit, MI, [2]Wayne state University, Detroit, MI, [3]Department of Veterans Affairs Medical Center, Detroit, MI

CARP-1, a perinuclear phospho-protein, regulates cell survival and apoptosis signaling induced by genotoxic drugs. However, kinase(s) phosphorylating CARP-1 and down-stream signal transduction events remain unclear. Here we find that CARP-1 Serine (S)^{626} and Threonine (T)^{627} substitution to Alanines (AA) inhibits genotoxic drug-induced apoptosis. CARP-1 T^{627} is followed by a Proline (P), and this TP motif is conserved in vertebrates. To further elucidate chemotherapy-activated, CARP-1-dependent signaling mechanisms, we UV cross-linked protein extracts from Adriamycin-treated HeLa cervical cancer cells with a CARP-1 (614-638) peptide, and conducted liquid chromatography-tandem mass spectrometry (LC-MS/MS) analyses of the peptide-bound protein complexes. This experiment revealed SAPK p38γ interaction with CARP-1 (614-638) peptide. Our studies further revealed that SAPK p38γ phosphorylates CARP-1 T^{627} in cancer cells treated with genotoxic drugs. CARP-1 T^{627} phosphorylation was also noted in breast tumors from patients treated with radiation or endocrine therapies. Loss of p38γ abrogates CARP-1 T^{627} phosphorylation, and results in enhanced survival of breast cancer cells by genotoxic drugs. We conclude that genotoxic drugs activate p38γ-dependent CARP-1 T^{627} phosphorylation and cell growth inhibition.

#1660 Tumor pharmacokinetics and pharmacodynamics assessment of TEAD inhibitor VT03989 in patient-derived xenograft models of glioblastoma.

T. Margaryan, Y.-W. Chang, J. Molloy, B. Hopkins, M. Elliott, E. Luna Melendez, C. White, N. Sanai, A.-C. Tien, A. Tovmasyan, S. Mehta;
Barrow Neurological Institute, Phoenix, AZ

Background: The Hippo-YAP/TAZ pathway regulates cell proliferation, cell growth and migration. The major effectors of the Hippo pathway are the TEAD transcription factors, which are deregulated in several cancers, including glioblastoma (GBM). In this study, we evaluated the pharmacokinetics and pharmacodynamics of VT03989, a highly potent TEAD inhibitor, in orthotopic patient-derived xenograft (PDX) models of GBM.
Methods: Mice with intracranial PDX GBM tumors were randomized into two cohorts to receive 10 mg/kg (oral) VT03989 or placebo for 4 days. VT03989 levels in plasma, tumor, and contralateral brain tissue were measured by liquid chromatography tandem mass spectrometry (LC-MS/MS) at 2, 6, and 12 hours after the last treatment of VT03989. Unbound fractions were determined by equilibrium dialysis. Quantitative RT-PCR was performed to assess levels of TEAD target genes, CTGF and CYR61. Immunohistochemistry of Ki67 and cleaved caspase 3 (CC3) was performed.
Results: The median unbound concentrations of VT3989 were 27 nM in plasma and 26 nmol/kg in the tumor. The median brain-to-plasma and tumor-to-plasma partition coefficients of unbound VT03989 were 0.65 and 0.99, respectively - indicating favorable brain and tumor penetration ability of VT03989. A decrease in CTGF and CYR61 indicated TEAD inhibition and was accompanied by an increase in CC3 (+) cells.
Conclusion: VT03989 is well tolerated, achieves pharmacologically relevant unbound concentrations in GBM PDX models, and is associated with significant target modulation. Ongoing studies are evaluating *in vivo* survival benefits from combining VT03989 inhibition with radiation therapy

#1661 Preclinical characterization of HMPL-295, a potent and selective ERK 1/2 inhibitor.

J. Hu, J. Ni, Y. Lv, W. Li, H. Zhang, X. Li, Y. Yu, Z. Zhong, J. Wang, Y. Sai, W. Qing, Y. Ren, M. Shi, W. Su;
HUTCHMED, Shanghai, China

Background: Although therapeutic agents targeting alterations in the MAPK pathway have achieved great clinical success, the overall benefit is still suboptimal. Several studies have shown that reactivation of MAPK signaling is the main basis to compromise the efficacy. Thus, co-inhibition of ERK, the terminal master kinase of MAPK pathway, and the upstream targets may effectively shut down the MAPK signaling cascade and induce deeper and more durable anti-tumor activities. Herein, we present the preclinical characterization of HMPL-295, a potent and selective ERK 1/2 inhibitor, discovered and being currently developed in phase I clinical trial (NCT04908046) by HUTCHMED.

Methods: The inhibition on ERK 1/2 kinase was determined using Z-LYTE™ kinase assay. The selectivity of HMPL-295 was evaluated against 394 kinases (KinaseProfiler^{TM}) and 86 safety-related proteins (SafetyScreen87^{TM}) by Eurofins. Cellular target inhibition on phosphorylation of RSK (p-RSK) was detected by ELISA. *In vitro* anti-proliferation activity of HMPL-295 as a single agent was measured by CCK-8 or CellTiter-Glo luminescent assay. Colony formation assay was used to evaluate the combination effect of HMPL-295 with targeted therapy. Multiple tumor models with RAS/RAF/MAPK pathway activation were applied in immune-deficient mice to investigate the anti-tumor activity of HMPL-295 as a single agent or in combination with either chemotherapy or targeted therapy.

Results: HMPL-295 strongly inhibited ERK1 and ERK2 kinase activities with equal IC_{50} at 4 nM. In human colon cancer cell line COLO 205 harboring *BRAF*^{V600E} mutation, HMPL-295 inhibited p-RSK, a direct substrate of ERK1/2, with an average IC_{50} of 180 nM from 3 independent experiments. With the inhibition of ERK and its downstream substrates, HMPL-295 treatment induced tumor cells arresting at G0/G1 phase via down-regulation of cyclin D1/p-RB signaling and consequently attenuated cell growth in a panel of MAPK pathway dysregulated tumor cell lines, but barely affected the growth of normal cells. Furthermore, HMPL-295 demonstrated favorable selectivity in the kinase and safety pharmacology profiling, indicating a low off-target risk. For *in vivo* studies, oral administration of HMPL-295 induced time- and dose-dependent inhibition of p-RSK and resulted in dose-dependent anti-tumor activity in several tumor models harboring *KRAS* or *BRAF* mutations. Moreover, HMPL-295 significantly improved the anti-tumor activity of standard-of-care chemotherapy as well as targeted agents in *KRAS*- or *BRAF*-mutant tumor models both *in vitro* and *in vivo*.

Conclusion: HMPL-295 is a potent and selective ERK1/2 inhibitor which demonstrates strong anti-tumor activity in preclinical models, supporting further clinical evaluation.

#1662 Evaluation of TEAD inhibitor, VT03989 treatment on growth of aggressive meningioma preclinical models.

S. Desai, A. Thaghalli Shivanna, M. Stavnichuk, E. Hayes, S. Patel, J. McNamara, A. DeSantis, N. Sanai, A.-C. Tien, S. Mehta;
Barrow Neurological Institute, Phoenix, AZ

Background: Aggressive meningiomas (WHO grade II/III) are incurable brain tumors and despite surgery and radiation therapy, tumors recur frequently without approved systemic treatment options. Hence, there is an unmet need for targeted inhibition therapy and biomarkers that predict vulnerability to targeted therapies in aggressive meningioma patients. Hippo signaling pathway has been shown to be dysregulated in meningioma, resulting in activation of its target TEAD as a transcriptional factor. We hypothesize that targeted inhibition of TEAD in recurrent high-grade meningioma with *NF2* loss will lead to increased inhibition of tumor growth. Here, we investigated the effect of VT3989, a potent TEAD inhibitor, in meningioma cell lines with *NF2* wild-type or *NF2* loss genotype.

Methods: Two meningioma cell-lines: IOMM-Lee (*NF2* wild-type) and MG309, a grade III meningioma patient-derived cell line with *NF2* loss were treated with various doses of VT3989 and cell viability was assessed. Relative expression of direct targets of TEAD including CTGF and CYR61 was determined with quantitative PCR (qPCR) to ensure target engagement. Global transcriptomic changes were examined via RNAseq analysis on RNA isolated from MG309 cells treated with VT03989 compared to vehicle treated cells.

Results: VT3989 treatment significantly decreased viability of both IOMM-Lee and MG309 cells. Canonical downstream targets of TEAD such as CTGF, CYR61, BIRC5, BCL-2 were downregulated in VT3989 treated cells compared to control. Furthermore, VT03989 treatment resulted in downregulation in cell cycle regulation and DNA damage response (DDR) pathway genes. Ongoing work is focused on combining VT3989 with agents targeting cell cycle and DDR pathways.

Conclusion: VT3989 treatment led to downregulation of TEAD direct targets CTGF and CYR61 and inhibited cell viability of both IOMM-Lee cell and MG309 meningioma lines. RNA-seq analysis identified cell cycle and DDR pathway genes to be downregulated upon TEAD inhibition.

#1663 Single-cell signaling analysis reveals that major vault protein facilitates RasG12C inhibitor resistance.

J. Z. Zhang, S.-E. Ong, D. Baker, D. J. Maly;
University of Washington, School of Medicine, Seattle, WA

Covalent inhibitors of RasG12C are the first clinically-approved drugs for targeting mutant Ras-driven cancers. However, the rapid development of clinical resistance to current Ras G12C inhibitors is common. It has been demonstrated that a subpopulation of cancer cells facilitate drug resistance but the mechanistic basis of this heterogenous response is not well understood. Here, we utilized recently developed Ras sensors to profile the environment of active Ras and to measure the activity of endogenous Ras to pair structure (Ras signalosome) to function (Ras activity), respectively, at a single-cell level. With this approach, we found that a subpopulation of KRasG12C cells treated with RasG12C-GDP inhibitors underwent oncogenic signaling and metabolic changes driven by WT Ras at the golgi and mutant Ras at mitochondria, respectively. Our Ras sensors identified Major Vault Protein (MVP) as a mediator of Ras activation at both subcellular locations by scaffolding Ras signaling pathway components and metabolite channels. We found that recently developed RasG12C-GTP inhibitors also led to MVP-mediated WT Ras signaling at the golgi, demonstrating that this a general mechanism of RasG12C inhibitor resistance. Overall, single-cell analyses enabled the discovery of a RasG12C inhibitor-resistant subpopulation driven by MVP, providing insight into the complex and heterogenous rewiring that confers drug resistance in cancer.

#1664 Combination of LUNA18, a novel RAS inhibitor, with KRAS G12C inhibitors augments anti-tumor activity via inhibition of MAPK pathway reactivation.

S. Michisaka, H. Sase, Y. Tachibana, M. Hasegawa, T. Fujii, S. Kuramoto, N. Shibahara, A. Ohta, M. Tanada, T. Shiraishi, H. Iikura, T. Kitazawa, H. Tanaka; Chugai Pharmaceutical Co., Ltd., Kanagawa, Japan

RAS gene alterations, found in approximately 15% of all cancers and known oncogenes, are recognized as promising therapeutic targets. KRAS G12C inhibitors were the first FDA-approved RAS targeting agent, but their efficacy of monotherapy is limited. Reactivation of the MAPK pathway is reported to be the one of the causes for attenuating efficacy of KRAS G12C inhibitors. LUNA18 is the cyclic peptide that binds to RAS mutants and wildtype, including KRAS, NRAS and HRAS, thereby inhibiting protein-protein interaction (PPI) between the inactive form of RAS and GEFs (guanine nucleotide exchange factors).We observed the rebound of ERK activation 24-72 hours after the treatment with a KRAS G12C inhibitor in cells with the KRAS G12C mutation though suppression of KRAS activity was maintained. This rebound was not suppressed by the KRAS G12C inhibitor retreatment. On the other hand, LUNA18 persistently suppressed ERK activity as well as KRAS activity up to 72 hours. LUNA18 also suppressed ERK reactivation caused by long-term treatment with the KRAS G12C inhibitor. The combination of the KRAS G12C inhibitor with siRNA for RAS wildtype showed durable inhibition of ERK activity, suggesting that RAS wildtype plays a key role for the rebound of ERK activity and inhibitory activity to RAS wildtype by LUNA18 contribute to the persistent inhibition of RAS signaling by LUNA18. In the experiment model that with strong RAS wildtype activation by stimulation with GFs (growth factors), the KRAS G12C inhibitor also did not suppress ERK activation. Conversely, LUNA18 suppressed it. Cell proliferation induced by GF stimulation was more strongly inhibited by LUNA18 than by the KRAS G12C inhibitors. Our data indicates that MAPK pathway reactivation via WT-RAS activation leads to resistance to KRAS G12C inhibitors and that the combination of LUNA18 and KRAS G12C inhibitors has the potential to overcome this resistance mechanism. In the in vitro cell growth assay, combination of LUNA18 and the KRAS G12C inhibitor showed more potent cell growth inhibition than single agents. We orally administered LUNA18 and the KRAS G12C inhibitor to a xenograft model, which showed temporal response and then acquired resistance to the KRAS G12C inhibitor, and found that LUNA18 significantly suppressed emergence of resistance to the KRAS G12C inhibitor. These results suggest that LUNA18 could be a promising candidate for combination therapy with KRAS G12C inhibitors.

#1665 Investigating Daple-FLT3 gene fusion in leukemia cells and its response to kinase inhibitors.

E. Nguyen, J. Ear;
California State Polytechnic University of Pomona, Pomona, CA

Gene fusions are frequently found in leukemia and other cancers. The signaling scaffold protein, Daple (CCDC88C), has been found to undergo gene fusion to the receptor tyrosine kinase, FLT3. Specifically, a fragment of the coiled-coil domain from Daple and tyrosine kinase domain (TKD) of FLT3 are found fused together. How the gene product from this gene fusion functions in rewiring the signaling network in cells and whether this gene product can be targeted though pharmacological inhibitions remain unclear. Cell surface receptors, such as receptor tyrosine kinases (RTKs), activate cell signaling and genetic mutations that lead to constitutive receptor activation can promote unregulated cell proliferation, survival, and migration. Leukemia patients with hyperactive RTKs are treated with tyrosine kinase inhibitors (TKIs), such as Imatinib and Sorafenib. Here we demonstrate how TKIs can directly block the activation of Daple-FLT3 and prevent hyperactivation of its downstream pathways. Our studies unveil a strategy to identify other compounds which may serve as an additive, or alternative, approach to treating patients with Daple gene fusion.

#1666 A novel sox-based continuous and homogeneous assay for the discovery of inhibitors of inactive and active AKT.

S. Cornell-Kennon, D. Urul, M. Hakar, H. McMahon, K. Huynh, E. May, E. Schaefer;
Assayquant Technologies, Inc., Marlborough, MA

Introduction: The activity of protein kinases plays a critical role in the aberrant activation of oncogenic signaling pathways which can drive tumorigenesis and malignant transformation in cancer. AKT has been shown to be both upregulated and mutated in cancer cells allowing it to serve as a driver of cancer cell growth and progression. Inhibition of AKT activation and activity are both attractive targets for effective cancer drug discovery.
Experimental Procedures: We developed continuous, homogeneous assays for unactive AKTs. A peptide substrate, modified with a sulfonamido-oxine fluorophore (Sox), utilizes chelation-enhanced fluorescence to enable a real-time readout of AKT-driven phosphorylation. First, a subset of 30,000 Sox-containing sequences were evaluated for AKT substrate candidates, selecting for assay robustness and specificity. A physiologically relevant peptide substrate was identified and used to develop a kinetic assay to monitor AKT1 activation and activity. Unactive AKT1 was incubated with DOPS/DOPC and PIP3, which mimics the plasma membrane, allowing the PH domain of AKT to bind, leading to a conformational change that enables full activation of AKT by PDK1 and MK2. Upon assay initiation, active AKT phosphorylates the sensor peptide, and the resulting signal is read in kinetic mode using a fluorescence intensity readout. First derivative plots for each progress curve were generated; the slope of the linear regions of each plot, representing acceleration towards a steady-state, were used to determine relative rates of activation for each AKT.
Results: We developed a novel assay for AKT activation and substrate phosphorylation utilizing AQT0076, DOPS/DOPC, PIP3, PDK1, and MK2. With a mix of classical AKT inhibitors and allosteric inhibitors that rely on an inactive “PH-in” conformation, we demonstrated inhibition and quantified inhibitor potency of both active “PH-out” AKT activity and inactive “PH-in” AKT activation via dose-response measurements of steady-state rate and rate acceleration, respectively.
Conclusions: A robust, homogeneous assay was developed to simultaneously monitor AKT activation and substrate phosphorylation kinetically over time. Through a continuous assay, we captured both steady-state rates and rate acceleration as a function of inhibitor concentration, allowing for accurate quantitation of both classes of AKT inhibitors in a single experimental format. With some inhibitors, we observed potencies that matched reported literature values, while with others we observed marked differences that may reflect a more physiological context that could translate through to higher efficacy in the clinic. This novel assay format provides a new tool that can be used in drug discovery to generate more effective next generation inhibitors of both AKT activation and subsequent substrate phosphorylation to prevent cancer cell growth and progression.

#1667 The role of CCN1 in mutant K-RAS addiction in pancreatic cancer.

A. Kambhampati, A. De, I. Haque, S. Banerjee, S. K. Banerjee;
Kansas City VA Medical Center, Kansas City, MO

Mutant K-RAS addiction of pancreatic ductal adenocarcinoma cells (PDAC) coordinates their transformation, proliferation, and survival. Therefore, initially, it had an impression that targeting mutant K-RAS could be an ideal strategy to treat PDAC. However, after decades of studies, no effective RAS inhibitors reached the clinic, indicating that RAS-oncoprotein is an undruggable target in PDAC. Thus, identifying a new target linked with K-RAS signaling was most needed. Using genetically engineered cell lines and K-RAS-driven genetically engineered mouse models (KC or KPC) with or without pancreas-specific CCN1 conditional knockout background, we identified a positive feedback circuit between CCN1 and mutant K-RAS expression. Moreover, blocking this feedback via conditional knockout of CCN1 in the pancreas significantly reduced invasive phenotypes, PDAC growth, and metastasis in the lung in KC and KPC mice. Mechanistically, we found that the K-RAS-CCN1 feedback circuit is regulated by microRNA miR-145 via a feedforward mechanism. Collectively, these studies highlight the clinical potential of targeting CCN1 in PDAC. (VA Merit Grant supports this work)

#1668 Association of stem cell-like phenotype with isoform specific functions of AKTs in hepatocytes.

I. Slarve, Y. Wang, M. Alba, L. He, B. Stiles;
USC - University of Southern California, Los Angeles, CA

Introduction: Liver cancer is the sixth most common cancer and the third leading cause of cancer-related deaths worldwide. It is associated with abnormal activation of the phosphatidylinositol 3-kinase (PI3K)/AKT pathway, which is implicated in regulation of cancer stem cells (CSCs). The present study investigated the effects of AKT loss on stem cell-like phenotype in immortalized mouse hepatocytes.

Methods: Immortalized hepatocytes were established from mice with *Akt1* (*Akt1*$^{-/-}$; *Akt1*-null) or *Akt2* (*Akt2*$^{-/-}$; *Akt2*-null) whole-body deletion. Cell morphology was assessed via microscopy. Cell proliferation was evaluated with hemacytometer count and MTT assay. Cell migration towards a chemoattractant was assessed via transwell assay. Cell viability was evaluated in response to chemotherapy treatment. The ability of cells to

Results: When compared to WT cells, which exhibited cuboidal epithelial-like features, *Akt1*-null and *Akt2*-null cells demonstrated elongated mesenchymal-like morphology. Loss of either isoform was associated with a significantly decreased cell growth ($p<0.05$). *Akt1*-null cells migrated faster towards a chemoattractant in the transwell assay, were significantly more resistant to sorafenib, and formed a significantly higher number of spheres in the sphere formation assay ($p<0.01$). Proteomic analysis revealed that both *Akt1*-null and *Akt2*-null cells exhibited increased expression of CSC marker CD44, along with other proteins associated with liver cancer, including PDGFRA, CDH2, MMP14, and COX2 ($p<0.05$). Additionally, *Akt1*-null cells exhibited elevated levels of ANXA1 and ANXA3 ($p<0.01$).

Conclusions: Loss of both AKT isoforms resulted in decreased cell proliferation and elevated expression of proteins with a previously reported role in liver cancer invasion, migration, and epithelial-mesenchymal transition. AKT1 loss correlated with an enhanced stem cell-like phenotype, including increased migration towards a chemoattractant, higher resistance to chemotherapy, and enhanced ability to form spheres. These results contribute to the understanding of the role of AKT isoforms in regulating stemness in liver cancer and may serve as a basis for investigation into isoform specific inhibitors. Further investigation into cellular mechanisms governing these phenotypes is required.

#1669 KRAS G12X mutants display differential preferences in downstream effector binding.

L. J. Ash[1], O. Bourdain[2], D. Lam[2], S. S. Pallas[2], A. L. Wolfe[2];

[1]The Graduate Center of the City University of New York, New York, NY, [2]Hunter College of the City University of New YorK, New York, NY

KRAS is among the most frequently mutated oncogenic driver proteins in human cancers including lung, colorectal, and pancreatic cancers. Activating KRAS mutants cause increased cell proliferation through direct binding and overactivation of effector proteins. Effector activation preference is driver mutation specific, as KRAS G12D and G12C purportedly bind both RAF and PI3K, whereas G12R has been reported to bind RAF but not PI3K. The mechanisms of effector binding of G12S action are under-investigated. Furthermore, most KRAS mutations remain clinically untreatable, as clinically approved KRAS inhibitors (KRASi) are currently limited to specifically targeting G12C. While experimental non-G12C inhibitors are being developed, resistance mechanisms to non-G12C mutations—including G12D/R/S/V—remain relatively understudied.

We set out to characterize the binding efficiency of KRAS to RAF1 and the PI3K subunit p110α, and to understand how isoforms differ in inhibitor resistance strategies. Our findings suggest that significant variances in KRAS mutation-specific effector binding preference exist and are cell line dependent. We performed proximity ligation based immunofluorescence assays (PLA) on an isogenic panel of human colorectal SW48 KRAS cells with G12C/D/R/S/V or wildtype. SW48 cells with G12S significantly prefer the KRAS-RAF1 mode of binding over otherwise isogenic WT cells, and G12V homologs prefer PI3K. Our findings suggest that in this model, G12R cells have no specific preference of one binding mode over the other. We hypothesize that G12 chemistry drives effector binding preference and that G12X inhibitor resistant cell cultures will demonstrate variant mechanisms of resistance in line with their preferred binding partner. Ongoing studies will further characterize understudied RAS isoform biology and evaluate the links between isoform chemistry and mechanisms of inhibitor resistance. These studies will expand our mechanistic knowledge of the interplay between G12X chemistry and adaptive resistance in human cancer.

#1670 Mechanistic insight into mTOR signaling identifies RNA splicing machinery as a potential therapeutic target for cancer.

G. Rondeau, M. Opichka, K. White, J. M. Yeakley, D. J. Eastburn, **B. Seligmann**;
BioSpyder, Carlsbad, CA

Aberrant signal transduction regulating cell growth and proliferation is a hallmark of many cancers. Activation of mTOR signaling is common and is an attractive therapeutic target with mechanistically different mTOR inhibitors in clinical use. One consequence of exposure to the mTOR inhibitor rapamycin is an alteration of gene expression through a global increase in alternative exon inclusion (Cheng et al. 2022, doi.org/10.3390/ijms232012416). To examine the mechanisms underlying this effect, we utilized the TempO-Seq targeted sequencing platform to profile both the whole transcriptome and a selection of alternatively spliced RNA targets in the rapamycin sensitive and resistant breast cancer cell lines MCF-7 and MDA MB 231 following exposure to 13 mTOR inhibitors, some closely related and some from distinct chemical classes. Recent publications have demonstrated that high quality dose response data can be obtained using this sequencing platform (Harrill et al. 2021, doi: 10.1093/toxsci/kfab009; Ramaiahgari et al. 2019, doi: 10.1093/toxsci/kfz065) and TempO-Seq has been widely adopted in toxicology for deriving compound-specific expression signatures to identify mechanisms of action and long-term toxicity. Treated cells were also profiled using TempO-LINC, a novel high-throughput single-cell assay based on the same platform. We observed that certain mTOR inhibitors induced both common and cell-specific differential expression as well as widespread alternative exon inclusion, as expected. Intriguingly, transcripts with the most significant changes in splicing upon treatment were those encoding members of the SR family of splicing factors, often overexpressed or amplified in breast cancers (Park, et al. 2019, doi: 10.1016/j.celrep.2019.10.110). This is significant because SR protein expression is autoregulated by alternative inclusion of an exon containing a premature stop codon in a feedback loop leading to nonsense-mediated decay (NMD) and lowered protein levels. Indeed, NMD is known to be inhibited by rapamycin (Martinez-Nunez, et al. 2017, doi: 10.1093/nar/gkw1109), which would lead to the observed accumulation of these transcripts. Thus, monitoring a targeted selection of alternative splicing events and regulators revealed mTOR regulation of mRNA isoform abundance consistent with regulation of the NMD RNA turnover process and with overexpression of SR proteins in breast cancers. Importantly, targeted bulk and single-cell TempO-Seq assays enable efficient sequencing and simplified data analysis without the expense and bioinformatic burden of RNAseq, making them particularly well-suited for drug discovery. These results support the use of this approach for further characterization of cell-specific effects of mTOR inhibitors and their mechanisms of action.

#1671 Exploring the mechanism of PP2A regulated cell death via macropinocytosis in pancreatic cancer.

I. Doraivel, G. Baral, C. M. Pfeffer, B. L. Allen-Petersen;
Purdue University, West Lafayette, IN

Pancreatic Ductal Adenocarcinoma (PDAC) is the 4th leading cause of cancer-related death in the United States. KRAS is an oncogene mutated in 90% of PDAC patients. Oncogenic KRAS leads to aberrant cell proliferation and survival. KRAS is considered hard to target because resistance mechanisms to KRAS inhibitors are common highlighting the need to understand alternative strategies. PDAC tumor microenvironment evolves with cancer cell progression leading to vascular remodeling and blood vessel collapse. This makes the tumors nutrient deplete. To circumvent this, cells employ KRAS-dependent macropinocytosis- a nutrient scavenging pathway. Macropinocytosis is the process by which cells take up extracellular material by membrane ruffling to form vesicles which then fuse with lysosomes to release nutrients. Targeting KRAS-driven macropinocytosis can be crucial to limiting nutrients to the cell to prevent tumor growth. Protein Phosphatase 2A (PP2A), a heterotrimeric Serine/Threonine phosphatase, is a downstream regulator of KRAS. Its activity is repressed by mutated KRAS. We have seen that the activation of PP2A with small molecular activator, DT061, prevents macropinosomes from fusing with lysosomes which leads to cell death. But how DT061 regulated PP2A activity affects the macropinocytosis pathway is still unknown. The purpose of this study is to understand the mechanism of cell death brough upon by the activation of PP2A with DT061. Membrane ruffling is critical for the initiation of macropinocytosis. Rac is a GTPase usually involved with membrane ruffling. To show that Rac is needed for DT061 mediated macropinocytosis, we used EHT 1864, a Rac family inhibitor. Cells were treated with EHT 1864 before being treated with DT061 and stained with crystal violet. The inhibition of Rac prevented DT061 driven cell death, indicating that Rac is crucial to DT061 driven cell death. High molecular weight TMR-Dextran can only be taken up by the cells through macropinocytosis. Cells were treated with TMR-Dextran and EHT 1864. Cells with Rac inhibition showed lower uptake of TMR-Dextran than cells that were treated with DT061. Together these findings indicate to us that Rac plays a crucial role in the initiation of macropinocytosis and the regulation of cell death caused by the activation of PP2A. Understanding the pathway of DT061 mediated cell death can be vital to developing this concept as a therapeutic method of treatment for PDAC patients who currently have the lowest 5-year survival rate (12%) of all cancers.

#1672 PKC-ι and 14-3-3 are crucial regulators of c-Raf and the Erk pathway in human medulloblastoma.

L. Lajmi, W. S. Ratnayake, J. Palathinkal, S. Breedy, A. Todman, M. Acevedo-Duncan;
University of South Florida, Tampa, FL

Medulloblastoma is the second most common childhood cancer, behind leukemia, and the most common pediatric brain tumor, comprising 20% of all childhood brain cancers. Current treatment options are limited to radiation therapy, surgical resection, and chemotherapy, which are extremely invasive. This underscores the need for more targeted and effective therapeutic treatments to improve patient outcomes. The following study will focus on exploring the PKC-ι specific inhibitor 5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S) and its effects on medulloblastoma cell lines Daoy and ONS-76. Our *in-vitro* treatments showed that PKC-ι functions an oncogenic protein that is necessary for Daoy and ONS-76 cell proliferation and that ICA-1S was found to be cytostatic to both Daoy and ONS-76 cells. The inhibition of PKC-ι in both cell lines resulted in a decreased phosphorylation of PKC-ι as well as downregulation of 14-3-3 and crucial components of the c-Raf/Erk pathway including total and phosphorylated levels of c-Raf, Mek1/2, and Erk1/2. This comes as a result of ICA-1S blocking the association of PKC-ι with 14-3-3 while PKC-ι and c-Raf were not found to directly associate with each other, indicating indirect modulation of c-Raf by PKC-ι. Additionally, PKC-ι inhibition decreased its association with Stat3. Expression levels of Stat1, Stat3, c-Fos, and c-Myc transcription factors were significantly downregulated, which is likely the result of reduced transcriptional activation due to upstream inhibition of PKC-ι and Erk signaling. Treatment with ICA-1S was also shown to substantially decrease cellular invasion of Daoy and ONS-76 cells and induce apoptosis. Taken together, these data suggest that PKC-ι likely plays a critical role in the regulation of the c-Raf/Erk pathway, which controls the proliferation and invasion of human medulloblastoma.

#1673 KRAS dependency, a gene editing approach.

C. Marcireau[1], F. Lacroix[1], D. Hoffmann[2], M. Cindhuchao[2], L. Calvet[1], Y. Ruffin[1], L. Debussche[1];
[1]Sanofi, Vitry-Sur-Seine, France, [2]Sanofi, Cambridge, MA

The RAS family genes encode small GTP-binding cytoplasmic proteins that are important signaling molecules. They regulate cell growth, survival and differentiation by coupling receptor activation to downstream effector pathways. Activating mutations of oncogenic RAS pathway genes are frequently detected in human cancers. The role of KRAS in tumor formation is not questionable. It's implication in tumor maintenance is less well validated. The KRAS dependency is a key question to answer before to develop KRAS inhibitor. Targeted genome editing using CRISPR/Cas9 is a relatively new, revolutionary technology allowing for efficient and directed alterations of the genome. CRISPR is a genome-editing platform that makes use of the bacterially-derived endonuclease Cas9 to introduce DNA double-strand breaks at precise locations in the genome using complementary guide RNAs. These double strand breaks can be repaired by homologous recombination DNA repair mechanisms thank to a donor DNA template. By this way mutations can be introduced at desired loci, DNA fragment can be deleted or introduce at the desired location. We aimed at investigating the KRAS dependence and we applied the CRISPR-Cas9 technology to engineer isogenic cancer cells harboring a "conditional KRAS gene knockout" by exchanging the KRAS endogenous promoter. This promoter replacement approach can be used also to validate new targets.

#1674 Inhibition of oncogenic nras signaling in acute myeloid leukemia cell lines through directed transcriptome alterations.

Michael Roberts, Sophia Kovatsis, Amelia Harper, Megan Cravinho, Kishan Mangru, Sher Bahadur, Keagan Hesse, Katy Meta, Cuong Nguyen

Dickinson College, Carlisle, PA

Oncogenic mutations in genes involved in proliferative signaling are hallmarks of malignant transformation. The Ras family of signal transducing proteins are involved in the activation of several proliferative pathways and therefore are found to be oncogenically mutated in a variety of cancer types. The NRAS-directed pathways resulting in Erk1/2 activation are dysregulated in a significant percentage of acute myeloid leukemia (AML), metastatic melanoma, Hodgkin lymphoma, and thyroid cancers. The consequence of oncogenic NRAS signaling is the establishment of a transcriptome commanding constitutive proliferation and survival. It has long been known that phorbol ester treatment of AML cell lines, resulting in activation of protein kinase C (PKC), causes phenotypic changes that include cell cycle arrest, myeloid differentiation, and apoptosis. The paradox is that numerous studies identify PKC as an activator of RAS/ERK signaling. Here we show that phorbol ester treatment of NRAS-driven AML cell lines results in the transcriptional upregulation of genes encoding negative regulators of RAS signaling including *DUSP1,2,4,5,6, SPRY2, SPRED1, RASA1, PEA15, RPS6KA1,* and *RASSF5.* Additionally, phorbol ester treatment eventually results to ERK1/2 inactivation through dephosphorylation. Several of these negative regulators, when overexpressed in AML cell lines, dampen proliferation, and induce senescence. We propose that the induction of RAS negative regulators alters the AML transcriptome to a non-proliferative state in part through the transcriptional regulation of genes such as *CDKN1A, CDKN2B, ZFP36L1,* and *MYC.* As gene therapy strategies develop, designed to provide negative regulators of proliferative signaling pathways that are repressed in the malignant cell, we imagine the RAS/ERK pathway as a target for transcriptome reprogramming.

#1675 Investigating the role of SRC-family kinases in MPNST tumorigenesis.

E. Zereg[1], L. Voisin[1], K. Grenier[2], M. Courcelles[1], S. Jung[2], P. Thibault[1], S. Meloche[1];
[1]Institute for Research in Immunology and Cancer (IRIC), Montreal, QC, Canada, [2]Department of Pathology, McGill University Health Centre, Montreal, QC, Canada

Purpose: Malignant peripheral nerve sheath tumor (MPNST), an aggressive soft-tissue sarcoma, is the leading cause of mortality in patients with neurofibromatosis type 1. Over the past two decades, significant advancement has been made in understanding the pathogenesis of MPNST. Still, this progress has not improved overall survival of patients. Therefore, ongoing efforts to identify alterations contributing to the transformation, progression, and metastasis of MPNST are essential for pinpointing targetable oncogenic signaling pathways for this cancer. Previous studies have revealed an increase in YAP/TAZ activity through both LATS1/2-dependent and LATS1/2-independent mechanisms, suggesting that YAP/TAZ hyperactivity may act as a convergence point for MPNST pathogenesis. YES and SRC, two members of the SRC-family kinases (SFKs), were shown to phosphorylate LATS1/2 and YAP/TAZ, and stimulate the transcriptional activity of YAP/TAZ by promoting their nuclear accumulation in hepatocellular carcinoma and colorectal cancer cells. Thus, we have investigated whether YES and SRC are involved in the pathogenesis of MPNSTs.
Experimental Design: To assess whether the SFK-YAP/TAZ signaling axis is implicated in the development of MPNST, we have used genetic and pharmacological approaches to investigate the roles of YES and SRC in the proliferation of a subset of human MPNST cell lines, and in the growth of xenografted MPNST tumors in ectopic and orthotopic mouse models. We also performed a phosphoproteome and a transcriptome analysis of YES and SRC-depleted MPNST cells to assess their oncogenic signaling network. Lastly, we evaluated the clinical significance of phospho-SFK and YAP in human MPNST TMAs.
Results: Our findings reveal that YES and SRC activity play an essential and redundant role in sustaining the proliferation of human MPNST cell lines. Further, the simultaneous depletion of both kinases impedes tumor growth in xenograft MPNST mouse models. Transcriptomic analyses identified YAP and TAZ as potential effectors of SFKs, as well as other family of transcription factors. Finally, TMA data suggested a correlation between the expressions of YAP, YAP/TAZ, and phospho-SFK and the progression of MPNST.

#1676 A continuous kinetic assay to quantitate specific protein kinase activity in unfractionated cell lysates.

V. Nemmara, S. Cornell-Kennon, Z. Lu, G. Pikul, Z. Belisle, M. Hakar, J. Chin, E. Schaefer, E. May;
Assayquant Technologies, Inc., Marlborough, MA

Protein kinases form a network of signaling pathways and are modified by multiple post-translational modifications, including phosphorylation, which regulate the kinase enzymatic activity, protein complexes formation, and its cellular location. Given this rich target complexity, >30% of all drug development is focused on kinases. However, these target only 15% of the human kinome and are primarily just one type (ATP-competitive) that can readily result in off-target inhibition and the development of resistance during cancer treatment. Most kinase inhibitor development is carried out *in vitro* assays with an epitope-tagged recombinant kinase. As a result, efficacy in patients can be limited due to poor inhibitor performance under physiological conditions (e.g., mM ATP and kinases being complexed with other proteins). In contrast, *in vitro* assays using unfractionated cell lysates provide a close approximation of the native kinase environment, including the complexity of interactions with other cellular components. Being able to selectively quantify the enzymatic activity of all protein kinases in crude cell or tissue homogenates would enable an improved understanding of kinase signaling biology, drug development, and personalized medicine. However, despite the large amount of literature on kinase assays, only a fraction is compatible with unfractionated lysates since most peptide substrates are not selective for a given kinase. To that end, we utilized a continuous assay format coupled with high-throughput Sox-sensor-peptide library synthesis using physiological sequences to identify selective sensor peptide substrates for multiple high-profile kinases implicated in cancer. As an example, we identified a highly selective sensor peptide for ERK1 and 2 mitogen-activated protein kinases (MAPKs) involved in pro-growth/oncogenic signaling. We demonstrated selectivity initially with the recombinant enzymes for ERK1/2 and a panel of other related MAPKs or CMGC kinases. Next, we extended the selectivity screen to 392 kinases using a large panel kinome profiling service. The screen also demonstrated high selectivity for ERK1/2 isoforms. We then tested our best sensor peptide substrate for ERK1/2 using unfractionated lysates from the HEK293T cell line with ERK2 overexpression and demonstrated high activity that could be increased 50-fold by the addition of recombinant MEK1 or 2, the upstream kinase that activates ERK1 and 2, and completely blocked with the addition of an ERK2-selective inhibitor. These results demonstrate a method to systematically generate a selective sensor peptide for ERK1/2 to continuously monitor this kinase activity in crude cell or tissue lysates. This poster will fully describe the methods and results pertaining to ERK-selective sensor peptide development and validation, and the ability to extend to other kinases of interest.

#1677 The emerging role of the Plasminogen-Apple-Nematode (PAN) domain in cancer therapy.

K. De, D. Pal, W. Muchero;
Oak Ridge National Laboratory, Oak Ridge, TN

The Plasminogen-Apple-Nematode (PAN) domain, with a core of four to six cysteine residues, is found in more than 28,000 proteins across 959 genera. However, its role in protein function still needs to be elucidated. Numerous proteins initially characterized the PAN domain, including a well-known master regulator for cancer cell proliferation, HGF (Hepatocyte growth factor). Abnormal regulation of HGF-mediated signaling results in multiple deadly cancers. The binding of HGF to its cell surface receptor, c-MET, triggers signaling pathways, which leads to cancer. Here, we show that mutating four core cysteine residues in the HGF PAN domain reduces c-MET interaction, subsequent c-MET autophosphorylation, and phosphorylation of its downstream targets, perinuclear localization, cellular internalization of HGF and its receptor, c-MET, and c-MET ubiquitination. Furthermore, transcriptional activation of HGF/c-MET signaling-related genes involved in cancer progression, invasion, metastasis, and cell survival was impaired. Thus, targeting the PAN domain of HGF may represent a mechanism for selectively regulating the binding and activation of the c-MET pathway. Additionally, we found this domain in the tumor suppressor gene, MST1 (macrophage stimulating 1), and mutating the domain altered the protein function through protein stability and ubiquitination. In another study, we show that cysteine residues in the vestigial plasminogen-apple-nematode (PAN) domain of NRP1 are necessary for SARS-CoV-2 spike protein internalization. Mutating novel cysteine residues in the PAN altered NRP1 stability and downstream activation of the extracellular signal-regulated kinase (ERK) signaling pathway, impairing its interaction with the spike protein. These results show the diverse critical role of the PAN domain beyond cancer therapy.

#1678 Docetaxel induces Rac1 and Cdc42 Rho GTPase activation in prostate cancer cells.

A. P. Lopez Gonzalez[1], J. Colon Gonzalez[1], M. C. Santa Maria Fuentes[1], S. Dharmawardhane[1], C. J. Diaz Osterman[2];
[1]University of Puerto Rico School of Medicine, San Juan, PR, [2]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Prostate cancer (PCa) is a major health burden that affects the quality of life of men worldwide. In the United States, PCa is the second leading cause of mortality among cancers that affect men. Treatment of advanced PCa aims to suppress androgen signaling and proliferation in cancer cells using anti-androgens and chemotherapy. However, the development of drug resistance is a major limitation to curing advanced prostate cancer and strategies to block mechanisms of therapy resistance would enhance treatment efficacy and potentially improve patient prognosis. Cdc42 and Rac1, members of the family of Rho GTPases, have been associated with the progression of different types of hormone-associated cancer, such as breast, ovary, and prostate, among others. The current study was designed to evaluate the role of Cdc42 and Rac1 in chemoresistant prostate cancer cells, including under castration-resistant and androgen-independent conditions. We did not observe significant differences in active (Rac-GTP) or total Rac1 levels in chemoresistant compared to parental PC3 or DU145 cells; similar findings were observed for Ccd42. Treatment of drug-naïve cells with a sublethal dose of docetaxel (10uM) induced gradual increases in Rac1-GTP up to 30 minutes in 22rv1, 60 minutes in LNCaP and DU145, and 24 hours in PC3 cells. Cdc42-GTP levels also increased with subacute docetaxel treatment up to 24 hours in 22rv1 and DU145. Chemoresistant 22rv1, PC3, and DU145 exhibited similar sensitivity to Rac1 and Ccd42 inhibitors including MB1-167, MBQ-168, EHop-097, with an IC50 of about 1uM for each compound and line. Ongoing studies are evaluating the role of these Rho-GTPases in 3-dimensional growth and survival.

#1679 Understanding the mechanism of Daple-PDGFRB gene fusion in leukemia.

A. C. Ibarra, V. Ly, J. Ear;
California State Polytechnic University of Pomona, Pomona, CA

Gene fusion between the scaffolding protein Daple and cell-surface receptor PDGFRB have been identified in several patients with leukemia. Patients with Daple-PDGFRB gene fusion are responsive to tyrosine kinase inhibitors, suggesting that the kinase domain on the receptor is active. How the Daple-PDGFRB gene fusion is activated and affects leukemia cells is poorly understood. It is hypothesized that the PDGFRB kinase domains found in gene fusion remain constitutively active, leading to hyperactivation of cell-signaling downstream of receptor tyrosine kinases (RTKs). To test this, identified Daple-PDGFRB mutants found in patients were ectopically expressed in cells and kinase activation were determined using a phospho-specific antibody. We demonstrated that indeed, the kinase domain on the gene fusion were active, and partake in rampant cell signaling. Because drug resistance is common in cancers such as leukemia, the implications from this work may uncover additional methods of therapeutic interventions for patients harboring these types of mutations.

#1680 Roles of EphA2 receptor signaling in prostate cancer development and progression.

R. Lingerak[1], A. Petty[2], H. Guo[1], H. Lin[1], X. Shi[1], S. Kim[1], B. Wang[1];
[1]Case Western Reserve University, Cleveland, OH, [2]The Cleveland Clinic, Cleveland, OH

Aggressive forms of prostate cancer (PCa), while initially responsive to androgen deprivation therapy (ADT), inevitably become resistant to therapy and are considered castration resistant PCa (CRPC). A major goal of PCa research has been to broadly identify molecular and cellular mechanisms that aid this progression to identify potential therapeutic targets. Using a combination of human data and unique animal models, we found that the receptor tyrosine kinase (RTK) EphA2 is overexpressed specifically in castration resistant and advancing prostate cancers. Furthermore we show that in metastatic PCa the receptor undergoes ligand-independent oncogenic signaling mediated by phosphorylation of EphA2 at S897. Together our data indicate a potential mechanism in PCa progression in which EphA2 becomes overexpressed and aids acquisition of castration resistance via acting as a driver of cell migration, invasion, and proliferation.

#1681 Characterizing signaling and localization of Daple-FLT3 gene fusion in leukemia cells.

M. Acquazzino, J. Ear;
California State Polytechnic University of Pomona, Pomona, CA

Receptor tyrosine kinases (RTKs) are cell surface receptors that regulate cell survival, cell proliferation, and cell migration upon ligand binding. Genetic mutations leading to hyperactivation of RTKs are often seen in cancer and allow signaling pathways to be constitutively active. In some hematological malignanices, the coiled-coil domain (CCD) of Daple, a cell signaling scaffold protein, has been found in gene fusions with the RTKs FLT3 and PDGFRB, and to the intracellular kinase JAK2. It is hypothesized that this gene fusion product causes the tyrosine kinase domain of FLT3 to become activated and mislocalizes in the cell, leading to rampant cell signaling of either the MAPK, AKT, and STAT5 signal transduction cascades. Using fluorescently tagged Daple-FLT3, it was shown that the gene fusion product is subcellularly localizes to the peri-centrosome space across all leukemia cell lines tested. Ectopic expression demonstrated activation of the kinase domain and subsequent increases in phosphorylation of STAT5α and AKT, but no significant increase in the phosphorylation of MAPK was observed. Further investigation is needed to identify direct substrates of the Daple-FLT3 gene fusion and transcriptional changes. Identifying the direct kinase substrates and insights gained through understanding the gene fusion localization, affects on cell signaling, and changes in gene expression, may unveil novel therapeutic strategies into targeting this protein in cancer.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Chromatin Organization and Regulators of Chromatin Biology
Poster Session

#1685 Investigating PAX8 interactions in ovarian cancer.
K. Sereti, A. Russo, R. Raisner, K. Gascoigne;
Genentech, Inc., South San Francisco, CA

Ovarian cancer is the most lethal gynecological cancer and there is a critical unmet need to develop novel therapies. The transcription factor, PAX8, is upregulated in ~80% of renal, ovarian, endometrial and thyroid tumors and its overexpression correlates with higher risk of death and recurrence. PAX8 represents a promising target because of its high specificity and low expected toxicity, but how it promotes tumorigenesis remains elusive. Using proximity labeling followed by mass spectrometry, we identified a list of PAX8 binding partners and have further confirmed these interactions at the genomic level through ChIP-seq and ATAC-seq. Our findings reveal novel PAX8 interactions and a potential therapeutic approach for ovarian cancer treatment.

#1686 Dissecting the 3D enhancer-promoter hubs in prostate tumorigenesis.

H. Cao, Z. Wu, L. Gonzalez-Smith, S. Yang, S. K. Rhie;
Norris Comprehensive Cancer Center, Keck School of Medicine of University of Southern California, Los Angeles, CA

The transcription process is controlled by regulatory elements that are often located in non-coding regions. Among regulatory elements, activities of enhancers that are bound by cell-type specific transcription factors (TFs) are tightly linked to cell identity. Enhancers loop to interact with the promoters of target genes at a distance to drive different cell fates. Evidently, transcriptional dysregulation linked to enhancers that are differentially activated in cancer is an underlying factor in tumorigenesis. To identify enhancers linked to prostate tumorigenesis, we analyzed hundreds of in-house and public H3K27ac ChIP-seq data generated from normal prostate and prostate cancer cell lines and tissues. We identified thousands of prostate cancer-specific enhancers (PSEs) that were activated exclusively in cancer conditions. To further identify the target genes of PSEs, we performed 3C-derived assays, such as Hi-C and Micro-C, and mapped genome-wide interactions. However, they were limited by the resolution to detect enhancer-promoter interactions. The recent development of Region Capture Micro-C (RCMC), a hybridization-based capture Micro-C method, allowed us to deeply map the highly nested interactions between regulatory elements. By utilizing RCMC, we generated high-resolution, focal contact maps that revealed comprehensive enhancer-promoter interactions near PSEs in prostate cancer cells. Interestingly, we found that PSEs loop to other PSEs clustered in the proximal genomic region, in addition to promoters of significantly upregulated genes in cancer compared to normal cells. We termed these regions as multi-connected "3D enhancer-promoter hubs". To mechanistically dissect these hubs, we deleted 5+ PSEs one by one using the CRISPR/Cas9 system and performed multi-omics analyses, including RNA-seq and ChIP-seq. We found that single deletions of a subset of PSEs led to the downregulation of multiple genes looped to the deleted PSE as well as to other PSEs. Moreover, we found that deletion reduced the activity of other connected PSEs. When we further evaluated the chromatin contacts of regulatory elements in the PSE-deleted cells, we observed that many chromatin contacts remained unaffected. Finally, we identified TFs that bind to PSEs, and we are currently in the process of investigating enhancer-promoter hub connectivity by performing knockdown experiments on these TFs. Furthermore, we are using molecular assays to identify PSEs that could exert a phenotypic shift in cancer cell identity to drive prostate tumorigenesis. Overall, our study not only provides mechanistic insights into the spatial regulation of 3D enhancer-promoter hubs but also identifies new non-coding drivers in prostate tumorigenesis.

#1687 Targeted degradation of MECOM in high-risk acute myeloid leukemia reveals a novel repressive function that is amenable to therapeutic small-molecule rewiring.

T. J. Fleming[1], M. Gundry[1], R. Voit[1], M. Antoszewski[1], W. J. Gibson[2], A. Sadagopan[2], V. G. Sankaran[1];
[1]Harvard Medical School, Boston, MA, [2]The Broad Institute, Cambridge, MA

Hematopoiesis relies on an intricate balance between stem-cell self-renewal and terminal maturation of blood cells. Disrupting this balance can lead to the development of deadly blood cancers, like acute myeloid leukemia (AML). Increasing evidence suggests that acquiring hematopoietic stem cell (HSC) gene expression programs in AML confers a particularly poor prognosis and increases risk of relapse with conventional therapy. Acquisition of these features in AML is commonly driven by dysregulation of MECOM, a transcription factor and master regulator of HSC self-renewal. To define the role of MECOM in AMLs, we engineered cell-line models of high-risk AML by endogenously tagging MECOM with an FKBP12^{F36V} degron. These models enable targeted degradation of MECOM which we employed in concert with multi-omic readouts to assess changes in nascent transcription and chromatin accessibility to identify direct transcriptional targets of MECOM. We demonstrate that MECOM degradation results in a rapid increase in chromatin accessibility at MECOM-bound sites and increased expression of cognate genes to establish a pro-differentiation gene program. These findings suggest a previously unappreciated mechanism for MECOM in repressing differentiation-promoting cis-regulatory elements (cisREs) and their cognate target genes in AML. We then employed a pooled CRISPR inhibition (CRISPRi) screen to functionally characterize the role that each cisRE plays in promoting high-risk features in AML. Utilizing CRISPRi to repress MECOM-bound cisREs in concert with dTAG-mediated MECOM degradation, we examined if repression of over 500 individual MECOM-bound cisREs is sufficient to maintain AML progenitors in the absence of MECOM. This functional dissection revealed that the individual repression of three cisREs that regulate *CEBPA, GFI1B, and RUNX1* is sufficient to maintain AML progenitor cells in the absence of MECOM. This result implicates MECOM as a direct repressor of known regulators of myeloid differentiation. Given these findings, we hypothesized that small molecule-based recruitment of a transcriptional coactivator to MECOM could rewire its repressive function to activate myeloid differentiation and subsequent leukemia cell death. To test this approach, we treated a MECOM-FKBP12^{F36V} AML degron model with the bifunctional small molecule NICE-01 (AP1867-PEG2-JQ1) to recruit an epigenetic activator (BRD4) to MECOM to functionally rewire this transcriptional network. NICE-01 treatment induced significant differentiation of AML progenitor cells relative to JQ1 treatment alone. Our work highlights the utility of targeted protein degradation to mechanistically interrogate the function of a key driver of high-risk AMLs and suggests the potential for small molecule-rewiring of stem cell gene regulatory networks to confer therapeutic benefit.

#1688 Nuclear receptor coactivator SRC-1 promotes colorectal cancer immune escape by enhancing PD-L1 transcription and protein stability.

Y. Hong[1], Q. Chen[2], Z. Wang[1], Y. Zhang[1], B. Li[1], X. Kong[1], P. Mo[1], N. Xiao[1], J. Xu[3], Y. Ye[4], C. Yu[1];

[1]Xiamen University, Xiamen, China, [2]Ningbo University, Ningbo, China, [3]Baylor College of Medicine, Houston, TX, [4]Fujian Cancer Hospital, Fuzhou, China

Programmed death-ligand 1 (PD-L1), one of the immunosuppressive molecules, overexpresses in multiple cancers and is critical for their immune escape. We previously showed that the nuclear coactivator SRC-1 promoted colorectal cancer (CRC) progression by enhancing CRC cell viability; however, the role of SRC-1 in CRC immune escape is unclear. Here, we demonstrated that SRC-1 was positively correlated with PD-L1 in human CRC specimens. SRC-1 deficiency significantly inhibited PD-L1 expression in both human and murine CRC cells and retarded murine CRC growth in subcutaneous grafts by enhancing CRC immune escape via increasing tumor infiltration and antitumor activity of effector $CD8^+$ T cells. Genetic ablation of SRC-1 in mice also decreased PD-L1 expression in AOM/DSS-induced murine CRC. These results suggest that tumor-derived SRC-1 promotes CRC immune escape by enhancing PD-L1 expression. Mechanistically, SRC-1 activated JAK-STAT signaling by inhibiting SOCS1 expression and coactivated STAT3 and IRF1 to enhance PD-L1 transcription as well as stabilized PD-L1 protein by inhibiting proteasome-dependent degradation mediated by speckle type POZ protein (SPOP). Pharmacological inhibition of SRC-1 improved the antitumor effect of PD-L1 antibody in both subcutaneous graft and AOM/DSS-induced murine CRC models. Taken together, our findings highlight a crucial role of SRC-1 in facilitating CRC immune escape and targeting SRC-1 in combination with PD-L1 antibody immunotherapy may be an attractive strategy for CRC treatment.

#1689 CRISPR functional genetic screening for immune enhancers of inhibitor receptors in human primary CD8 T cells.

P. Wang, J. R. Giles, H. Huang, J. Shi, E. Wherry;
University of Pennsylvania, Philadelphia, PA

The restrained efficacy of T cell therapies in cancer treatment is associated with T cell exhaustion (T_{EX}), an impaired effector function state that is marked by distinct epigenetic landscape. These unique epigenetic features promoted the progression of T_{EX}, hindered reinvigoration of T_{EX} state and controlled the abnormal expression of inhibitor receptors (IRs), which could serve as target sites in cancer treatment. Thus, deciphering the regulatory elements in primary human T cells will deeply reveal the mechanism controlling T_{EX} and provide novel therapeutic strategies to promote clinical response. However, how enhancers can be effectively applied in anti-cancer treatment is still poorly understood because high throughput identifying the functional enhancers of inhibitor receptors at scale is technically limited in human T cells. Here, we first developed a pooled screening platform that employs a compact CRISPRi system and enabled efficient one-step delivery of pooled screening libraries to primary human T cells. Leveraging this platform, we screened large genomic regions (~300kb) at saturation around key T_{EX} genes, two IRs—*PDCD1*, *HAVCR2* and one transcription factor (TF)—*TBX21* to interrogate functional enhancers in human primary CD8 T cells. We identified two enhancers for *PDCD1*, three enhancers for *HAVCR2* and three enhancers for *TBX21*, all of which are located over 12kb away from each gene's transcription start sites. Then, to parse the essential sequences that fulfill enhancer function, we employed Cas9-based in-situ saturation mutagenesis screening to the identified enhancers of *PDCD1* and *HAVCR2*. We found disrupt essential sequences impaired the entire enhancer function, quantitatively phenocopied the effect of targeting the entire enhancer with CRISPRi. Transcription factor motifs analyses of these sequences revealed potential regulation of ZFX for controlling *PDCD1* expression and STAT for *HAVCR2* expression. Finally, we explored the functional consequences of applying enhancers to anti-cancer treatment. Indeed, targeting the identified enhancers of *PDCD1* and *HAVCR2* in CAR T cells lead to enhanced cancer cell killing efficiency in vitro. Together, our study provides a platform and paradigm to interrogate functional enhancers in human T cells, illuminated the great potential of manipulating enhancers in T cell therapies.

#1690 LSD1 and CoREST2 demethylate STAT3 to promote enteroendocrine cell differentiation in mucinous colorectal cancer.

C. A. Ladaika, A. H. Ghobashi, W. C. Boulton, H. M. O'Hagan;
Indiana Univerisy, Bloomington, IN

Across different cancer types, tumor heterogeneity has been shown to drive tumor progression, metastasis, and therapeutic resistance. Adenocarcinoma to neuroendocrine lineage transition is an emergent mechanism of targeted therapy resistance in several cancer types, including lung and prostate cancer. Therefore, understanding the dynamics and mechanisms driving neuroendocrine cell fates in cancer is critical. Mucinous colorectal cancer accounts for upwards of 20% of colorectal cancer cases and is characterized by tumors with mucous accounting for at least 50% of the tumor volume. The normal colon epithelium consists of several specialized cell types, including hormone secreting enteroendocrine cells (EECs), which are the neuroendocrine cell of the intestine. We have previously shown that EEC progenitors are enriched in mucinous colorectal cancer and promote cancer cell survival via secreted factors. Additionally, we have shown that lysine specific demethylase 1 (LSD1) promotes EEC differentiation in these tumors; however, the mechanism by which LSD1 promotes EEC differentiation has remained unknown. Typically to carry out its enzymatic function, LSD1 must be a part of a transcriptional regulatory complex. One such complex is the CoREST complex, which contains LSD1, HDAC1, and one of three CoREST protein family members. Here we report that LSD1 and CoREST2 promote EEC differentiation by demethylating the transcription factor signal transducer and activator of transcription 3 (STAT3) to promote STAT3 chromatin binding. Additionally, we demonstrate that knocking down CoREST2 decreases tumor growth and lung metastases of mucinous colorectal cancer cells injected orthotopically into the colons of immunocompromised mice. Furthermore, we utilized single cell multi-omics that combines single cell RNA sequencing with single cell ATAC sequencing to show that during EEC differentiation there is an increase in chromatin accessibility at regulatory regions of known EEC-promoting transcription factors. Finally, through our single cell multi-omics analysis we identify a new rare cell type with neuron-like but not secretory characteristics. Mucinous colorectal cancer is an aggressive and chemotherapeutically intractable form of CRC that is enriched for EEC progenitors. Our data demonstrates that LSD1 and STAT3 promote EEC differentiation, suggesting that inhibiting LSD1 and or STAT3 may have benefits for patients with mucinous colorectal cancer.

#1691 p300 catalytic inhibition selectively targets IRF4 oncogenic activity in multiple myeloma.

M. R. McKeown[1], G. Giorgetti[2], W. F. Lenoir[1], M. J. Kobylarz[1], T. D. Hopkins[1], W. L. Glore[1], M. G. Shum[1], Y. Calderon[1], K. R. Mori[1], H. Gao[1], L. A. Carvajal[1], N. D. Obholzer[1], B. W. Trotter[1], C. D. Dinsmore[1], N. C. Munshi[2], P. B. Rahl[1], M. Fulciniti[2], **C. Y. Lin**[1];
[1]Kronos Bio, Inc., Cambridge, MA, [2]Dana-Farber Cancer Institute, Boston, MA

Multiple myeloma (MM), an incurable plasma cell malignancy, is addicted to oncogenic transcription factor (TF) IRF4 signaling. Lineage TFs like IRF4 are difficult to drug but represent high value oncology targets owing to the depth and context selectivity of their genetic dependency. Using a transcription regulatory network (TRN) based approach to integrate a high dimensional multi-platform dataset, we defined the key regulatory activity of IRF4 and its druggable co-factors. This unbiased analysis identified p300 lysine acetyl transferase (KAT) function as the nearest selective neighbor for therapeutic intervention, with more potent and selective effects than historically observed with p300/CBP bromodomain inhibitors.

To further probe this biology, we developed a highly selective inhibitor of the KAT domain of p300 and its close homolog CBP. p300 KAT inhibition led to selective downregulation of IRF4 at the mRNA and protein level as well as reduction in acetylation at highly specific sites co-localized with IRF4, in contrast to more general agents like BET inhibitors. Gene expression reduction was most pronounced at IRF4/p300 co-bound genes, in particular IRF4 itself and MYC. IRF4 and p300 also directly bind to each other and other key MM nodes regulating them at the chromatin, mRNA, and protein levels.

p300 KAT inhibition exhibits strong antiproliferative activity across *in vitro* MM models regardless of cytogenetics or resistance to other therapies. Moreover, this relationship is mediated by the KAT domain and not its acetyl-lysine recognizing bromodomain. Comparative pharmacology studies found that a p300 KAT inhibitor downregulated the IRF4 TRN and induced apoptosis in MM cells more effectively than existing standard of care agents, including IMiDs and glucocorticoid receptor agonists, or p300/CBP bromodomain inhibitors. Combinations of a p300 KAT inhibitor with clinically active molecules such as IMiDs and glucocorticoid agonists showed synergistic impacts on reducing key MM TFs and cell line viability.

Ex vivo treatment of primary patient samples demonstrated broad anti-proliferative activity with loss of IRF4 and induction of apoptosis in relapsed-refractory MM patient samples, independent of prior lines of therapy. Importantly, the induction of MM cell apoptosis occurs in the milieu of CD138 negative bone marrow stromal cells while also sparing them from toxicity, supporting a potential therapeutic index.

Finally, p300 KAT inhibition demonstrated activity in *in vivo* MM models with robust tumor growth inhibition at tolerated doses and exposures correlated to reduced p300-dependent substrate acetylation. IRF4 dependency is a hallmark of MM that has been challenging to target with existing therapies, motivating further development of p300 KAT targeting therapeutics.

#1692 MAPK and NF-kappaB signaling converge on the epigenome to transcriptionally activate genes involved in pancreatic cancer metastasis.

J. E. Aggrey-Fynn[1], M. Manjunath[2], S. A. Johnsen[2];

[1]Mayo Clinic Graduate School of Biomedical Sciences, Robert Bosch Center for Tumor Diseases (RBCT), Rochester, MN, [2]Robert Bosch Center for Tumor Diseases (RBCT), Stuttgart, Germany

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive and lethal type of pancreatic neoplasm. Unfortunately, most patients are diagnosed with unresectable or metastatic disease, making current treatments insufficient. As a result, the 5-year survival rate for PDAC is below 10%.Pancreatic neoplasms are primarily initiated by the KRAS mutation, accounting for 95% of cases. However, the progression of PDAC to a highly aggressive and therapy-resistant cancer is accelerated by chronic inflammation. The role of mutant KRAS signaling and NF-κB inflammatory signaling in promoting PDAC progression has been extensively studied. Yet, the transcriptional mechanism of their cooperation remains unclear. Additionally, the interaction between PDAC tumor cells and signals in the tumor microenvironment (TME) is not yet fully understood. Our study demonstrates that the simultaneous activation of KRAS/MAPK and NF-κB by epidermal growth factor (EGF) and TNFα, respectively, increases cell migration as shown through live-cell imaging analysis. An integrated analysis of epigenetic and transcriptomic data (ChIP-seq and RNA-seq) was performed after dual stimulation of both pathways. This revealed a high occupancy of the active mark, H3K27ac at transcription start sites of a subset of genes involved in cell migration and subtype switch. Through gain and loss-of-function studies, FOSL1 and RELA were identified as the key transcription factors. The epigenome mapping of FOSL1 and RELA after the stimulation of both pathways revealed their occupancy at RELA-dominant and FOSL1/RELA co-occupied regions. Inhibitor treatments and loss-of-function studies revealed that RELA binding controls RNA polymerase recruitment for transcription initiation and enhances cell migration. Further analysis of RNA-seq data on PDAC cell lines and cells from patient-derived xenografts highlighted that active inflammatory signaling contributes to a subtype switch from the classical to the more migratory basal subtype. Our study, combined with single-cell RNA-seq analysis of published data, shows that macrophages in the tumor microenvironment supply TNFα that activates NF-κB signaling, leading to changes in cell migration. Our study has provided a comprehensive understanding of the mechanism by which mutant KRAS and inflammatory signaling contribute to the progression of PDAC. These findings could offer a new perspective in the development of mechanism-based therapeutic approaches that can improve the efficacy of chemotherapeutic agents and make tumors more amenable to surgical resection.

#1693 Mitochondrial-associated DNAJA3 variant and its role in NASH-driven hepatocellular carcinoma.

Y. Shiode, C.-W. Chang, X. W. Wang;
National Cancer Institute, Bethesda, MD

Nonalcoholic fatty liver disease (NAFLD) is increasingly recognized as a major risk factor for hepatocellular carcinoma (HCC). Despite the known progression from NAFLD to nonalcoholic steatohepatitis (NASH) and eventually HCC, the genetic underpinnings driving this transition remain underexplored. A comprehensive genomics assessment was conducted, encompassing a genome-wide study of variants linked to body fat distribution in 344,369 individuals. Correlating these, significant variants associated with NASH and HCC were discerned in a cohort of 1,009 participants from the NCI-UMD study. Candidate variants underwent further eQTL analysis. Our investigation unveiled the rs3747579-TT variant emerged as significantly associated with NASH-related HCC, serving as an eQTL for mitochondrial DNAJA3. HCC patients harboring this variant presented with diminished DNAJA3 expression, correlating with an unfavorable prognosis. Exploration into the 3D genome architecture has identified potential chromatin topology sites that may influence the regulation of DNAJA3 by rs3747579. Specifically, enhancer loops exhibit allele-specific interactions with rs3747579 in the regulation of DNAJA3. Notably, the rs3747579-CC variant was found to interact with RBFOX2. Beyond its known RNA splicing functions, RBFOX2 might have implications in the chromatin landscape, influencing chromatin dynamics and gene transcription. RBFOX2 knockdown experiments showcased significantly reduced DNAJA3 expression, and luciferase assays highlighted increased activity for the rs3747579-CC allele versus its TT counterpart. In summary, our findings spotlight the rs3747579-TT variant as a potential oncogenic factor in DNAJA3, elucidating its role in the genesis of NASH and progression to HCC. This understanding could pave the way for novel therapeutic interventions in HCC stemming from NAFLD/NASH.

#1694 Using high-throughput screening to identify DNA response elements that sense cancer dysregulated pathways.

E. Stroebele, Y. Zhang, I. Podar, C. Xia, A. Rojc, D. Wodziak, M. Louie, D. Suhy;
Earli Inc., Redwood City, CA

Earli is developing a highly sensitive, orthogonal approach that is designed to be delivered via IV injection and uses a genetic construct to usurp dysregulated pathways, and actively forces cancer cells to drive the expression of a detectable 'synthetic' biomarker. The key element of our cancer-activated construct that drives specificity and sensitivity of expression is a promoter sequence, synthetically engineered to leverage transcription factors (TFs) activated in cancer pathways. Acting as a molecular sensor for dysregulated TF levels, the DNA construct expresses a measurable biomarker in cancer cells, while remaining transcriptionally silent in normal adjacent tissues and benign lesions. Previously, we described a multiomics factor analysis (MOFA) to interrogate 200 non-small cell lung cancer (NSCLC) and matched normal adjacent tissue samples comprised of RNA-seq based transcriptional profiling, and MS-based proteomics and phospho-proteomics from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) dataset, and generated a list of top TFs dysregulated in NSCLC. In this study, we show the capability to design, engineer, and test cancer specific activity of combinations of response elements using a Massively Parallel Reporter Assay (MPRA) high-throughput pooled screening (HTS) method. More than 2,000 unique sequences of homotypic or heterotypic TF binding sites corresponding to the top 100 TFs were arrayed with diverse spacing and individually barcoded for the high-throughput screens in NSCLC cell lines. To validate our top hits, we individually tested 10 sequences from the top 25% and 8 sequences from the bottom 25%. Nine of the top sequences produced signals 5-10X higher than the background, whereas only one of the eight bottom sequences produced signal higher than the background. We have individually validated 30 different response elements and found that 28 of 30 drove the expected expression, with the majority of response elements (n=20) showing expression 5-10X higher than background. Remarkably, two of the engineered response elements were able to drive expression 20-30X higher in a specific cell line activated by WNT-signaling, suggesting that these response elements can sense specific cancer dysregulated pathways. Our lead response elements are being tested across a broad range of *in vitro* primary tumor lines with diverse genetic backgrounds and transcriptional profiles prior to *in vivo* testing using our imaging platform to distinguish malignant lung nodules. In summary, we have established a robust screening platform to identify response elements that can be activated by cancer dysregulated pathways. We are currently expanding this platform to other cancer models and indications, and leveraging this to explore more complex response elements that use combinations of TFs and natural spacing.

#1695 Genomic clustering tendency of transcription factors reflects phase-separated transcriptional condensates at cancer super-enhancers.

Z. Wang, S. Wang, **C. Zang**;
University of Virginia, Charlottesville, VA

Many transcription factors (TFs) have been shown to bind to super-enhancers, forming transcriptional condensates to activate transcription in various cellular systems including cancer. However, the genomic and epigenomic determinants of phase-separated transcriptional condensate formation remain poorly understood. Questions regarding which TFs tend to associate with transcriptional condensates and what factors influence their association are largely unanswered. Here we systematically analyzed 528 DNA sequence motifs across the human genome and 6,650 TF binding profiles across different cell types to identify the molecular features contributing to the formation of transcriptional condensates. We found that the genomic distributions of sequence motifs for different TFs exhibit distinct clustering tendencies. Notably, TF motifs with a high genomic clustering tendency are significantly associated with super-enhancers. TF binding profiles showing a high genomic clustering tendency are further enriched at cell-type-specific super-enhancers. TFs with a high binding clustering tendency also possess high liquid-liquid phase separation abilities. Compared to non-clustered TF binding, densely clustered TF binding sites are more enriched at cell-type-specific super-enhancers with higher chromatin accessibility, elevated chromatin interaction, and stronger association with cancer outcomes. Our results indicate that the clustered genomic binding patterns and the phase separation properties of TFs collectively contribute to the formation of transcriptional condensates at cancer super-enhancers.

#1696 ACTL6A deficiency drives cell death through KLF4-involved chromatin accessibility changes in colorectal cancer.

H.-J. Yang[1], E.-J. Kim[1], S.-H. Song[1], T.-Y. Kim[2];

[1]Seoul National University, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

ACTL6A is a subunit of the SWI/SNF and INO80 chromatin remodeling complexes and plays roles in neural development and cancer cell proliferation. Additionally, it is known to be upregulated in various types of cancer and is associated with a decrease in patient survival rates. However, the mechanism of how chromatin remodelers including ACTL6A cause cell death has yet to be defined. Therefore, we would like to investigate how the depletion of ACTL6A promotes cell growth reduction by mediating changes in the epigenetic landscape in colorectal cancer cells. We engineered ACTL6A knockout by CRISPR-Cas9. We performed Assay for transposase-accessible chromatin using sequencing (ATAC-seq), RNA sequencing (RNA-seq), and Chromatin Immunoprecipitation sequencing (ChIP-seq) for SMARCB1 and INO80, as representative members of their respective families, and KLF4. Moreover, HCT116 cells stably transduced with doxycycline-inducible shGFP or shACTL6A were implanted into the flank of nude mice. One week after tumor implantation, mice were randomly allocated to 4 groups (n=13-15 per group) and doxycycline treated group was administered with doxycycline (1mg/ml) and 5% sucrose in the drinking water. Tumor volume was measured with calipers. Upon depletion of ACTL6A, the regions of increased chromatin accessibility were correlated with the upregulated genes. After the loss of ACTL6A, there was a significant increase in KLF4 expression and genomic binding largely increased, coinciding with an increase in newly accessible regions containing KLF4 motifs. Interestingly, there is a strong positive correlation between changes in chromatin accessibility and overall changes in the binding of KLF4, SWI/SNF, and INO80 complexes. We find that changes in chromatin accessibility are co-regulated by KLF4, the SWI/SNF and the INO80 complex, while SWI/SNF and INO80 complex have a low correlation in binding between the SWI/SNF and INO80 complexes at newly accessible regions, indicating no physical interactions between these two chromatin complexes. Overall, we demonstrated that the redistribution of ACTL6A-deficient two chromatin remodeling complexes and KLF4 is associated with changes in chromatin accessibility, which are also linked to upregulated genes that promote the p53 pathway. These findings revealed the role of KLF4 along with the SWI/SNF and INO80 complexes, in regulating the chromatin landscape and gene expression in ACTL6A-depleted colorectal cancer cells.

#1697 Phase separation of BHLHE40 up-regulates SREBF1 and inhibits ferroptosis in pancreatic cancer cells.

Y. Cao, X. Wang, Y. Liu, P. Liu, J. Qin, Y. Zhu, S. Zhai, M. Shi, W. Wang, X. Deng, C. Peng, H. Chen, R. Ren, L. Jiang, B. Shen;
Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Pancreatic cancer (PCa) is one of the most lethal malignancies in human cancers. The enhanced infiltration of stromal tissue of PCa tumor microenvironment limits the identification of key tumor-specific transcription factors and epigenomic abnormalities in malignant epithelial cells. Integrated transcriptome and epigenetic multi-omics analysis of paired PCa organoids indicated that the basic helix-loop-helix transcription factor 40 (BHLHE40) was significantly upregulated in tumor samples. Increased chromatin accessibility at promoter region and enhanced mTOR pathway activity contribute to the elevated expression of BHLHE40. Integrated analysis of chromatin immunoprecipitation (ChIP)-seq, RNA-seq and high-through chromosome conformation capture (Hi-C) data together with chromosome conformation capture (3C) assay indicate that BHLHE40 not only regulates the sterol regulatory element-binding factor 1 (SREBF1) transcription as a classic transcription factor, but also links the enhancer and promoter regions of SREBF1 via forming liquid-liquid phase-separated droplets. Then, we find the BHLHE40-SREBF1-stearoyl-CoA desaturase (SCD1) axis protects PCa cells from ferroptosis, leading to the reduced accumulation of lipid peroxidation in cells. Moreover, SREBF1 inhibitor, Fatostatin, significantly suppresses the cell growth of PCa tumors with higher expression of BHLHE40. This study highlights the important roles of BHLHE40 mediated lipid peroxidation in inducing ferroptosis of PCa cells and provides a novel mechanism underlying the SREBF1 overexpression in PCa.

#1699 Defining the impact of aberrant transcription on the chromatin structure.

N. Thomas[1], T. E. Reznicek[2], E. Aiden[3], M. Rowley[2], E. Wagner[4], G. Nir[1];
[1]University of Texas Medical Branch (UTMB), Galveston, TX, [2]University of Nebraska Medical Center, Omaha, NE, [3]Baylor College of Medicine, Houston, TX, [4]University of Rochester Medical Center, Rochester, NY

Genome organization in humans is governed by two major mechanisms: loop extrusion by cohesin and CTCF and the spatial compartmentalization of the chromosomes. These folding mechanisms have been shown to regulate several genomic functions, including gene expression. However, how transcription might regulate the chromatin structure remains a subject of many ongoing investigations. In this study, we use the Integrator protein complex as a tool to understand the impact of aberrant transcription on the 3D structure of the genome. During transcription initiation, RNA Polymerase-II (Pol-II) often pauses proximally to the promoter before further elongating transcripts. The Integrator protein complex regulates this checkpoint by its endonuclease and phosphatase activity. This protein complex is essential in premature transcription termination in hundreds of protein-coding genes. It also facilitates the synthesis of non-coding (ncRNA), such as enhancer RNAs (eRNAs) and long non-coding RNAs (lncRNAs), which have been shown to support loop extrusion domains, and their absence may disrupt these domains. Using HiC sequencing, we found that depleting Integrator proteins can interfere with forming and maintaining loop domains. This study aims to be the first to decipher the relationship between chromosome structure and Integrator protein activity and address our very little knowledge of how misregulation of transcription termination may influence the folding of chromosomes.

#1700 Interplay of pioneer and chromatin remodeling factors: New insights into breast cancer mechanisms.

M. Takaku, M. Cooper, M. Saotome;
University of North Dakota, Grand Forks, ND

Eukaryotic cells utilize chromatin to package their genomic DNA, which can hinder transcription factor binding and gene activation. Pioneer factors, which can activate silent chromatin by binding to nucleosomes in closed (inactive) chromatin regions, thereby increasing chromatin accessibility, are essential in multiple developmental pathways. Their misregulation has been linked to various human diseases, including cancer. Yet, the involvement of pioneer factor mutations in tumorigenesis and tumor progression remains largely unexplored. GATA3 is one of the most frequently mutated genes in breast cancer. We and other groups found that a subset of GATA3 mutations promote tumor growth by redirecting luminal transcriptional network governed by Estrogen Receptor alpha (ER-alpha), FOXA1, and GATA3. Our genomics data also suggested that GATA3 requires multiple co-factors to maintain and establish active enhancers. Through IP-mass spectrometry, we identified several chromatin remodeling factors as potential GATA3 binding partners, with CHD4 being particularly notable. Our genomic data, including ChIP-seq, ATAC-seq, and RNA-seq, suggest that during GATA3-induced mesenchymal-to-epithelial transition (MET), CHD4 plays a critical role in maintaining closed chromatin structure, particularly at enhancer regions. Depletion of CHD4 results in the activation of chromatin and genes that are not essential for successful MET. Furthermore, we observed functional interactions between GATA3 and PARP1 in both luminal and basal breast cancer cells, with notable changes in GATA3 mutant cells. Through these studies, we aim to uncover epigenetic vulnerabilities in GATA3-altered breast cancer cells, ultimately contributing to the development of new breast cancer treatments.

#1701 ABI1 regulates prostate tumor plasticity through chromatin remodeling and transcriptional regulation.

L. Kotula;
SUNY Upstate Medical University, Syracuse, NY

Background: Prostate cancer remains a challenging issue affecting men worldwide. In contrast to localized disease, metastatic prostate cancer tumor is incurable. Progression to metastatic disease is characterized by tumor heterogeneity and plasticity regulated by epigenetic changes of tumor cells. While tumor heterogeneity is often associated with gene mutations, tumor plasticity is ascribed to transcriptional regulation and chromatin activity. The latter is modulated by treatment of prostate cancer leading to treatment resistance. Here, we identified a novel mechanism of epigenetic regulation in prostate cancer by an actin regulatory and signaling protein, Abelson Interactor 1 (ABI1).
Methods: To demonstrate the ABI1-DNA binding, we employed in vitro binding assays, NMR spectroscopy, and ChIP-seq. from cells expressing alternatively spliced isoforms of ABI1 that contain or lack the DNA binding HHR domain. To determine the ABI1 interactions with several transcriptional factors, we used immunoprecipitation and/or proximity ligation assay (PLA). We used ATAC sequencing to determine the chromatin accessibility in the presence or absence of ABI1 gene. RNA-seq established the activity of transcriptional factors and signaling pathways regulated by ABI1.
Results: Using NMR spectroscopy, we established that ABI1 demonstrated DNA binding dependent on the presence of alternatively spliced Exon 4. Exon 4 is located within the homeobox homology region (HHR). The DNA binding activity was confirmed using in vitro binding assays; the assay results confirmed the role of ABI1 HHR. Moreover, cells lacking ABI1 or expressing ABI1 lacking Exon 4 show low accessibility and activity of chromatin. In contrast, cells expressing ABI1 containing Exon 4 show active chromatin. RNA-seq analysis demonstrated that ABI1 regulated transcription in an Exon 4-dependent manner.
Conclusions: We uncovered a role of ABI1 in chromatin stability, that is dependent on the presence of the DNA binding region. Notably, ABI1's contribution to transcriptional activity occurs via a transient yet precisely defined interaction between its intrinsically disordered region and DNA. This regulatory control plays a pivotal role in managing tumor plasticity by establishing connections between the actin cytoskeleton, cellular signaling, and transcriptional regulation. Based on these findings, we propose that ABI1 functions as an epigenetic regulator, maintaining transcriptional homeostasis in prostate cancer.

#1702 Loss of KEAP1 promotes R-loop formation independent of NRF2.

P. Mukhopadhyay, N. Bassani, A. J. R. Bishop;
UT Health San Antonio Greehey Children's Cancer Res. Inst., San Antonio, TX

This study investigates the mechanism of R-loop formation as a consequence of KEAP1 depletion. R-loops, described as three-stranded nucleic acid structures consisting of a DNA:RNA hybrid and a non-template single-stranded DNA, are assemblies often attributed with pathological consequences like genomic instability and replication stress. However, they have significant physiological roles, inter alia, regulation of transcription initiation, splicing and termination. Loss in R-loop resolution factors (like RNaseH nucleases, senataxin) can result in “unscheduled” or “pathological” R-loops, which can compromise genome stability. R-loops are commonly associated with an active transcription bubble, with nascent RNA trailing the RNA polymerase re-annealing to the template DNA strand. Increased transcriptional stress can lead to accumulation of R-loops. In a 2016 eLife study by Stork et al., estrogen induction resulted in concomitantly increased transcription and R-loop formation in the same subset of genes. Similar to estrogen induction, activation of the NRF2/KEAP1 pathway upon oxidative stress causes NRF2 to be released from KEAP1 and enter the nucleus to turn on transcription of its target genes. Kelch-like ECH associated protein 1, encoded by the *KEAP1* gene, is a canonical binding partner of NRF2. Under basal conditions, KEAP1 binds NRF2 and targets it for degradation. Mutations in *KEAP1* and epigenetic modifications have been reported in lung and breast cancer phenotypes. In lieu of chemical manipulation, NRF2 can be activated by knocking down KEAP1 via RNAi. We therefore asked whether transcription activation downstream of the NRF2/KEAP1 pathway can lead to accumulation of R-loops.We have observed the consequences of depleting KEAP1 (for NRF2 activation) with RNAi on global transcription using ethynyl uridine (EU) incorporation with click-iT chemistry and flow cytometry, on R-loop levels using S9.6 antibody immunocytochemistry and on transcriptional profile changes with RNA-seq. We observe that loss of KEAP1 leads to an increased accumulation of R-loops. Surprisingly, this is not accompanied by an expected increase in transcription as measured quantitatively with EU flow cytometry. This phenomenon was found to consistently occur in various cell lines across cancer types (breast, lung). Interestingly, depleting NRF2 cannot mitigate the effects of KEAP1 loss, suggesting that KEAP1 loss-associated R-loop formation is independent of NRF2 activation. Analysis of RNA-seq data shows that TOP2 is downregulated in KEAP1 deficient cells. As TOP2 has been previously known to regulate R-loop formation, we predict that KEAP1 loss can sensitize cells to topoisomerase inhibitors.In conclusion, interaction of KEAP1 with other players in its interactome outside of NRF2 may regulate R-loop formation and therefore R-loop-induced genome instability.

#1703 SMARCA2/4 degraders relieve the differentiation block in AML via changes in chromatin looping and accessibility.

S. Aminov[1], K. Pradhan[1], S. Sahu[1], S. Gordon-Mitchell[1], E. Rabinovich[1], A. Fromowitz[1], J. Chakraborty[1], S. Aluri[1], R. Zhao[1], N. Haque[1], M. Carbajal[1], A. Shastri[1], U. Steidl[1], S. Samajdarr[2], A. Kumar[2], M. Ramachandra[2], R. A. Coleman[1], K. Stengel[1], A. K. Verma[1];

[1]Albert Einstein College of Medicine, Bronx, NY, [2]Aurigene Oncology Limited, Bangalore, India

Acute Myeloid Leukemia (AML) is characterized by the unfettered proliferation and poor differentiation of myeloid cells causing reduced survival. The mammalian BAF complexes (also known as SWI/SNF) are important regulators of *MYC* and the cell cycle. There are three BAF complexes (cBAF, ncBAF and pBAF) that share several subunits. SMARCA2 and 4 are mutually exclusive ATPase subunits within the BAF complexes that use ATP hydrolysis and helicase activity to remodel chromatin via nucleosome sliding and removal. PBRM1 is a SMARCA4 associated factor present in pBAF. The association of SMARCA4 with regulatory elements of transcription factors makes it an intriguing target for AML. To evaluate the role of SMARC2/4 in AML, we analyzed RNA transcripts from highly purified primary AML initiating populations and control samples. Sorted leukemia stem cells (Lin-ve, CD34+, CD38-) overexpressed SMARCA2/4 when compared to healthy cells. A novel and highly selective SMARCA2/4 and PBRM1 PROTAC degrading agent AU-15330 was used to investigate the therapeutic effectiveness of targeting BAF complexes as well as the role of SMARCA2/4 in leukemic pathogenesis. Our data demonstrate that AU-15330 effectively degrades SMARCA2/4 and PBRM1 in human leukemia cell lines with varying mutational profiles; MV4-11 was the most sensitive cell line. When evaluating healthy CD34+ HSPCs as well as patient derived AML cells in colony assays, AU-15330 treatment increased differentiation in patient AML samples with minimal effects on healthy CD34+ cells. A xenograft of patient derived AML cells in irradiated mice was performed to determine the requirement of SMARCA2/4 in leukemia stem cell maintenance. Mice treated with AU-15330 had greater myeloid differentiation, fewer human cells in their bone marrows and reduced leukemia stem cell activity, seen in secondary transplants. To understand the underlying mechanism of how SMARCA2/4 and PBRM1 promote leukemic pathogenesis, we used a multi-omic analysis of transcription and chromatin dynamics in MV4-11 cells: ATAC-seq and RNA-seq identified downregulated genes with decreased accessibility, PRO-seq determined early transcriptional changes and HiChIP showed changes in enhancer promoter loops with SMARC2/4 degradation. Several leukemia related transcription factors as well as inflammatory genes were identified from these analyses as possible targets of the BAF complexes in the context of AML. Finally, to determine the effect of SMARCA2/4 degradation on pBAF association with chromatin, single cell imaging was performed of U2OS cells with HALO-tagged PBRM1 treated with the degrader or DMSO. pBAF in the degrader treated cells improved engagement with target chromatin however, a decrease in the stability of the complex binding to the nucleosome when compared to DMSO treated cells was shown. Taken together, these studies will determine the role of SMARCA2/4 in leukemia disease.

#1704 Interplay of MITF and NCOA3 in orchestrating oncogenic transcriptional network in uveal melanoma.

A. Rusin[1], M. E. R. Echartea[1], S. P. R. Manikonda[1], D. G. Skapura[1], C. M. Davis[2], E. A. Ehli[2], S. L. Grimm[1], C. Coarfa[1], S. Kaochar[1];
[1]Baylor College of Medicine, Houston, TX, [2]Avera Genetics, Sioux Falls, SD

Uveal melanoma (UM) originates from melanocytes residing in the uveal tract of an eye. Despite effective local control, 50% of patients develop metastatic disease responding poorly to chemotherapy, targeted therapy, and immunotherapy. The molecular basis of events leading to initiation of UM is related to mutations in G alpha proteins GNAQ or GNA11, rendering them constitutively active and activating downstream PKC, ERK and AKT pathways sustaining cell proliferation.

In our previous work, we showed that NCOA3 regulates proliferation of UM cells in vitro and the growth of UM xenografts in vivo downstream of GNAQ or GNA11. The critical role of NCOA3 in UM is manifested by transcriptional regulation of proliferation-related genes that are massively suppressed by NCOA3 knockout or knockdown. Here, we interrogated transcription factors that NCOA3 interacts with in UM to execute oncogenic programs and identified Melanocyte inducing transcription factor (MITF) as its critical partner.

Chromatin immunoprecipitation (ChIP) using an NCOA3 recognizing antibody followed by sequencing was performed to determine NCOA3 binding sites in the human genome. The known transcription binding motifs within NCOA3 peaks were discovered using HOMER algorithm. Co-immunoprecipitation was performed to examine direct NCOA3 and MITF interaction. ChIP sequencing for MITF was performed to determine co-localization of NCOA3 and MITF at chromatin. Proliferation of UM cells after inhibition of MITF by either siRNA mediated knockdown or MITF inhibitor ML329 was evaluated using MTT assay. Functional enrichment analysis of transcriptome was used to identify classes of genes regulated by MITF, with specific attention to the subset regulated by MITF partnered with NCOA3.

NCOA3 chromatin peaks are highly enriched in MITF binding motifs, and 77% of the NCOA3 peaks co-localizes with the MITF peaks. NCOA3 co-immunoprecipitates with MITF. Among transcriptional programs regulated by MITF in UM are those related to melanocyte biology, differentiation, and melanin production, but also those related to melanoma growth, especially cell division, DNA replication, myc response, purine and pyrimidine metabolism, and mTOR signaling. Strong suppression of these transcriptional signatures by inhibition of MITF using siRNA-mediated knockdown or pharmacological inhibition correlates with dramatic loss of cell viability. Clinical data indicate that higher expression of MITF-positively regulated genes correlates with lower survival rates of UM patients. Importantly, the transcriptional programs regulated by MITF cooperating with NCOA3 were related to TGF beta signaling, cell adhesion, ECM interaction and actin cytoskeleton.

Importance of MITF as an oncogene is manifested in uveal melanoma cell lines and clinical data. Oncogenic function of MITF is partially dependent on its interaction with a transcription co-activator NCOA3.

#1705 3D growth modulates the competition between STAT3 and STAT5 in breast cancer.

A. E. Temple, S. R. Walker;
University of New Hampshire, Durham, NH

Approximately 13% of women are diagnosed with invasive breast cancer. Signal Transducer and Activator of Transcription 3 (STAT3) is a transcription factor that is often inappropriately activated in breast cancer and is frequently associated with Triple Negative Breast Cancer (TNBC). STAT5 can also be activated and inappropriate activation of STAT5 alone or with STAT3 is generally correlated with a more favorable prognosis, a lower grade tumor, and a better response to therapies compared to inappropriate activation of STAT3 alone. Therefore, knowing the activation status of STAT5 and understanding how STAT5 activation can attenuate STAT3-driven breast cancers could help guide therapeutic choices and patient treatment. STAT3 and STAT5 can regulate a set of overlapping target genes. For example, STAT3 and STAT5 can regulate BCL6 expression, where STAT5 represses expression and STAT3 enhances it. Importantly, STAT5 outcompetes and preferentially binds in the presence of activated STAT3. This suggests that the overlapping target genes could play an important role in understanding how activation of STAT5 can lead to a more favorable breast cancer compared to activation of STAT3 alone. This previous work was conducted in a 2D cell culture model; however, 3D models can better mimic clinical settings and the use of 3D models can help bridge the gap. Therefore, understanding the relationship between STAT3 and STAT5 in 3D is important. SK-BR-3 cells (HER2+ cells with low basal STAT3 activity) and MDA-MB-231 cells (TNBC cells with constitutive STAT3 activity) are being compared between 2D cell culture and 3D media suspension. We have shown using chromatin immunoprecipitation that STAT3 DNA-binding is enhanced in 3D at certain binding sites, whereas STAT5 is not. STAT5 has reduced dominance and preferential binding over STAT3 for BCL6 in 3D compared to 2D. In other cases, STAT3 binding is decreased upon STAT5 activation in 3D but not 2D. To begin to understand these differences, we analyzed phosphorylation of these STATs in 2D and 3D. Phospho-STAT3 levels were similar between 2D and 3D in SK-BR-3 cells when activated with LIF stimulation but were higher in 3D in the MDA-MB-231 cells which contain constitutive STAT3 activity. STAT5 activation by prolactin stimulation did not directly affect STAT3 phosphorylation in 2D or 3D but does affect STAT3 binding in 3D growing cells. However, prolactin induced phospho-STAT5 seems to be reduced in 3D in both cell lines. We are currently analyzing additional binding sites to better define the differences between STAT3 and STAT5 mediated gene regulation in 2D and 3D since STAT phosphorylation does not fully address it. Overall, our data suggests that differences between 2D and 3D breast cancer models will be important for translation to patient tumors and understanding the relationship between STAT3 and STAT5 will help elucidate how STAT5 activation status can be used when treating patients with breast cancer.

#1706 Investigating the interaction between ETS family members and mutant p53.

S. Metcalf, P. Hollenhorst;
Indiana University School of Medicine, Bloomington, IN

Cancer cases are on the rise globally requiring a deeper understanding of the disease and identification of novel therapeutic targets. Mutations in genes often result in tumor formation. TP53 encodes p53, a tumor suppressive transcription factor, and is mutated in nearly 50% of all cancer cases. Once mutated, p53 loses its tumor suppressive function while simultaneously gaining oncogenic function. p53 mutations disrupt direct p53 binding to DNA and promotes p53 binding to regulatory regions of oncogenes via protein-protein interactions with other transcription factors. One of these interacting partners is ETS2, a member of the ETS transcription factor family. ETS binding sites are present in 50% of all mutant p53 occupied regulatory elements. Other ETS family members have also been linked to mutant p53 but these interactions have either been deemed weak (ETS1) or have yet to be identified as direct (ERG). It is my aim to determine the scope of interaction between the ETS family and mutant p53 and to elucidate whether this interaction is required for the observed oncogenic phenotypes of ETS proteins and mutant p53.To determine which ETS proteins interact with mutant p53 purified ETS proteins were used for affinity pull-down of purified mutant p53. The entire ETS family interacted with mutant p53 to some degree, and several ETS proteins had stronger interactions than ETS2. Truncation studies were used to determine interaction domains. One interacting region was the conserved DNA binding domain, which may explain interaction across the entire family. ERG and ETS2, both strong mutant p53 interactors, had two interaction interfaces. I hypothesize that the second interaction interface defines strong interactors. To determine if interacting ETS are responsible for targeting mutant p53 to the genome, chromatin immunoprecipitation sequencing measured mutant p53 binding in the presence or absence of different ETS factors. These data indicate that each of the conditions resulted in different p53 binding patterns and that there is a requirement for ETS in mutant p53 binding. Lastly, I wanted to determine if there was a correlation between p53 mutation and expression of strong mutant p53 interactors in certain cancer types. Analysis of TCGA samples showed that in ovarian cancers with p53 mutations, ETS factors that are strong mutant p53 interactors were upregulated in a mutually exclusive pattern, while weak interactors tended to be downregulated, or unchanged. Similar trends were observed among some other cancer types. My studies have shown that several ETS proteins interact with mutant p53 in vitro, recruit p53 to the genome, and that this interaction pattern correlates with expression in mutant p53 driven cancers. Additionally, studies are ongoing to determine phenotypes related to this interaction. Ultimately, if ETS/mutant p53 interactions are deemed important for oncogenesis, these will be attractive targets for drug development.

#1707 YAP-driven epigenetic reprogramming in head and neck cancer.

A. Officer[1], F. Faraji[1], S. Ramirez[2], A. Goren[3], P. Tamayo[1], J. Gutkind[1];
[1]UCSD Moores Cancer Center, La Jolla, CA, [2]La Jolla Institute for Immunology, La Jolla, CA, [3]University of California San Diego, La Jolla, CA

The ability to measure tumor evolution is difficult due to a lack of model systems able to capture tumor initiation, development, and invasion. We have developed a Dox-inducible spatiotemporally controlled HPV- and YAP-driven model of head and neck squamous cell carcinoma (HNSCC) with a well-defined cancer stem cell population. In order to better understand the epigenetic reprogramming associated with tumorigenesis we have systematically characterized the chromatin accessibility, histone landscape and YAP binding sites in this model.

Cell lines were generated from tongue epithelia of normal and Dox-induced tumor-containing mice. Gene expression was measured using RNA-seq and chromatin accessibility was measured using ATAC-seq. CUT&Tag for H3K27me3, H3K27ac, and YAP was used to measure epigenetic reprogramming and YAP-DNA interactions.

Differential gene expression shows that genes involved in hormone signaling, glutathione-related metabolism, fatty acid metabolism and p53 signaling were highly enriched in the normal tongue suggesting a change in metabolism upon tumorigenesis.Differential ATAC-seq peaks with higher binding levels in the normal tongue showed enrichment for p53 motifs as well as homebox motifs including Otx2, GSC and CRX suggesting p53 signaling is lost upon carcinogenesis and lineage determination is altered. Motifs for TEAD, AP-1, and KLF5 were enriched in the tumor-specific ATAC-seq peaks showing that YAP is involved in chromatin accessibility changes. CUT&Tag for YAP shows clear YAP binding near canonical YAP target genes including Axl, Ccn1, Ccn2 and Birc3. YAP peaks with higher binding in the normal tongue cell line were enriched for RUNX2 and p63 motifs and peaks higher in the tumor contained KLF5 motifs showing YAP is directly involved in the reprogramming of lineage determination. Multi-omics integration shows YAP-driven chromatin remodeling is associated with differential expression of genes involved in keratin production, EGFR and ER signaling.

Direct epigenetic characterization of YAP involvement in tumor initiation is key to understanding the mechanisms of tumorigenesis in head and neck cancer. This work shows that YAP directly binds and affects the expression of genes involved in lineage determination and growth factor signaling to induce cancer progression and generate a cancer stem cell population.

#1708 Transposable element derived enhancers in ovarian cancer.

L. L. Nguyen[1], A. Ivancevic[1], B. G. Bitler[2], E. B. Chuong[1];
[1]University of Colorado, Boulder, Boulder, CO, [2]University of Colorado, Anschutz, Denver, CO

There is global epigenetic dysregulation during transformation from normal to cancerous cells. One of the many consequences of this global epigenetic dysregulation is the reactivation of transposable elements (TEs). TEs compose roughly half of the human genome and are normally repressed through epigenetic mechanisms such as DNA methylation and histone modifications. Endogenous retroviruses (ERVs) are a class of TEs that contain long terminal repeats (LTRs) with putative gene regulatory motifs. LTRs can be co-opted to be pro-tumorigenic by becoming non-canonical promotors for oncogenic genes. While several examples of TE-derived promotors have been reported in cancer, the potential significance of TE-derived enhancers remains largely unexplored. Here, we utilized publicly available multi-omics datasets (bulk and single-cell ATAC-seq, bulk and single-cell RNA-seq, and chromatin profiling) in the context of ovarian cancer to determine if there are tumor specific, TE-derived-enhancers that have gene regulatory function. We used CRISPRi technology to functionally validate a putative TE-derived enhancer and gene regulatory axis. We discovered that on the bulk tissue level, several TE families are enriched at open chromatin sites and sites marked by H3K27Ac (enhancer mark) of ovarian tumors, suggesting the presence of tumor specific, TE-derived enhancers. On the single-cell level, we discovered that ovarian cells have the highest expression of these TE transcripts compared to stromal and immune cells in the tumor microenvironment, suggesting that the increased TE-derived enhancer activity observed on the bulk level are specific to ovarian cells. Lastly, when we silenced a specific LTR18 locus upstream of a gene, *TIPARP*, TIPARP gene expression was also repressed, suggesting that these putative TE-derived enhancers have gene regulatory function. Determining the regulatory role of these TE-derived enhancers will provide novel insights into cancer-related transcriptomes.

#1710 DPF3 over-expression oncogenic effect in renal cancer is through SWI/SNF BAF complex.

L. A. Costa[1], A. G. Souza[1], V. C. Silvestrini[1], T. Myers[2], V. M. Faca[1], S. Chanock[2], L. M. Colli[1];
[1]University of Sao Paulo - FMRP, Ribeirao Preto, Brazil, [2]National Cancer Institute - NIH, Bethesda, MD

Renal Cancer (RCC) is the seventh most common type of cancer in the United States, and most part of these tumors do not respond to radiation and chemotherapy treatments. A Genome Wide Association Study (GWAS) identified 13 regions that are related to the risk of developing RCC, and one of this regions is the 14q24 region, a region that has already been shown to have a Single Nucleotide Polymorphism (SNP) involved in the development of RCC, by which the presence of the risk allele is capable of increase the expression of *DPF3* and this increase is capable of regulated the RCC cell line proliferation. It is very published the oncogenic effect of *DPF3* in RCC, however, the mechanism by which *DPF3* is acting is not very knew. Our objective is to understand the mechanisms by which *DPF3* regulate renal cancer development. For this, we did a co-immunoprecipitation of DPF3 with nuclear extract of RCC cell line that overexpress DPF3 and analyze the interactions between DPF3 and other proteins of SWI/SNF Complex. We did a proteomic analyzes in Targeted Mass Spectrometry (MRM) for see the proteins levels. We could see an increase in expression of other SWI/SNF BAF Complex proteins in RCC cell line that overexpress DPF3, such like SMARCA2, SMARCE1 and ARID1A, suggesting a relation between DPF3 and SWI/SNF BAF Complex and evidencing that DPF3 is acting through BAF Complex. To extend the evaluation of DPF3 we inhibit the expression of the SNP associated with the 14q24 region, rs4903064, in renal cancer cell lines (UOK121, SN12C and 786-O) using the CRISPRi technic and analyze the role of this SNP in *DPF3*, *CEMIP* and *IL23R* expression. Our initial results demonstrate that in the UOK121 and SN12C lineage, the inhibition of the SNP was able to decrease the expression of *DPF3*, and in the SN12C cell line we also see a decrease in *CEMIP* expression. When we analyze the 786-O cell line, we see that the blockade of SNP does not change the expression of *DPF3*, nor of the other genes, indicating that the action of the SNP on *DPF3* occurs only in the presence of the risk allele for RCC. We also use a murine (Renca) RCC cell line that overexpress *DPF3* under regulation of TetOn promoter and we did an *in vivo* experiment in mouse (Balb/c and Balb/c Nude), for analyze the function of *DPF3* in tumor growth, migration and proliferation. When we inject (s.c) in Balb/c Nude we could see an increase in tumor growth, in tumor volume and weight in the group treated with doxycycline diet when compare with de control group, suggesting that *DPF3* is capable of increase RCC growth. We also analyze the *DPF3* function in RCC invasion and migration, and when we inject (intrarenal) in Balb/c we could see a metastatic signal in the lung. The lung of the animals treated with doxycycline diet presents an increase in volume and weight when compare with the control group. In this way, the study of genetic and proteomic behind DPF3 function and RCC development is essential for a biomarker discovery and help in the patient prognosithes and treatment.

#1711 Rearranged active enhancers and promoter-enhancer contacts promote lipid metabolic reprogramming during secondary trastuzumab adaptation of HER2 positive breast cancer.

N. Duan[1], Y. Hua[2], Y. Yin[1];

[1]Jiangsu Province Hospital, Nanjing, China, [2]Nanjing Medical University, Nanjing, China

Background: The development of secondary trastuzumab resistance signifies an evolutionary adaptation within HER2-positive breast cancer during anti-HER2 treatment. Our research reveals a comprehensive metabolic reprogramming, with a particular emphasis on the synthesis of unsaturated fatty acids and the degradation of arachidonic acid, accompanying this adaptation. Non-mutational epigenetic variations, particularly alterations in active enhancers, coupled with the rearrangement of enhancer-promoter contacts, demonstrate robust correlations with lipid metabolic reprogramming. These findings suggest that non-mutational epigenetic variations play a crucial role in driving the adaptation to trastuzumab.

Materials and Methods: In a prior investigation, we successfully generated secondary trastuzumab-resistant SKBR3_HR cells. In our current study, total RNA was extracted from both trastuzumab-resistant SKBR3_HR and trastuzumab-sensitive SKBR3 cells for transcriptome analysis. Additionally, mass spectrometry was employed to analyze cellular metabolism in both resistant and sensitive cell populations. Simultaneously, we utilized the CUT&Tag kit with an anti-H3K27ac antibody to create a sequencing library for active enhancer measurement. Furthermore, the Micro-C kit was applied to generate a sequencing library for genome contact measurement.

Results: In our study, secondary trastuzumab-adaptive SKBR3_HR cells demonstrated a reduction in cellular unsaturated fatty acids, with more than 110 UFAs or UFA-containing lipids showing decreases, while only 36 exhibited increases. This phenomenon may be attributed to the downregulation of SCD, FADS2, and HACD2. Simultaneously, the upregulation of PTGS1 and PTGES may contribute to a higher conversion of arachidonic acid to prostaglandin E2 (PGE2), resulting in immune inhibition. In SKBR3 and SKBR3_HR cells, 10,955 and 10,889 non-promoter H3K27me3 peaks, respectively, were identified as active enhancer regions. Among them, 379 enhancers became silent, and 313 transitioned into an active state during the formation of trastuzumab adaptation. Trastuzumab adaptation led to an increase in intra-chromosomal interactions, particularly short-distance contacts (< 1MB). By employing the activity-by-contact (ABC) algorithm, we observed significant variant contacts between PTGES and SCD promoters and enhancers within 1MB genomic regions in SKBR3_HR cells compared to SKBR3 cells.

Conclusion: The formation of secondary trastuzumab adaptation involves the rearrangement of active enhancers and promoter-enhancer contacts, serving as an effective force to drive lipid
metabolic reprogramming, especially the synthesis of unsaturated fatty acids and PGE2 production, reshaping the cellular fatty acid composition and anti-tumor immunity.

#1712 Identifying a novel alternative promoter usage in HDAC9: Implications for LUAD prognosis and therapy.

A. Bolatkan[1], K. Asada[1], S. Kaneko[2], M. Komatsu[1], R. Hamamoto[1];
[1]RIKEN, Chuo City, Japan, [2]NCC, Chuo City, Japan

Promoters are key elements in gene regulation. It has been estimated that more than half of protein-coding genes in the human genome possess multiple promoters. Aberrant expression and dysregulated activity of alternative promoters have been correlated with numerous diseases, especially cancer. In this study, we utilized RNA-seq data from 608 lung adenocarcinoma (LUAD) patients and systematically analyzed promoter activities using the proActiv algorithm. Of the expressed genes in LUAD, approximately 57% have at least two distinct promoters. In addition, we identified 1852 tumor-specific alternative promoters that showed a significant shift (2-fold changes) in promoter activity without any notable changes in the expression of corresponding 1603 genes between tumor and adjacent non-tumor tissues. Functional enrichment analysis showed that these genes were associated with key cellular functions such as signaling pathways, cell cycle, and cell junctions. Unsupervised clustering of patients based on altered promoters revealed a significant prognostic value. Among them, we observed a major promoter switch in *HDAC9*, which mainly utilizes three promoters: prmt3280, prmt3283, and prmt3287 in our LUAD dataset. Notably, prmt3287 was exclusively active in tumor samples and functioned as the dominant promoter, while prmt3283 served as the main promoter in adjacent non-tumor samples. Intriguingly, even though the overall expression of HDAC9 mRNA lacked prognostic relevance both in our dataset and in the TCGA dataset, higher expression of the alternative promoter prmt3287 (using ≥50% activity level as a cutoff) was associated with adverse outcomes in LUAD patients. We further compared the DNA methylation level around the *HDAC9* domain between paired tumor and non-tumor samples and found that positions with the most significant differences ($p<0.001$) overlapped with the prmt3287 region. Moreover, DNA methylation levels around prmt3287 significantly decreased in prmt3287 high-activity patient groups. Next, we investigated the ChIP-seq levels over the *HDAC9* region, and ChIPseeker successfully annotated the alternative promoters of *HDAC9*. In addition, the alternative promoter prmt3287 exhibited the highest active enhancer signals. Furthermore, we performed PCR to determine the expression of six distinct transcript isoforms from alternative promoters in four different LUAD cell lines, and we observed high expression of isoform 10, which is possibly generated by prmt3287 in all cell lines. The impact of prmt3287 on cell proliferation, cell cycle, and cell migration will be further addressed. Our results indicate that alternative promoter usage can capture insights that might be missed at the overall gene expression level, and alternative promoter usage in *HDAC9* could be a novel biomarker and a promising therapy target.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Epigenetic Targets in Oncology
Poster Session

#1716 A proteome-wide association study identifies putative causal proteins for breast cancer.

T. Zhao[1], S. Xu[1], J. Ping[1], G. Jia[1], Y. Dou[2], B. Zhang[2], X. Guo[1], Q. Cai[1], X.-O. Shu[1], W. Zheng[1], J. Long[1];
[1]Vanderbilt University Medical Center, Nashville, TN, [2]Baylor College of Medicine, Houston, TX

Background: Genome-wide association studies (GWAS) have identified over 200 breast cancer risk associated genetic loci, yet the causal genes and biological mechanisms for most loci remain elusive. Proteins, as final gene products, are pivotal in cellular function. In this study, we conducted a proteome-wide association study (PWAS) to identify proteins in breast tissue in relation to breast cancer risk.
Methods: We profiled the proteome in breast tissue samples from 120 cancer-free European-ancestry women from the Susan G. Komen Tissue Bank. Protein expression levels were log2 transferred and then normalized via quantile and inverse-rank transformations. The *elastic net* method was used to build statistical models to predict protein expression levels via genetic variants. The prediction models were then applied to the GWAS summary statistics data of 133,384 breast cancer cases and 113,789 controls to assess the associations of genetically predicted protein expression levels with breast cancer risk overall and its sub-types using the S-PrediXcan method.
Results: A total of 6,388 proteins were detected in the normal breast tissue samples from 120 women with a high detection false discovery rate (FDR). Among the 5,823 proteins detected in more than 80% of participants, prediction models were successfully built for 2,041 proteins with R>0.1 and P<0.05. Among these 2,041 proteins, six proteins were significantly associated with overall breast cancer risk at an FDR P< 0.05. Among these six proteins, the corresponding genes for proteins DCTN3 and DDX6 were located at least 500kb away from the GWAS-identified breast cancer risk variants. Both DCTN3 and DDX6 were associated with a decreased risk of breast cancer with P values of 8.46×10^{-4} and 2.27×10^{-4}, respectively. The corresponding genes for the remaining four proteins, LMNA, LSP1, RPS6KA5, and DNAJA3, were located in previously GWAS-identified breast cancer risk loci. After adjusting for GWAS-identified risk variants, the associations for LMNA and RPS6KA5 were still significant ($P=2.54 \times 10^{-7}$ and 2.79×10^{-5}, respectively), however, the associations for LSP1 and DNAJA3 became weaker with P values of 0.65 and 2.10×10^{-4} respectively.Stratification analyses by breast cancer subtypes identified three proteins, LMNA, LSP1, and NCKAP1L, associated with luminal A, luminal B, and ER-positive subtypes. NCKAP1L was located at least 500kb away from risk loci. After adjusting for GWAS-risk variants, the associations for LMNA were still significant ($P=2.58 \times 10^{-5}$ and 4.08×10^{-6} for luminal A and ER-positive respectively).
Conclusion: We conducted the first breast-tissue-based PWAS and identified seven proteins associated with breast cancer, including six proteins that were not previously implicated. These findings help improve our understanding of the underlying genetic mechanism of breast cancer development.

#1717 RAS and PP2A co-regulated phosphosite on KDM1A dictates its substrate specificity & transcriptional outcome.

M. Sharma[1], A. Aakula[1], J. Kamila[1], R. Natkin[2], T. Bonaldi[3], S. Minucci[3], M. Nykter[2], J. Westermarck[1];
[1]University of Turku, Turku, Finland, [2]Tampere University, Tampere, Finland, [3]Istituto Europeo di Oncologia, IEO, Milan, Italy

RAS-mediated human cell transformation requires simultaneous inhibition of tumor suppressor phosphatase PP2A; however, the target phosphosites co-regulated by RAS and PP2A are poorly characterized. In this study, we describe the phosphoregulation of an epigenetic regulator, KDM1A, by RAS and PP2A. KDM1A is a lysine-specific demethylase that can act as a transcriptional activator or inhibitor, depending on its specific activity toward various histone marks. However, the post-translational modifications regulating the substrate specificity of KDM1A are poorly addressed. We found that KDM1A physically interacts with PP2A through a conserved binding motif, and that mutating the motif residues decreased its interaction with PP2A. Additionally, PP2A activation or RAS inhibition led to increased chromatin recruitment of KDM1A. This enhanced chromatin recruitment of KDM1A was recapitulated upon CRISPR/CAS9-mediated substitution of the PP2A/RAS-targeted serine to alanine. Using histone proteomics, we further identified that the RAS/PP2A-regulated phosphosite determines the substrate specificity of KDM1A. This is evidenced by an increased demethylation of histone H3K9me2/3, a marker of gene activation. The differential gene expression profile of the phosphorylation mutants of KDM1A predominantly showed increased gene expression, further validating our findings. The gene expression profiles of KDM1A phosphomutant RAS mutant cells demonstrate gene level specificity indicating that this newly discovered KDM1A phosphoswitch has an important role in specifying KDM1A function in cancer. Collectively, our results demonstrate that RAS and PP2A activities converge on phosphoregulation of epigenetic machinery in cancer cells. This RAS and PP2A co-regulated phosphosite on KDM1A dictates both its histone mark specificity and transcriptional outcome.

#1718 The lysine demethylase KDM2A regulates tumor cell clustering to potentiate metastasis.

C. Kravitz[1], K. D. Patel[1], W. L. Cai[2], A. Arnal-Estape[1], D. Zhao[1], E. Wingrove[1], L. Stevens[1], T. F. Westbrook[3], Q. Yan[1], D. X. Nguyen[1];
[1]Yale University, New Haven, CT, [2]University of Pittsburgh, Pittsburgh, PA, [3]Baylor College of Medicine, Houston, TX

Approximately 70% of patients diagnosed with non-small cell lung cancer (NSCLC) are not eligible for curative resection, often due to disseminated disease at diagnosis. Thus, the advent of novel therapeutics, especially those efficacious for metastatic disease, is of primary importance. Metastasis correlates with epigenetic alterations that drive tumor plasticity and adaptive heterogeneity in response to the multiple microenvironments metastatic cells see, yet the molecular mechanisms underlying these epigenetic alterations remain poorly understood.

We performed a functional genomic screen and identified the lysine 36 on histone H3 (H3K36) demethylase KDM2A as a mediator of *in vivo* and *in vitro* metastatic competence in multiple models of NSCLC. KDM2A depletion in highly metastatic NSCLC cell lines reduces their capacity to form multi-tumor cell clusters. *In vivo*, KDM2A depletion does not impact lung orthotopic tumor cell growth or the total number of circulating tumor cells (CTCs) but does reduce their ability to colonize distant metastatic sites. This is consistent with the fact that human CTCs found in clusters are more metastatic than CTCs which disseminate as single-cells.

Because the molecular and biological consequences of H3K36 regulation are context dependent, we performed for the first time an integrated transcriptomic-epigenomic analysis of target gene regulation, KDM2A genomic binding, H3K36 methylation, and H3K27 acetylation, in metastatic cell clusters. KDM2A enhances the expression of cell adhesion and anti-oxidant genes, while suppressing inflammatory gene responses, and this regulation preferentially occurs in tumor cell clusters. Transcriptomic analysis of CTCs from patients confirms that KDM2A regulated transcriptional responses correlate with metastatic relapse across multiple cancer types. Moreover, KDM2A may function both as a transcriptional activator and repressor in metastatic clusters. As KDM2A encodes for several domains which can independently regulate E3-ubiqutin ligation, H3K36me2 demethylation, and DNA methylation, we have also performed a structure function analysis of K2MDA in the context of metastatic phenotypes. Thus, the distinct biochemical functions of KDM2A in relation to its regulation of CTC gene transcription and histone modification will also be presented.

In conclusion, we have identified KDM2A as a novel regulator of NSCLC metastatic spread. The ability to inhibit KDM2A with small molecule inhibitors may be translated into effective therapeutic interventions for NSCLC patients with metastasis disease.

#1719 Targeting H3.3 serine 28 phosphorylation as a novel therapeutic strategy for diffuse midline glioma.

Y. Yan;
Mayo Clinic, Rochester, MN

Background: Diffuse midline glioma (DMG) is a highly aggressive pediatric brain cancer with a poor prognosis [1]. Mechanistically, DMG harbors a lysine-to-methionine substitution at position 27 of histone H3.3 (H3.3K27M), which leads to global hypomethylation and a dramatically altered epigenetic landscape [2, 3].
Aim: This study aims to explore the H3.3K27M mutation from a novel perspective by investigating its effects on H3.3 ubiquitination, with the goal of identifying effective, novel therapeutic targets.
Methods: Mass spectrometry was used to identify potential E3 ligases for H3.3, while immunoprecipitation to verify this interaction. Cell viability and survival were determined by MTS and clonogenic survival assays, respectively. Nucleosome fractionation was performed to detect the distribution of wild-type (WT) or K27M mutant H3.3 histones.
Results: Mass spectrometry identified UBR7, an E3 ligase, as exhibiting a stronger binding affinity with WT H3.3 than its K27M mutant counterpart. Further nucleosome fractionation assay revealed that K27M histones are more likely deposited in nucleosomes than WT H3.3. Further analysis demonstrated that a non-phosphorylation mimic mutation (serine to alanine) at amino acid 28 (S28A) restored the binding affinity of K27M mutant H3.3 with UBR7. Importantly, this mutation disrupted H3.3 phosphorylation and significantly diminished cell survival, whereas the constitutively activated phosphorylation mutation (S to glutamine (E)) on S28 (S28E) mimics K27M mutation in promoting cell proliferation and survival.
Conclusion: These findings suggest that S28ph impairs UBR7-mediated K27M ubiquitination and promotes DMG cell growth, suggesting that targeting S28ph is an effective therapeutic strategy. However, the underlying mechanisms by which K27M interplays with S28ph in promoting tumorigenesis require further investigation.

#1720 53BP1 regulates heterochromatin through liquid-liquid phase separation (LLPS).

X. Geng, Y. Zhang;
Case Western Reserve University, Cleveland, OH

As compacted DNA, heterochromatin represses abnormal gene expression by inhibiting DNA transcription and maintains genome integrity by protecting aberrant chromosome segregation. Therefore, abnormalities in heterochromatin function are commonly found in cancer. However, how exactly heterochromatin preserves the genome integrity remains poorly understood due largely to the complex structure of heterochromatin. Recently, increasing evidence suggests that heterochromatin factors, including HP1α, KAP1, and SUV39H1/2, could drive the soluble heterochromatin into phase-separated droplets/condensates to promote gene silencing, which is referred to as liquid-liquid phase separation (LLPS). TP53-binding protein 1 (53BP1) has traditionally been a critical factor in DNA double-strand break (DSB) repair. We recently reported an unexpected finding that under normal growth conditions, 53BP1 regulates heterochromatin function through LLPS, which is independent of its DSB repair function. Our studies reveal a new paradigm in studying 53BP1, heterochromatin, and genome stability. However, an important question remains unanswered: how 53BP1 is recruited to heterochromatin to undergo LLPS and the associated broad biological impact. To address this question, we performed a special crosslinking coupled mass spectrometry to uncover potential factors in the 53BP1 condensates assembled on heterochromatin. We identified many factors associated with DNA methylation and histone modification, which are the two main steps in restoring heterochromatin epigenetic modification. Their interactions with 53BP1 at heterochromatin were confirmed by different approaches. We further focused on one of the key factors, PCNA, and carried out a detailed analysis of the interaction between PCNA and 53BP1 and the role of such interaction in 53BP1 LLPS, DSB repair, and heterochromatin function. These findings reveal the previously uncharacterized function of 53BP1 at heterochromatin during normal DNA replication.

#1721 Epigenetic heterogeneity of osteosarcoma reveals distinct cellular states driven by enhancer regulation.

E. Lopez Fuentes, A. Clugston, A. Lee, L. Sayles, M. Pons, A. Sweet-Cordero;
UCSF - University of California San Francisco, San Francisco, CA

Osteosarcoma (OS) is characterized by structural rearrangements and copy number changes which drive considerable heterogeneity. What is less clear is how these genetic rearrangements alter are in turn regulated at the epigenetic level to drive gene expression. Defining the epigenetic circuitry of osteosarcoma could help to understand the role of chromatin accessibility in determining cell plasticity. Chromatin accessibility can prime gene expression and define a cellular state. As chromatin accessibility is a major determinant of epigenetic transcriptional regulation, understanding the variability of chromatin accessibility could identify clinically-relevant subtypes and biomarkers of therapy response in Osteosarcoma, a disease that has seen few advances in therapy for over 40 years. Using ATAC-seq, we identified two epigenetic subtypes (EC1 and EC2) of OS with distinct chromatin accessibility. These studies were done in a panel of 11 PDX-derived cell lines and 9 established OS cell lines. We also performed ATACseq on the matching PDX for the 11 PDX-derived lines as well as 8 primary tumor samples. Analysis of transcription factor (TF) motifs and footprints of ATAC-seq peaks identified transcription factors distinctly activated in these two subtypes. For example, EC1 is characterized by high level of activity of developmental transcription factors including RUNX2, MEF2C and homeobox TFs. In contrast, EC2 is characterized by high activity of AP1 transcription factors such as FOSL1 and FOSL2. In order to understand the underlying transcriptional circuitry of these cell states, we performed CUT&RUN assay for the complete panel of PDX-derived cell lines. We found that the subtypes are driven by enhancer regulation (H3K27ac). We defined the specific Core Regulatory Circuitry (CRC) per subtype by defining the superenhancers by ROSE. We overlapped ATAC-seq data in the acetylated regions to demarcate TF binding regions dramatically and reduce the search space for TF cis-regulatory sites. In parallel, we used our PDX-derived cell line panel to screen cluster-specific targeted therapies and found differential responses dependent on cellular states defined by chromatin accessibility. For example, cell lines in the EC2 cluster are marked by upregulation of AP1 transcription factors, have evidence of ERK activation and are highly responsive to ERK inhibitors. In contrast cell lines in the EC1 cluster are sensitive to AURKA and AURKB inhibitors. Single-cell RNAseq analysis indicates that these subtypes may coexist within a single tumor. In summary, we discovered two epigenetically distinct cell states that are controlled by a state-specific collection of transcription factors, creating a gene signature that may aid in distinguishing osteosarcoma subclasses and predicting treatment response.

#1722 Subtype classification of small cell lung cancer (SCLC) tissues using the EpiCheck methylation sensitive restriction-based PCR platform.

O. Savin[1], **D. Netanely**[1], S. Heeke[2], C. M. Gay[2], M. R. Estecio[2], S. Danan[1], S. Zaouch[1], A. Shuali[1], M. Ehrich[3], L. A. Byers[2], J. V. Heymach[2], A. Wasserstrom[1], D. Frumkin[1];

[1]Nucleix, Rehovot, Israel, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]Nucleix, San Diego, CA

Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy with poor survival rates. Despite molecular and clinical heterogeneity, SCLC is currently treated as a single entity without guidance of predictive biomarkers leading to expectedly poor outcomes. A recent study suggested classifying SCLC into four subtypes (“A”, “N”, “P” and “I”), each with unique molecular features and therapeutic vulnerabilities. While initially this classification was based on gene expression (RNA-seq) data, subsequent data suggest it can be recapitulated using reduced-representation bisulfite sequencing (RRBS) methylation profile. While the classification system accurately predicts responses to therapies, including immunotherapies, in retrospective analysis, both tissue-based RNAseq and RRBS are cumbersome, time-consuming and impractical for prospective treatment assignment in an aggressive malignancy. In this pilot study, we developed a methylation-based PCR assay for classification of SCLC subtypes based on the EpiCheck platform, which combines methylation-sensitive restriction endonuclease (MSRE) digestion with qPCR amplification to detect differential methylation at the DNA level. We developed a 13-marker assay and successfully classified, in a blinded study, 96.55% of FFPE tissue samples originating from SCLC patient of A, N and P subtypes. First, a bioinformatic analysis identified 41 candidate biomarkers that are differentially methylated between pairs of SCLC subtypes (A-N, A-P, and N-P) using RRBS data from 56 RNA-seq classified SCLC tumor samples (34 “A”, 19 “N”, 3 “P”). Development of primers and probes for these markers was followed by a biochemical selection process, identifying 13 markers that displayed optimal performance. A PCR EpiCheck assay, employing these 13 markers, was applied to a blinded set of 29 DNA samples from SCLC FFPE tumor tissues (21 “A”, 6 “N”, 2 “P”). Each sample received two ranks based on methylation levels of 5 A-N and 9 P-AN markers and was classified using determined thresholds for each rank. Finally, when comparing PCR-based and RNA-seq-based classifications, the 13-marker PCR assay classified 28/29 (96.55%) of the samples concordantly, misclassifying one "P" sample as "A".

This pilot demonstrates the potential of a simple PCR EpiCheck-based assay to accurately differentiate between SCLC subtypes. For complete subtype classification, “I” markers need to be added to the panel, and the assay should be further validated using a larger cohort, particularly for the “P” subtype. Early detection and classification are critical for timely personalized therapy, and such an assay, performed on cfDNA samples, could potentially be used to shorten the time between a patient diagnosis and tailored treatment initiation or clinical study inclusion from a month in best case scenarios to a few days.

#1723 Targeting SMARCA1 in rhabdomyosarcoma: Potential therapeutic implications.

A. Aljabri[1], K. Hebron[1], Y. Kriga[2], J. Caravaca[2], A. Althobaiti[3], S. Stauffer[1], A. Kim[1], L. Stoak[1], M. Porter[1], J. Shetty[1], B. Tran[1], M. Geisler[3], J. Davie[3], M. Yohe[1];

[1]National Institutes of Health, Frederick, MD, [2]National Institutes of Health, HHS, Frederick, MD, [3]Southern Illinois University, Carbondale, IL

Background: Rhabdomyosarcoma (RMS) is the most common soft tissue in pediatric sarcoma, and studies demonstrate that RMS arises from skeletal muscle precursor cells. RMS, genetically divided into two subtypes: PAX-FOXO1 fusion positive RMS (FP-RMS), which is driven by chromosomal translocation involving PAX3 or PAX7 genes with FOXO1 and PAX-FOXO1 fusion negative RMS (FN-RMS), which is marked by mutations in RAS isoforms and some other genes. Chromatin was one of the earliest identified targets for cancer therapy. Several chromatin remodeling proteins are associated with cancer progression processes such as proliferation, differentiation, apoptosis, and tumorigenesis. Components of chromatin remodeling complexes have been classified as both oncogenes and tumor suppressors. The ISWI family protein, SMARCA1 has been implicated in tumorigenesis for several cancer types. ISWI complexes regulate cell differentiation and proliferation in other cell systems, but their impact on myogenesis is not well understood.
In this study, we will characterize the function of SMARCA1 in RMS cells and skeletal muscle.
We hypothesize that SMARCA1 acts to modulate chromatin accessibility and drive RMS tumorigenic growth.
Methods: We employed RNA-seq, ATAC-seq, and CUT&RUN to study the impact of SMARCA1 in RMS cells. Furthermore, phenotypic experiments were performed to determine the influence of SMARCA1 on differentiation and proliferation.
Results: SMARCA1 is expressed at a high level in RMS tissues but not in muscle tissues. Our findings show that SMARCA1 is modestly upregulated during differentiation in normal myogenesis. Upon treatment with trametinib, FP-RMS cell lines with SMARCA1 knockout exhibited a dramatic decrease in cell confluency and viability. Intriguingly, the control FP-RMS cell lines demonstrated increased SMARCA1 protein levels in response to trametinib, which could suggest a resistance mechanism to the treatment. Trametinib also affected SMARCA1 mRNA expression in FN-RMS cells. Additionally, it was discovered that the elimination of SMARCA1 not only resulted in a reduction in cell migration but also led to a failure of these cells to develop spheres, unlike the control cells, where the migration gap healed in the usual manner and the spheres were observed. These findings may align with our hypothesis that SMARCA1 regulates chromatin accessibility, potentially impacting adhesion properties and signaling pathways. Analysis of gene clusters in RMS transcriptomic data indicated that SMARCA1 co-expresses with a RAS effector, RALA. SMARCA1 is also clustered with HDAC2. In addition, SMARCA1 interacted with HDAC2 in RMS cells, as determined by co-immunoprecipitation experiments.
Conclusions: Our findings suggest that SMARCA1 may influence RMS tumor growth. This study might contribute to a deeper understanding of SMARCA1's role in RMS and support its credentialing as a novel therapeutic avenue.

#1725 Role of PRMT5 in neuroendocrine prostate cancer development.

H. S. Nam, X. Deng, C.-D. Hu;
Purdue University, West Lafayeette, IN

Background: Neuroendocrine prostate cancer (NEPC) is a lethal subtype of prostate cancer responsible for an estimated 20-30% of castration resistant prostate cancer (CRPC) deaths. While NEPC can arise de novo, the majority of these cases emerge as treatment-induced NEPC (tNEPC). Our data establish PRMT5:MEP50 as a key epigenetic regulator in NEPC and provide a potential predictive biomarker for tNEPC.
Methods: Here we generated an in vitro cell culture model and mouse model to mimic the clinical conditions in androgen signaling inhibitor (ASI) or androgen deprivation treatment (ADT) We developed an *in vitro* cell culture and *in vivo* model to mimic the clinical conditions in enzalutamide-resistant prostate cancer. Regulation and role of protein arginine methyltransferase 5 (PRMT5) and its cofactor methylosome protein 50 (MEP50) were determined by treating cells and mice tumors with doxycycline inducible-shRNAs and catalytic inhibitors followed by analysis of cell viability, neurite growth, and effects on neuroendocrine related gene transcription. Pro-NEPC development effects were analyzed by immunofluorescence, immunohistochemical analysis, and western blot. PRMT5:MEP50-dependent methyltransferase activity was further validated by observing histone deposition levels via western blot and ChIP-qPCR. For clinical correlation, PRMT5 and MEP50 expression levels were comprehensively analyzed in both CRPC and NEPC patient prostate tissue samples.
Results: Our clinical and computational analyses have identified increased expression of PRMT5:MEP50 in NEPC. Overexpression of PRMT5 and MEP50 in prostate cancer cells is sufficient to induce neuroendocrine differentiation (NED) in prostate cancer cells. Gene depletion of PRMT5 and MEP50 prevented the NE phenotype induced by androgen receptor inhibition and resensitized the prostate cancer cells to ASI/ADT. PRMT5 and MEP50 facilitate chromatin modulation through the dimethylation of H4R3, which is highly correlated with the NED phenotype. Moreover, overexpression of PRMT5 and MEP50 in mouse prostate induces NEPC development, and gene downregulation can prevent NED in a xenograft mouse model. Elevated PRMT5 and MEP50 correlated with increased recurrence in prostate cancer patients receiving ADT and their recurrence probability after the treatment.
Conclusion: Our data establish PRMT5:MEP50 as a key epigenetic regulator in NEPC and provide a potential predictive biomarker for tNEPC.

#1726 Targeted epigenomic control of MYC as a strategy to treat EGFR inhibitor-resistant NSCLC.

E. Lee, P. Flahardy, C. Vergato, S. Siecinski, J. Chen, C. O'Donnell, G. Hodgson, D. Yarar, T. McCauley;
Omega Therapeutics, Cambridge, MA

EGFR tyrosine kinase inhibitors (EGFRi) have improved outcomes for non-small cell lung cancer (NSCLC) patients harboring activating *EGFR* mutations. However, patients receiving EGFRi therapy frequently relapse with an EGFR T790M mutation. While osimertinib, a third generation EGFRi, blocks EGFR T790M activity, resistance eventually develops through various EGFR-dependent and EGFR-independent mechanisms, such as acquiring additional mutations in EGFR (e.g. C797S), activating bypass signaling pathways, or undergoing an epithelial to mesenchymal transition (EMT). MYC is a master transcription factor critical for mediating oncogenic signal transduction and has been implicated in EGFRi resistance, suggesting that MYC targeting may overcome multiple EGFRi resistance mechanisms. To evaluate this, we have developed a NSCLC-specific programmable epigenomic mRNA therapy, termed a MYC epigenomic controller (NSCLC MYC-EC), designed to selectively target regulatory elements in MYC's insulated genomic domain and downregulate MYC expression. We have previously shown that NSCLC MYC-EC effectively decreases MYC expression pre-transcriptionally and have demonstrated that MYC-EC combination with osimertinib synergistically reduces viability of EGFR mutant NSCLC cells. Here, we demonstrate NSCLC MYC-EC activity in models that have developed EGFRi resistance through EGFR-dependent and -independent mechanisms. To test the effect of NSCLC MYC-EC in NSCLC cells with T790M mutant EGFR, we treated H1975 (L858R, T790M) and PC9-T790M cells (del19, engineered T790M) with MYC-EC alone or in combination with osimertinib. MYC-EC combination with osimertinib enhanced MYC protein downregulation and synergistically reduced cell viability in both models. To evaluate the effect of MYC-EC in osimertinib-resistant cells, we engineered H1975 and PC9-T790M cells with an EGFR C797S mutation. While osimertinib treatment did not impact cell viability in these models, MYC-EC maintained activity, downregulating MYC levels and reducing cell viability. To investigate MYC-EC activity in cells with alternative resistance mechanisms, we generated osimertinib-resistant H1975 cells by stepwise dose escalation. Protein analysis showed highly reduced phospho-EGFR levels, suggesting an EGFR-independent mechanism of survival. RNA-sequencing analysis revealed that EMT pathway was highly activated in these resistant cells. Importantly, this model retained sensitivity to NSCLC MYC-EC treatment, demonstrating that selectively targeting MYC can treat osimertinib-resistant NSCLC cells with a mesenchymal phenotype. Together, these data demonstrate that pre-transcriptional downregulation of MYC through NSCLC MYC-EC treatment effectively inhibits viability of EGFRi-resistant NSCLC through both EGFR-dependent and -independent mechanisms and supports the development of NSCLC MYC-EC in EGFRi-resistant NSCLC.

#1727 Silencing of novel m6A reader PRRC2A as a therapeutic strategy for oral cancer.

B. Kannan, V. P. Jayaseelan, S. M, P. Arumugam;
Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences (SIMATS), Saveetha University, Chennai, India

Background: Oral squamous cell carcinoma (OSCC) poses a substantial global health challenge characterized by limited treatment options and unfavorable prognoses. Recent research has illuminated the pivotal role of N6-methyladenosine (m6A) modification and its regulators in cancer biology. However, the precise involvement of a novel m6A regulator (m6A reader), PRRC2A in OSCC remains inadequately understood.
Objective: This study aims to unravel the role of PRRC2A in OSCC and ascertain its potential as both a diagnostic biomarker and a therapeutic target.
Methods: We collected 76 OSCC tumor samples and 38 adjacent non-tumor samples from OSCC patients. Comprehensive analyses, including RT-qPCR, western blotting, histopathological examination, and associations with clinicopathological features, were performed to assess PRRC2A expression in cancer tissues. Furthermore, we explored its links with key factors like metastasis and its implications for patient prognosis. *In vitro* experiments were conducted using OSCC cell lines and human normal oral keratinocytes (NOKs). PRRC2A knockdown in OSCC cell lines was assessed for its effects on cell proliferation, apoptosis, cell cycle, migration, invasion, and sphere-forming abilities. The study also delved into its impact on immune cell infiltration and involvement in biological pathways.
Results: Our investigation unveiled significant overexpression of PRRC2A in OSCC tissue samples and cell lines, relative to adjacent non-tumor tissues and NOKs ($P < 0.001$). These findings were further validated by the Cancer Genome Atlas - Head and Neck Squamous Cell Carcinoma (TCGA-HNSC) dataset. PRRC2A expression displayed significant correlations with nodal metastasis, higher tumor grades, and advanced cancer stages in OSCC samples, suggesting its crucial role in driving cancer progression and aggressiveness. Silencing PRRC2A *in vitro* led to reduced metastasis, diminished tumor colony formation, and increased apoptosis in oral cancer cell lines. Furthermore, the study uncovered PRRC2A intricate connections with immune regulatory genes, highlighting its potential to influence the tumor immune microenvironment.
Conclusion: PRRC2A emerges as a promising candidate for both diagnosis and therapeutic intervention in OSCC. Its pronounced overexpression in oral cancer tissues, coupled with its associations with metastasis and intricate interactions with immune regulatory networks, underscores its significance in the context of oral cancer malignancies. This research offers valuable insights into the multifaceted role of PRRC2A in OSCC and lays the groundwork for future investigations and potential clinical applications.

#1728 Senescent cancer-associated fibroblast drives colorectal cancer progression in a METTL1-dependent manner.

J. Weng, X. Wang, X. Liu, Y. Luo, **H. Yu**;
The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Colorectal cancer (CRC) is a leading cause of cancer-related mortality worldwide. More comprehensive studies of key molecular alterations were urgent. Cancer-associated fibroblasts (CAFs) exhibit the senescence-associated secretory phenotype (SASP) which contributes to the progression of cancer through the transcriptomic reprogramming at their senescent states. N7-methylguanosine (m7G), one of the most common RNA modifications, is catalyzed by Methyltransferase-like 1 (METTL1) in human RNA. We therefore investigated the role of METTL1-mediated transcriptomic reprogramming in the crosstalk between senescent CAFs (s-CAFs) and cancer cells.
Methods: The SA-β-gal staining and immunofluorescence assays were conducted to characterize the senescent cells. The transwell, wound scratch and organoids assays were preformed to test the abilities of viability, migration and invasion. The concentrations of cytokines and chemokines were determined by Luminex liquid suspension chip. The methylated RNA immunoprecipitation and dot blot assays were performed to characterize the RNA m7G levels in the transcriptome.
Results: Through the activation of mTOR signaling, the expression of P16 gene was significantly up-regulated in s-CAFs which was treated by H_2O_2, accompanied by an increased proportion of SA-β-gal+ cells and altered expression level of METTL1 protein. Luminex liquid suspension chip analysis revealed a significant increase in SASP cytokines such as TNF-α and PDGF-BB in the conditioned media of s-CAFs. Co-culturing CRC cell and organoids with s-CAFs resulted in down-regulation of METTL1 expression and significantly enhanced its invasion and migration abilities, while organoids exhibited increased activity and proliferated more rapidly. TNF-α and PDGF-BB down-regulated the METTL1 expression in CRC cell, while inhibitors targeting TNF-α and PDGF-BB rescued this trend. Interestingly, the regulatory effect on METTL1 of CRC cell by s-CAFs which treated by rapamycin was disappeared. These results indicated that METTL1 modulates RNA m7G modifications influenced by SASP cytokines for promoting CRC metastasis flow.
Conclusions: In summary, our findings illustrated that METTL1 plays a role in relaying tumor-promoting signals from s-CAFs in response to SASP cytokines. This ultimately contributes to the tumor-promoting signal flow from s-CAFs. This highlights the importance of understanding the molecular mechanisms underlying the communication between different cell types in the tumor microenvironment. In addition, it also provides a novel strategy for clinical treatment in advanced CRC.

#1729 SUV420H1 depletion reveals therapeutic potential in HPV-negative head and neck squamous cell carcinoma.

Arfa Moshiri[1], Sohyoung Kim[2], Marie Luff[1], Vassiliki Saloura[1]

[1]Thoracic and GI Malignancies Branch, National Cancer Institute, Bethesda, MD,[2]Laboratory of Receptor Biology and Gene Expression, National Cancer Institute, Bethesda, MD

Human Papilloma Virus (HPV)-negative head and neck squamous cell carcinoma (HNSCC) poses a significant clinical challenge with limited treatment options. *SUV420H1*, which encodes for a protein lysine methyltransferase (PMT) that methylates H4K20 (H4K20me3), is recurrently amplified in ~5% of HPV-negative HNSCC tumors and is the second most frequently amplified PMT in this disease, suggesting an oncogenic function in this subset of HPV-negative HNSCC patients. Gene set enrichment analysis using the TCGA database of HPV-negative HNSCC tumors revealed that SUV420H1 overexpressing tumors showed enrichment in the mitotic spindle related pathways, and repression of immune-related pathways. To assess whether SUV420H1 depletion affects the proliferation of HPV-negative HSNCC cells, CCK8 and colony formation assays were pursued after siRNA-mediated knockdown of SUV420H1 in five SUV420H1-overexpressing HPV-negative HNSCC cell lines and revealed a significant reduction in cell proliferation and colony forming capacity. SUV420H1 CRISPR knockout (KO) HPV-negative HNSCC human and mouse cell lines were generated. Proliferation and colony formation assays with the SUV420H1 KO cell lines are ongoing to validate the aforementioned phenotypes. To identify oncogenic mechanism of SUV420H1, genome-wide mapping of H4K20me3 after siRNA-mediated depletion or enzymatic inhibition of SUV420H1 (A-196) was pursued using CUT&RUN assays combined with RNA-seq in a *SUV420H1* amplified cell line (SCC-151), and analysis is ongoing. Preliminary RNA-seq analysis revealed upregulation of a number of type I IFN response genes after siRNA-mediated knockdown of SUV420H1. In vivo mouse experiments using SUV420H1 KO mouse cell lines are planned in a syngeneic HPV-negative HNSCC flank mouse model (MOC1) with or without anti-PD-1 treatment with the goal to assess whether SUV420H1 depletion affects tumor growth and/or sensitizes cancer cells to anti-PD-1 therapy. These data provide preliminary support for the function of SUV420H1 as an oncogene in HPV-negative HNSCC.

#1730 Unraveling the oncogenic potential of KDM2A with gastric organoids.

Shilpa S. Dhar, Calena Brown, Constantin Zod, Jaffer A. Ajani, Min Gyu Lee

UT MD Anderson Cancer Center, Houston, TX

Background: Gastric adenocarcinoma (GAC), prevalent and often lethal, imposes a serious global health challenge. Therefore, it is critical to identify novel oncogenes (drivers) that can be therapeutically targeted. Of epigenetic modifications, histone lysine methylation is a hallmark of epigenetic and transcriptional regulation of gene expression. Therefore, investigating the involvement of histone methylation modifiers in GAC is paramount to gaining a comprehensive understanding of the disease but also to discover novel targets. Our analysis of the GAC genome indicates that these epigenetic modifiers are amplified in GAC.
Objective and Hypothesis: The overall objective is to define the oncogenic role of KDM2A in GAC pathogenesis and progression. The central hypothesis is that KDM2A promotes GAC by upregulating the expression of oncogenic proteins via the activation of epigenomic signatures/pathways.KDM2A (FBXL11) is a histone lysine demethylase that demethylates H3K36me2 and represses target genes involved in various biological processes, including cell proliferation, DNA damage repair, and stem cell maintenance. Previously, we reported that KDM2A was necessary for the tumorigenic and metastatic capabilities of non-small lung cancer cells through transcriptionally repressing the expression of DUSP3 and HDAC3, which led to activation of ERK signaling and upregulation of cell cycle-associated genes.
Results: Our analysis of the GAC genome indicates that KDM2A is one of the top demethylases frequently amplified and overexpressed (14%). In addition, *KDM2A* expression was significantly higher in GAC samples than in normal tissues, and high expression of KDM2A was associated with poor survival in GAC patients. To examine the effect of KDM2A knockdown on characteristics of GAC, we used gastric organoids generated from KDM2A$^{flox/flox}$ mouse stomach. We expressed wild-type (Flag-KDM2A) and catalytic mutant (Flag-KDM2A-mut) in these organoids. Ectopic expression of KDM2A wild-type, but not mutant, increased the proliferation of organoids. We showed that KDM2A knockdown decreased the proliferation and invasion of two GAC cells, GA0518 and AGS. In addition, we determine the effect of overexpression of KDM2A on cell proliferation by comparing the control organoids to KDM2A overexpressed using IHC staining of Ki-67 (a proliferation marker) and other activated oncogenic signaling PI3KCA/mTOR/AKT, EGFR. We showed that GA5018 cells were very sensitive to the KDM2A inhibitor (daminozide) alone and in combination with erlotinib (EGFRi inhibitor) and RAD001 (RAD1 mTOR inhibitor).
Significance and Innovation: In contrast to advances in cellular signaling pathways in GAC pathogenesis, how GAC development is epigenetically regulated remains largely unknown. Our results from using organoids indicate that KDM2A is an oncoprotein.

#1732 Linker histone h1 inhibits topoisomerase IIa *in vitro* and *in vivo*.

S. Lasater, H. Hamdan, P.-Y. Ho, T. Wu, K. Cao, R. Yang, Y. Zhang, **Y. Fan**;
Georgia Institute of Technology, Atlanta, GA

H1 linker histones play a crucial role in organizing chromatin into higher-order structures and regulating gene expression, contributing significantly to various cellular processes. Topoisomerase IIa (TopoIIa) is essential for multiple cellular functions via regulating DNA topology. Here, we report a direct interaction between H1 linker histones and TopoIIa through both N- and C-terminal domains of H1 variants. H1 suppresses the decatenation enzymatic activity of TopoIIa *in vitro* in a dose-dependent manner. Overexpressing specific H1 variants in HeLa cells results in a marked decrease in cell proliferation and a dramatic increase in the occurrence of cells displaying abnormal mitotic chromosomes. Additionally, we find that the inhibitory effect of the specific H1 variant on TopoIIa activity occurs prior to the formation of DNA-TopoIIa complexes. These results reveal a novel mechanistic link between histone H1 and Topo IIa in the regulation of chromatin function.

#1733 SET-NUP214 rearranges the DNA-methylation landscape to upregulate the HOX-gene cluster in acute myeloid leukemia.

S. Roy Choudhury, A. Kaushal;
University of Arkansas for Medical Sciences, Little Rock, AR

The SET-NUP214 (S/N) fusion gene, which results from either cryptic t(9:9) (q34;q34) or del(9) (q34.11q34.13), is found in a very narrow spectrum of patients diagnosed with Acute Myeloid Leukemia (AML) or T-cell acute lymphoblastic leukemia (T-ALL). AML patients with S/N fusion were reported to have relatively poor prognostic outcomes despite receiving myeloablative conditioning. While previously, the fusion has been described to overrepresent HOX cluster genes, the underlying mechanism of gene regulation that contributes to the pathology remains elusive due to the rare incidence of the disease. The current study used the MEGAL (ACC719, DSMZ) cell line, identified as the solo megakaryocytic AML line expressing the S/N-fusion, for determining genome-wide DNA methylation (DNAm) and gene expression using 935K Infinium MethylationEPIC v2.0 BeadChip array and RNA-sequencing, respectively. The differential DNAm and expression data were analyzed and compared to the hematopoietic stem progenitor cells (HSPC) or normal megakaryocytes (MK). The ChIP-sequencing data from the S/N positive T-ALL cell line LOUCY has been used to represent the coincidence of regulatory chromatin marks and differentially methylated CpG (mC) sites. We observed n=1934 genes upregulated and n=2396 downregulated in MEGAL, compared to both HSPC and MK. The direction of expression changes between MEGAL and HSPC and MEGAL and MK showed a high correlation (r=0.92, p< 0.01). Per the previous literature, we observed an overrepresentation of *HOX* genes (n=19) in MEGAL. Based on DNAm profiling, we noticed a propensity of hypermethylation in MEGAL across the promoters (93%±0.6), bodies (93%±0.8), and intergenic (85%±0.3) regions, compared to HSPC/MK. Next, we integrated the mC and expression at the promoters and identified that the majority (75%±3) of the genes belong to the hyper-down (n=2563 against HPSC; n=1907 against MK) or hyper-up (n=965 against HPSC; n=923 against MK) clusters. We further investigated the *HOXB* (*HOXB7, HOXB8, HOXB9*) and *HOXC* (*HOXC10, HOXC12, HOXC13, HOXC13-AS, HOXC4, HOXC5, HOC6, HOXC8, HOXC9, HOXC-AS1, HOXC-AS2*, and *HOXC-AS3*) cluster genes, where hypermethylated CpGs mainly were concentrated at the CpG islands and overlapped with active promoter (H3K4me3, H3K4me1) signatures or enhancer-like (CTCF bound) elements. We also observed frequent overlaps between mC and H3K36me3 across the observed genes. The differentially expressed genes in this AML subtype were enriched for the hippo-signaling pathway, calcium signaling, focal adhesion, and PI3-Akt pathways. Collectively, our data showed that S/N favors genome-wide hypermethylation, which, in conjunction with the cis-regulatory elements, induces overrepresentation of the HOX cluster genes. These novel epigenetic vulnerabilities are worth pursuing for investigating the cellular function and pathophysiology of the disease.

#1734 Dissecting the bifaceted function of SMYD3 as a transcriptional activator and repressor in HPV-negative HNSCC.

J. Akhtar, S. Kim, V. Saloura;
National Institute of Health, Bethesda, MD

Background: Approximately 75% of Human-papilloma-virus (HPV)-negative head and neck squamous cell carcinoma (HNSCC) tumors carry genetic and expression alterations in the family of protein methyltransferases and demethylases, underscoring the importance of these enzymes in the pathogenesis of HNSCC. SMYD3 a lysine methyltransferase that is overexpressed in HPV-negative HNSCC. We recently reported that nuclear SMYD3 plays dual role in immune-related gene regulation through H3K4me3 or H4K20me3, leading to gene activation or silencing, respectively in HPV-negative HNSCC. While SMYD3 has been reported to write and bind to H3K4me3 activating target gene expression, its function in gene silencing is understudied. This study aims to determine the mechanism(s) through which SMYD3 functions both as a transcriptional activator and a repressor within the same cell context, specifically in HPV-negative HNSCC. **Methods:** immunoprecipitation (IP) of SMYD3 was performed from nuclear extracts isolated from HN-6 cells to identify candidate interacting partners of SMYD3. The nuclear immunoprecipitates were sent for MS analysis to identify candidate nuclear interacting partners of SMYD3. CUT&RUN assays for selected candidate interacting proteins and SMYD3 will be performed in control HN-6 cells versus SMYD3 KO cells to assess genomic co-occupancy with SMYD3. Further, CUT&RUN assays for repressive marks H4K20me3, H3K27me3 and H3K9me3 have been performed in HN-6 and SMYD3 KO cells to assess co-occupancy with SMYD3 as well as its effect of SMYD3 on the genome-wide mapping of these marks. Finally, CUT&RUN assays for SMYD3 followed by re-CUT&RUN of repressive histone marks are ongoing to identify co-occupied loci. **Results:** Preliminary analysis of our nuclear SMYD3 IP results has identified a chromatin modifier with known repressive function. Co-immunoprecipitation experiments to validate this interaction are planned. CUT&RUN assays for repressive histone marks in HN-6 versus SMYD3 KO cells have revealed impact on H4K20me3 and H3K27me3. **Conclusions:** Our preliminary results suggest that SMYD3 may exert its silencing function by regulating the genome-wide deposition of H4K20me3.Our nuclear SMYD3 IP analysis has identified candidate interacting
partners that may assist SMYD3 in promoting the deposition of these repressive marks. CUT&RUN assays for SMYD3 followed by re-CUT&RUN for H4K20me3 and H3K27me3 bound chromatin may provide further insight about whether SMYD3 co-occupies specific genomic regions together with these repressive marks. This project is expected to provide mechanistic insights into the bifaceted functions of SMYD3 within the same cell context using HPV-negative HNSCC cell lines as an experimental model system..

#1735 DNA demethylating agents have cell type-specific effects on viability and *BRCA2* alternative splicing.

J. Werner[1], H. Siddiqui[1], S. Syed[1], O. Khan[1], S. Casillas Garabito[2], **J. D. Fackenthal**[1];
[1]Benedictine University, Chicago, IL, [2]College of DuPage, Glen Ellyn, IL

Introduction: *BRCA2* is one of two principal tumor suppressors responsible for hereditary breast/ovarian cancer syndrome (HBOC). Patients with strong family histories of breast/ovarian cancer may carry *BRCA2* DNA sequence variants of unknown clinical significance (VUSs). To evaluate which of these VUSs may contribute to cancer risk by altering splicing patterns, naturally occurring *BRCA2* mRNA alternate splicing events have been extensively characterized, but it is not yet known which if any of these alternate splicing events plays a role in *BRCA2* function. One variant lacking exon 3 (Δ3), which maintains the full length translational reading frame, lacks sequence encoding EMSY and PALB binding domains as well as transactivation function. Previous work has shown that, while some VUSs associated with increased levels of Δ3 in lymphoblastoid cell lines are not pathogenic, germline deletions that eliminate *BRCA2* exon 3 are associated with increased breast cancer risk. It is therefore of interest to characterize the factors that influence the frequency of naturally occurring *BRCA2* exon 3-skipping, including cell types and therapies. DNA demethylating agents are used as cancer therapy to promote expression of tumor suppressor genes that may be epigenetically silenced in tumors. However, DNA methylation has been shown to be more frequent in exonic than intronic regions of protein-coding genes, suggesting that methylation may play a role in recruiting spliceosomal components to nascent pre-mRNA. It is therefore of interest to determine whether genomic demethylation affects alternative splicing patterns. Here, we explore whether *BRCA2* exon 3 alternative splicing patterns are altered by demethylating agents.

Methods: To determine whether DNA demethylating agents can alter the levels of Δ3, MCF7 and/or the non-cancer breast cell line MCF 10A was treated with 5-aza 2'-deoxycytidine (5-AzadC) or 5-Azacytidine (5-AzaC), and isoform-specific RT-PCR was used to compare relative levels of splice junctions containing or skipping exon 3.

Results and Conclusions: 1) While the IC_{50} for both 5-AzadC and 5-AzaC in MCF 10A was similar (less than 1 μM), MCF7 showed considerably more resistance to 5-AzaC than 5-AzadC (IC_{50} of ≥ 5 μM vs ≤ 0.2 μM). 2) 5-AzaC treatment reduces the proportion of MCF 10A cultures in apoptosis but does not increase the proportion of viable cells, indicating it causes cell death by some other means. 3) While both 5-AzaC and 5-AzadC reduce relative levels of Δ3 in MCF7, 5-azadC does not reduce relative levels of Δ3 in MCF 10A, suggesting there may be a cell type-specific splicing response to genomic demethylation therapies.

#1736 Elucidating the oncogenic mechanisms in diffuse midline glioma: Comparative analysis of h3k27m mutation and k27 methylation loss on gene expression profiles via RNA sequencing.

S. Bhattarai[1], F. L. Hakkim[1], C. Day[1], F. Grigore[2], A. Langfald[1], E. Hinchcliffe[1], J. Robinson[1];
[1]The Hormel Institute, University of Minnesota, Austin, MN, [2]New York Presbyterian Hospital, New York City, NY

Background: Diffuse Midline Glioma (DMG), a severe pediatric brain tumor, is characterized by its aggressive nature and poor prognosis. Common in brain midline structures like the thalamus and brainstem, DMGs often harbor H3K27M mutations, leading to reduced histone trimethylation at lysine 27 and loss of serine 31 phosphorylation. Building on these findings, our laboratory has undertaken a novel approach by engineering a knockout of the Polycomb Repressive Complex 2 (PRC2) in selected cell lines. This was achieved using CRISPR-Cas technology to target the EZH1 and EZH2 methyltransferases (PRC2KO), alongside the introduction or reversal of histone H3.3 mutations. The goal of this study is to investigate the effects of K27 Methylation loss and H3.3 mutations on gene expression in DMG to better understand DMG pathogenesis and potential therapeutic avenues.
Methods: RNA and ATAC sequencing were performed on DMG cell lines including H3.3WT, H3.3 S31A, H3.3K27M, and PRC2KO. Utilizing 150 bp paired-end reads, 25 to 45 million unique reads were mapped to the human genome (hg38) using STAR. Differential gene expression was analyzed using DESeq2 in R, complemented by ATAC-sequencing to explore potential epigenetic changes.
Results: The analysis identified 2,564; 2,946; 4,618; and 5,490 differentially expressed genes (DEGs) in the K27M, S31A, K27M-PRC2KO, and WT-PRC2KO cell lines, respectively, when compared to WT. A four-way Venn diagram analysis identified unique and shared gene cohorts among the different mutations. H3K27M cells showed 414 downregulated and 385 upregulated genes, mainly affecting cell migration. In contrast, PRC2KO cells, characterized by a complete loss of histone methylation, showed extensive changes with 1,302 genes downregulated and 1,779 upregulated, primarily impacting cell cycle and developmental processes. The S31A cells displayed a unique profile with 548 genes uniquely downregulated and 547 genes upregulated. The lack of enrichment in specific pathways for these genes suggests their involvement in a broader range of affected pathways. A significant discovery was the identification of a set of genes common to both S31 and K27M cells, but absent in PRC2 knockouts. This cohort, consisting of 350 downregulated and 389 upregulated genes, may represent a molecular link between serine phosphorylation and the K27M mutation. Additionally, ATAC-sequencing analysis was conducted to determine if the expression changes were a direct result of epigenetic dysregulation or an indirect effect.
Conclusion: This study delineates the intricate gene regulation in DMG resulting from H3K27M mutations beyond loss of loss of K27 Methylation. It highlights unique and overlapping pathways influenced by, providing valuable insights into the molecular basis of DMG and guiding future therapeutic strategies.

#1737 METTL3-mediated m^{6}A modification promotes tumor progression in upper tract urothelial carcinoma.

L.-J. LIN[1], P.-H. PENG[2], K.-W. HSU[1];

[1]China Medical University, Taichung, Taiwan, [2]Chang Gung Memorial Hospital, Taoyuan, Taiwan

Upper tract urothelial carcinoma (UTUC), comprising 5% of urothelial neoplasms, is a rare malignancy arising from the transitional epithelium of the renal pelvis and ureter. Its rarity and diverse histology pose diagnostic and therapeutic challenges, often lead to delayed diagnoses. The absence of targeted therapies, coupled with a limited understanding of molecular pathogenesis, underscores the ongoing research in urological oncology for effective UTUC management. N6-methyladenosine (m^{6}A) is the predominant RNA methylation in mammalian cells, with its inscription primarily orchestrated by METTL3, a crucial methyltransferase. METTL3 has been implicated in various cancers, affecting critical processes like proliferation, migration, and tumor progression. However, the specific mechanisms and biological function of how METTL3/m^{6}A regulates the progression of UTUC remain unclear. In our study, we found that m^{6}A modification and METTL3 expression were elevated in aggressive UTUC, both are negatively correlated with unfavorable clinical outcomes and poor patient survival. By overexpressing METTL3 in less aggressive UTUC cell lines BFTC909 and KTCC28, the abilities of cell proliferation, migration, invasion, and colony formation increased. Notably, overexpression of METTL3 also increased tumor growth and metastasis in the in vivo orthotopic mouse model. In contrast, knockdown of METTL3 decreases tumor progression in a highly aggressive UTUC cell line KTCC28M. Furthermore, our comparative analysis of RNA-seq and m^{6}A MeRIP-seq datasets unveiled the regulation of 1660 genes by METTL3. This diverse set includes genes associated with tumor growth and metastasis (such as *MYC*, *JAK2*, and *STAT3*), as well as RNA processing-related genes which their critical roles in modulating mRNA stability and splicing (such as *GEMIN5* and *PABPC1L*). Together, we noticed METTL3/m^{6}A is a crucial protagonist in the oncogenic landscape of UTUC, which suggested that it can be used as a target for novel therapeutic strategy for UTUC treatment.

#1738 Precise detection of benign and malignant renal tumor via epigenetic characteristics of urinary cell-free DNA.

W. Kong[1], **H. Dong**[2], H. Tang[2], P. Du[2], S. Jia[2], J. Zhang[1];

[1]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

Early detection of clear cell renal cell carcinoma (ccRCC) and accurate differentiation between malignant and benign lesions pose clinical challenges. Profiling the epigenetic pattern of patients through liquid biopsy offers a promising strategy for non-invasive cancer identification. This study utilizes the methylation characteristics of urinary cell-free DNA to enhance the precise diagnosis of ccRCC. In this study, 32 patients with malignant RCC, 20 patients with benign kidney lesions, and 28 age- and sex-matched healthy donors were enrolled. Urine samples were collected and applied by PredicineEPIC assay to analyze the whole genome methylation profiles. We assessed the methylation differences on cancer-specific altered regions and constructed a machine learning model for malignant and benign classification. Beta values were calculated for differentially methylated regions identified through literature mining and our current work. These features carry methylation signals that are recognized by gradient boosting machine and used for classification training. The leave-one-out cross-validation method compensated for the shotage of sample size. The sensitivity and specificity of the optimal model in the training set are both greater than 0.97, and it can achieve an accuracy of 0.95 on the validation set. This performance surpasses traditional diagnostic methods such as contrast-enhanced CT and MRI. This study demonstrated the technical feasibility of leveraging epigenetics profiles to discriminate malignant from benign lesions, suggesting a promising liquid biopsy-based approach for the precise detection of renal cell carcinoma.

#1739 Detection of regulatory T cells, a comparison of flow cytometry and epigenetic qPCR immunophenotyping using healthy donor and oncology patient whole blood.

U. Baron, L. Lozza, **A. Bisconte**, E. Raschke, D. Phippard, S. Olek;
Precision for Medicine, Frederick, MD

Human regulatory T cells (Tregs) are part of the adaptive immune response and play a pivotal role in suppressing both the immune and anti-tumor responses. Infiltration of Tregs into the tumor microenvironment has been associated with poor clinical prognosis. In addition, increased peripheral Treg frequency is associated with disease progression. Monitoring Tregs in both the blood and in the tumor of patients is being used to evaluate clinical prognosis and response to treatment in immuno-oncology studies. The key challenge is the ability to detect Tregs with high accuracy and precision. Here, we have used epigenetic qPCR (Epiontis ID®) as a method to detect and quantify Tregs in peripheral whole blood and compared it with flow cytometry. Flow cytometry is the current gold standard for immunophenotyping. For method comparison, we analyzed 113 whole blood samples from healthy donors. We have demonstrated equivalence and shown a strong correlation between epigenetic qPCR and flow cytometry-based data, indicating that Epiontis ID® is a robust and sensitive DNA-based method for Treg quantification. This epigenetic qPCR method does not require fresh samples or intact cells, since DNA can be extracted from frozen blood. We then evaluated Treg levels in blood samples from solid tumor cancer patients by epigenetic qPCR to demonstrate the clinical application and relevance for immune monitoring. Here, Treg frequencies were reported as relative (%) and absolute counts (cells/µL) values. Epigenetic qPCR for immune monitoring mitigates the operational and technical challenges of monitoring Tregs in the periphery for immuno-oncology studies which traditionally been performed by flow cytometry. This Epiontis ID® method provides the sensitivity and accuracy needed for determining patient response in progressive disease.

#1740 Histone proteomic profiling of EMT-transformed MCF10A breast cells demonstrates a loss in novel histone arginine methylation sites via dual p53 and PTEN deletion.

C. B. McGuinness[1], M. A. Wilson[1], M. V. Leonard[1], M. Ouzounova[2], H. Korkaya[3], A. Y. Shull[1];
[1]Presbyterian College, Clinton, SC, [2]Cancer Research Center of Lyon, Lyon, France, [3]Karmanos Cancer Institute, Wayne State University, Detroit, MI

Metastatic potential of basal-like breast cancers typically is initiated by genetic alterations that lead to a process known as epithelial-mesenchymal transition (EMT). However, much is currently not understood regarding the role of epigenetic modifications that lead to invasive characteristics and EMT phenotype of metastatic breast cancers. Based on the previous notion connecting epigenetic changes to breast cancer metastasis, we performed DIA-based mass spectrometry of isolated histones from an isogenic panel of MCF10A breast cell lines where the tumor suppressor genes TP53 and PTEN were silenced and induced EMT. With this approach, we determined which histone modifications were differentially enriched in the non-EMT and EMT-induced MCF10A cell lines. From approximately 72 histone modifications identified and annotated from our mass spectrometry results, we were able to identify 5 histone events that were differentially enriched in our MCF10A cell line panel. Two events of note were histone H3 lysine-14 acetylation (H3K14ac) significantly increasing and histone H4 arginine 55 dimethylation (H4R55me2) significantly decreasing in our EMT-transformed MCF10A p53-/PTEN- cell lines when compared to the parental, non-tumorigenic MCF10A cell line, showing these events are differentially affected during the EMT process in breast cancer cells. Furthermore, significant arginine demethylation of H4R55me2 & H3.1R83me in the EMT-transformed MCF10A p53-/PTEN- cell lines corresponded with JMJD6, an established histone arginine demethylase, being overexpressed in basal-like breast cancer cell lines as well as basal-like breast cancer patients from The Cancer Genome Atlas (TCGA) and METABRIC datasets. Based on histone proteomic profiling of our isogenic cell line model, the loss of specific histone arginine methylation events corresponding with JMJD6 overexpression could highlight the potential for a targetable epigenetic mechanism in breast cancer metastasis.

#1741 AlidaBio EpiPlex: A platform for multiplexed detection of RNA modifications in clinical samples.

A. Price[1], Z. Miles[1], J. Chevillet[1], B. Purse[1], R. I. Gregory[2], **G. Stengel**[1];
[1]Alida Biosciences Inc., San Diego, CA, [2]Harvard Medical School, Boston, MA

It is becoming increasingly appreciated that RNA modifications are widespread in development and homeostasis, regulating RNA stability and translation, and that alterations to these modifications are associated with cancer development and progression. Although 170 different RNA modifications have been identified using mass spectrometry, there is a paucity of convenient, validated tools immediately available to cancer researchers to explore these modifications using relevant clinical samples in sufficient numbers, and accurately determine their suitability for use as diagnostic or drug targets. In addition, most existing methods concentrate only on m6A, the most prevalent modification in mRNA. Alida Bio has developed an end-to-end assay platform with an integrated bioinformatics solution that detects multiple modifications in the same reaction. This platform exploits targeted, multiplexed barcoding to reveal the quantitative abundance of modified transcripts, co-localization of multiple RNA modifications to the same gene, and gene expression profiles. Alida Bio's mission is to equip translational researchers with tools that will significantly improve their understanding of gene regulation through seamless measurement of RNA modifications.

#1742 A universal spike-in normalization strategy for CUT&RUN, CUT&Tag and ATAC-seq.

S. Traynor, B. Townsley, J. Weber, M. Jelinek, B. Egan, **B. Delatte**;
Active Motif, Calrlsbad, CA

The development of simple and efficient genome-wide approaches has recently democratized the study of epigenetics. For instance, CUT&RUN and CUT&Tag were developed as fast and affordable alternatives to ChIP-seq, whereas ATAC-seq readily identifies regions of open chromatin. These methods are ideal to look for genome-wide alterations in chromatin structures but are only semi-quantitative and can miss global changes when performed without normalization spike-ins. In fact, many standard computational pipelines fail to detect a reportedly substantial global H3K27me3 decrease in the presence of *GSK126*, a therapeutic target for lymphoma and potent inhibitor of the EZH2 methyltransferase. To overcome this challenge, we developed a spike-in approach using *Drosophila melanogaster* nuclei for normalization of ATAC, CUT&RUN and CUT&Tag experiments using human cells. The addition of the spiked-in nuclei allowed for the detection of the expected global changes in open regions of chromatin (ATAC-seq), H3K27me3 (CUT&Tag), R-loops (CUT&Tag), EED and p53 binding (CUT&RUN) upon treatment of K562 cells with GSK126. By contrast, these same changes were all missed when omitting the spike-in nuclei. This streamlined spike-in normalization strategy can be easily applied to any number of cells and on a large variety of conditions.

#1743 Pan-cancer review of TP53 somatic alterations as a function of tumor type: Sometimes lost, sometimes gained, frequently altered.

Ubaid A. Tanveer[1], David N. Hayes[1], Julie George[2], Jeremiah R. Holt[1], Martin Peifer[2], Roman Thomas[2]

[1]Hematology and Oncology, University of Tennessee Health Science Center, Memphis, TN,[2]University of Cologne, Cologne, Germany

Background: TP53 is the gene most frequently disrupted by somatic alterations in cancer. Mutations include single nucleotide variants resulting in functional alterations, as well as premature stop codons, splice variants, and cryptic alterations. TP53 gene dosage is disrupted by heterozygous and homozygous deletions, copy-neutral loss of heterozygosity, and other structural changes such as intragenic deletions and fusions. TP53 is altered by epigenetic events and viral oncogenes, such as E6 expressed by the human papillomavirus. The readout of altered TP53 includes decreased gene expression of either variant or wild-type alleles. Epistatic alteration of TP53 pathway components have also been described, with the E3 ubiquitin ligase MDM2 being the canonical example. Depending on the type of TP53 alteration, there may be differential signaling consequences, ranging from loss of function and dominant negative to oncogenic signaling.
Hypothesis: Patterns of TP53 mutations will vary based on tumor type. Differential alterations of TP53 will suggest differential pathway dependence and downstream pathophysiology that may be relevant to signaling and therapeutic potential.
Methods: We analyzed extensive cancer genomics repositories, such as the Pan-Cancer Atlas (10,000+ tumors, >30 cancer types) from The Cancer Genome Atlas project and the International Cancer Genome Consortium. Assessing genes in the TP53 pathway, we examined somatic mutations, copy number alterations, structural changes, and gene expression. Epigenetic data was considered when available.
Results: A significant pattern amongst sarcomas, prostate cancers, and urothelial carcinomas emerged, revealing that certain tumors exhibited a predominant classic tumor suppressor gene genotype. This genotype featured frequent homozygous deletions, inactivating mutations, and relatively low TP53 gene expression, often accompanied by epistatic MDM2 amplification. By contrast, other tumors demonstrate an atypical pattern in which TP53 mutations were rarely if ever associated with loss of TP53 gene expression with low levels of homozygous TP53 gene deletion. Likewise, atypical TP53 mutant tumor types rarely demonstrated MDM2 amplifications, and in opposition to typical TP53 cases, MDM2 amplification was positively associated with TP53 mutation rather than anti-correlated. Head and neck squamous cell carcinoma, uterine carcinoma, and pancreatic adenocarcinoma followed this pattern. Investigation within selected tumor types such as lung squamous cell carcinoma suggested that both typical and atypical TP53 mutation patterns could be observed.
Conclusions: TP53 mutation patterns were strongly associated with tumor type and may suggest differential pathway activation according to the somatic alteration status.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genomic Characterization of Cancers and Cancer Subgroups
Poster Session

#1746 KRAS mutant lung adenocarcinoma is associated with distinct mutational signature profiles.

L. C. Woodhouse[1], A. Hawari[1], A. J. Gruber[2], C. R. Lindsay[1], D. C. Wedge[1];
[1]University of Manchester, Manchester, United Kingdom, [2]University of Konstanz, Konstanz, Germany

Background: Lung cancer is the 3rd most common cancer in the UK and leading cause of cancer mortality worldwide. Somatic *RAS* mutations are the most common oncogenes in human cancer, and *KRAS* mutations are the largest molecular subset of lung adenocarcinoma (LUAD). Each cancer genome accumulates a unique combination of somatic mutations, and these mutational signatures provide a genetic imprint of mutational processes that have occurred during tumorigenesis. Mutational signatures provide information on tumor aetiology/maintenance and could highlight potential therapeutic targets. This is the largest study to date to profile *KRAS* mutant LUAD mutational signatures using whole genome sequencing (WGS) data.
Methods: Paired tumor and germline WGS data were obtained through the 100 000 Genomes Project (Genomics England). *KRAS* mutations were profiled using Ensembl Variant Effect Predictor (VEP) v109.0. Single base substitution (SBS), doublet base substitution (DBS), small insertion and deletions (ID) and copy number (CN) mutational signature extraction was performed using SigProfiler (COSMIC version 3.3). Statistical analysis and plotting were performed in R; a two-tailed p-value <0.05 was considered statistically significant.
Results: 680 LUAD patients were included; 301 *KRAS* mutant (44%), 379 *KRAS* wild type (63%). Common *KRAS* variants were present, including *G12C (38.9%), G12V (15.9%) and G12D (14.0%)*. 17 SBS, 9 DBS, 10 ID and 9 CN signatures were extracted and present in both *KRAS* mutant and wild type cohorts. *KRAS* mutant samples were enriched in smoking related signatures (SBS4, DBS2, ID3; odds (OR) ratio 5.54, 3.80, 4.97 respectively, p <0.001) and diploid CN signature (CN1, OR 1.41, p = 0.03). Conversely, *KRAS* mutant samples were less likely to have clocklike (ID5, OR 0.61, p = 0.012; ID8, OR 0.44, p <0.001), APOBEC (SBS2, OR 0.49, p <0.001; SBS13; 0.50, p <0.001), chromosomal instability (CN9, OR 0.63, p = 0.019), loss of heterozygosity (CN14, OR 0.47, p = 0.015), or homologous recombination deficiency (CN17, OR 0.58, p <0.001) signatures.
Discussion: These results show distinct mutational signature profiles between *KRAS* mutant and wild type LUAD. As previously described, *KRAS* mutant LUAD is dominated by smoking related signatures; however, the majority of remaining signatures were more common in the *KRAS* wild type cohort where there was a statistically significant difference. This data suggests different mutational processes are observed in *KRAS* mutant compared to wild type LUAD. *KRAS* mutations are commonly clonal and thought to initiate tumorigenesis: timing signatures relative to *KRAS* mutations is necessary to further our understanding of *KRAS* cancer evolution and the subject of future work. Combined with clinical data integration, mutational signatures could provide prognostic information and inform predictive models.

#1747 The mutational landscape and its longitudinal dynamics in relapsed and refractory Hodgkin lymphoma.

H. Witte[1], A. Kunstner[2], T. Hahn[3], V. Bernard[4], S. Stoelting[4], K. Kusch[4], K. Nagarathinam[2], N. von Bubnoff[3], C. Khandanpour[5], A. Bauer[1], M. Grunert[1], A. Arndt[1], K. Steinestel[1], H. Merz[4], H. Busch[2], A. Feller[4], N. Gebauer[3];

[1]Bundeswehrkrankenhaus Ulm, Ulm, Germany, [2]University of Luebeck, Lubeck, Germany, [3]University Hospital Schleswig Holstein Campus Lubeck, Lubeck, Germany, [4]Hematopathology Lubeck, Lubeck, Germany, [5]University Hospital Schlesiwg Holstein Campus Lubeck, Lubeck, Germany

Introduction: In classical Hodgkin-lymphoma (cHL), only a few cases recur, and only a limited fraction of patients is primary-refractory to standard-polychemotherapy. Underlying genomic features of unfavorable clinical courses remain sparsely characterized. Here, we investigated the genomic characteristics of primary-refractory/relapsed cHL in contrast with long-term-responders (LTR).

Methods: Therefore, ultra-deep next-generation panel-sequencing was performed on a total of 59 samples (20 LTR, 26 relapsed (rHL: 11 initial-diagnosis, 15 relapse) and 13 primary-refractory (prHL: 8 initial-diagnosis, 5 progression) from 44 cHL-patients applying a hybrid-capture approach. We compared samples associated with distinct disease courses concerning their oncogenic drivers, mutational signatures, and perturbed pathways.

Results: Compared to LTRs, mutations in genes such as *PMS2, PDGFRB, KAT6A, EPHB1,* and *HGF* were detected more frequently in prHL/rHL. Additionally, we observed that in rHL or prHL, *BARD1*-mutations occur, whereas *ETV1, NF1,* and *MET*-mutations were eliminated through clonal selection. A significant enrichment of non-synonymous variants was detected in prHL compared to LTRs and a significant selection process in favor of NOTCH-pathway mutations driving rHL or prHL was observed.

Conclusion: This study delineates distinct mutational signatures between LTR and rHL/prHL, whilst illustrating longitudinal dynamics in mutational profiles using paired samples. Further, several exploitable therapeutic vulnerabilities for rHL and prHL were identified.

#1748 Dearth of smoking-induced mutations in oncogene-driven NSCLCs despite smoking exposure.

C.-Y. Huang[1], N. Jiang[2], M. Shen[3], G. Lai[3], A. Tan[3], A. Jain[3], S. Saw[3], M.-K. Ang[3], Q. Ng[3], D.-T. Lim[3], R. Kanesvaran[3], E.-H. Tan[3], W. Tan[3], B.-H. Ong[4], K. Chua[3], D. Anantham[5], A. Takano[5], T. Lim[5], W. Tam[6], N. Sim[7], A. J. Skanderup[7], D. Tan[3], S. G. Rozen[8];

[1]Chang Gung Memorial Hospital - Linkou Branch, Taoyuan City, Taiwan, [2]Duke-NUS Medical School, Singapore, Singapore, [3]National Cancer Centre Singapore, Singapore, Singapore, [4]National Heart Centre Singapore, Singapore, Singapore, [5]Singapore General Hospital, Singapore, Singapore, [6]National University of Singapore, Singapore, Singapore, [7]Genome Institute of Singapore, Singapore, Singapore, [8]Duke University School of Medicine, Durham, NC

Non-small cell lung cancers (NSCLCs) in non-smokers are mostly driven by mutations in the oncogenes *EGFR, ERBB2,* and *MET*, and fusions involving *ALK* and *RET*. We term these “non-smoking-related oncogenes” (NSROs). NSRO-driven tumors account for approximately half of NSCLCs in East Asia, and, alarmingly, their age-adjusted incidence is increasing for unknown reasons. In addition to occurring in non-smokers, NSRO-driven tumors also occur in smokers. However, the clonal architecture and genomic landscape of these tumors remain largely unexplored. Here, we investigated genomic and transcriptomic alterations in 173 tumor sectors from 48 patients with NSRO-driven or typical-smoking NSCLCs. Overall, NSRO-driven NSCLCs in smokers and non-smokers had similar genomic landscapes and clonal architectures that were distinct from those in typical-smoking NSCLCs. Surprisingly, even in patients with prominent smoking histories, the mutational signature caused by tobacco smoking was essentially absent in NSRO-driven NSCLCs. We confirmed this unexpected finding in two large NSCLC data sets from other geographic regions. However, we observed differences in the tumor transcriptomes of NSRO-driven NSCLCs in smokers and non-smokers, with tumors in smokers displaying higher transcriptomic activities related to regulation of the cell cycle. This suggested that smoking does have an impact on tumor phenotype in NSCRO-driven NSCLC, likely through non-genetic mechanisms. We concluded that NSRO-driven NSCLCs, whether in non-smokers or smokers, constitute an important disease entity that is very different from typical-smoking NSCLC.

#1749 Esophageal adenocarcinoma single-cell resolution ecotypes and subtypes mediate chemoradiation resistance.

R. Ye, Y. Qiao, S. Bai, E. Sei, M. Hu, J. He, N. Li, Y. Wang, P. Lopez, W. Zhang, F. Ye, B. Weston, E. Coronel, W. Ross, P. Ge, B. Manoop, N. Navin, S. Lin; UT MD Anderson Cancer Center, Houston, TX

Esophageal adenocarcinoma (EAC) is an aggressive and lethal disease with a 5-year survival rate less than 20%. The current standard of care for locally advanced EAC patients is neoadjuvant chemoradiation (CRT) followed by surgery and the pathological response rate is low in clinic. An unresolved question is how the cancer cells and their tumor microenvironment (TME) mediate CRT resistance in EAC. To address this question, we performed single-cell RNA sequencing on 84 longitudinal samples from a cohort of patients (N=47) containing 20 good responders (GR) and 27 non-responders (NR). In total, we obtained 302,918 single cells which enabled us to delineate the phenotypic heterogeneity landscape in EAC at baseline, and identify reprogramming in both the immune and tumor cells during treatment that lead to CRT resistance. We identified 4 major cell type compartments in the EAC TME: lymphoid cells (T cells, NK cells, B cells, and plasma cells), myeloid cells (macrophages, neutrophils, dendritic cells, and mast cells), stromal cells (fibroblasts and endothelial cells) and epithelial cells. Our data shows that the TME enriched in lymphoid cells, including resident and effector memory CD8 T cells, follicular helper CD4 T cells, and B cells was associated with better CRT responses. Moreover, a significant myeloid cell infiltration was observed across most patients during CRT and the infiltrated macrophages from GR harbored a more pro-inflammation phenotype. In addition, we identified 4 major ecotypes of the TME cells and 4 major expression subtypes of the cancer cells. Notably, the interactions between TME ecotypes and cancer subtypes are significantly associated with CRT responsiveness. In summary, this study has provided valuable insights into the biology of EAC CRT response, and identified novel predictive biomarkers and actionable targets to enhance CRT efficacy.

#1750 Decoding breast cancer: Unraveling subtype and model differences through multi-model single-cell RNA sequencing data integration.

J. E. Altman[1], C. J. Walker[1], E. K. Zboril[1], N. S. Hairr[1], R. K. Myrick[1], D. C. Boyd[1], J. E. Koblenski[1], M. Puchalapalli[1], B. Hu[1], M. G. Dozmorov[1], X. Chen[2], Y. Chen[3], C. M. Perou[4], B. D. Lehmann[2], J. E. Visvader[3], A. L. Olex[1], J. Harrell[1],

[1]Virginia Commonwealth University, Richmond, VA, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

Breast cancer's complex transcriptional landscape requires a deep understanding of sample and cell diversity to identify effective treatments. In this study, we amalgamate single-cell RNA sequencing data from breast cancer patient-derived xenografts (PDX), organoids, cell lines, patient tumors and reduction mammoplasties resulting in a comprehensive dataset of 117 samples with 506,719 total cells. These samples encompass hormone receptor positive (HR+), human epidermal growth factor receptor 2 enriched (HER2E), and triple-negative breast cancer (TNBC) subtypes. We aimed to delineate similarities and distinctions across model systems and patient samples while also exploring stratification of therapeutic drug efficacy based on subtype proportions within tumors. Mammary tumor PDXs, organoids, and established cell lines exhibited higher proliferation and lower heterogeneity observed via UMAP dimensionality reduction compared to most patient tumors or normal breast epithelium. TNBCs had elevated proliferative and pro-metastatic signatures compared to HR+ and HER2E samples. Interestingly, compared to matched PDX tumors, organoids from these same models were found to exhibit stark differences in gene expression, including upregulation of metabolically active aldo-keto reductase family genes, highlighting differences in the model systems with implications for pre-clinical drug testing. Single-cell tumor subtyping analyses with scSubtype and TNBCtype methods found that therapeutically treated samples had shifts in the proportions of cell-wise subtype annotations when compared to matched untreated samples. Similarly, patient lymph node metastasis when compared with matched primary tumors were significantly linked to decreases in Basal-like and HER2-enriched cell-wise annotations in untreated ER+ samples. In vitro assessment of anti-cancer compounds on PDX cells showed significant correlation of subtype proportion with cell viability following treatment with targeted therapeutic agents. This subtyping methodology offers a powerful tool to monitor the evolving gene expression landscape within samples and predict responses to therapeutic agents. We present here a dynamic approach to cell-wise sample annotation and a substantial multi-model dataset for use facilitating informed decision-making in preclinical research and therapeutic development.

#1751 Deep multi-omics analysis of uterine leiomyosarcoma reveals defective HRD signature, a novel gene fusion and the amplification of the poor-prognosis CTHRC1 gene.

R. M. Falcao[1], J. E. de Souza[1], W. Mathieson[2], J. W. Carlson[3], T. B. Petta[3];

[1]Universidade Federal do Rio Grande do Norte, Natal, Brazil, [2]Integrated Biobank of Luxembourg, Dudelange, Luxembourg, [3]University of Southern California, Los Angeles, CA

Uterine leiomyosarcoma (uLMS) is a rare and aggressive cancer representing approximately 2-5% of all uterine malignancies. The molecular heterogeneity and pathogenesis of uLMS are notwell understood. To unravel the intricate molecular landscape of uLMS, we conducted a multi-omics workflow consisting of 4 high-throughput sequencing technologies; short- and long-readwhole genome sequencing (WGS), RNA-Seq, and Tandem mass tag (TMT) labeling enablingmassively parallel proteome proteomic analyses. Our study cohort consisted of 97 fresh frozentissue samples collected from 68 female patients, with 19 uLMS, 37 leiomyoma (LM), and 41normal myometrium (MM). A deep analysis of somatic variants with clinical impact revealed 46variants present in 90% of samples and two actionable therapeutic targets: IDH1_p.Arg132Cysand KRAS_p.Gly12Val. Also, 80% of the samples presented a chromothripsis signature and 60%presented the SBS3 COSMIC signature related to homologous recombination deficiency (HRD).Analysis of the proliferation score in RNA-Seq data revealed a notable difference among thetumor groups, signifying a higher proliferation index in the uLMS group, suggesting a moreaggressive growth pattern with implications for clinical behavior and disease progression. Afterapplying a customized workflow to identify balanced chromosomal abnormalities of genefusions with clinical impact, the proto-oncogene eukaryotic elongation factor 1 alpha (EEF1A1)emerged as a prominent fusion partner. Eight fusions in 7 samples were identified withtranscriptional overexpression in positive cases. At the proteomic level the enrichment analysisunveiled activated pathways associated with the innate immune system, while suppressedpathways pertained to extracellular matrix (ECM) organization and smooth muscle contraction.With an integrated bioinformatics pipeline, we identified copy number amplification of theCTHRC1 gene in 80% of the samples, accompanied by increased gene expression and proteinlevels. This gene is related to collagen remodeling and degradation and has been demonstratedto be upregulated in some solid tumors and is closely associated with malignancy. Survivalcurve analysis highlighted a significantly poorer prognosis in uLMS exhibiting CTHRC1 geneamplification with potential clinical relevance of CTHRC1 amplification as a prognostic indicatorin uLMS. Taken together these results show the overall suppression of ECM and collagenremodeling in uLMS associated with poor prognosis. Additionally, these data provide the firstevidence that the EEF1A1 gene has a strong selective pressure in uLMS underscoring theindispensable role of precision genomics in advancing precision medicine.

#1752 Comprehensive genomic profiling of advanced breast cancer subtypes: Insights from liquid biopsy analysis and implications for personalized therapies.

X. Liu[1], Y. Liu[1], C. Jia[2], Y. Zhang[2], F. Xie[2], H. Tang[2], S. Jia[2], H. Li[1];

[1]Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), department of breast oncology, Peking University Cancer Hospital & Institute, Beijing, China, [2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

Background: Breast cancer stands as the most prevalent malignancy affecting women's health. The disease consists of three subtypes, including hormone receptor (HR) positive, HER2-positive, and triple-negative breast cancer (TNBC). In recent years, the advent of targeted therapies such as PI3K inhibitors has significantly improved the prognosis of breast cancer patients. However, the detection of relevant molecular markers, such as PIK3CA mutations, relies on tissue samples, which imposes limitations on the clinical application of these therapies. Consequently, this study presents a comprehensive analysis of genomic profiling that compares breast cancer patients across distinct pathological classifications, utilizing a liquid biopsy approach.

Methods: In this retrospective study, 214 patients with advanced breast cancer were recruited. Plasma samples collected prior to first line treatment were analyzed using PredicineCARE, a targeted next-generation sequencing (NGS) liquid biopsy assay, to detect somatic alterations in ctDNA of blood, including single nucleotide variations (SNVs), gene fusions, and copy number variations (CNVs).

Results: Based on the IHC classifications of tumor tissue, this cohort comprised 119 HR-positive, 61 HER2-positive, and 34 TNBC patients. The assay identified a total of 1456 mutations and 2357 gene copy number variants in plasma samples. Among these, the most frequently mutated genes and those with copy number variations (top 5) in HR-positive patients were TP53 (40%), PIK3CA (39%), ATM (22%), ERBB2 (19%), and FGFR1 (19%). In HER2-positive patients, they were TP53 (39%), PIK3CA (31%), ERBB2 (30%), NTRK1 (20%), and RAD50 (20%). For TNBC patients, the top genes were TP53 (59%), ERBB2 (44%), PIK3CA (35%), NTRK1 (35%), and BRCA2 (26%). Regarding the PIK3CA gene, the most prevalent mutation site was H1047, occurring in 12.61% of HR-positive patients, 14.75% of HER2-positive patients, and 11.76% of TNBC patients. Similarly, both E542 (4.20% in HR-positive, 3.28% in HER2-positive, and 2.94% in TNBC patients) and E545 (3.36% in HR-positive, 3.28% in HER2-positive, and 2.94% in TNBC patients) showed equivalent prevalence across the three classifications. These findings suggest the potential efficacy of PI3K inhibitors in various pathological types of breast cancer.

Conclusions: This study offers insights into the genomic landscape of advanced breast cancer subtypes through liquid biopsy. The observed prevalence of PIK3CA mutations supports the potential efficacy of PI3K inhibitors across these diverse types of breast cancer, laying the groundwork for personalized therapeutic strategies and biomarker identification for prognosis and targeted therapies.

#1753 *SHOC2* is a genetic dependency in *NRAS*-mutant melanoma.

A. Y. Gu[1], T.-W. Lee[1], A. Khan[1], F. W. Hunter[2], D. C. Singleton[1], **S. M. Jamieson**[1];
[1]University of Auckland, Auckland, New Zealand, [2]Janssen Research and Development, Spring House, PA

Melanoma is the most lethal form of skin cancer, with over 300,000 new cases worldwide every year. Specifically, melanoma with *NRAS* mutations are of particular clinical concern due to their association with a poor prognosis and lack of specific treatment options. Therefore, there is a pressing need for novel approaches to address the treatment of *NRAS*-mutant melanoma. A current approach to identify novel drug targets is based on the genetic concept of induced essentiality, where functional interactions that occur in response to oncogene addiction create a dependency on another gene. To identify genetic dependencies in *NRAS*-mutant melanoma, whole-genome CRISPR-Cas9 knockout screens were conducted in 6 *NRAS*-mutant and 7 *NRAS*-wild-type (wt) early-passage New Zealand melanoma (NZM) cell lines that were established and maintained at 5% oxygen to mimic physiological oxygen conditions. The NZM cell lines were stably transduced with the whole-genome Brunello lentiviral single guide (sg) RNA library and screened for up to 35 days. BAGEL (Bayesian Analysis of Gene Essentiality) analyses of the NZM whole-genome knockout screens, alongside CRISPR-Cas9 screening data using the Avana sgRNA library from an additional 28 melanoma cell lines, available on the Cancer Cell Line Encyclopaedia (CCLE) database, revealed prospective gene candidates that exhibit greater detrimental effects on the fitness of *NRAS*-mutant cell lines compared to the *NRAS*-wt lines. These genes are being further validated as essential genes for *NRAS*-mutant melanoma cells through custom sgRNA library knockout screens and *in vitro* individual gene knockout studies. In particular, we demonstrate that knockout of *SHOC2*, a gene that encodes a scaffold protein essential for activation of the MAPK signalling pathway, results in the prevention of ERK phosphorylation and a more substantial reduction in cell growth in *NRAS*-mutant NZM cell lines when compared to *NRAS*-wt lines. These results support previous studies that have identified SHOC2 as a potential therapeutic target for *RAS*-driven cancers and suggest that targeting of SHOC2 may have utility in *NRAS*-mutant melanoma, where greater treatment options are urgently needed.

#1754 Test-the-test: Clinical utility of comprehensive whole exome sequencing (WES) and RNA-seq for lymphoma patients.

D. Chihara,[1], K. Balakrishnan,[1], G. Masand[1], A. Novokreshchenova[2], A. Bagaev[2], N. Kotlov[2], E. Postovalova[2], E. Shugaev-Mendosa[2], Y. Gracheva[2], A. Love[2], K. Nomie[2], N. Fowler[2], C. R. Flowers[1], J. Westin[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]BostonGene Corporation, Waltham, MA

Background: Due to the rapidly evolving landscape of targeted therapies, there is an unmet need for comprehensive molecular profiling to guide treatment decisions for patients with lymphoma. To meet this need, we designed a pilot study to assess the feasibility and turnaround time (TAT) of a comprehensive WES and whole transcriptome sequencing (RNA-seq) assay (BostonGene Tumor Portrait™ test) in large B-cell lymphoma (LBCL) patients for clinical decision-making (NCT05464823).

Design: Patients aged ≥18 years with histologically documented LBCL requiring therapy were eligible. Formalin-fixed paraffin-embedded tissues underwent WES, RNA-seq, and copy number analysis (CNA) with concomitant peripheral blood or saliva for germline DNA sequencing. Samples with <20% tumor purity and median coverage of <142x for tumor and/or <95x for normal samples were labeled as quantity not sufficient (QNS). Genomic and transcriptomic data were profiled to uncover clinically relevant biomarkers and match patients with clinical trials on ClinicalTrials.gov.

Results: To date, 63 patients received WES and RNA-seq, with 45 full Tumor Portrait™ test clinical reports delivered and 3 partial reports for QNS samples. Cell of origin (COO, n = 41), LymphGen (n = 41), and lymphoma microenvironment (LME, n = 42) classifications were applied. The median TAT was 8 days for advanced reports, and 76% of reports had a TAT ≤9 days.

WES identified frequent *TP53* (n = 13) and CDK2NA (n = 5) alterations. COOs were designated as activated (n = 16, 39%) or germinal center (n = 25, 61%) LBCL. The LymphGen classifier showed the EZB MYC- (n = 9, 22%), A53 (n = 6, 15%), and MCD (n = 6, 15%) subtypes as the most prevalent. LME classification revealed most LMEs as mesenchymal (n = 30, 71%). Immune-depleted (n = 7, 17%), immune-inflamed (n = 4, 10%), and germinal center-like (n = 1, 2%) LMEs were less prevalent, but the immune-depleted LME was more common in patients with relapse. Clinically significant findings, such as ABC COO (n = 16), *TP53* loss (n = 13), DHITsig+ (n = 6), and *CARD11* mutations associated with ibrutinib resistance (n = 3), were identified in 33 samples. On average, 8 clinical trials were identified per delivered report.

Conclusion: Our results show the clinical utility and acceptable TAT of using a comprehensive WES and RNA-seq assay on a cohort of lymphoma patients. The produced BostonGene Tumor Portrait™ test reports included findings on significant alterations, LymphGen and LME subtypes, COOs, and potential clinical trial matches. These robust findings, coupled with the rapid TAT, demonstrate the feasibility of using integrated WES and RNA-seq to guide clinical decision-making in lymphoma patients.

#1755 Integrative genomic and transcriptomic profiles from a prospective cervical cancer study (RAIDs).

M. Kamal[1], S. Barraud[1], L. Lecompte[2], M. Halladjian[1], E. Jeannot[3], E. Girard[2], S. Baulande[4], P. Legoix[4], F. Lecuru[5], L. Pauly[5], M. Saint-Ghislain[1], S. Cyrille[6], C. Dupain[1], C. Lamy[1], O. Chouchane-Mlik[7], A. Oniga[7], M. Mittelbronn[7], C. Le Tourneau[8], A. Latouche[6], N. Servant[2], S. Scholl[1], I. Bieche[9],

Background: Cervical cancer (CC) remains a leading cause of gynecological cancer related mortality worldwide and constitutes the third most common malignancy in women. We have previously reported a “metagene” of genomic markers in the PI3K pathway and epigenetic regulators associated with poor outcome. Immune therapy recently showed promising results yet new biomarkers for targeted therapeutic approaches in this type of cancer remain to be determined.

Patients & Methods: Patients included in this study were enrolled in BioRAIDs [NCT02428842]. Whole exome sequencing (WES), shallow whole genome sequencing (sWGS) and RNA sequencing were performed on quality-controlled primary frozen tumor samples in 297, 306 and 280 patients, respectively who subsequently had received primary radio chemotherapy. Multi-omics bioinformatics analyses were performed to identify alterations representing new valid drug targets in CC. Tumor-stromal characteristics such as transcriptome deconvolution, CD8+, CD45+, CD68+ staining cells, PD-L1 expression, tumor infiltrating lymphocytes (TILs) together with the degree of tumor necrosis were assessed.

Results: 273/306 were HPV positive (89%). Most frequently altered (≥10%) oncogenes were *PIK3CA* (30%) and *TERT* promoter (14%). Most frequently altered (≥10%) tumor suppressor genes were *FBXW7* (14%), *KMT2D* (11%), *KMT2C* (11%) and *FAT1* (11%).Microsatellite instability (MSI) was detected in 8/297 (3%) patients, homologous recombination deficiency (HRD)-high status in 8/297 (3%) patients and TMB-high (>10mut/Mb) in 32/297 (11%) patients. The most frequent mutational signatures were APOBEC, deaminase and MMR (DNA mismatch repair deficiency (74%, 28% and 11% respectively). Interestingly, *FGFR3 f*usions were detected in 8/297 patients (3%). Transcriptomic analyses showed 510 differentially expressed genes between HPV positive and HPV negative CC (adjusted p-value<0.01 and |log2FC|>1). No significantly differentially expressed genes were detected between FIGO 2018 stages (I/II *vs* III-IV). Both stages as well as tumor necrosis were highly significantly associated with progression-free survival (PFS), with tumor necrosis as an independent prognostic factor in a multivariable analysis (p<0.001).Presence or absence of CD8-positive lymphocytes, or CD68-positive cells of the myeloid cell compartment, histopathological subtype or number of TILs did not correlate with PFS.

Conclusion: Our results confirm the high level of altered genes involved in chromatin remodeling with or without PI3K pathway mutations suggesting the relevance of epidrugs in CC. *FGFR3* fusions and HRD tumors - although being rare (3%) - to be considered as new targeted approaches. Additionally, MSI and TMB high are of interest for immunotherapy beyond PD-L1 expression. Integrative analyses of omics and pathology data and correlation with PFS are ongoing and will be presented in the meeting.

#1756 Characterizing the mutational spectrum of metastatic mucinous adenocarcinoma of the appendix.

D. J. Gironda[1], M. Leung[2], G. Jin[1], L. Liu[1], K. I. Votanopoulos[1], E. A. Levine[1], L. D. Miller[1];

[1]Wake Forest University School of Medicine, Winston Salem, NC, [2]The Atrium Health Wake Forest Baptist Comprehensive Cancer Center, Winston Salem, NC

Background: Appendiceal cancer (AC) is an orphan malignancy with only 1-2 cases per 100,000 people in the US. The genomic composition of metastatic, mucinous AC is yet to be resolved at the whole exome level and few groups have assessed the clinical actionability of target genes. Here we performed whole-exome sequencing (WES) on AC specimens to 1) elucidate the mutational spectrum of AC, 2) identify recurrent mutations at frequencies unique to AC or in common with colorectal cancer (CRC), and 3) uncover recurrent AC mutations that are associated with patient survival outcomes.

Methodology: Twenty-four FFPE samples, one from each of 24 AC patients treated at our institution with cytoreductive surgery (CRS) followed by heated intraperitoneal chemotherapy (HIPEC), were collected from our tumor bank with IRB approval. DNA from tumor and corresponding normal tissue (PBMCs) was extracted, assessed for integrity and quantity, then analyzed by WES using the Illumina NextSeq 6000 platform. The resulting data were processed using both GATK and DRAGEN pipelines. The frequencies of recurrent mutations in AC were compared with those of CRC from cBioPortal and statistically compared by Fisher's Exact Test. Logrank test was performed to estimate survival associations based off mutation status. Mutational signatures derived from the Pan-Cancer Analysis of Whole Genomes (PCAWG) Consortium were cross-compared to our cohort to identify previously unknown mutational processes in AC.

Results: The most frequent mutations were found in MUC6 (63%), KRAS (58%), HLA-B (54%), PABPC1 (50%), and MUC5AC (50%). Distinct from a 534-patient CRC cohort, AC had lower rates of alteration in APC (4% vs 73% CRC, $p<0.001$) and TP53 (21% vs. 62%, $p<0.001$), with higher rates of alteration in HLA-B (54% vs 3%, $p<0.001$), GNAS (38% vs 5%, $p<0.001$), and ABCA1 (29% vs 7%, $p=0.001$). Notably, ABCA1 mutation frequency was higher in mucinous CRC (n=56) when compared to non-mucinous CRC (n=478, 20% vs 7%; $p<0.001$), suggesting that ABCA1 may be uniquely altered in bowel cancers of mucinous phenotype. Alterations in Rho-A were a statistically significant predictor of poor survival in both AC ($p<0.001$) and CRC ($p=0.05$). PCAWG analysis showed that the predominant mutational signature in AC most resembles SBS5, suggesting that the mutational etiology of AC may be linked to age and/or smoking status.

Discussion: Here we present the largest whole-exome sequencing analysis of AC analyzed to date and identify previously undescribed recurrently mutated genes unique to AC as compared to CRC. We demonstrate novel associations between altered genes and patient survival, which opens discussion regarding the clinical utility of molecular markers in AC for assisting treatment decision making.

#1757 Pan-cancer analysis identifies signatures of HRD-positivity in germline BRCA1/2 mutated non-BRCA associated cancers.

D. M. Muldoon, M. Mehine, S. Tischfield, A. Brannon, M. Ladanyi, Z. K. Stadler, D. B. Solit, A. Drilon, M. F. Berger, Y. Murciano-Goroff, C. Bandlamudi; Memorial Sloan Kettering Cancer Center, New York City, NY

Introduction: BRCA-associated cancers (breast, ovarian, pancreas, and prostate) with germline pathogenic mutations in *BRCA1/2* (*gBRCA1/2*) are associated with homologous recombination deficiency (HRD) and benefit from platinum/PARPi. However, the role of *gBRCA1/2* in non-BRCA assoc. cancers is poorly understood. HRD tumors present with 'genomic scars' that can be quantified in tumor profiling ("HRD-sum" score). We reasoned that the HRD-sum score together with germline mutation status (including loss of wild-type) is a strong correlate of HRD-positivity. Leveraging 42,448 prospectively sequenced patients across 63 cancer types, we sought to characterize the prevalence of the HRD-positivity in non-BRCA-assoc. cancers.

Methods: Allele-specific copy number data was inferred using FACETS. HRD-sum was calculated as a sum of the numbers of telomeric imbalances, large-scale transitions and genome-wide losses of heterozygosity. Calculating each score was iteratively optimized to improve detection of the scars using MSK-IMPACT targeted sequencing data using patient-matched WES data from 1841 tumors as reference. Germline mutations were identified by a clinically validated pipeline and annotated for pathogenicity using ClinVar. After excluding low quality tumors, 27,375 patients were retained for analysis. "HRD-positive" tumors are those with *gBRCA1/2* mutations, loss of wild type, and an HRD-sum score >=42.

Results: Expectedly, g*BRCA1/2* mutations were more frequent in BRCA-assoc. cancers (7.2%, 558 of 7,737 patients) compared to non-BRCA-assoc. cancers (2.6%, 500 of 19,638) (p=5e-60). Among non-BRCA-assoc. cancers, g*BRCA1/2* were most common in esophagogastric (3.9%), lung (3%), hepatobiliary (2.9%), and bladder (2.8%) cancers. Although biallelic loss in g*BRCA1/2* patients was sig. higher in BRCA-assoc. cancers (80% vs. 37% in non-BRCA-assoc.), several cancer types showed high rates of loss of wild-type including g*BRCA1* tumors in hepatobiliary (5/5) and endometrial (10/11) cancers. HRD-sum scores in all *gBRCA1/2* biallelic tumors were sig. higher (median 58) compared to monoallelic (26) or wild-type (25) tumors. Notably, the non-BRCA assoc. cancers with biallelic *gBRCA1/2* harbored higher HRD-sum scores compared to monoallelic (median 51 vs. 22, p<0.0001). These include cancer types such as endometrial (64 vs. 37, p= 0.0014) and esophagogastric (62 vs. 45, p=0.0017). In all, 68% of *gBRCA1/2* patients in BRCA-assoc. cancers showed HRD-positivity. Interestingly, 18% (91/500) of *gBRCA1/2* patients in non-BRCA-assoc. cancers also showed HRD-positivity. These included 52% of esophagogastric, 28% of lung, and 22% of bladder cancer patients with *gBRCA1/2*.

Conclusion: Using a robust measure to detect HRD scars from MSK-IMPACT panel data, we demonstrate evidence for BRCA-mediated tumorigenesis in an expanded spectrum of cancers with potential therapeutic relevance.

#1758 Chromosome 3 copy number loss alone drives tumor evolution to aggressive disease in uveal melanoma.

S. Srinivasan[1], J. Rose[1], R. Minelli[1], C. Terranova[1], P. Shah[1], J. R. Daniele[1], M. Peoples[1], M. He[1], C.-Y. Liu[1], J. Gay[1], M. Soeung[1], S. Soni[2], F. Wang[1], C. Bristow[1], K. Wani[1], L. Perelli[1], D. Loza[1], N. Feng[1], M. Tarabichi[3], P. Van Loo[1], A. Futreal[1], S. Woodman[1], A. Lazar[1], C. P. Vellano[1], J. Marszalek[1], G. F. Draetta[1], T. Heffernan[1], A. Carugo[4], G. Genovese[1], V. Giuliani[1],

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX, [3]Universite Libre de Bruxelles, Bruxelles, Belgium, [4]IRBM, Rome, Israel

Uveal Melanoma (UM) is a rare tumor characterized by mutations in GNAQ or GNA11, followed by a mutation in BAP1, SF3B1 or EIF1AX. Notably, a large subset of BAP1 mutant patients present with a unique chromosome 3 copy-number (CN) loss and higher likelihood of metastases. The biology underlying the causes and consequences of Monosomy 3 (M3), and its role in metastases is largely unexplored. This can be partially attributed to the relatively few numbers of preclinical models of UM, and the inability to delineate M3 from BAP1 loss. To address this, we derived a preclinical isogenic model of chromosome 3 CN loss through CRISPR-based centromere targeting in a well characterized UM cell line lacking a BAP1 mutation. Clones with and without chromosome 3 loss were derived from these efforts. Recent studies have evaluated genomic events in primary UM and described five CN aberration-based subtypes expanding beyond M3, with the fifth subtype being called the “ultra-high-risk UM” based on poor survival and extremely high metastatic rate. Whole genome sequencing across our clones confirmed chromosome 3 CN loss, and in addition to this, recapitulated all of the core genomic features characteristic of the ultra-high-risk UM group. In comparison, our models without chromosome 3 CN loss maintained a genomic profile more characteristic of lower risk UM subtypes. The genomic landscape of our isogenic low risk (LR) and high risk (HR) clones suggest that chromosome 3 CN loss alone in the absence of BAP1 mutations can be the driver for acquisition of downstream genomic events seen in aggressive UM. Further, using single cell DNA sequencing on the parental model, LR and HR clones, we confirmed that chromosome 3 CN loss in our clones was engineered, and not a pre-existing subclone in the parental cell line. Bulk RNAseq on our LR and HR clones demonstrate concordance with genomic regions of losses and gains, while also highlighting upregulation of pathways such as cell cycle and DNA damage response in the HR clones. Next, we developed patient derived xenograft (PDX) models demonstrating differential behavior in paired *in vivo* settings, where HR clones had higher fitness advantage and metastatic potential, specifically to the mouse liver. This modeling has enabled us to employ spatial transcriptomics in a PDX setting, adapt existing methodology to infer chromosomal copy number events in our system and inform transcriptional and genomic phenotypes akin to the aggressive HR clones. Thus, using our engineered preclinical models, we demonstrate that chromosome 3 loss, in the absence of BAP1 mutations is capable of driving aggressive disease in UM, characterized by genomic evolution, transcriptional reprogramming and *in vivo* invasiveness.

#1759 Integrative longitudinal genomic analysis of therapy-resistant and metastatic pediatric cancers.

H. J. Martell[1], A. T. Shah[1], A. G. Lee[1], S. G. Leung[1], S.-J. Cho[1], M. Pons Ventura[1], A. Golla[1], A. E. Marinoff[1], E. P. Young[1], B. Tanasa[1], I. Behroozfard[1], H.-Y. Liu[1], A. Spillinger[1], M. L. Turski[1], N. Elzie-Tuttle[1], C. Espinosa-Mendez[1], A. Rangaswami[1], T. M. Cooney[1], C. Kline[1], A. Agrawal[1], J. Michlisch[1], E. Stieglitz[1], M. Loh[1], A. J. Sabnis[1], K. T. Vo[1], S. Spunt[2], N. Lacayo[2], H. C. Beal[3], F. K. Hazard[2], S. Salama[3], D. Haussler[3], O. M. Vaske[3], M. R. Breese[1], E. Sweet-Cordero[1]; [1]UCSF - University of California San Francisco, San Francisco, CA, [2]Stanford University, Stanford, CA, [3]UCSC - University of California Santa Cruz, Santa Cruz, CA

Pediatric cancer patients are commonly profiled with gene-panel sequencing tests that yield few actionable results, in part due to the complex genomic alterations that define these malignancies. We hypothesized that integration of whole-genome (WGS) and RNA sequencing (RNAseq), would lead to a more comprehensive understanding of these diseases. Our study is uniquely focused on metastatic and relapsed disease, whereas previous studies focused on primary cases. We also prioritized longitudinal profiling, including with deep sequencing, to capture tumor evolution across primary and metastatic sites and to quantify the utility of resampling.

We assembled a cohort of 219 high-risk pediatric oncology patients, including solid tumors, CNS tumors, leukemias/lymphomas, patients with relapsed/refractory disease (75), metastatic disease at diagnosis (7), rare diagnoses (17), prior cancer history, and estimated overall survival <50%. We characterized 286 samples with WGS (tumor ~60X; germline ~30X) and/or RNAseq (polyA selected, ≥20 million reads), including 95 samples taken from 44 patients at different time points (diagnosis, relapse, etc.). Variants, structural rearrangements, mutational signatures, and copy-number alterations were identified using WGS. RNAseq was used to profile gene expression outliers, gene fusions, and expression of variants. Integrated results were used to prioritize potentially actionable variants. For 20 patients (44 samples), we performed targeted deep sequencing of the DNA (~500X).

RNAseq identified potentially druggable outlier gene expression and fusions, including 102 novel fusions where the 3' gene is overexpressed. WGS identified aneuploidy, loss of heterozygosity and whole genome duplication across histotypes. Mutational burden and mutational signatures analyses identified profound effects from platinum drugs on tumor evolution, but treatment effects were not universal. Multiple sampling per patient uncovered drastic spatial and temporal differences in the genomes and transcriptomes of these tumors. Custom deep sequencing confirmed these findings, captured evolution missed by WGS, and furthered our understanding of the complex impacts of treatment on clonal evolution. Histotypes differed by whether actionability was higher for WGS or RNAseq alone, but in 66% of samples modality integration increased actionability. Integration also identified a subset of tumors that may be amenable to immunotherapy, but which lack canonical markers of response. Longitudinal analysis highlighted both the opportunities and risks of targeted therapy, with targetable variants gained and lost between timepoints. Our study shows that integrated multi-modality sequencing can elucidate novel insights into the biology of pediatric cancers and identify potential therapeutic targets not detected using gene-panel testing alone.

#1760 Mutational landscape of the canine acute myeloid leukemia exome.

R. Harris, E. Conaway, A. Avery;
Colorado State University, Fort Collins, CO

Over 21,000 newly diagnosed cases of human acute myeloid leukemia (hAML) and 10,000 hAML-related deaths are reported in the United States every year. hAML is considered a highly diverse aggressive hematopoietic malignancy, with over 16 recurrent gene rearrangements, 60 recurrent point mutations, and hundreds of rarely mutated genes. There are large ongoing multi-institutional studies devoted to advancing medical management for hAML by providing targeted therapeutics to patients based on their molecular characteristics. A preclinical spontaneous large animal model for testing novel therapies could accelerate the development of better treatments in people. Dogs spontaneously develop AML with similar clinical features and outcomes. As such, the dog may be a useful pre-clinical model, but little is known about the molecular landscape and/or drivers of canine AML (cAML). The goal of this work was to identify somatic mutation candidates in cAML and determine the overlapping features with hAML. We utilized whole exome sequencing at 300x coverage to identify candidate mutations in 51 cAML samples. Somatic variant calling was performed per the GATK best practice recommendations using Mutect2 and a reference panel of normals (n=77) and a variant call file of canine germline variants. We focused our analysis on novel variants predicted to have a moderate to high impact and that occurred in genes implicated in cancer. At least one variant was identified in genes involved in the RTK/RAS pathway (e.g. *NRAS, KRAS, PTPN11, FLT3, KIT*) in over 75% of cAML samples, a trend that is also found in people. Additionally, recurrent point mutations were predicted in *NRAS* and *KRAS*, and some of which, such as the codon changes G13R and Q61R/H in *NRAS*, were noted to be shared between hAML and cAML. Mutations in *DNMT3A* were uncommon (n=3/44) and *NPM1* mutations were not identified in our cohort, both of which are common hAML-associated genes. However, mutations in other epigenetic modifiers, such as *KDM5C* and *KDM6A*, occurred at a high frequency. This data provides insight into the candidate mutations potentially driving cAML pathogenesis and highlights the overlapping molecular features with hAML.

#1761 Comprehensive profiling of the FAT3-associated gene signature in deciphering immunophenotypes of gastrointestinal cancers: Analysis of institutional cohort and TCGA dataset.

P. Ahluwalia, T. Leeman, A. Mondal, A. Vashisht, H. Singh, R. Kolhe;
Augusta University, Augusta, GA

Gastrointestinal (GI) cancers are among the most prevalent cancers affecting the US population. Anatomically, GI cancer includes cancers of the organs in the digestive tract, from the esophagus to the rectum. Advances in molecular oncology have started to transform the therapeutic landscape and offer tremendous promise for patients across diverse lineages. However, the equitable benefit of this approach has been hampered due to tumor heterogeneity and the lack of accurate, tumor-agnostic biomarkers with prognosis and predictive utility. Thus, there is a need to identify novel biomarkers that affect gastrointestinal malignancies to improve the management of cancer patients. This study analyzed a single institution's whole genome sequencing dataset to explore the genomic variation in GI cancers. Between 2020 and 2022, 302 AU patients underwent molecular profiling, including whole-exome sequencing (WES) profiling at Caris Life Sciences. WES is an NGS assay that analyzes the DNA sequences of all protein-coding exons in the genome, representing approximately 1-2% of the human genome with coverage of over 22,000 genes. We analyzed the TCGA dataset for comparative analysis, which included cancer data from >1800 GI cancer patients. In addition, survival and network analyses were performed to identify a 6-gene *FAT3*-related signature for GI cancers. In our cohort, we identified *FAT3* (Fat atypical cadherin 3) as the most frequently mutated gene after *TP53*, *APC*, and *KRAS*. *FAT3* encodes a cadherin protein involved in cell-cell interactions and adhesion. In the institutional cohort, *FAT3* was found to be mutated in 16% of all GI cases. Further analysis of TCGA datasets comprising 1808 GI cancer patients revealed *FAT3* mutations in 12% of the cases. To identify additional prognostic biomarkers associated with *FAT3*, we performed network analysis and identified a 6-gene *FAT3*-related signature (*FAT3*, *RYK*, *FAT2*, *EGFLAM*, *NTRK3*, *IGSF9*, and *HMGA2*) that significantly stratified GI cancer patients based on overall survival, progression-free survival, and disease-specific survival. The perturbation profile of the 6-gene signature was associated with 509 patients or 28% of total GI patients. Further, immune deconvolution analysis of stratified patients revealed increased infiltration of immune cells with immunosuppressive phenotypic properties in GI cancer patients with higher expression of the *FAT3*-related gene signature. In summary, this analysis reveals the distribution of *FAT3* mutational profiles in GI patients and identifies a gene signature that stratifies patients based on survival outcomes. This analysis can provide new tools for patient stratification and therapy implementation, leading to better outcomes for cancer patients.

#1762 Characterization of somatic copy number deletion of chromosome 22q in papillary thyroid carcinoma.

Olivia W. Lee[1], Danielle Karyadi[1], Stephen Hartley[1], Weyin Zhou[1], Mitchell Machiela[1], Mykola Tronko[2], Tetiana Bogdanova[2], Liudmyla Zurnadzhy[2], Lindsay Morton[1], Stephen Chanock[1]

[1]National Cancer Institute, Rockville, MD,[2]V.P. Komisarenko Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Deletion in the long arm of chromosome 22 (22qDEL) is the most prevalent somatic copy number alteration (SCNA) observed in papillary thyroid carcinoma (PTC). Despite its recurrence, the specific characteristics and role of 22qDEL in PTC have not been fully studied. We conducted a pooled analysis of 22qDEL by integrating patient and clinical information and molecular profiles from 1,094 primary PTC tumors across four major published PTC genomic studies: The Cancer Genome Atlas (TCGA) PTC profile study, the National Cancer Institute (NCI) post-Chornobyl PTC study, the Memorial Sloan Kettering Cancer Center Integrated Mutation Profiling of Actionable Cancer Targets (MSKCC-IMPACT) PTC cases, and the Seoul National University (SNU) thyroid cancer profile study. The majority of PTC with 22qDEL demonstrated arm-level loss of heterozygosity (86%). Even in PTC cases with partial 22qDEL, we observed a loss across 70% of chromosome 22, encompassing regions 22q12 and 22q13, which harbors known cancer genes (*NF2* and *CHEK2*). More than 90% of 22qDEL co-occurred with established oncogenic drivers of PTC, though a full assessment of PTC drivers was not available for all cases. 22qDEL occurred more frequently with *RAS* point mutations (50.4%) than other drivers (9.3%). A higher fraction of 22qDEL was clonal in *RAS*-driven PTCs (78.3%), suggesting 22qDEL occurs early in *RAS*-driven tumor development. We did not observe any association between 22qDEL and established PTC risk factors such as age, sex, and radiation, nor with clinical features including tumor size, multifocality, and metastasis (p-values>0.22). RNA sequencing gene expression analysis based on 22qDEL status revealed downregulation of most genes residing on chromosome 22q and significant differential expression activity of immune-related genes, further implicating a role of immune dysregulation in PTC. Our study suggests that 22qDEL may not act as a primary driver of PTC but plays an important role as a co-factor of *RAS* point mutations, which could further drive PTC development.

#1763 Long-read sequencing of pediatric leukemia identifies clinically relevant genomic rearrangements.

B. Yoo[1], A. Keskus[2], C. Bi[1], L. Lansdon[1], T. Ahmad[2], I. Pushel[1], A. Walter[1], M. Gibson[1], E. Guest[1], T. Pastinen[1], M. Kolmogorov[2], M. S. Farooqi[1];
[1]Children's Mercy Kansas City, Kansas City, MO, [2]National Cancer Institute, Bethesda, MD

Clinical detection of genomic rearrangements currently depends on a range of complementary and overlapping methods including fluorescence *in situ* hybridization (FISH), karyotyping, and DNA and/or RNA sequencing. This requirement for multiple tests results in higher total costs, extended analysis time, and increased usage of sometimes limited tumor material. In our laboratory, we apply long high-fidelity reads to human samples using PacBio circular consensus sequencing (HiFi-GS) of 12-18kb DNA fragments, which offers better structural variant detection relative to short-read sequencing. Here, we assess the ability of HiFi-GS to detect clinically relevant genomic rearrangements (CRGRs) in pediatric leukemia.

We selected 11 pediatric leukemia cases with corresponding normal (remission) samples, including 7 cases of B-cell acute lymphoblastic leukemia (B-ALL) and 4 cases of acute myeloid leukemia (AML); 5 of these 11 leukemia cases had known CRGRs as below. The remaining 6 leukemia cases had also undergone clinical genetic profiling via karyotyping, FISH, microarray, and sequencing yet a clinical grade genomic driver was not identified. DNA from each sample was sequenced on a Revio instrument (PacBio, Menlo Park, CA) to a target depth of 30x. The PacBio Human Whole Genome Sequencing (WGS) workflow was used to process HiFi reads for haplotagged alignment and phasing, followed by somatic structural variant calling using Severus. Subsequent analysis focused on the presence of break ends in known cancer-relevant genes.

We found that HiFi-GS detected the known CRGRs in all 5 cases with prior findings, providing precise break ends and clarifying sometimes unclear cytogenetic observations (such as exact partner genes), in these cases. These included detection of an *ETV6-RUNX1* fusion, *NUP98-NSD1* fusion, *KMT2A-AFF1* fusion, *KMT2A-AFDN* fusion, and *RUNX1-RUNX1T1* fusion. HiFi sequencing also detected CRGRs in 2 of the 6 “undiagnosed cases”; namely, one case of *ZNF384-TCF3* fusion and one case of *KMT2A-MLLT10* fusion. The former can be cytogenetically cryptic, while the latter can often be missed due to its potentially complex nature.

Our results demonstrate that HiFi-GS can reliably detect CRGRs, bringing us closer to the promise of a single comprehensive genetic test for cancer characterization. Additional work examining other somatic structural and copy number variants (i.e., inversions, deletions, and duplications) in these cases, as well as oncogenic sequence variants, is ongoing.

#1764 Long read sequencing allows comprehensive molecular profiling of complex karyotype acute myeloid leukemia (CKAML) with 5q deletions.

F. Schick[1], E. Slonova[2], E. Straeng[1], S. Huet[3], M. Raso[1], M. Tilgner[1], F. Damm[1], P. Sujobert[3], O. Blau[1], L. Bullinger[1], A. Dolnik[1];
[1]Charite - University Medicine Berlin, Berlin, Germany, [2]German Cancer Research Center (DKFZ) and German Cancer Consortium (DKTK), Berlin, Germany, [3]Hospices Civils de Lyon, Lyon, France

Background Acute myeloid leukemia with complex karyotype (CKAML) does frequently show del(5q), deletion of chromosome 5q. Previous work in MDS and AML showed that CKAML form clusters distinguishing del(5q) cases with commonly retained regions (CRRs) in the telomeric (≥5q34) and centromeric (≤5q14.2) ends from cases with loss of the telomeric and/or centromeric regions. Interestingly, del(5q) patients with CRRs were shown to have less genomic lesions and were associated with a better prognosis than other 5q-deleted CKAML cases.
Aim: Combining the advantages of two different long read sequencing technologies, Pacific Biosciences (PacBio) and Oxford Nanopore Technologies (ONT), we aimed to more comprehensively characterize the molecular landscape of CKAML with del(5q). Our integrative workflow enabled an in-depth characterization of copy number variations (CNV), genomic rearrangements, transcriptomic and epigenomic changes.
Methods: Low coverage whole genome sequencing (WGS) using ONT was performed on 209 patients with CKAML to identify del(5q) cases for further in-depth analysis. For 10 selected cases with known CRR status, genomic deep sequencing using PacBio Revio and ONT PromethION was performed, as well as PacBio Revio MAS-seq for fusion transcript detection.
Results: A mean sequencing depth of 3-fold (range 0.4-17.3-fold) was obtained by low coverage WGS of the 209 CKAML cases. With a resolution of 0.1 Mbp n=134 del(5q) cases were identified in our CKAML cohort (64%) and commonly deleted regions on 5q could be resolved at 5q21.2 to 5q23.3 and 5q33.3 to 5q35 (Fisher test, FDR Benjamini-Hochberg, $p<10^{-30}$). These regions separated del(5q) in n=52 cases showing CRR retention and n=82 showing partially no CRR, (either the centromeric or telomeric regions, n=74, or of both regions, n=8 involved). Subsequent co-occurrence analysis provided evidence of an association between the loss of telomeric 5q region with a 3p12-25 deletion. In-depth analysis (30-50 fold) of ten distinct del(5q) cases by PacBio and ONT revealed additional insights into the complex clonal composition of del(5q) cases. For example, one case showed two distinct subclones with 5q14.2-5q35.1 deletion and with translocation t(3;5)(p14;q14) respectively. Moreover, we could demonstrate that 5q-aberrations are far more complex than initially thought showing, e.g. inverted terminal duplications that resulted in fusion transcripts involving *PDE4D* and leading to its deregulated expression.
Conclusion: Using our long read deep sequencing approach we could further delineate the structural complexity of del(5q) CKAML. While gene expression profiling, methylation analysis and correlation of findings with clinical outcome are ongoing and will be presented at the meeting, our results help to further pinpoint the biology underlying del(5q) and to further refine this heterogeneous CKAML subgroup.

#1765 The genetic landscape of head and neck cancer using brush biopsy.

E. John[1], T. Lesluyes[2], T. Baker[2], M. Tarabichi[3], P. Van Loo[1], X. Zhao[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]The Francis Crick Institute, London, United Kingdom, [3]Universite Libre de Bruxelles, Brussels, Belgium

Oral premalignant lesions (OPLs) with genomic alterations have a heightened risk of evolving into oral squamous cell carcinoma (OSCC). Currently, genomic data are obtained through invasive tissue biopsy. Brush biopsy has been utilized for diagnosing dysplasia but its effectiveness in reflecting the complete genomic landscape of OPLs remains uncertain. This study investigates the potential of brush biopsy samples in accurately reconstructing the genomic profile of OPLs. The evolution and heterogeneity were assessed by assessing SNVs, copy number analysis, and subclonal architecture reconstruction of paired tissue-brush biopsy samples of oral epithelium, dysplastic lesion, and OSCC lesion. We found that brush biopsy accurately reflects the genomic landscape of oral lesions, mirroring about 90% of SNVs and comparable CNA profiles found in tissue biopsies. Genomic profiling with brush biopsy was tissue-specific, as SNVs identified in OPL or OSCC lesions were not found in adjacent normal mucosa. Shared SNVs and CNAs were observed between OPL and OSCC samples. This suggested a common ancestor giving rise to these lesions. Subclonal architecture reconstruction confirmed that both lesion types shared a common ancestor clone and then diverged evolutionarily. These findings underscore the potential of brush biopsies in accurately reconstructing the genomic profile of OPL and OSCC, highlighting their usefulness in understanding the biological processes involved in tumor evolution.

#1766 *CREBBP*, *NOTCH2* and *GNAS*mutational profile in uterine sarcomas.

L. G. dos Anjos, G. N. Quevedo, E. C. Baracat, **K. C. Carvalho**;
University of Sao Paulo, Faculty of Medicine, Sao Paulo, Brazil

Background: Uterine sarcomas (US) present clinical challenges due to their dynamic behavior and limited treatment options. Representing 1-3% of uterine cancer cases, these tumors exhibit rapid growth, high recurrence rates, and resistance to the standard treatments. The present study aimed to validate several Loss-of-function mutations (LOF), obtained by NGS analysis in the *CREBBP*, *NOTCH2*, and *GNAS* sequences, in US through Sanger sequencing. **Methods:** Twenty-five samples of US were collected between 2000 and 2015 for genomic DNA extraction. An initial genetic screening of the samples by NGS method was followed by Sanger sequencing validation. Bioinformatics analysis through SnapGene confirmed the results. **Results:** A c.4063G>A mutation was confirmed in uterine leiomyosarcomas (ULMS), in the both strands. Notable variations in the forward strand, such as a C>G substitution at position 38 of the alignment and a degenerate base S at position 113, differentiated ULMS from uterine sarcomas (US). Two ULMSs exhibited the highest substitution rates: one with 18 and another with 6 substitutions. Despite the absence of the c.5527T>C *CREBBP* mutation, ULMS displayed increased insertions and deletions. Assessing the *NOTCH2* gene in US revealed a complex genetic landscape, with a unique SU-specific duplication in the forward strand. The reverse strand maintained high genetic stability. Mutation c.6094C>A was exclusive to one US sample. Notably, the c.7223T>A mutation in *NOTCH2* was not identified. Shared mutations between ULMS and US suggest genomic similarities in these regions. In the *GNAS* analysis, the c.2381A>C mutation was not found. However, in the forward sequence of one US sample, a deletion at the expected substitution site was detected, suggesting a specific genetic alteration. The c.706G>A mutation was consistently present in sample ULMS, indicating genetic stability in this sample. US exhibited a G>C substitution in the reverse sequence, hinting at a unique pattern of genetic variation. These findings underscore the complexity of genetic alterations in these critical gene regions. **Conclusion:** Our analysis identified specific alterations in ULMS and US. ULMS showed the c.4063G>A *CREBBP* mutation and unique variations, while US had a specific c.6094C>A *NOTCH2* mutation. The absence of the c.2381A>C *GNAS* mutation in both ULMS and US, along with distinct genetic patterns (c.706G>A in ULMS and G>C substitution in US), underscores significant mutational differences in these critical gene regions. These findings enhance our understanding of uterine sarcoma genetics, prompting further exploration for potential diagnosis, prognosis and therapeutic advancements.

#1767 Molecular subclassification of gastrointestinal stromal tumors by genomic backgrounds.

H. Yamamoto, E. Nakada, S. Kawano, F. Kato, C. Fukano, M. Futagawa, Y. Urakawa, R. Ohsumi, S. Ueno, H. Yanai, A. Hirasawa;
Okayama University Hospital, Okayama, Japan

Gastrointestinal stromal tumors (GISTs) are the most common gastrointestinal mesenchymal tumors. While about 10% of GISTs are known to be developed from the *KIT* or *PDGFRA* gain-of-function mutations, the rest, which is the majority of GISTs, is so-called as wild-type GISTs. There are attempts to make subclassification of wild-type GISTs in syndromic or non-syndromic group as promising for understanding of heterogeneity or treatment strategy. Genomic states of succinate dehydrogenase B (SDHB) and neurofibromatosis type 1 (NF1) have been raised as candidates for subclassification of wild-type GISTs. In this presentation, we will discuss our recent three cases of wild-type GISTs, carrying germline pathogenic variants in *SDHB* or *NF1*. Two cases with *SDHB* germline pathogenic variants showed stomach GISTs with good clinical course, the maintained performance status and long survival nevertheless of the recurrence. The other case with an *NF1* germline pathogenic variant showed multiple GISTs in small intestine which was controlled surgically and the late onset of other clinical symptoms of NF1. These cases might clinically suggest potential prognostic and predictive markers in genomic alterations of *SDHB* or *NF1* for the cases with wild-type GISTs.

#1768 Investigating oncogene amplifications in brain metastasis of esophageal adenocarcinoma samples.

Nora Lawson[1], Lingqun Ye[2], Bo Zhao[2], Andy Futreal[2], Kadir Akdemir[3]

[1]School of Health Professions, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Neurosurgery-Research, The University of Texas MD Anderson Cancer Center, Houston, TX

Esophageal Adenocarcinoma (EAC) exhibits a rising incidence and dismal survival rate in the US, primarily attributed to frequent distant metastases. Brain metastasis, though uncommon is an aggressive tumor type, remains poorly understood in EAC. To address this knowledge gap, we conducted a comprehensive analysis of 9 brain metastasis samples, profiling their whole-genome with matched normal and comparing them to the primary EAC tumors, other EAC metastasis types and other brain metastasis types, including the Hartwig Institute and PCAWG. Overall, our sample size comprised over 4,500 tumor whole-genome data and we utilized a uniform data analysis pipeline for robust comparisons between cohorts. Our analysis revealed that brain metastasis samples have significantly higher single-nucleotide variants, however, the structural variant burden in brain metastases closely resembled those observed in the primary tumor. Notably, the incidence of whole genome doubling is significantly higher in brain metastasis compared to other primary cancer types and metastases. This significant difference stems from the higher WGD incidence in primary EACs compared to other tumor types. Mutational signature analysis revealed no significant changes compared to the primary tumor, and we observed an enrichment of SBS 17a/b, previously associated with tumor progression in primary esophageal adenocarcinoma, along with a prevalent presence of the APOBEC mutagenesis signature in most samples. Notably, ERBB2 and TP53 emerged as prominent driver genes present in most brain metastasis samples. We also observed an upregulation of ERBB2 expression in brain metastasis samples. Interestingly, ERBB2 appeared to play a more significant role in brain metastasis progression compared to the primary tumor and other metastasis types, suggesting its potential as a therapeutic target. These findings advance our comprehension of brain metastasis in EAC, providing crucial insights into genomic alterations and mutational processes that could inform future therapeutic strategies and clinical management for this previously understudied metastatic type.

#1769 Pan-cancer genomic characterization of human papillomavirus associated tumors reveals patterns of somatic alteration that associate with virus status and anatomic site.

J. R. Holt[1], P. Little[1], H. Jo[1], X. Zhao[1], H. Choi[1], V. Walter[2], B. Wahle[3], J. P. Zevallos[4], A. Mazul[4], K. A. Hoadley[5], M. Hayward[6], D. N. Hayes[1];
[1]University of Tennessee Health Science Center, Memphis, TN, [2]Penn State College of Medicine, Hershey, PA, [3]Washington University School of Medicine, St. Louis, MO, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of North Carolina School of Medicine, Chapel Hill, NC, [6]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Human papilloma virus (HPV) infection causes over 600,000 human cancers yearly and accounts for nearly all cervical cancers, increasing rates of head and neck squamous cell carcinomas (HNSCC), and many anogenital cancers - all with varying clinical outcomes due to a lack of personalized care. While recent integrative genomic studies have described molecular features of individual cancer types, few studies have compared genomic changes between HPV(+) and HPV(-) cancers across anatomic sites. Here, we conducted the first pan-cancer genomic analysis of HPV-associated tumors across multiple anatomic tumor types using whole exome and transcriptome data from The Cancer Genome Atlas (TCGA) cohorts of cervical (n=254) and HNSCCs (n=514), and targeted exome sequencing of 800 cancer genes plus full length HPV16/18 genomes in a clinical cohort of squamous tumors from the head and neck (n=458), cervix (n=78), vulva (n=23), anal canal (n=5), and vagina (n=2). Somatic variant calling and filtering, followed by an integrative pathway analysis of commonly altered targets, defined the catalog of somatic mutations and copy number alterations (CNAs) that drive HPV(+) and HPV(-) tumorigenesis. Sequencing reads from viral RNA or DNA determined HPV status, and HPV type, genome structure, integration events, and viral load were characterized in a subset of samples via de novo assembly of viral aligned reads followed by copy number analysis, breakpoint identification, and the calling of structural variants. Overall HPV positivity was 50% (668 out of 1334 total), with HPV16 accounting for 96%, 89%, and 60% of all HPV(+) anogenital, head and neck, and cervical tumors respectively. Significant differences in somatic mutation frequency between HPV(+) and HPV(-) tumors were observed in the full cohort, as well as in analyses stratified by anatomic site. Interestingly, we noticed recurrently mutated “hotspots” attributable to increased APOBEC-mutagenesis in HPV(+) samples across anatomic sites (PIK3CA:E545K, FGFR3:S249C, EP300:D1399N), while hotspot mutations likely caused by tobacco smoking predominate HPV(-) HNSCC (PIK3CA:H1047R/L, CDKN2A:R80*, TP53:R282W). Focal and arm level CNAs were distinctive, including gains of 11q22 in HPV(+) cervical and HPV(-) HNSCC, and losses of 11q22 in HPV(+) HNSCC. Biological pathways commonly altered include epithelial differentiation, cell death, innate immunity, growth factor/kinase signaling, and cell cycle control. In summary, pan-cancer genomic analysis revealed distinct patterns of somatic alteration of conserved biological pathways that associate with HPV status and anatomic site. These findings improve our understanding of tumor biology unique to HPV-associated cancers and may lead to novel treatment and classification strategies to improve patient outcomes in the clinical setting.

#1770 Right oncogene, wrong tumor - CBL mutations in pediatric CNS and solid tumors.

L. M. Brown[1], C. Mayoh[1], P. Acera Mateos[1], A. De Weck[1], R. Salomon[1], T. Sadras[2], N. Manoharan[3], M. Wong[1], M. J. Cowley[1], P. G. Ekert[1];
[1]Children's Cancer Institute, Sydney, Australia, [2]Peter MacCallum Cancer Centre, Parkville, Australia, [3]Sydney Children's Hospital, Randwick, Australia

The molecular analysis of individual patient tumors by personalized medicine programs like the Zero Childhood Cancer Program (ZERO) enables the detection of potentially targetable lesions, unlocking new therapeutic opportunities for patients. Somatic mutations in the E3-ubiquitin ligase, CBL, are known to activate receptor tyrosine kinases (RTKs) in cancer and have been exclusively characterized in hematological malignancies. This includes acute myeloid leukemia, where CBL mutations lead to FLT3 activation. Using molecular data from ZERO we have identified known and novel *CBL* variants in novel tumor contexts. Our findings raise the possibility that CBL mutation may be a marker of RTK activation in a range of paediatric cancer types and may represent a group of patients who could benefit from tyrosine kinase inhibitor (TKI) therapy.

We analyzed whole genome and RNA sequencing data from the ZERO cohort and identified 26 somatic *CBL* variants in 22 individual patients, the majority of which were in CNS tumors (14 patients). In 8 patients with CNS tumors, we identified missense and splicing variants, which were either novel or not previously seen in this tumor type, that are predicted to have a functional impact on CBL E3 ligase activity due to their location in the linker region or RING finger domain of CBL. Interestingly, most of these patients did not fall into a pre-defined DNA methylation-based subtype classification of CNS tumors and had no significant upregulation of RTK genes.

In addition to the novel variants, we identified an established oncogenic CBL deletion variant, CBL exon 8/9 deletion (CBL ex8/9Δ), in novel tumor types - neuroblastoma and a germ cell tumor. Functionally, we show that overexpression of CBL ex8/9Δ enhances cell proliferation and maintains EGFR signaling by blocking CBL mediated degradation of phosphorylated EGFR in neuroblastoma cells.

In this study, we demonstrate that CBL is mutated in a range of pediatric cancer types beyond hematological malignancies and may represent a marker of RTK activation and a new target for high-risk patients with limited therapeutic options.

#1771 NYU Langone Genome PACT - Genome Profiling of Actionable Cancer Targets (LG-PACT) for clinical patient molecular diagnostics and treatment.

V. Vasudevaraja, Y. Yang, J. Serrano, K. Wrzeszczynski, M. Snuderl;
NYU Langone Health, New York, NY

Next-generation sequencing (NGS) for the detection of somatic variants has become the tool of choice in a variety of molecular oncology fields and in the clinic. Its use ranges from sequencing entire tumor genomes and transcriptomes to targeted clinical diagnostic gene panels. The NYU Langone Genome PACT assay is a qualitative in vitro diagnostic test that uses targeted next generation sequencing of formalin-fixed paraffin-embedded (FFPE) tumor tissue matched with normal specimens from patients to detect gene alterations in a 607-gene panel. Indications for testing are cancer (solid tumors or hematological malignancies) where a mutational profile from multiple genes would be informative for disease stratification, prognosis, or treatment options including targeted therapies and eligibility for clinical trials. The test is intended to provide information on somatic mutations including point mutations, copy number aberrations, and small insertions/deletions (indels) for diagnostic and treatment decisions. LG-PACT is a United States Food and Drug Administration (FDA) approved diagnostic test. The clinical interpretation of sequencing data of molecular tumor markers from NGS encompasses automated variant calling tools with human interpretation. The final mostly manual review of data is intensive, involving highly trained scientists, encompassing literature review, interpretation and tier classification by pathologists, who then provide a complete molecular diagnostic report to the treating oncologists. Since January 2022 to present (October 2023) we have provided clinical genomic reports for 1029 oncological cases from 124 different cancers and their subtypes, including Brain (489 cases incl. meningioma, glioma and glioblastoma), Gastrointestinal (123), Lung (114), among others. We first present the technical challenges of validating an NGS oncological diagnostic targeted assay for appropriate clinical grade accuracy and sensitivity acceptable for patient care. We show how copy number alterations provide a more comprehensive description of the tumors genomic profile. We then outline the actionability of targeted panel sequencing for our current patient cohort. Where analysis of variant detection has led to 47% (490) of our clinical tumor samples containing known tier 1 therapeutic variants. We conclude with presenting case studies that identify both the clinical utility and informatic challenges of variant calling specific to gene panel sequencing e.g., i) the capture of potential targetable rare and novel indels and multivariant mutations in exons 19 and 20 of EGFR, and ii) a unique KIT tandem duplication event in a gastrointestinal stromal tumor (GIST). We demonstrate the value in precision oncology for multiple cancer types and how the capture of unique variants can provide better targeted treatment options to cancer patients.

#1772 A naturally occurring canine model of peripheral T-cell lymphoma, not otherwise specified.

E. Owens, A. Harris, A. Avery;
Colorado State University, College of Veterinary Medicine & Biomedical Sciences, Fort Collins, CO

Despite being the most common subtype of human peripheral T-cell lymphoma (PTCL), PTCL-not otherwise specified (PTCL-NOS) remains a poorly understood diagnosis of exclusion with poor survival times and treatment responses. Canine PTCL clinically and immunophenotypically resembles human PTCL-NOS, and PTCL is more common in dogs than humans, leading to their interest as a naturally occurring preclinical model. Canine models of cancer offer several unique advantages: in contrast to traditional rodent models, these are spontaneous tumors in genetically diverse and immunocompetent animals living in a shared environment with humans, but relative to their human counterparts, they offer accelerated lifespans with shorter clinical courses of disease. Here, we analyzed the gene expression profile of 96 canine CD4+ PTCLs to determine similarities to human PTCL-NOS and investigate a possible cell of origin. Bulk RNA-seq was performed on lymph node aspirates of 96 cases of canine CD4+ PTCL diagnosed by flow cytometry and sorted CD4+ nodal lymphocytes and CD4+ thymocytes from healthy control dogs. Raw reads were aligned to the Ensembl canine reference genome (ROS_Cfam_1.0) and tabulated. Data normalization and differential expression analysis was conducted with DESeq2, and differentially expressed genes were compared to human PTCL-NOS and various stages of T-cell development via gene set enrichment analyses (GSEA). Global gene expression in canine CD4+ PTCL was analogous to that of human PTCL-NOS (NES = 2.3, $p < 0.001$). Additionally, canine CD4+ PTCL had increased expression of *GATA3* (log2fc = 1.9, padj = 6.5e-07) and was enriched for gene signatures associated with downregulation of PTEN (NES = 1.7, p = 0.0001) and upregulation of PI3K/AKT/mTOR signaling (NES = 1.5, padj = 0.0007), resembling the more aggressive human GATA3-PTCL subtype. Canine CD4+ PTCL was also enriched for human and murine gene signatures associated with early thymocyte progenitor cells and had increased expression of genes of immaturity, including *CD34* (log2fc = 7.8, padj = 2.6e-14), *KIT* (log2fc = 3.3, padj = 7.7e-05), and *CCR9* (log2fc = 4.8, padj = 3.9e-11), although surface CD34 expression is not detected by flow cytometry. These findings were confirmed when we compared the canine PTCL gene expression programs to a canine single cell transcriptomic atlas of hematopoietic precursors and T cells across canine bone marrow, thymic, and lymph node tissues. Canine CD4+ PTCL cells were significantly ($padj < 0.05$) enriched for gene signatures associated with early thymic and bone marrow precursors (NES 1.3-2.1), and negatively enriched for gene signatures associated with naïve nodal CD4+ T cells (NES = -3.2, padj = 0.006). In conclusion, the gene expression profile of canine CD4+ PTCL resembles human PTCL-NOS, supporting its potential as a naturally occurring preclinical model, and a subset of these neoplasms may arise from a thymic precursor cell of origin.

#1773 Deciphering the roles of germline predisposition variants and somatic mutations on breast cancer cells and the tumor microenvironment.

F. Martins Rodrigues, K. Gallant, R. Jayasinghe, M. Iglesia, A. Houston, S. Chen, P. Lal, R. Fields, W. Gillanders, F. Chen, L. Ding;
Washington University in St. Louis, Saint Louis, MO

While great progress has been made in the understanding and treatment of cancer, tumor heterogeneity remains a diagnostic and prognostic challenge. Single-cell sequencing techniques and high-resolution cellular imaging now afford researchers the ability to investigate the effects of germline variants (especially when compared to somatic mutations) on molecular characteristics of cancer cells and non-cancer cells in the tumor microenvironment (TME). Here, we investigated a breast cancer (BRCA) cohort of over 100 individuals, for which we have generated sc/sn RNA-seq, snATAC-seq, and CODEX imaging data as well as bulk whole exome sequencing and RNA-seq data. We identified 21 BRCA cases carrying pathogenic and likely pathogenic rare germline variants in known cancer predisposition genes, such as BRCA2, BRIP1, ATM, and TP53. These predisposition genes showed diverse expression patterns across stromal and immune cell types, indicating roles in cell types beyond breast epithelia. For cases carrying pathogenic germline variants in such genes, we use snRNA-seq/snATAC-seq to assess gene expression changes and pathway alterations (e.g.,HRD and apoptosis) across all cell types and investigate phenotypic changes associated with pathogenic germline variants in cancer cells compared to stroma and immune cells in the TME. By evaluating chromatin accessibility changes and allele-specific expression, we reveal the connection between epigenetic regulators and differential roles of germline variants across cell types. Finally, the integrated analysis of germline variants and somatic mutations from predisposition genes at single cell resolution broadened our understanding of the role of germline variants in TME during tumorigenesis.

#1774 Examination of variants of unknown significance (VUSs) and co-occurring mutations from comprehensive genomic profiling (CGP) results in a cross tumor model.

T. Simon, R. Oliver, R. Harrell, P. Conkling, E. Paul;
Ontada, Boston, MA

Data from Comprehensive Genomic Profiling (CGP) generates both actionable and non-actionable results for oncology patients. While the actionable results are included in reports, the non-actionable are less often investigated. This study explored the results of both actionable and non-actionable mutations as well as the co-occurrence of mutations in a pan-tumor model.In this study, we explored data generated from 41 oncology practices where patients (+ 18yo) were tracked within the iKnowMed EHR and had received CGP as part of their care. CGP is defined as a large-scale (300+ genes) NGS-based assay. As part of this study, results between 2017 - present were collected across tumor types and stages.Assessment of the data pool demonstrated that a majority of the 44,769 profiles were generated from Stage IV patients (n=24,545) and NSCLC, colorectal, and breast cancers were the highest representing disease populations in the cohort. The tested gene targets aligned with the diseases that were most represented, with EGFR, PIKC3A, ERBB2, and KRAS genes as the most common genes to have documented results . Exploration of the actionable biomarkers showed the expected pathogenic mutations in the relevant disease context. When exploring the remaining reported variants, it was found that CGP results yield a significant ($p \leq 0.05$) number of VUSs as well (n=23106). The complexity of mutations was also examined on an intra- and intergenic basis. Intragenic assessment for variants focused on complex mutations, qualified by 2+ mutations including multiple SNV, multiple indels, or SNVs and deletions in the same gene. Trends of co-occurring alterations were not obvious, with TP53 having the most reported occurrences of complex mutations (n=7491). Exploration moved to intergenic assessment and, while disease-bounded exploration did not reveal trends, a disease-agnostic approach revealed co-occurrences of mutations. The top 5 genes with co-existing mutations are TP53, KRAS, APC, PIK3CA, and ATM. Co-occurrence of alterations in any gene with tumor agnostic markers was also explored, notably TMB. The presence of mutation with TMB-high was similar to that of intergenic complex mutations and the same genes had high co-incidence levels. This study has demonstrated that CGP data provide insights beyond actionable biomarkers, and that a pan-tumor approach allows new trends to be observed. Real-world data bias for reported biomarkers skewed the results observed. Taking the results out of disease context allows us to visualize new possibilities for identifying variants implicated in disease processes. Future studies could allow the exploration of unreported data from raw files, overlaid with cellular pathways on complex patient profiles to identify exploitable targets. Inclusion of treatment and outcome data can demonstrate the influence of genetics on a patient journey.

#1775 The profiling of *MTAP* homozygous deletion (MTAPhd) in a Chinese pan-cancer cohort.

Shuirong Zhang, Wenjin Liu, Mingmin Wang, Caiping Chen, Xiaowei Dong, Aodi Wang, **Kai Wang**

OrigiMed, Shanghai, China

Background: Protein arginine methyltransferase 5 (PRMT5) is an enzyme that catalyzes the transfer of methyl groups from S-adenosylmethionine (SAM) to the arginine residues on histones and other proteins. The dysregulation of this methylation is critical in the development of certain cancers. MTAPhd can cause anti-tumor effect of PRMT5 inhibitor via a synthetic lethality mechanism.
Methods: 9,202 cases were collected and subjected to NGS for genomic alteration detection. The testing was carried out by a College of American Pathologists (CAP) accredited and Clinical Laboratory Improvement Amendments (CLIA) certified laboratory, Shanghai, China. The hybrid capture panel covered 450 genes, heterozygous snps were used for MTAPhd identification, the detection rate of MTAPhd was measured and fisher's exact test was used for analyzing the correlation with age, stage, subtype and gender.
Results: In total, 6.8% (626/9202) cases had MTAPhd. In 626 dataset, 220 was female and 406 was male. Age was from 3 to 91 with median 63. 25, 43, 74 and 119 was in clinical stage I, II, III, IV, respectively. Patients with age < 60 had lower odds (OR 0.60; 95% CI 0.51-0.71; p < 0.001) of occurring MTAPhd compared to age >= 60. Clinical stage I and II had lower odds (OR 0.59; 95% CI 0.44-0.79; p < 0.001) compared to stage III and IV. Adenocarcinoma had lower odds (OR 0.17; 95% CI 0.14-0.21; p < 0.001) compared to squamous carcinoma. Female had lower odds (OR 0.70; 95% CI 0.59-0.83; p < 0.001). MTAPhd occurred in multiple cancers, among which it was more likely to occur in esophageal carcinoma (72/298; 24.2%), brain tumor (14/66; 21.2%) and bladder urothelial carcinoma (67/348, 19.3%). The detection rates of the top three cancer types in the sample size were lung cancer (208/2743, 7.6%), pancreatic cancer (48/794, 6.0%) and colorectal carcinoma (7/756, 0.9%), respectively. Lung squamous cell carcinoma (LUSC) (13.5% vs 19.3%, p = 0.008) and bladder urothelial carcinoma (BLCA) (19.3% vs 25.5%, p = 0.045) of Chinese cohort had lower rate of MTAPhd compared to TCGA cohort. 53 out of 626 had no driver mutations associated with recommended drug use currently. One lung adenocarcinoma patient received crizotinib (*MET* amplification) in 2021, then changed to osimertinib (*EGFR* exon19del), underwent chemotherapy in 2023, developed hip metastases, and was currently undergoing radiotherapy.
Conclusion: This study, for the first time, revealed that MTAPhd were found in approximately 6.8% of Chinese patients across different tumors. Patients with age >= 60, stage III and IV, squamous carcinoma and male, were more likely to occur MTAPhd. Esophageal carcinoma and brain tumor had a higher detection rate. Chinese cohort had lower detection rate of MTAPhd for LUSC and BLCA compared to TCGA cohort. Our results indicated that PRMT5 inhibitors would be a potential therapeutic strategy to be considered for Chinese patients with MTAPhd in the near future.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolic Pathways 2
Poster Session

#1779 *De novo* purine pathway enzyme ATIC promotes tumor progression and modulates metabolic reprogramming in breast cancer.
D. Murthy, K. S. Attri, J. Park, B. A. Kaipparettu;
Baylor College of Medicine, Houston, TX

Breast cancer (BC), a complex and heterogeneous disease, poses a significant global health challenge with a pressing need for enhanced prognostic markers and therapeutic targets. This study focuses on 5-Aminoimidazole-4-carboxamide ribonucleotide formyltransferase/IMP cyclohydrolase (ATIC), an enzyme essential in *de novo* purine biosynthesis and previously implicated in myeloma and hepatocellular carcinoma progression. Leveraging publicly available datasets, including TCGA, METABRIC, and GENT2, we identified elevated ATIC expression in BC tissues compared to normal tissues. Notably, patients with elevated ATIC expression displayed significantly diminished overall survival rates, underscoring ATIC's potential as a prognostic marker. Functional assays involving ATIC downregulation in BC cell lines revealed suppressed cell growth, migration, and increased sensitivity to chemotherapeutic drug, Doxorubicin, implicating ATIC in BC progression. Further, RNA-sequencing analysis of ATIC knockdown (KD) BC cell lines revealed a positive correlation between ATIC expression and the activation of MYC and E2F-regulated pathways. The marked attenuation in cell growth and various tumor properties upon ATIC KD provides mechanistic insights into the role of ATIC in fueling BC progression, potentially through the modulation of MYC and E2F target gene expression. Gene Set Enrichment Analysis (GSEA) on differentially expressed genes identified between tumors with high ATIC expression and low ATIC expression in BC patients from the TCGA cohort revealed a notable enrichment of genes associated with MYC and E2F targets, providing additional support for the observed molecular associations in our experimental model. Intriguingly, ATIC KD in Triple Negative BC cell line unexpectedly led to an increase in fatty acid β-oxidation (FAO), uncovering a metabolic vulnerability in these cells. In conclusion, this study unravels the multifaceted role of ATIC in BC, demonstrating its influence on BC tumor progression and metabolism. The observed increase in FAO upon ATIC KD presents a novel metabolic vulnerability that could be explored for targeted therapeutic interventions in BC. This comprehensive analysis contributes valuable insights toward understanding ATIC as a potential therapeutic target and prognostic indicator in BC.

#1780 Utilizing bisbiguanide compounds to disrupt metabolic heterogeneity in non-small cell lung cancer.

V. Y. Matsuk, C. M. Knippler, J. L. Arnst, I. E. Robinson, T. O. Khatib, M. Shanmugam, T. Ganesh, J. K. Mouw, A. I. Marcus;
Emory Winship Cancer Institute, Atlanta, GA

Metastasis accounts for 90% of cancer-related deaths; however, the molecularmechanisms by which cancer cells invade and metastasize remain poorly understood.Around 80% of lung cancer patients present with metastatic disease and have only a 5%5-year relative survival. Metastases are often seeded by heterogeneous cells that invadecollectively in cellular packs. However, most studies and treatments focus on bulk cellularpopulations leaving subpopulations that drive metastasis masked. We previouslypublished on metabolic heterogeneity within collectively invading lung cancer cells andidentified the bisbiguanide compound alexidine as a disrupter of lung cancermitochondrial metabolism and invasion. To expand on these findings, we developed newbiguanides and identified promising candidates, AX-4 and AX-7. These analogs inducemitochondrial structural defects and cause metabolic rewiring. Treated lung cancer cellsexhibited reduced oxygen consumption and increased lactate production. Importantly,AX-4 and AX-7 reduced collective cell invasion, highlighting the potential of these newbiguanides to limit cancer metastasis. Taken together, we have developed new chemicaltools to disrupt mitochondrial metabolism. These tools will be useful to further parse theroles of metabolically heterogenous cancer cells on tumor growth and metastasis.

#1781 Elucidation of glutathione related dipeptide metabolism in cancer.

F. Alimohammadi[1], F. Hecht[1], M. Zocchi[1], E. Tuttle[1], G. Asantewaa[1], T. Scales[1], N. Ward[2], G. DeNicola[2], I. Harris[1];
[1]University of Rochester Medical Center, Rochester, NY, [2]Moffitt Cancer Center, Tampa, FL

There is a long-standing belief that supplementation with antioxidants could potentially treat diseases like cancer. Recent year studies showed, however, that they can behave like a double-edged sword and can also increase tumor proliferation and metastatic progression. The exact mechanism behind antioxidants' impact on tumors is poorly understood. Glutathione (GSH), the most abundant antioxidant in mammalian cells, is a tripeptide containing glutamate, cysteine, and glycine. GSH levels are reported to be significantly elevated within the extracellular space of the tumor. Our preliminary findings show that the breakdown of extracellular GSH can support tumor cell survival under cystine-free conditions. Extracellular GSH catabolism releases cysteinylglycine, which can enter the cell through a dipeptide transporter and be further broken down to supply cysteine and glycine to cells. Alternatively, cysteinylglycine can also be broken down extracellularly into cysteine and glycine, allowing for the uptake of these individual peptides. The molecular mechanisms surrounding the utilization of GSH-breakdown products by the tumor cell are largely unknown. We hypothesize that the proteins responsible for the supply of cysteinylglycine to the tumor cell are required for tumor growth and survival. To test this, we will use unbiased genetic and pharmacologic screening approaches to elucidate the proteins involved in cysteinylglycine processing. Preliminarily, we have found that inhibitors of dipeptidases prevent the ability of cysteinylglycine to support tumor cell survival under cystine starvation, suggesting that tumors require downstream utilization of GSH products. By identifying the mechanisms involved in cysteinylglycine breakdown and supply to tumor cells, we will potentially reveal novel therapeutic targets for cancer treatment, including those not relied upon by normal tissues. Further, our studies will potentially provide a better understanding of how antioxidants impact tumor growth and progression.

#1783 Understanding lipogenesis in bladder cancer.

J. Leak, D. Matye, E. Abbott, B. Woolbright, J. A. Taylor III;
University of Kansas Medical Center, Kansas City, MO

Cancer cells are known to have different metabolic needs for growth and survival and by understanding these demands of individual cancers, targeted novel therapies may be developed. Lipogenesis and ß-oxidation serve to balance lipid levels in the cell. Lipogenesis is rate limited by a series of reactions that include enzymes fatty acid synthase (FASN) and acetyl-CoA carboxylase (ACC1) that facilitate lipid formation; whereas ß-oxidation is rate limited by the transporter carnitine palmitoyltransferase 1 (CPT1) and the enzyme thiolase that catalyzes the final step of the ß-oxidation cycle. Many cancers are dependent on lipogenesis, but the role of these factors in BCa is poorly defined. The Cancer Genome Atlas was used to assess levels of relevant metabolic proteins in normal and cancerous BCa tissue, and showed FASN levels were elevated in BCa tissue and were associated with worse survival. The purpose of this project is to better understand the metabolic demands of bladder cancer (BCa) cell lines, and we hypothesized lipogenesis is a major metabolic pathway for BCa cell growth. T24, HTB-5, and HTB-9 BCa cell lines were used to evaluate the role of metabolism. CPT1 was inhibited with etomoxir, thiolase with trimetazidine, FASN with cerulenin, and ACC1 with 5-(Tetradecyloxy)-2-furoic acid (TOFA). Cell viability was assessed at 48 and 72 hours with an enzymatic activity assay measuring ß-hexosaminidase activity as a surrogate for cell proliferation. The IC50 (concentration of a drug to reduce cell proliferation by 50%) was calculated from this data. At 48 hours, cerulenin-treated cells had an IC50 of 11.80 µM, 13.28 µM, 18.31 µM for HTB-9, T24, and HTB-5 respectively. At 48 hours, TOFA-treated cells had an IC50 of 64.25 µM, 59.29 µM, 32.03 µM for HTB-9, T24, and HTB-5 respectively. Cellular proliferation was not inhibited by CPT1 or trimetazidine at enzymatic IC50 concentrations consistent with their known levels of efficacy. When adding the lipid palmitate (20µM) to TOFA-treated cells, it appeared to mediate a rescue of cell proliferation almost to control, although statistical significance was not achieved. Crystal violet assays were performed to assess long-term cell viability. There was visible reduction in colony formation in a dose-dependent manner at 5 µM and 10 µM cerulenin in T24 cells at 14 days of culture, and there were similar results in HTB-9 cells treated with 20 µM and 40 µM TOFA at 17 days. In both cerulenin and TOFA-treated cells, there was elevated cleaved caspase-3 protein expression, indicating initiation of apoptosis. In conclusion, inhibition of lipogenesis in BCa cell lines reduces cell viability by reducing proliferation and inducing apoptosis whereas inhibitors of ß-oxidation did not produce the same effect at relevant concentrations. These data indicate lipogenesis is a key metabolic pathway for BCa cell growth.

#1784 Glucose metabolism and *de novo* palmitate synthesis under normoxia and hypoxia in breast cancer cells that preferentially metastasize to lung and liver.

M. A. Layosa[1], M. Conrad[1], S. Hursting[2], D. Teegarden[1];
[1]Purdue University, West Lafayette, IN, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Cancer cells are exposed to variable oxygen and nutrient availability during the metastatic process which can influence metabolic adaptations of cancer cells to metastasize to distant sites. Thus, we investigated the metabolic adaptations of breast cancer cells that preferentially metastasize to lung (metM-Wnt^{Lung} cells; MLg) and liver (metM-Wnt^{Liver} cells; MLr) in normoxia and hypoxia and at different glucose concentrations. In normoxia, ^{14}C-glucose uptake is similar, but mRNA abundance of hexokinase, the initial rate-limiting step in glycolysis, was 22% higher in MLg cells. This is consistent with higher $^{13}C_6$-glucose flux into glycolytic metabolites pyruvate (M+3) and lactate (M+3) in MLg compared to MLr. Also, *de novo* palmitate synthesis from $^{13}C_6$-glucose was 7.6% higher in MLg and was accompanied by higher mRNA expression of ATP-citrate lyase (ACLY), which converts citrate to acetyl-CoA for fatty acid synthesis. These suggest greater glucose metabolism in MLg compared to MLr in normoxia, consistent with reduced viability of MLr by 39% in high glucose (25 mM) concentrations. Further, mRNA abundance of CPT1A, a rate-limiting step in fatty acid oxidation, is 23% higher in MLg. Moreover, the fatty acid oxidation inhibition (etomoxir) reduced viability of MLg by 26.7% compared to MLr, suggesting that fatty acid synthesis and oxidation are critical for MLg. Protein expression of HIF1α, a transcription factor that induces glycolysis during hypoxia, is 1.5-fold higher in MLr than MLg in normoxia, consistent with higher MLr mRNA abundance of pyruvate dehydrogenase kinase (PDK1), a target of HIF1α that inhibits pyruvate dehydrogenase (PDH) activity. Surprisingly, mRNA abundance of pyruvate carboxylase (PC), the enzyme that converts pyruvate to oxaloacetate, is also higher in MLr (39%) than MLg, thus supporting a potential alternative mechanism for glucose metabolites to enter the TCA cycle in normoxia in MLr. In hypoxia, viability of MLr, relative to MLg, increased by 11% at high glucose concentration. This was accompanied by higher hexokinase (33%) and PDK1 (83%) mRNA abundance suggesting MLr's shift towards a glycolytic phenotype. However, *de novo* palmitate synthesis from $^{13}C_6$-glucose is higher in MLg, suggesting that palmitate synthesis is maintained in MLg even in hypoxia. Altogether, results demonstrate that glucose utilization shifts in breast cancer cells that preferentially metastasize to lung vs liver, but *de novo* fatty acid synthesis is higher in MLg in different oxygen conditions. Thus, targeting breast cancer cells' adaptation to glucose and *de novo* fatty acid synthesis may be a potential strategy to prevent breast cancer progression to distant organs.

#1785 The role of *BRCA1* on metabolic pathways in an *in vivo* system.

S. L. Hembruff, A. Dekonenko, J. Thyfault, M. Sardiu, M. Washburn, R. A. Jensen, L. M. Harlan-Williams;
University of Kansas Medical Center, Kansas City, KS

The role of *BRCA1* in cellular metabolism is not well characterized and what we do understand has been mostly demonstrated *in vitro*. Our studies aim to fully characterize the role of *BRCA1* in metabolic pathways in a whole-body system. *In vivo* studies using C57BL/6 wild-type and transgenic humanized *BRCA1* mice demonstrate the effect of human *BRCA1* on the whole-body metabolic phenotype and start to elucidate the mechanism by which this occurs. We used Promethion metabolic chambers and glucose tolerance tests to measure a number of metabolic outputs of male and female mice that had either normal mouse *Brca1* gene expression (wild-type/WT mice) or a knock-out mouse *Brca1*/knock-in human *BRCA1* (humanized/HU mice). Humanized *BRCA1* mice are more lean, hyperactive and demonstrate a sexual dimorphism in glucose tolerance when compared to wild-type mice on the same genetic background. To begin to elucidate the mechanisms behind the observed metabolic phenotype, we used a metabolic tissue, female mouse skeletal muscle, to perform mass spectrometry, SuperArray, and Western blot analysis. Proteomic samples were sent to the IDeA National Resource for Quantitative Proteomics at the University of Arkansas Medical Sciences for processing and analysis. Proteomic and genomic analysis showed changes in a number of metabolic pathways that may be implicated in the observed whole body metabolic phenotype. We can conclude that changing the expression levels of *BRCA1* in an *in vivo* model altered the overall metabolic profile of C57BL/6 mice. This is the first *in vivo* evidence demonstrating the effects of *BRCA1* expression in whole body metabolism.

#1786 Metabolic rewiring induced by protein or calorie restriction provides unique therapeutic vulnerabilities in translocation and select clear cell renal cell carcinomas.

S. A. Orsi[1], C. Rupert[1], S. Colligan[1], M. Chang[1], A. Jawadwala[1], I. Delle Fontane[1], F. de Nigris[2], R. Pili[1];
[1]University at Buffalo, Buffalo, NY, [2]University of Campania L. Vanvitelli, Naples, NY

While the approval of several combinations with immune checkpoint inhibitors have significantly improved the outcome of kidney cancer patients, advanced clear cell and non-clear cell renal cell carcinoma (RCC) remain a clinical challenge. There has been a longstanding interest in using dysregulated metabolism as a therapeutic target due to its association with the pathogenesis and progression of several cancer types. As one of these highly metabolic tumors, RCC has the potential to greatly benefit from strategies targeting tumor metabolism. Dietary interventions are an innovative adjunct therapy that has the potential to induce a wide range of anti-cancer effects by disrupting metabolism due to the role diet plays in providing tumors with macromolecules for energy metabolism. Unfortunately, tumor cell plasticity, intratumor heterogeneity, and a lack of understanding regarding metabolic vulnerabilities in tumors limit the efficacy of implementing these strategies and a fundamental gap in the field remains as to how basic metabolic requirements of the tumor can be targeted with specific dietary interventions. In this study, the inherent metabolic phenotypes of translocation RCC (tRCC) and clear cell RCC (ccRCC) were characterized by integrating *in vivo* metabolomics and transcriptomics data, assessing mitochondrial and glycolytic activity *in vitro* via Seahorse, and performing immunohistochemical analyses of patient samples. Interestingly, the respective mitochondrial and glycolytic dependencies in tRCC and ccRCC patient-derived xenograft (PDX) models appear to influence the response to nutrient deprivation as seen by *in vitro* assays conducted after amino acid or glucose restriction. Importantly, these results indicate that dietary interventions may be able to selectively target metabolic vulnerabilities in tRCC and ccRCC. Ongoing combination studies with either protein or calorie restriction and targeted therapies, such as standard of care receptor tyrosine-kinase inhibitors, suggest the benefit of using dietary interventions as an adjunct therapy in RCC. Overall, these studies reveal that selective dietary interventions alter the metabolic landscape of RCC and expose vulnerabilities that can be exploited with targeted therapy. As dietary interventions are a safe, affordable, and potentially well tolerated adjunct therapy, we anticipate that the results of these studies will provide the biologic and mechanistic support for translating this strategy to advanced RCC patients.

#1787 The β3-adrenergic receptor as novel target of metabolic phenotype in Ewing sarcoma.

Cristina Banella[1], **Francesco Carrozzo**[1], Laura Zocca[1], Amada Pasha[1], Gianluca Mattei[2], Marina Mola[1], Lara Ballerini[1], Nicla Lorito[3], Annalisa Tondo[1], Claudio Favre[1], Maura Calvani[1]

[1]Meyer Children's Hospital - IRCCS, Firenze, Italy,[2]University of Florence Department of Information Engineering, Firenze, Italy,[3]University of Florence, Department of Experimental and Clinical Biomedical Sciences, Firenze, Italy

Purpose of study: Metabolic targeted therapies may represent an innovative strategy in Ewing sarcoma (ES).
Introduction: Ewing sarcoma (ES) is highly aggressive round cell mesenchymal neoplasm, most often occurring in children and young adults. Metabolic peculiarities of ES cells are indeed involved in tumor growth, survival and resistance to therapy. We have further investigated apoptotic role of ***β***;;3-adrenergic receptor (***β***;;3-AR) SR59230A (SR) antagonist for its ability to reduce cells viability due increased oxidative stress, now we underline the metabolic role of SR.
Materials & Methods: The metabolic profile after SR administration in A673 ES cell model was studied using the Seahorse XF Analyzer. Viability was evaluated with MTS. Changes in gene expression was evaluated with RNA sequencing. Western blot analysis and Immunofluorescence was performed for redox signature and metabolic alteration. Ros production and cell death was assessed by flow cytometry.
Results: Metabolic analysis reveals glucose and fatty acid dependency in A673 cells using the Fuel Flex Test of Seahorse XFe Analyzer. Quantification of transcript abundance using Salmon in A673 after SR treatment showed decrease in response to reactive oxygen species, increase of Thioredoxin Interacting Protein (TXNIP) inhibits the antioxidative function of thioredoxin, moreover reduced glucose uptake, consequently, decrease NADPH/NADP resulting in the accumulation of ROS coincident with a decrease of GLUT1, SOD2, TrDX an increase of LC3IIA protein expression. SR enhances A673 pyruvate dependency, and decrease glyco and mito ATP production rate, more over observed under glucose deprivation. Furthermore, apoptotic effect was significantly amplified when cells were under nutrient starvation, revealing a 56% apoptotic rate after 24 hours of SR treatment.
Conclusion: SR antagonist of ***β***;;3-AR and combination of SR with BUF could be an innovative therapeutic option to raise awareness ES.

#1789 Machine learning-based method to analyze metabolic fluxes of patient tumors.

B. Meghdadi, A. Mittal, A. J. Scott, S. Palavalasa, D. R. Wahl, D. Nagrath;
University of Michigan, Ann Arbor, MI

Personalized oncology must overcome the complex challenge of distinct cancer phenotypes in each patient, formed in part in response to unique metabolic crosstalk among cells in the tumor microenvironment which can be a determining factor in therapeutic response. Although isotope tracing sheds light on differences of metabolite enrichments in tumor and normal tissues, quantifying the metabolic fluxes in patients remains elusive. The conventional metabolic flux analysis tools are unable to estimate patient metabolic fluxes because we are limited to a single time point enrichment datapoint from each patient's in-vivo measurement at isotopic non-steady state. We overcame this challenge by generating training data from the limited patient data and implementing a machine learning model to predict fluxes. To generate training data, we first simulated constrained random fluxes and enrichment patterns at different time points using patient circulating metabolites enrichment via an isotopic non-stationary metabolic flux analysis framework. Using this data, we trained a convolutional neural network to predict flux ratios. To validate our model, we compared predicted flux ratios to the experimental data from mouse models for two different treatments. Our recent findings from a glioblastoma (GBM) mouse model study using conventional metabolic flux analysis revealed higher de novo guanosine monophosphate (GMP) synthesis in GBM than normal cortex. These tumors can be sensitive to mycophenolate mofetil (MMF) which inhibits inosine monophosphate dehydrogenase, but only if the major source of GMP production is de novo synthesis and not salvage. Our machine learning model can discriminate between sources of GMP synthesis in patients, thus enabling prediction of potential responders. Furthermore, we previously showed that serine uptake is higher in GBM than normal cortex, and a serine- and glycine-restricted diet slows tumor growth in mice. While both circulating serine and microenvironment-derived serine could account for serine uptake in GBM, we hypothesized that the circulating serine dependence would better predict response to dietary serine depletion. Hence, we combined patient scRNA-seq and metabolomics data to feed our neural network framework to estimate microenvironmental and circulating serine uptake in six patients with brain cancer. Thus, we have shown that our model can identify patients who will benefit from MMF treatment or a serine- and glycine-restricted diet, enabling administration of highly effective personalized treatments for GBM patients.

#1790 Pyruvate carboxylase regulates tumor progression through central carbon metabolism and immunosuppression.

M. F. Coleman[1], E. Kulkoyluoglu Cotul[2], A. J. Pfeil[1], A. N. Ho[1], E. N. Devericks[1], M. H. Safdar[2], H. Chen[2], N. Attaar[1], V. A. Kiesel[1], D. Teegarden[2], S. D. Hursting[1], M. K. Wendt[3],

[1]UNC Chapel Hill, Chapel Hill, NC, [2]Purdue University, West Lafayette, IN, [3]University of Iowa, Iowa City, IA

The tumor microenvironment (TME) is characterized by metabolic reprogramming and immune evasion, essential features in tumor progression. Tumor metabolic dysregulation, particularly the high production of lactate, plays a pivotal role in suppressing antitumor immunity within the TME. Pyruvate carboxylase (PC), responsible for converting pyruvate to oxaloacetate, is a critical determinant for lung metastasis in triple-negative breast cancer (TNBC). Herein we test the hypothesis that PC-mediated regulation of central carbon metabolism controls TME immunosurrveilance. Wild-type C57BL6/J and NSG mice received orthotopic injections of E0771 or M-Wnt tumor cells with shRNA targeting PC or a scramble control. RNA from tumors underwent transcriptomic profiling using Affymetrix Clariom D microarray (n=3-6/group per experiment). Gene set enrichment analysis identified pathways enriched in each condition, including a PC-associated hypoxia signature. Immunohistochemistry with anti-CD3 antibody and full spectrum flow cytometry assessed T cell infiltration and TME immune cell composition. Untargeted metabolomics, extracellular flux analysis, and high-resolution respirometry determined how loss of PC altered cellular metabolism. We found that suppressing PC expression increased primary tumor growth (~2 fold), potently drove immunosuppression, and remodeled cellular metabolism towards lactate production. Injection of PC-suppressed cells increased regulatory T cell levels in wild type mice. Importantly, PC-suppressed cells injected into NSG mice, which lack T, B, and NK cells, demonstrated slower, rather than accelerated, tumor growth. PC-suppression reduced oxygen consumption rate (OCR), but supply of anaplerotic carbon through exogenous malate or oxaloacetate restored OCR. Conversely, both the rate of and reliance on lactate production was increased by PC suppression. Notably, loss of immunosurveillance following downregulation of PC was reversed by inhibiting lactate transport. Additionally, lower PC expression was associated with increased hypoxia in tumors, supporting in vitro evidence of PC-repression by hypoxia. In summary, hypoxia-induced PC suppression emerges as a crucial mechanism through which primary tumors hinder antitumor immunity, partly via increased lactate production. These findings underscore the significance of PC-directed tumor metabolism as an understudied nexus in the interplay between tumor progression and antitumor immunity.

#1791 Metabolic rewiring promotes metastatic potential upon glutamine deprivation in STK11 null KRAS-driven lung adenocarcinoma.

S. Prior, L. Sands, S. Lenahan, H. Sarausky, M. Scheiber, D. Seward, P. Deming;
University of Vermont, Swanton, VT

Lung adenocarcinoma (LUAD) with concurrent oncogenic KRAS and STK11 loss-of-function mutations define an aggressive subtype characterized, in part, by increased metastasis. Loss of STK11, a tumor suppressor and nutrient sensor, leads to dysregulation of many critical cellular processes, including metabolism. As such, STK11 null cancers are “glutamine addicted” to support proliferative properties and the tumor microenvironment therefore becomes glutamine depleted. We hypothesize that conditions of glutamine stress promote metastatic potential in STK11 null KRAS-driven LUAD due to metabolic rewiring. To test this hypothesis, we utilized a cell culture model of KRAS-driven LUAD cell lines and corresponding STK11 knockout cell lines (ΔSTK11). Parental and ΔSTK11 cells underwent the Seahorse mitochondrial stress test in full and glutamine-deficient media to obtain parameters of mitochondrial respiration at baseline and under conditions reflective of the tumor microenvironment, respectively. At baseline, ΔSTK11 cells had a hypermetabolic phenotype associated with enhanced glutamine utilization. Deprivation of glutamine resulted in decreased mitochondrial respiration along with a significant increase in live, detached ΔSTK11 cells compared to the parental line. Upon further examination, the detached ΔSTK11 cells maintained the ability to re-adhere and proliferate in full media while the detached parental cells did not. Additionally, expression of pro-survival, anti-apoptotic and EMT markers in ΔSTK11 cells were increased upon glutamine deprivation. To determine the mechanism(s) underlying this pro-metastatic phenotype, we employed heavy nitrogen labeling which revealed an upregulation of the hexosamine biosynthetic pathway (HBP). The HBP is an offshoot of glycolysis that serves as a central hub to regulate many cancer fitness pathways via O-GlcNAcylation; the addition of a GlcNAc moiety to serine/threonine residues of target proteins. Further assessment of O-GlcNAcylation levels via western and far western blot analysis revealed that parental cells had decreasing HBP flux concordant with decreasing glutamine concentration while ΔSTK11 cells, conversely, had enhanced HBP flux upon decreasing glutamine availability. These observations suggest ΔSTK11 cells utilize the HBP as a protective shunt under decreased glutamine availability. We are currently characterizing the invasive potential and anchorage-independence of parental and ΔSTK11 LUAD cells upon glutamine deprivation. Future studies aim to establish the impact of HBP perturbation, both genetically and pharmacologically, on the described measures of metastatic potential. Overall, this work reveals novel insight into the molecular mechanisms altered downstream of STK11 loss that link glutamine metabolism with metastatic properties in KRAS-driven LUAD.

#1792 Synthetic lethal vulnerabilities stemming from inhibition of one carbon metabolism in anaplastic thyroid cancer.

A. Forrest, A. Ahsan, **A. Di Cristofano**;
Albert Einstein College of Medicine, Bronx, NY

Reprogramming of metabolic processes by tumor cells is essential to cope with their increased proliferative activity, and with the challenges of the unique microenvironment they inhabit. These metabolic alterations are attractive targets to design novel therapeutic approaches.The most aggressive subtype of thyroid cancer, Anaplastic Thyroid Cancer (ATC), is often unresectable at presentation, highly resistant to therapy and usually lethal. We have recently discovered that ATCs overexpress several genes encoding enzymes involved in one-carbon metabolism (1C-Met), which utilizes serine and dietary folates to produce glycine and tetrahydrofolate-bound one-carbon units, required for nucleotide biosynthesis and for NADPH and glutathione (GSH) production. We have shown that i) the increased activity of the 1C-Met pathway supports the high purine demand of ATC; ii) inhibition of 1C-Met impairs tumor growth in vitro and in vivo, leading to growth arrest; iii) inhibition of 1C-Met renders thyroid cancer cells glycine-auxotroph.We now demonstrate that the profound addiction of ATC cells to 1C-Met creates a series of targetable vulnerabilities that can be harnessed to induce massive ATC cell death.Our new data demonstrate that:1- The purine depletion consequent impaired 1C-Met induces replicative stress and triggers the DNA Damage Response (DDR). Activation of DDR, coupled with the absence of functional TP53 in the vast majority of ATCs, leads to synthetic lethality between inhibition of 1C-Met and G2/M checkpoint kinases.2- Inhibition of 1C-Met in ATC cells generates an absolute dependence on extracellular glycine uptake. We have identified and validated the main glycine transporter(s) in ATC cells and show that inhibition of 1C-Met is synthetic lethal with inhibition of glycine uptake.3- Impaired 1C-Met leads to increased oxidative stress and decrease of NADPH and glutathione levels. These alterations create a synthetic lethality relationship with the glutathione-depleting activity of PRIMA-1 (APR246), a small molecule originally identified as a compound restoring mutant p53 conformation and function, but later shown to be converted within cells into the reactive electrophile methylene quinuclidinone, which acts in a p53-independent manner through a variety of mechanisms, including reduction of cellular GSH levels.Our data shed light on the molecular consequences of 1C-Met upregulation in ATC and support the efficacy of novel rationally designed therapeutic approaches with curative intent not only for ATC, but also for other aggressive, dedifferentiated solid tumors.

#1793 Transmembrane serine protease TMPRSS11B promotes tumorigenesis in lung squamous cell carcinoma through enhanced lactate export and modulation of the tumor microenvironment.

H. Sunil[1], B. L. Updegraff[2], J. Zhu[1], L. Thomas[1], B. M. Evers[1], J. R. Clemenceau[3], I. Barnfather[3], J. D. Minna[1], R. J. Deberardinis[1], T. G. Oliver[4], T. Hwang[3], K. A. O'Donnell[1];

[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Seagen, Bothell, WA, [3]Mayo Clinic, Jacksonville, FL, [4]Duke University, Durham, NC

Lung cancer is the leading cause of cancer-related deaths worldwide. Existing therapeutic options have limited efficacy, underscoring the critical need for the identification of new actionable therapeutic targets. We previously identified the Transmembrane Serine Protease *TMPRSS11B* as a novel gene that promotes the transformation of human bronchial epithelial cells *in vitro* and induces tumorigenesis *in vivo*. TMPRSS11B promotes extracellular release of Basigin, an obligate chaperone of the lactate monocarboxylate transporters MCT1/4, enhancing lactate export and glycolytic metabolism, and thereby promoting tumorigenesis. Importantly, *TMPRSS11B* is frequently overexpressed in human lung squamous cell cancers (LSCC) and high expression is associated with poor patient survival. Moreover, as a cell surface protein and enzyme, TMPRSS11B represents a tractable target for therapeutic intervention. To investigate whether TMPRSS11B activity impacts the host immune system and the tumor microenvironment (TME), we evaluated the effect of *Tmprss11b* depletion in a syngeneic LSCC mouse model, KLN205. *Tmprss11b* loss of function in KLN205 LSCC cells significantly reduced tumor burden in immunocompetent mice and triggered an accumulation of CD4+ T cells. We are currently extending these studies by investigating the effect of *Tmprss11b* loss of function using CRISPR/Cas9 editing in the *Rosa26*$^{\text{LSL-Sox2-IRES-GFP}}$; Nkx2-1$^{\text{fl/fl}}$; *Lkb1*$^{\text{fl/fl}}$ (SNL) mouse model of LSCC. Tumor burden analysis and pH-sensitive fluorescent imaging are ongoing to assess changes in lactate accumulation. Moreover, RNA FISH analysis and spatial transcriptomics revealed that *Tmprss11b* expression is highly enriched in lung squamous tumors compared to lung adenocarcinomas and normal lung in SNL mice. Spatial analysis of the transcriptome is currently ongoing to assess the effects of *Tmprss11b* expression on the TME. Collectively, these studies will elucidate the molecular mechanisms through which TMPRSS11B promotes tumor growth and alters the tumor microenvironment in LSCC.

#1794 PAF1 reprograms metabolism in pancreatic cancer by interacting with HIF1α.

A. O. Ogunleye, N. Gayen, S. Marimuthu, R. Nimmakayala, S. Rauth, Z. Alsafwani, J. L. Cox, S. K. Batra, M. P. Ponnusamy;
University of Nebraska Medical Center, Omaha, NE

Background: Reprogrammed cellular metabolism has been refocused on in the past decade, as many cancer cells rewire various metabolic pathways to facilitate their survival, unlimited cell growth, and division. RNA Polymerase II-Associated Factor 1 (PAF1)/Pancreatic Differentiation 2 (PD2) is a core subunit of the human PAF1 Complex (PAF1C) that regulates the RNA polymerase II function during transcriptional elongation in normal cells; however, its overexpression has been implicated in promoting pancreatic tumorigenesis and metastasis through epigenetic regulation, chemoresistance, radioresistance and maintenance of cancer stem cells. While most of these studies have provided evidence of the multifunctional nature of PAF1/PD2 in PDAC progression, no study has investigated the role of PAF1/PD2 during the metabolic rewiring of cancer.
Methods: In this study, we sought to examine the role of PAF1/PD2 in the metabolic rewiring of cancer cells in pancreatic ductal adenocarcinoma (PDAC) and decipher how PAF1/PD2 mediates this metabolic reprogramming in PDAC. Pancreatic cancer cell lines were transfected with shRNAs to knock down PAF1/PD2. Metabolic genes regulated by PAF1/PD2 were identified by qPCR and western blot upon PAF1/PD2 depletion. Metabolic assays were performed to investigate the role of PAF1/PD2. Immunoprecipitations identified proteins that interact with PAF1/PD2. Confocal microscopy confirmed the co-localization of PAF1/PD2 with its protein partners. We performed chromatin immunoprecipitation (ChIP) - Polymerase chain reaction to confirm the binding of the PAF1 sub-complex to its target gene.
Results: Our results showed that pancreatic cancer cells depleted PAF1/PD2 downregulate genes involved in aerobic glycolysis compared to control cells. Also, the lactate release assay indicated that more lactate was produced in control cells than in cells with PAF1/PD2 knockdown. Interestingly, we identified that HIF1α interacts with PAF1, specifically in pancreatic cancer cells. PAF1 and HIF1α co-localization was observed in pancreatic cancer cell lines. We also observed that the PAF1/PD2- HIF1α complex bound to the promoter region of LDHA to regulate the expression of LDHA in pancreatic cancer cells, reprogramming the metabolism to utilize the aerobic glycolysis pathway preferentially.
Conclusions: In conclusion, our study shows that PAF1/PD2 rewires the metabolism of PDAC by interacting with HIF1 α to regulate the expression of LDHA, which is the rate-limiting step of aerobic glycolysis.

#1795 Tumor-targeting *Salmonella* A1-R selectively delivers recombinant methioninase and inhibits syngeneic-cancer mouse models.

Y. Kubota[1], Y. Aoki[1], N. Masaki[1], K. Obara[1], S. Morinaga[1], K. Mizuta[1], M. Sato[1], M. Zhao[1], Q. Han[1], B. Michael[2], T. Tsunoda[3], R. M. Hoffman[1];
[1]AntiCancer Inc., San Diego, CA, [2]University of California San Diego, San Diego, CA, [3]Showa University School of Medicine, Tokyo, Japan

Background: Methionine addiction, termed the Hoffman effect, is a general hallmark of cancer. Methionine restriction (MR) using an MR diet or recombinant methioninase (rMETase) is effective for all types of cancer. However, methionine restriction also inhibits the activity of CD8-positive T-lymphocytes. Therefore, we hypothesized that methionine depletion in the tumor only may be more effective for cancer therapy. We previously developed *Salmonella* A1-R, which selectively targets and kills tumors. In the present study, we established rMETase-producing *Salmonella* A1-R, by transfer of the *Pseudomonas putida* methioninase gene, to target and inhibit syngeneic cancer mouse models.

Methods: A plasmid containing the *Pseudomonas putida* methioninase gene was extracted from rMETase-producing *E. coli* and inserted into *Salmonella* A1-R using electroporation. The rMETase-producing *Salmonella* A1-R (A1-R-rMETase) infected several cancer cell lines in vitro, including HT29, PC-3, MDA-MB-435, and Lewis Lung Carcinoma (LLC). LLC was chosen for in vivo studies as it supported extensive growth of A1-R-rMETase. We determined 10^8 A1-R-rMETase was a safe dosage in C57BL/6 mice. LLC cells (10^6) were injected in male C57BL/6 mice aged 4-6 weeks subcutaneously. After tumor growth, 18 mice were divided into three groups of 6. One group was injected with phosphate-buffered saline (PBS) via the tail vein, twice per week as a control. Another group was injected with 10^8 Salmonella A1-R via the tail vein, twice per week. Another group was injected with 10^8 A1-R-rMETase via the tail vein, twice per week for two weeks. Tumor size was measured with calipers three times per week for 3 weeks. On day 22, tumor methionine level was measured using HPLC in the PBS control and the mice injected with A1-R-rMETase.

Results: The mean LLC tumor size of each group on day 22 was as follows: The PBS control: 741.5 mm^3; mice injected with A1-R: 566.3 mm^3; and mice injected with A1-R-rMETase: 198.8 mm^3. Turkey's multiple comparisons test showed a significant difference between the PBS control and mice injected with A1-R-rMETase ($p<0.0001$) and between mice injected with A1-R and mice injected with A1-R-rMETase ($p=0.0036$). However, the PBS control and the mice injected with A1-R did not show a significant difference ($p=0.1794$). The mice injected with A1-R-rMETase showed a significantly lower mean methionine level than mice injected with PBS (5.9 nM/mg protein vs. 11.1 nM/mg protein, $p=0.0095$, Mann Whitney test).

Conclusion: Tumor-targeting *Salmonella* A1-R modified to express the *Pseudomonas putida* methioninase gene (A1-R-rMETase), inhibited LLC tumor growth in a syngeneic mouse model and reduced the methionine level in the tumor. A1-R-rMETase combines the tumor targeting and killing capability of A1-R itself and restriction methionine selectively in tumors.

#1796 Role of FASN in pancreatic neuroendocrine cancer cells survival.

B. M. Evers[1], Z. Chow[1], Y. Zaytseva[1], E. Y. Lee[1], C. M. Townsend, Jr.[2], T. Gao[1], B. Evers[1], P. G. Rychahou[1];
[1]University of Kentucky, Lexington, KY, [2]University of Texas Medical Branch, Galveston, TX

Introduction. Pancreatic neuroendocrine tumors (pNETs) are among the most frequently occurring neuroendocrine neoplasms. Up-regulation of fatty acid synthase (FASN) has been reported in many cancers, but the role of lipid metabolism in pNETs remains unclear. The purpose of this study was to determine whether FASN inhibition can be used as a target for pNET treatment.
Methods. Immunohistochemistry and western blot analysis were used to determine protein levels of FASN in pNET tissues and cell lines. Expression of FASN was evaluated in pancreatic neuroendocrine primary and metastatic tumors and scored by a pathologist. Neutral lipid droplet levels in pNET cell lines were determined with BODIPY 493/503 staining. Clonogenic and SRB assays were used to evaluate cytotoxic effects of FASN inhibition by TVB-3664 in QGP-1 and BON pancreatic NET cell lines. Western blot analysis was used to determine levels of cleaved PARP and cyclin D1 after FASN inhibition. FASN knockdown was used to determine the effects of FASN downregulation on proliferation and lipid synthesis.
Results. FASN expression was determined at the maximum scores of 6 and 5 in 98% of patient samples. BON, QGP-1 and NT-3 cell lines were stained with BODIPY 493/503; the highest levels of neutral lipid droplets were observed in the BON cell line. BON and QGP-1 cells were treated with TVB-3664 in either complete media with fatty acids (FA+) or complete media prepared with fatty acid depleted FBS (FA-). Treatment with TVB-3664 resulted in significant inhibition of BON and QGP-1 cell proliferation and cyclin D1 expression in both FA+ and FA- conditions. Depletion of extracellular FA enhanced the effect of TVB-3664 therapy on NET cells, especially in the BON cell line. FASN inhibition with TVB-3634 suppressed pNET cell proliferation and colony formation.
Conclusions. Our study identified high protein levels of FASN in pNET patient samples and cell lines. Moreover, we demonstrated variability in the response of pNET cells to FASN inhibition. QGP cell viability was significantly decreased with FASN inhibition even in the presence of extracellular lipids. FASN inhibition in BON cells had only a minimal effect on cell viability and required depletion of extracellular lipids to achieve a decrease in cell viability and cyclin D1 expression. These data demonstrate that de novo lipid synthesis is involved in the pathogenesis and progression of pNETs. Importantly, our findings show that some pNETs are highly sensitive to FASN inhibition, suggesting that FASN inhibition may be considered as a treatment option in selected pNETs.

#1797 Investigating the significance of OXPHOS activity in non-small cell lung cancer brain metastases.

N. G. Hammond, M. Alsamraae, M. Kaur, R. Zuckerman, B. Chang, R. Cameron, A. Dyas, B. Faubert;
University of Chicago, Chicago, IL

Background: Brain metastasis is a common and devastating occurrence for patients with non-small cell lung cancer (NSCLC). NSCLC patients with brain metastases have a poor median overall survival of 2-3 months, highlighting the urgency for novel treatment strategies. One approach to understanding and potentially targeting metastasis is via cancer metabolism. During the metastatic cascade, cancer cells must survive and adapt to the differential nutrient environments they encounter, including the brain. The blood brain barrier limits the availability of many metabolites, leading metastatic cells to alter their nutrient use to survive. RNA sequencing analyses of NSCLC brain metastases suggest that increased oxidative phosphorylation (OXPHOS) may be one such metabolic adaptation in the brain. The aim of this study was to determine the necessity of OXPHOS activity as a metabolic adaptation for NSCLC cells to proliferate in the unique metabolic environment of the brain.

Materials and Methods: NSCLC cells were cultured in media mimicking the metabolic environments of the brain and blood. Expression of mitochondrial markers were evaluated by immunoblot in cells cultured across media conditions. The effects of the OXPHOS inhibitor IACS-010759 were assessed by cell growth as well as stable isotope tracing with [U-^{13}C] glucose. Patient derived xenografts (PDXs) were derived from a cohort of patients with NSCLC who underwent stable isotope tracing with [U-^{13}C] glucose. Mice bearing subcutaneously implanted PDXs were treated daily with 5mg/kg IACS-010759 and metastatic burden was measured by flow cytometry and histology.

Results: Tracing studies in patients revealed that high enrichment in OXPHOS-related metabolites in the primary tumor correlated with worse patient outcomes. Compared with other media conditions, cells cultured in media replicating the metabolic environment of the brain have increased expression of mitochondrial proteins, increased ^{13}C glucose labeling in the TCA cycle, and a larger reduction in proliferation with IACS-010759 treatment. Using our PDX models, inhibition of OXPHOS with IACS-010759 had little effect on subcutaneous tumor growth but reduced metastasis in the lung and the brain.

Conclusions: OXPHOS activity may be enhanced in NSCLC brain metastases due to the unique metabolic environment of the brain. This elevated OXPHOS activity may be necessary for NSCLC brain metastasis growth, as OXPHOS inhibition reduced metastasis in the brain. NSCLC cells may undergo mitochondrial biogenesis to support survival in this unique metabolic environment, and this may represent an area of therapeutic vulnerability for brain metastases.

#1798 Glyoxalase 1 (*GLO1*) as an oncometabolic enabler of prostate cancer progression: CRISPR/Cas9-based *GLO1*-deletion from human DU145-Luc2 cells blocks EMT and bone metastasis in SCID mice.

J. Jandova[1], A. E. Cress[2], **G. T. Wondrak[1]**;
[1]R Ken Coit College of Pharmacy and UA Cancer Center, The University of Arizona, Tucson, AZ, [2]College of Medicine and UA Cancer Center, The University of Arizona, Tucson, AZ

Glyoxalase 1 (encoded by *GLO1*) is a glutathione-dependent enzyme detoxifying the glycolytic byproduct methylglyoxal (MG), an oncometabolite involved in metabolic reprogramming. Recently, we have demonstrated that *GLO1* is overexpressed in human prostate cancer cells and patient tumors. In order to inform the ongoing debate on the role of *GLO1* as an oncometabolic enabler of tumor glucose metabolism and malignant progression, we performed CRISPR/Cas9-based *GLO1*-deletion in human DU145-Luc2 malignant prostate cancer cells. NanoString nCounter™ ('PanCancer-Progression-Panel') comparative gene expression profiling (*GLO1*_KO versus *GLO1*_wt) revealed a significant downregulation of EMT-related pathways in *GLO1*_KO cells; concordantly, phenotypical screening indicated a pronounced attenuation of matrigel invasiveness observable in *GLO1*_KO cells. Likewise, inclusion of MG or a small molecule GLO1 inhibitor (TLSC-702) blocked invasiveness of DU145 *GLO1*_wt cells. Downregulation of EMT-related genes (including *MMP3, SPP1, CXCL8*) was accompanied by increased expression of *TXNIP* (thioredoxin-interacting protein), a master regulator of cellular energy metabolism and redox homeostasis. In a bioluminescent SCID mouse bone metastasis model (intracardial injection of DU145-Luc2 *GLO1*_wt and *GLO1*_KO cells), *GLO1* expression was necessary to cause mandibular bone metastases (as evidenced by the complete absence of bone metastases after *GLO1* deletion). Given the availability of drug-like small molecule inhibitors of GLO1 enzymatic activity these data suggest that GLO1 represents a novel molecular target for the pharmacological suppression of prostate cancer bone metastasis.

#1799 Regulation of epidermal stem cell proliferation and adhesion by ACSS2.

Nicholas K. Chamberlain, Xiaomin Bao

Molecular Biosciences, Northwestern University - Evanston, Evanston, IL

Acetyl-CoA Synthetase Short-Chain Family Member 2 (ACSS2) is an enzyme that converts acetate into acetyl-CoA, a crucial metabolite required for protein acetylation and lipogenesis. Acetyl-CoA is membrane-impermeable and must be synthesized in the compartment in which it will be used. Among ACSS enzymes, ACSS2 alone is found in the nucleocytoplasmic compartment rather than the mitochondria. This enzyme shows dynamic localization dependent on cell nutrient status, with nutrient stress promoting nuclear localization where ACSS2 activity promotes cell growth and survival. Emerging evidence suggests ACSS2 may also play roles in promoting metastasis, and has been proposed as a potential therapeutic target. However, the role of ACSS2 in controlling normal tissue homeostasis is understudied. Addressing this knowledge gap is critical to ensure safety and efficacy of cancer therapeutics. As 80% to 90% of human cancers originate from epithelial tissues, we have leveraged human epidermal stem cells to further interrogate the role of ACSS2. As progenitor keratinocytes differentiate, they detach from the basal lamina and migrate from the metabolically privileged basal layer to the more challenging environment at the surface of the epidermis. Using shRNA-mediated knockdown, we first found ACSS2 knockdown dramatically decreases progenitor keratinocyte clonogenicity, abolishing proliferative capacity. Analysis of RNA sequencing data following ACSS2 knockdown with five constructs showed significant increases in expression of genes related to cell adhesion, extracellular matrix organization, collagen catabolism, and cell migration, in addition to keratinocyte differentiation. Downregulated genes were associated with cell division, DNA repair, and DNA replication. Live cell imaging revealed knockdown cells show striking differences in cell adhesion compared to control. These results indicate a role for ACSS2 in regulating keratinocyte proliferation and adhesion during the maintenance of epidermal homeostasis.

#1800 Cytosolic NADK is conditionally essential for folate-dependent nucleotide synthesis in human cells.

K. M. Flickinger, K. S. Huggler, J. R. Cantor;
University of Wisconsin - Madison, Madison, WI

The genes that are required for the growth of mammalian cells can depend on an interplay of cell-intrinsic factors and environmental context. However, there is often little investigation into how nutrient availability impacts gene essentiality. Moreover, efforts such as DepMap have catalogued genes that contribute to cancer cell fitness using *in vitro* CRISPR screens in hundreds of cancer cell lines cultured in traditional media that poorly recapitulate the nutrient availability of human blood. Previously, we developed Human Plasma-Like Medium (HPLM), a physiologic medium designed to better model the nutrient availability of human blood. We recently tested the hypothesis that nutrient availability influences gene essentiality. By performing paired CRISPR-based screens in human blood cancer cells, we identified sets of genes that are differentially required to support cell growth in HPLM versus traditional media such as RPMI. Among the strongest scoring HPLM-essential genes was NAD kinase (*NADK*), which encodes an enzyme critical for the generation of cytosolic NADPH. NADK has been previously suggested as an anti-cancer therapeutic target, given the central importance of NADPH for enabling proliferative metabolism through macromolecule synthesis and ROS management. Interestingly, *NADK* has been annotated as an essential gene in only 1% of the cell lines included in DepMap, suggesting that the essentiality of *NADK* may have been largely masked by the nutrient conditions used to generate the DepMap. To investigate the conditional CRISPR phenotype for *NADK*, we engineered *NADK*-knockout cells and found that they showed a 50% stronger growth defect versus control cells in HPLM relative to RPMI. Next, we used localization and activity studies to confirm that cytosolic NAD^+ kinase activity is required for the conditionally essential role of *NADK*. We then employed systematic approaches in media engineering and metabolomics to identify the medium component(s) that contribute to the *NADK* gene-nutrient interaction and to gain insights into the conditionally essential role of *NADK*. Through these studies, we traced the cause of *NADK* essentiality to an inhibition of folate-dependent nucleotide synthesis linked to differential folic acid availability. Finally, we examined the pre-translational potential of NADK as an anti-cancer therapeutic target by demonstrating that the reported NADK inhibitor thionicotinamide largely phenocopies *NADK*-knockout in a folic-acid dependent manner in the K562 cell line. Collectively, our work improves understanding of how *NADK* contributes to human cell growth and reveals how the relative importance of cytosolic NAD^+ kinase activity can depend on nutrient availability.

#1801 Rewiring of cortical glucose metabolism fuels human brain cancer growth.

Andrew J. Scott[1], Anjali Mittal[1], Baharan Meghdadi[1], Sravya Palavalasa[1], Abhinav Achreja[1], Alexandra O'Brien[1], Ayesha Kothari[1], Weihua Zhou[1], Jie Xu[1], Angelica Lin[1], Kari Wilder-Romans[1], Donna M. Edwards[1], Vijay Tarnal[1], Nathan Qi[1], Theodore S. Lawrence[1], Sriram Venneti[1], Nathalie Y. R. Agar[2], Costas A. Lyssiotis[1], Wajd N. Al-Holou[1], Deepak Nagrath[1], Daniel R. Wahl[1]

[1]University of Michigan, Ann Arbor, MI,[2]Dana-Farber Cancer Institute, Boston, MA

The brain avidly consumes glucose to fuel neurophysiology. Cancers of the brain, such as glioblastoma (GBM), lose aspects of normal biology and gain the ability to proliferate and invade healthy tissue. How brain cancers rewire glucose utilization to fuel these processes is poorly understood. Here we perform infusions of ^{13}C-labeled glucose into patients and mice with brain cancer to define the metabolic fates of glucose-derived carbon in tumor and cortex. By combining these measurements with quantitative metabolic flux analysis, we find that human cortex funnels glucose-derived carbons towards physiologic processes including TCA cycle oxidation and neurotransmitter synthesis. In contrast, brain cancers downregulate these physiologic processes, scavenge alternative carbon sources from the environment, and instead use glucose-derived carbons to produce molecules needed for proliferation and invasion. Targeting this metabolic rewiring in mice through dietary modulation selectively alters GBM metabolism and slows tumor growth.

#1802 Melanoma addiction to GCDH.

N. Nadig, S. Verma, Z. A. Ronai;
Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

Rewiring of metabolic pathways often underlies the malignant state, including melanoma. In our previous studies we have demonstrated melanoma addiction to Gutaryl Co-dehydrogenase (GCDH), an enzyme in the lysine catabolism pathway. Our studies revealed that blocking GCDH activity in melanoma, but not colon, lung or breast cancer cells, led to cell death which abolished growth both in culture and in vivo. Important cellular component which was found to mediate melanoma addiction to GCDH was the transcription factor NRF2, which exhibited tumor suppressor function upon GCDH inhibition. Notably, coinciding with NRF2 tumor suppressor role seen upon GCDH inhibition was its glutarylation, a post translational modification which acquired NRF2 stability and ability to induce transcription of ATF4, ATF3 and CHOP which led to extensive cell death program. Knockdown of NRF2, ATF3 or DTHDK-1 effectively blocked the cell death phenotype seen upon GCDH knockdown. Analyses of patient data confirmed that low GCDH expression coincided with prolonged survival of melanoma but not colon, breast or prostate cancer patients. These findings led us to perform an unbiased screen to identify cellular components, which underlie melanoma addiction to GCDH. The results of this analysis will be discussed.

#1803 ACOD1 is a key regulator of immunosuppressive MDSCs, prostate cancer progression, and resistance to immunotherapy.

C. S. Mak, X. Liang, J. Suh, D. Liang, M. Zhu, **G. Wang**;
UT MD Anderson Cancer Center, Houston, TX

Although Immune checkpoint therapy (ICT) is highly effective in a wide range of malignancies, patients with metastatic castration-resistant prostate cancer (mCRPC) are largely resistant to ICT. Yet, the cellular and molecular basis of the poor response to ICT in lethal prostate cancer remain poorly defined. Polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs) have emerged as a key driver of prostate cancer progression and resistance to immunotherapy. Yet the molecular mechanisms underlying the immunosuppressive activities of PMN-MDSCs remains poorly defined. By performing single-cell RNA-sequencing (scRNA-seq) of prostate tumors, we identified *Acod1*, a gene that encodes cis-aconitate decarboxylase (ACOD1) and catalyzes the synthesis of itaconate from cis-aconitate in the tricarboxylic acid (TCA) cycle, is among the top 5 metabolic-related genes that are overexpressed in PMN-MDSCs. Moreover, bulk RNA-seq and microarray datasets revealed that intratumoral and splenic PMN-MDSCs express a significantly higher level of *Acod1* compared to less immunosuppressive bone marrow PMN-MDSCs. Importantly, high ACOD1 expression is strongly associated with significantly shorter overall survival and higher Gleason scores in human mCRPC. Using an autochthonous whole-body *Acod1*-KO mouse model, we showed that Acod1 KO in TRAMP mice led to a reduction in tumor burden and an increase in overall survival. Furthermore, using syngeneic prostate cancer models, we showed that whole-body or PMN-specific *Acod1*-KO delayed tumor progression. As expected, Acod1 KO dramatically reduced the production of itaconate in bone marrow-derived MDSCs (BM-MDSC) as shown by targeted metabolic profiling. Importantly, we found that *Acod1* KO impaired immunosuppressive activities of BM-MDSC and an increase in CD3+ and CD8+ T cell infiltration in the tumors. Also, Acod1-KO in BM-MDSC led to a reduction of H2DCFDA staining intensity suggesting a reduction in the production of reactive oxygen species (ROS). Gene set enrichment analysis (GSEA) revealed that *Acod1*-KO MDSCs have hyperactive oxidative phosphorylation (OXPHOS) compared to *Acod1*-WT BM-MDSCs. KO of *Acod1* also leads to suppression of key MDSC functions signaling such as TNFα/NFκB, IL6/JAK/STAT3, and C/EBPβ pathways. In summary, our data suggests that the upregulation of ACOD1 in PMN-MDSCs has a vital role in prostate cancer progression and resistance to ICT by regulating their immunosuppressive activities through metabolic reprogramming. Also, our data suggest that targeting ACOD1 could be an effective therapeutic strategy for lethal prostate cancer as a monotherapy and in combination with immunotherapy.

Poster Session

#1806 Induction of KRAS G13D dimers as a therapeutic strategy for colorectal cancer.
D. Angira, L. Li, Z. Zhou, S. Lee, J. Ready, K. Westover;
UT Southwestern Medical Center, Dallas, TX

Colorectal cancer (CRC) is the third leading cause of cancer deaths. Most CRCs arise from polyps in the colon/rectum that acquire gene mutations, including frequent activation of the oncogene Kirsten rat sarcoma virus (KRAS) observed in 40% of cases, particularly at codons 12, 13, and 61. KRAS oligomerization is critical for MAPK pathway signaling, which drives CRC pathogenesis. This study evaluated compounds that bind mutant KRAS G13D to induce non-physiological dimerization. Screening of a 4.1 billion compound DNA-encoded library led to the identification of pyridinylpiperazine/quinoline compounds. These compounds demonstrated the ability to induce RAS dimer formation, subsequently reducing MAPK signaling, exhibiting similarities to BI-2852, which is known to induce formation of non-physiologic RAS dimers. Structure-activity studies yielded indole, piperidine, and morpholine variants showing improved activity in thermal shift assays (DSF) and in cell-based assays evaluating RAS signaling (p-ERK inhibition).

#1807 New strategies to target the pseudokinase receptor PTK7 in the Wnt pathway.

J.-P. Borg[1], M. Pierre[1], L. Ganier[1], A. Daulat[1], A. Molliex[2], J. Duez[2], M. Sanchez[1], E. Lallemand[2], A. Goncalves[1], G. Bollot[1];
[1]Centre de Recherche en Cancerologie de Marseille (CRCM), Marseille, France, [2]Synsight Inc., Paris, France

Colorectal cancer (CRC) remains the second cause of death by cancer worldwide and its survival is currently estimated at 60%[1]. There is therefore a crucial need to identify biomarkers and new targets for therapy. In 90% of CRC, the Wnt/β-catenin pathway is constitutively activated due to mutations of *β-catenin*, *APC* (Adenomatous Polyposis Coli) or *axin-1*[2]. These alterations cause an accumulation of β-catenin and lead to an over-transcription of target genes involved in tumorigenesis[3-4]. Studies of our team pointed out an overexpression of the Protein Tyrosine Kinase 7 (PTK7) in CRC, an event associated with metastatic development, reduced metastases-free survival, and resistance to chemotherapy. In CRC cells, the pseudokinase PTK7 has pro-metastatic and pro-migratory functions, and thus appears to be a promising new therapeutic target[5-6]. The role of PTK7 in the Wnt/β-catenin pathway has been demonstrated in several studies[7-8]. Our group identified β-catenin as a partner of PTK7. We selected a first series of small molecules inhibitors targeting PTK7/β-catenin interaction[9]. This strategy could represent, in the future, a new therapeutic strategy to inhibit CRC cell growth dependent on the Wnt signaling pathway. However, the compounds identified had weak activity, with an IC_{50} of around 10-25 mM. We have set up a new method with SYNSIGHT to select more potent chemical inhibitors targeting PTK7/β-catenin in CRC in order to counteract the Wnt/β-catenin signaling pathway deregulation. #1808 Discovery of highly selective novel MTA-cooperative PRMT5 inhibitors for the treatment of cancers.

W.-L. Wu[1], T. Hu[1], Z. Deng[1], H. Li[2], Q. Shen[2], L. Zhang[2], X. Ma[2], P. Sun[2], C. Cheng[1], F. Liu[1], X. Chen[1], Y. Hua[1], B. Huang[1];
[1]BioNova Pharmaceuticals, Shanghai, China, [2]PharmaResources Co., Shanghai, China

Protein arginine methyltransferase 5 (PRMT5), a type II PRMT catalyzing the formation of symmetric dimethylation of arginine residues on histone and non-histone proteins, regulates many biological pathways in mammalian cells, including cell growth and differentiation. Methylthioadenosine phosphorylase (MTAP) is required for the methionine salvage pathway, deletion of MTAP leads to the accumulation of inhibitory PRMT5 cofactor methylthioadenosine (MTA). MTAP gene is adjacent to and frequently co-deleted with CDKN2A gene, the most commonly deleted tumor suppressor gene in human cancers. The increase in MTA significantly reduced PRMT5 activity in MTAP-deficient cancer cells, rendering them more vulnerable to PRMT5 inhibition than normal cells. Selective Inhibitors of PRMT5-MTA complex (MTA-cooperative) are supposed to exhibit an increased therapeutic index compared to first generation PRMT5 inhibitors for the treatment of MTAP-deleted (MTAP-del) cancer patients. Guided by computation-aided drug design (CADD), binding mode analysis of known PRMT5 inhibitors has led to the design and synthesis of a novel series of MTA-cooperative PRMT5 inhibitors. Many compounds within this series were found to inhibit PRMT5/MEP50 complex with single digit nM of IC_{50} in enzymatic assay. Cell based activity of these compounds was assessed by measuring the symmetric demethylarginine (SDMA) and 10-day cell proliferation assays. Several compounds exhibited low double-digit nM of cellular potency in HCT116 MTAP-del cells, the inhibition of SDMA and anti-proliferation activities in HCT116 MTAP-del cells over HCT116 MTAP-WT cells have excellent selectivity (80 - 400 fold). Further optimization of *in vitro* and *in vivo* pharmacokinetic properties has yielded candidate compounds suitable for evaluation of pharmacodynamic effect in the LU99 MTAP-del NSCLC xenograft model. Tumor growth inhibition (TGI) was observed in a dose-dependent manner, accompanied by a reduction of PRMT5-mediated SDMA levels in both the tumor and bone marrow. In summary, we have identified compounds with novel scaffolds that are potent and highly selective MTA-cooperative PRMT5 inhibitors. Further development of the second-generation PRMT5 inhibitors for treatment of cancers is also planned.

#1809 Discovery of novel AXL and MER inhibitors as potential anticancer and immunomodulatory drugs.

H.-P. Hsieh[1], M.-C. Li[1], W.-C. Yen[1], S.-Y. Wu[1], T.-K. Yeh[1], C.-C. Kuo[1], S.-H. Ueng[1], H.-C. Wu[2];
[1]National Health Research Institutes, Miaoli County, Taiwan, [2]Academia Sinica, Taipei, Taiwan

In cancer progression, abnormal AXL expression can promote tumor growth, metastasis, and chemotherapy resistance, while MER can identify apoptotic cancer cells and induce immune suppression in the tumor microenvironment. Combining AXL and MER inhibitors could generate a synergistic effect, enhancing antitumor responses, and further suppressing resistance formed by monotherapy with AXL selective or MER selective inhibitors. According to the explicit function of AXL and MER, the development of dual AXL and MER inhibitors may provide tremendous advantages to cancer patients. Drawing on our experience in the discovery of an anti-EGFR and anti-HER2 clinical candidate, we introduced several AXL-active and MER-active pharmacophores into DBPR112. Furthermore, we modified the scaffold and the solubilizing groups to improve the drug-like properties. Our comprehensive structure-activity relationship study led to the discovery of several potent dual AXL and MER inhibitors. Among approximately 200 synthesized compounds, BPR5K230 demonstrated strong inhibitory activities against AXL and MER, along with favorable oral bioavailability (F% = 55%) and promising *in vivo* antitumor effects in various mouse xenograft models, including MDA-MB-231, 4T1, and MC-38 tumor models. BPR5K230 effectively addressed sorafenib resistance in the Hepa 1-6 model and exhibited significant synergistic antitumor effects when combined with an anti-PD-L1 antibody in the EMT-6 model. As a result, BPR5K230 represents a promising dual AXL/MER kinase inhibitor, and further preclinical evaluation is underway for its development as a potential anticancer and immune-modulating drug.

#1810 Development of new phthalic hydrazide scaffold for potent TNKS inhibitors.

H. Ryu[1], H.-R. Seo[1], J. Lee[2], K. Lee[3], **J. Ahn**[1];

[1]Korea Institute of Radiological & Medical Sciences (KIRAMS), Seoul, Korea, Republic of, [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of, [3]Korea Research Institute of Chemical Technology, Seoul, Korea, Republic of

Tankyrase 1 and 2 (TNKS1/2) catalyze post-translational modifications of target proteins through poly-ADP-ribosylation. Inhibition of TNKS stabilizes AXIN and induces β-catenin degradation in adenomatous polyposis coli (APC)-mutated colorectal cancer (CRC) cells. Therefore, TNKS emerges as a therapeutic target for APC mutant CRC, and there is a critical need for drug development against it. Tankyrase 1 and 2 (TNKS1/2) catalyze the post-translational modification of target proteins through poly-ADP-ribosylation. Their inhibition stabilizes AXIN and induces β-catenin degradation. Therefore, TNKS is a therapeutic target for APC mutant colorectal cancer (CRC), and there is a need for drug development against it. However, reported TNKS inhibitors have serious limitations in that they cause intestinal toxicity. To address these issues and enhance efficacy, we synthesized 60 compounds based on the tetrahydrophthalazine scaffold using protein structure modeling-AI technology. Using an in vitro TNKS1 and TNKS2 enzyme assay and derivatizing Hit compounds, we confirmed that TI-61987 significantly inhibits TNKS enzyme activity at low nanomolar levels. TI-61987 stabilized AXIN2, reduced active β-catenin, and downregulated β-catenin target genes in COLO320DM, APC-mutated CRC cells. Additionally, TI-61987 exhibited excellent anticancer effects not only in COLO320DM cells but also in in vivo xenograft mouse models. Our findings demonstrate that TI-61987 is a therapeutic candidate targeting TNKS for the treatment of APC-mutated CRCs, and this anticancer drug may represent an effective therapy regimen for APC-mutated CRCs.

#1811 Efficient identification of new small molecules targeting succinate dehydrogenase in non-small cell lung cancer.

L. Silva[1], N. Skiados[1], N. Murugavel[1], N. Luna[1], K. Cover[1], M. K. Gupta[1], S. C. Contreras[2], T. E. O'Brien[2], W. Zhang[1];
[1]University of Central Florida, Orlando, FL, [2]Atomwise Inc., San Francisco, CA

Efficient lung cancer treatment remains challenging due to the lack of therapeutic targets. The succinate dehydrogenase (SDH) enzyme plays a critical metabolic role as an intermediate between the citric acid cycle and the electron transport chain associated with the cancer disease state. Although several existing compounds have been applied to target metabolic diseases in vitro, modulating SDH for lung cancer treatment is still elusive. By integrating the AtomNet® technology for compound identification with mitochondria- and cell-based enzyme activity assays, we identified two new small molecules from 96 predicted candidates. Cellular thermal shift assay confirmed that these small molecules bind directly to SDH subunits in lung cancer cells. Mechanistically, treatment with these small molecules increased cellular and mitochondrial reactive oxygen species, accumulated succinate, and DNA damage-induced apoptosis in lung cancer cell lines. Functionally, these small molecules reduced the growth, migration, and formation of 3D organoids in vitro in lung cancer cell lines, both in the short and long term. Our study sheds light on the function of SDH in metabolic dysfunction related to cancer and highlights the potential of modulating SDH as a viable therapeutic strategy for targeting lung cancer and other cancer types. LS, NS, and WCZ contributed equally to this work.

#1812 Development of novel topoisomerase 1 inhibitor PBX-7 payload-based ADC including tandem cleavable linker system.

Y. Chun, A. Go, H. Cho, B. Lee, S. Shin, J. Lee, S. Kweon, H. Han, S. Park, D. Jung;
PINOTBIO, Inc., Suwon-si, Korea, Republic of

Antibody-Drug Conjugates (ADC) employing camptothecin-based payloads are gaining high interests as a new modality to treat various cancers, especially solid tumors. Among them, novel ADCs containing synthetic camptothecin-based payloads specially optimized for ADC applications (e.g., DXd) are of special interest due to their successful clinical results. Despite the remarkable success of ADCs exploiting these payloads, such as Enhertu (DS-8201a), there are still clear unmet needs, including the improvement of safety profile (minimization of ILD and neutropenia) and the development of novel ADCs with multiple MoA payloads to combat cancer heterogeneity.

To address these unmet needs, we have synthesized and evaluated a series of PBX-7 payloads, derived from novel camptothecin FL118, a potent, dual inhibitor of Top 1/anti-apoptotic pathway known for its favorable safety profile. These compounds showed strong *in vitro* cytotoxicity across various cancer cell lines and inhibition of Top 1 comparable to DXd or other related camptothecin compounds. They had excellent safety profile in the preliminary toxicity study in mice that can be attributed to their physicochemical properties.

PBX-7 series payloads based ADC exhibited superior cellular cytotoxicity and *in vivo* tumor regression compared to Enhertu in Her2-positive cell line and CDX mouse model. Notably, PBX-7 based ADC demonstrated remarkable efficacy in reducing tumor volume more than Enhertu in the T-DM1-resistant JIMT-1 xenograft mouse model. Furthermore, PBX-7 based ADC have bystander effects similar to Enhertu, leading to reduced viability of antigen-negative cells when co-cultured with antigen-positive cell lines. In NHP toxicity study in Cynomolgus monkeys, no sign of toxicity was observed when dosed with Trastuzumab-PBX-7016 up to 30mg/kg.

As another way of addressing unmet needs, we synthesized novel linker including tandem cleavage site to reduce payload mediated toxicity. Two distinct enzyme, beta-glucuronidase and cathepsin B cleave linker sequentially. This linker system has a higher stability during circulation in the body and higher specific payload release in the tumor tissue than single cleavable linker.

In conclusion, our research shows the promising potential of novel camptothecin PBX-7 based ADCs and tandem cleavable linker system as potent and safe ADC candidates for cancer therapy. These advancements hold great promise in addressing the current challenges in ADC development with their enhanced safety profiles and targeted efficacy.

#1813 Discovery, biomarker validation, and pre-clinical profiling of a novel PKMYT1 inhibitor.

A. Brennan, J. Lanz, D. S. Miller, O. Vipond, N. Harrison, J. Aaronson, A. Hercot;
Evariste Ltd, London, United Kingdom

Protein kinase membrane-associated tyrosine/threonine 1 (PKMYT1) is a negative regulator of CDK1 activity and has been identified as a putative synthetic lethal target in cancers which upregulate cyclin E (CCNE1). We used high-throughput virtual screening to identify inhibitors of PKMYT1 with high lipophilic ligand efficiency (LLE), which were rapidly optimized to potent leads with exceptional selectivity over a key off target, WEE1. Machine learning-driven optimization rapidly reduced mouse hepatocyte clearance to acceptable levels, delivering a compound with best-in-class potency, selectivity, and pharmacokinetic profiles in relevant animal models. Tool compounds from this series were used to validate a differentiated biomarker for sensitivity to PKMYT1 inhibition in cellular models, which could significantly expand the potential patient population. In vivo proof-of-concept studies are ongoing in a variety of cell line- and patient-derived xenograft models which represent the novel biomarker previously identified, to further validate our therapeutic strategy.

#1814 Development and evaluation of Hsp90β-selective inhibitors to overcome the safety challenges associated with pan-Hsp90 inhibitors.

S. Mishra[1], T. Reynolds[2], B. Blagg[2];
[1]Grannus Therapeutics Inc., South bend, IN, [2]University of Notre Dame, Notre Dame, IN

The 90 kD heat shock proteins (Hsp90) are molecular chaperones that are responsible for the folding of select proteins, many of which are directly associated with cancer progression. Consequently, inhibition of the Hsp90 protein folding machinery results in a combinatorial attack on numerous oncogenic pathways. More than 20 small-molecule inhibitors of Hsp90 have entered clinical trials for the treatment of cancer, all of which bind the Hsp90 N-terminus and exhibit pan-inhibitory activity against all four Hsp90 isoforms (Hsp90a, Hsp90β, Grp94 and TRAP-1). Most of these clinical trials have failed as pan-Inhibition of Hsp90 appears to be detrimental with toxicities reported alongside induction of the pro-survival heat shock response, which leads to additional dosing challenges/toxicities. The cytosolic Hsp90 isoforms Hsp90a and Hsp90β are the major contributors to cancer growth/survival. It has been established that inhibition of Hsp90a is associated with cardiac toxicity, retinal toxicity, and induction of the heat shock response. Therefore, the development of Hsp90β -selective inhibitors represents an alternative approach for the treatment of cancer with limited side effects. Towards this goal, Hsp90β-selective inhibitors that exhibit >150-fold selectivity over Hsp90a have been developed, which exhibit efficacy against select cancers while overcoming the safety challenges associated with previous Hsp90 inhibitors. The results from such studies will be presented.

#1815 Optimization of Lin28 inhibitors: A promising therapeutic approach for the suppression of cancer cell proliferation, stemness properties, and spheroid growth.

V. M. Matias-Barrios, M. Radaeva, G. Rosellinny, A. Cherkasov, X. Dong;
University of British Columbia, Vancouver, BC, Canada

Background: The pluripotency factor known as Lin28 plays a crucial role in the regulation of cancer cell stem-like characteristics, hence facilitating the formation of cancer and the evolution of therapy-resistant tumors. The protein exerts its function by utilizing its cold shock domain and zinc knuckle domain (ZKD) to engage with the Let-7 pre-microRNA and impede the process of Let-7 production. The implementation of chemical agents to hinder the interaction between Lin28 and Let-7 has been proven as a therapeutic approach for treating aggressive tumors.
Methods: Computer-aided drug design techniques were employed in the development of a novel series of small molecule inhibitors, which are derivatives of our previously identified lead compounds Ln115, Ln15, and Ln7. Fluorescent Polarization Assay (FP), and Electrophoretic Mobility Shift Assay (EMSA) were used to screen the chemicals as Lin28-Let7 interaction disruptors using Lin28A/B ZKD domain. To further screen the chemicals, the Incucyte cell proliferation assay was performed using two Lin28A and Lin28B positive cells, IGROV-1, and DuNE cells, respectively. The inhibition of Lin28 activity was subsequently evaluated by measuring Let-7 micro-RNA and Lin28 protein levels using RT-PCR and Western Blot. Then, the metabolism profile was explored using Microsomal Stability Assay. Incucyte proliferation assay and MTS assay determined the IC50 of lead compound in Lin28 positive cells. The anti-stemness properties of the lead compound were subsequently evaluated through assays for stem gene expression levels and colony formation. To evaluate the potential of the lead compound to further move into animal studies, we tested it on a newly developed 3D Neuroendocrine Prostate Cancer (NEPC) model.
Results: In this study, we provide a novel set of derivatives, within which, Ln268 was chosen as the lead compound. Ln268 shows higher metabolic stability with a half-life time of 462 min and clearance rate of 5 ul/min/mg, compared to its father compound at 347 min and 46 ul/min/mg, respectively. Ln268 treatment resulted in a time-dependent inhibition of cell growth with an IC50 of 2.5 uM at 72 hrs. Ln268 reduces mRNA levels of stemness and neurodifferentiation markers such as CHGA, CHG, SYP, SCGN, OCT3/4, NANOG, ID4, FOXC1, ALDH1A2, and FOXO3. In the 3D NEPC model, Ln268 suppresses spheroid growth in a dose- and time-dependent manner. Ln268 achieved 100% spheroid growth inhibition at the concentration of 100 uM, while the current commercially available C1632 only reached 50%.
Conclusion: We discovered a novel Ln15 derivative named Ln268, which has a better metabolism profile and increased inhibitory activity to distrust Lin28-Let7 interaction and cancer cell proliferation. Ln268 has the potential to be improved and used as an anti-cancer treatment for a variety of malignancies, such as prostate cancer.

#1816 In silico design of novel multitarget small molecule inhibitor LCI139 for the treatment of PTEN-mutant endometrial carcinoma.

V. Mujumdar, R. Delara, H. Dryden, D. Pal, K. Maddeboina, P. M. Arditti, B. Yada, R. W. Naumann, Y. Casablanca, E. Crane, J. Brown, D. Durden, C. McHale; Atrium Health Levine Cancer, Charlotte, NC

Background: Previously we described multitarget CDK4/6-CDK9 inhibitor, LCI133 for the treatment of endometrial carcinoma (EC). We have optimized LCI133's chemical properties to increase PI3K p110α potency to better target epithelial-derived cancers, resulting in nanomolar potent LCI139. We characterized LCI139's in vitro potency, target specificity, activity in in vitro EC models, safety against normal cell lines.
Methods: LCI139's chemical structure was determined using nuclear magnetic resonance and high-resolution mass spectrometry. Specific target inhibition was assessed by cell-free kinase hotspot/lipid kinase assay and selectivity profile. LCI139 (0.001-10μM) was screened against EC cell lines AN3CA, RL95-2, Ishikawa, KLE, HEC-1-A and -B for 48 hours; IC50 values determined by CellTiter-Glo Assay. EC cells were treated with LCI139 or single agent control for 24 hours and stained with Annexin V/7-AAD to assess apoptosis by cytometer. Representative PTEN wildtype (HEC-1) and mutant (AN3CA) EC cell lines were chosen for mechanistic studies and treated 6 to 24 hours with multitarget or single agent inhibitor. RNA was isolated to determine gene expression by qRT-PCR, cells were stained with Vybrant DyeCycle Violet to determine cell cycle arrest by cytometer, or cellular lysates were prepared for Western blot (WB).
Results: LCI139's has a molecular weight of 502.57Da and is a highly potent PI3Kα-CDK4/6-CDK9 inhibitor by cell-free kinase assays: 0.070μM (PI3Kα), 0.461μM (PI3Kγ), 0.214μM (PI3Kδ), 0.0015μM (CDK4), 0.0036μM (CDK6), 0.000039μM (CDK9). KINOMEscan revealed a favorable S(35) selectivity score of 0.221 screened against 403 non-mutant kinases. PTEN mutant AN3CA (IC50 243.6nM), RL95-2 (IC50 22.8nM), Ishikawa (IC50 9.8nM) had nanomolar LCI139 IC50 values, while PTEN-wild type cell lines were insensitive up to 10μM; confirmed by dose-dependent apoptosis and colony-forming assays. WB revealed LCI139 treatment ablated MCL-1 expression, decreased phosphorylation of AKT, Rb, Rpb1 (Ser2), induced significant amounts of cPARP. MCL-1 ablation correlated to decreased Mcl1 expression ($p<0.0010$) assessed 6 hours post treatment. LCI139 generated heterogenous cell line specific effects on cell cycle progression and arrest. LCI139 displayed a favorable toxicity profile against normal human kidney cells (HEK-293) compared to single agent controls.
Conclusions: Triple PI3K-CDK4/6-CDK9 inhibitor, LCI139, is nanomolar potent against PTEN mutant EC cell lines and displays decreased toxicity compared with CDK9 inhibitor reference compounds, AZD4573 and flavopiridol. Our results merit further mechanistic dissection of PTEN interaction with PI3K pathway signaling, cell cycle machinery, CDK9-mediated transcriptional control. These data support extensive in vivo potency, toxicity, PK/PD studies to assess LCI139's clinical utility in treating EC.

#1817 Association of nuclear morphometrical variables with drug cytotoxicity: A proof of principle using NCI-60 anti-cancer drug screening panel.

G. Klorin[1], L. Rodriguez[2], E. Sabo[3], G. Izmirlian[2], A. Amit[1], P. Meltzer[2], A. Roschke[2];
[1]Rambam Medical Center, Haifa, Israel, [2]National cancer Institute, Bethesda, MD, [3]Carmel Hospital, Haifa, Israel

The National Cancer Institute's panel of 60 cancer cell lines (NCI-60) have been extensively used to screen compounds for anti-cancer activity in a wide range of molecular and pharmacologic assays. We completed a detailed analysis of the nuclear morphometric variables of 57 cancer cell lines from this drug-discovery panel using recently developed computerized method that allows simultaneously assess 42 variables related to morphology/texture of the cell nuclei. The goal of this study was to determine whether unique nuclear patterns seen in cancer cells can effectively predict response to anti-cancer therapies. Stained sections prepared from paraffin cell blocks were used to measure each cell nucleus by size (e.g. area, perimeters); by shape (e.g. area box, fractal dimensions, roundness); and by optical density of the pixels and texture (e.g. margination, heterogeneity). The obtained values were then summarized at the cell line level, generating a dataset comprising 84 variables, represented by mean values and coefficients of variation. We filtered the complete set of chemical compounds, tested on the NCI-60 panel, based on sufficient GI50 variability, narrowing the list down to 4,839 compounds. These compounds were further refined using the Benjamini-Hochberg false discovery rate (FDR) method at 1% FDR, based on the p-values from "goodness of fit" tests. This process identified 1,314 compounds where the inclusion of morphometric variables significantly improved the fit of our models. To determine which variables were highly predictive for GI50 in each compound, we performed lasso regression per compound of logged GI50 versus dummied tissue of origin and morphometric variables. We tabulated the proportion of compound models selecting each variable as well as the median relative strength for each variable. This procedure identified 10 promising compound models, in which the top 5 values of relative strength from each of the tested variables emerged. Our primary objective in this analysis was to find associations between certain nuclear morphometric parameters of tumors cells and drug sensitivity. Better defining how to use these previously untapped clues may pave the way for future studies able to predict sensitivity to cancer drugs and to help in the selection of the best anticancer treatments. Additionally, our work may draw new attention to compounds not now used for anticancer treatments, but whose increased cytotoxicity can be linked to abnormal morphometric parameters that indicate possible anti-tumor activity.

#1818 Novel efficient isolation and water-soluble prodrug preparation of anti-cancer natural product narciclasine.

A. Kornienko, R. Rutledge;
Texas State University (San Marcos Campus), San Marcos, TX

Narciclasine is a promising anti-cancer agent produced by plants of the family *Amaryllidaceae*. Narciclasine has been shown to be a potent anti-cancer agent against a variety of cancers carrying dismal outcomes, including glioblastoma, non-small cell lung cancer, and non-Hodgkin's lymphoma. It is particularly effective in animal studies of brain cancer both primary, such as glioblastoma, metastatic tumors to the brain, such as melanoma and non-small cell lung cancer. Its isolation from plants has generally been accompanied with variable success as it depends on the plant species, their location and the time of plant collection. In this study, an optimized procedure for the extraction of narciclasine yielding 300 mg/kg of dried plant material. This represents a crucial step towards the development of optimized narciclasine derivatives, as the price of narciclasine from commercial sources ranges from $100-$500 per milligram. Additionally, clinical advancement of narciclasine and its derivatives has been severely thwarted, potentially owing to its sparing water-solubility. Insolubility in water makes administration at therapeutic dosages difficult and can lead to unfavorable pharmacokinetic and pharmacodynamic characteristics. To this effort, the synthesis of five prodrug esters of narciclasine is presented, with the target of a water-soluble narciclasine prodrug.

#1819 Esculetin modulates SLC31A1 and ATP7B to influence copper homeostasis and trigger cell death in colorectal cancer.

Fangyue Guo, Mengying Liu, Kaihe Zhu, Jiapeng Ru, Pei Li, **Shanfeng Zhang**

Basic Medical Experimental Center, School of Basic Medical Science, Zhengzhou University, Zhengzhou, Henan, China

Background: Esculetin is a naturally occurring dihydroxycoumarin with anti-inflammatory, antioxidant, and anti-tumor activities. Copper ion transport proteins, notably SLC31A1 and ATP7B, are essential in maintaining intracellular copper homeostasis, averting disruptions that might lead to copper-induced cell death under normal physiological conditions. However, prior research has not explored Esculetin's role in inducing copper-induced cell death. Hence, this study aims to investigate the biological process of Esculetin-induced cell death and the molecular mechanism underlying dysregulation of intracellular copper ion homeostasis.
Methods: Initially, the CCK-8 assay was used to determine the IC50 values of Esculetin on colorectal cancer cell lines (HCT116, HT29, SW480) and normal colonic epithelial cell lines (NCM460). In terms of biological behaviors, the effects of Esculetin on the proliferation of colorectal cancer cell lines were assessed using CCK-8, colony formation assay, and EdU staining. Flow cytometry was used to examine the impact of Esculetin on apoptosis and cell cycle distribution in colorectal cancer cells. A subcutaneous xenograft tumor model in nude mice was employed to evaluate the in vivo anti-tumor effects of Esculetin, while IHC staining was conducted to detect Ki-67 levels, and Western blotting was performed to assess EMT-related protein expression. To investigate copper ion homeostasis, qPCR was used to measure the expression levels of copper ion transporters SLC31A1 and ATP7B before and after Esculetin treatment.
Results: The CCK-8 results revealed that the IC50 of Esculetin for normal colonic epithelial cell lines was significantly higher than that for colorectal cancer cell lines. Meanwhile, a notable inhibitory effect of Esculetin on the proliferation of colorectal cancer cells was observed. Additionally, Esculetin treatment suppressed colony formation and reduced the proportion of EdU-positive cells in colorectal cancer cells. Flow cytometry demonstrated an increase in apoptosis and S-phase arrest following Esculetin treatment. The subcutaneous xenograft tumor model showed significant inhibition of tumor growth by Esculetin, as evidenced by reduced Ki-67-positive cells in the Esculetin-treated group. Western blot analysis revealed a significant decrease in the expression levels of Vimentin and N-Cadherin and an increase in E-Cadherin expression. Furthermore, qPCR analysis post-Esculetin treatment showed an elevation in the inward copper transporter SLC31A1 levels, while the outward transporter ATP7B expression decreased.
Conclusion: Esculetin induces dysregulation of intracellular copper ion homeostasis by upregulating SLC31A1 expression and downregulating ATP7B expression, leading to intracellular copper accumulation and subsequent disruption of copper homeostasis, thereby inducing copper-induced cell death.

#1820 Investigating the anticancer effects and pharmacological mechanisms of phenanthridine Amaryllidaceae alkaloid in bladder cancer.

Y.-C. Su, **M.-C. Chen**;
Taipei Medical University, Taipei, Taiwan

Bladder cancer (BC) ranks as the tenth most common malignancy worldwide. Despite the improved five-year survival rate of around 80% for bladder cancer patients, 25% of cases progress to muscle-invasive bladder cancer with associated metastases, leading to a notable five-year survival of 5%. This underscores the urgent clinical necessity for the development of novel therapeutic strategies in the management of bladder cancer. In this study, we demonstrate the anticancer potential of a *phenanthridine* Amaryllidaceae *alkaloid (PAA)*, and investigate its underlying mechanisms in bladder cancer. The data demonstrates the selective cytotoxicity of *PAA* towards bladder cancer cells, revealing IC_{50} values of 2.47 μM in RT112 cells and 8.99 μM in normal uroepithelial SV-HUC-1 cells. Protein array analysis further showed that *PAA* attenuated phosphorylation of several kinases, which functions as critical regulators of cell survival and proliferation. *PAA* induces S phase retardation and increases the phosphorylation of ATM, potentially enhancing DNA damage capability. Furthermore, *PAA* induced apoptosis, as evidenced by the accumulation of sub-G1 cells and caspase activation. In summary, our findings demonstrate that *PAA* exerts diverse effects on cell cycle regulation and apoptosis. These results suggest that *PAA* holds promise as a potential candidate for the treatment of bladder cancer.

#1821 Conessine inhibits cell proliferation, migration and invasion, and induces apoptosis in liver cancer cells.

Sheng-I Lee[1], Chia-Yang Li[1], Yu-Sheng Lin[2]

[1]Graduate Institute of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan,[2]School of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan

Cancer-related deaths from hepatocellular carcinoma (HCC) rank first worldwide. Although many attempts have been made to treat HCC, the survival rate remains unsatisfactory. Many plants from the family *Apocynaceae*, such as *Holarrhena floribunda*, contain conessine, a steroidal alkaloid. Several studies have indicated that conessine acts as an antihistamine with cancer therapy and antimicrobial resistance, but it hasn't been tested for its anti-cancer activity against liver cancer. Our study aimed to investigate the anticancer properties of conessine against liver cancer. We tested the effects of conessine on cell proliferation, migration, invasion, and epithelial-mesenchymal transition (EMT) markers using both Huh7 and Mahlavu cells. Our experimental results indicated that conessine inhibited cell proliferation, migration, motility, and invasion in Huh7 and Mahlavu cells. Results of Western blot analysis showed that conessine induced apoptosis and EMT in liver cancer cells. Taken together, our results demonstrated that conessine exhibits anticancer activity in liver cancer through suppressing cell proliferation, migration, and invasion, and inducing apoptosis, suggesting it may have benefits for liver cancer treatment.

#1822 *Artemisia annua L*polyphenols augment b-lapachone effects on oxaliplatin-resistant HCT 116 colorectal cancer cells by downregulating TERT, CD44, EGFR and oxaliplatin resistance-related proteins of OXP-R-Hct 116 cells.

W. Lee[1], E. Jung[1], H. Kim[2], S. Shin[2], G. Kim[2], J.-M. Jung[1], S. Hong[1], C. Kim[2];
[1]Gyeongsang National Univ. Hospital, Jinju, Korea, Republic of, [2]Gyeongsang National Univ., Jinju, Korea, Republic of

We previously demonstrated that β-lapachone (β-Lap) exerts stronger anticancer activity on oxaliplatin-resistant HCT116 colorectal cancer cells (Oxp-R-HCT 116 cells) than parental HCT116 cells (p-HCT 116 cells) by downregulating the oxaliplatin resistance-related upregulated proteins (Oxp-RR-Proteins) proteins in Oxp-R-HCT 116 cells, such as SOD1, MAPK, and nucelophosmin. We also demonstrated polyphenols extracted from Korean Artemisia annua L. (pKAL) exerts anticancer activity on radio-resistant MDA-MB-231 human breast cancer cells by suppressing stem cell phenotype, β-catenin, and MMP-9. In this study, we found that pKAL significantly enhanced the anticancer activity of β-lapachone (β-Lap) on oxaliplatin-resistant (Oxp-R) HCT116 colorectal cancer cells. The aim of this study is to elucidate how pKAL enhance the anticancer effects of β-Lap on Oxp-R-HCT 116 cells. CCK-8 assay, phase-contrast microscopy analysis, and morphological analysis with hematoxylin stain revealed that the anticancer effect of β-Lap is more enhanced by pKAL on Oxp-R-HCT 116 cells over 60 hr. This phenomenon was associated with suppression of oxaliplatin resistance-related upregulated proteins (Oxp-RR-Proteins) (p53, ERK, and β-catenin), and downregulation of cell survival- and stemness-related proteins (TERT, CD44 and EGFR) that were not up-regulated in Oxp-R-HCT 116 cells. Protein-protein interaction network analysis of the 21 proteins that showed large difference in expression between before and after the combined treatment of pKAL and β-Lap in HCT116-OxPt-R cells revealed that the enhanced anticancer effect of β-Lap by pKAL was related to the inhibition of negative regulation of apoptotic process and the induction of DNA damage through TERT, CD44, and EGFR-mediated multiple signaling networks. The detailed western blot analysis for anti-cancer effects of pKAL revealed that pKAL alone also suppressed the expression of TERT, CD44 and EGFR in p-HCT 116 cells as well as Oxp-R-HCT 116 cells while β-Lap alone did not influence the expression of them. In addition, for some of the Oxp-RR-Proteins of Oxp-R-HCT 116 cells (p53, ERK, and β-catenin) were suppressed by pKAL alone, but not others. However, some other Oxp-RR-Proteins of Oxp-R-HCT 116 cells that were not suppressed by pKAL alone were significantly suppressed by the combination treatment of pKAL and β-Lap. These findings suggest that pKAL enhanced the anti-cancer effects β-Lap by suppressing TERT, CD44, and EGFR-mediated multiple signaling networks as well as some of the Oxp-RR-Proteins of Oxp-R-HCT 116 cells. In conclusion, this study suggests that pKAL enhance the anticancer effects of β-Lap on OXP-R-Hct 116 cells by downregulating CD44, EGFR and some of the Oxp-RR-Proteins of Oxp-R-HCT 116 cells.

#1823 *In vitro* evaluation of novel pyrimidine nucleosides for the treatment of pancreatic cancer.

R. Bulusu[1], J. Okoro[1], E. Frimpong[1], B. Han[2], S. Rogers[3], X. Zhu[1], E. Agyare[1];
[1]Florida A&M University, College of Pharmacy and Pharmaceutical Sciences, Tallahassee, FL, [2]KECK School of Medicine, University of Southern California, California, FL, [3]University of Florida College of Medicine, Gainesville, FL

The **purpose** of the study is to synthesize and characterize novel 5-FU analogs (AGY_1 and AGY_2) and investigate their anticancer activity against pancreatic cancer cell lines.

Methods: 5-FU derivatives were synthesized and characterized using Nuclear magnetic resonance (NMR), high-performance liquid chromatography (HPLC), and elemental analysis to determine the presence of new bond formation and the purity of the derivatives or analogs. 2D cell viability, 3D models, cell migration, and cell cycle studies were performed on MiaPaCa-2 (MP-2) cells and PANC-1 cells. Apoptosis was performed on PANC-1 cells by staining with Acridine Orange and Ethidium Bromide. The metabolic stability of the analogs was determined by using human liver microsomes. PARP, p53, and BAX expressions in PANC-1 were determined by Western Blot.

Results: NMR data showed the conjugation of alkyl and tetrahydrofuran groups to the 5-FU ring confirming the formation of AGY_1 and AGY_2. The elemental analysis of AGY_1 and AGY_2 showed 99.6% and 99.5 % purity respectively. The IC_{50} value of the AGY_1 against 2D MP-2 was found to be 12.2 ± 1 µM, while the IC_{50} value of AGY_2 was determined to be 2.9 ± 0.2 µM. Both AGY_1 and AGY_2 anticancer activities were significantly higher than 5-FU (18.5 ± 1.1 µM). However, AGY_2 was more effective compared to AGY_1. A similar trend was observed for AGY_2 analog where the IC_{50} value for treated 2D PANC-1 was 3.1 ± 0.29 µM and demonstrated a higher anticancer activity compared to AGY_1 (6.4 ± 0.38 µM) or 5-FU (7.5 ± 1.1 µM). For cell migration studies, AGY_2 (43 ± 5.5) exposed MP-2 cells showed significant arrest towards the wound gap compared to AGY_1 (74 ± 18.5) and 5-FU (86 ± 15.6). A similar result of cell migration arrests AGY_2 was observed in PANC-1 treated-AGY_1, AGY_2, and 5-FU. Organoid and spheroid models demonstrated high and comparable anticancer activity of AGY_1 and AGY_2 compared to 5-FU treated organoid and spheroid models. The cell-cycle analysis showed that AGY_2-treated MP-2 cells at 1µM concentration showed a higher G_1 population arrest (64.25%) compared to AGY_1 (54.2%) and 5-FU (55.75%). Similarly, in PANC-1 cells, AGY_2 at 1µM concentration showed a higher S-phase arrest (53.86%) compared to AGY_1 (50.76%) and 5-FU (36.14%). Metabolic stability data showed higher stability of AGY_2 (95% intact) compared to AGY_1 (85% intact) compared to 5-FU (55% intact) after 2 hour of human liver microsomal incubation. The expressions of p53 and BAX proteins in PANC-1 cells were significantly upregulated and PARP was downregulated at higher concentration when treated with AGY_1 and AGY_2 compared to 5-FU.

Conclusion: We demonstrate that AGY_2 showed more promising anticancer activity compared to AGY_1 and 5-FU against pancreatic cancer cells. AGY_2 has the potential to improve 5-FU's metabolic stability and enhance its therapeutic efficacy.

#1824 Hexadecanoic acid mediated cell cycle arrest involving inhibition of cell migration.

S.-g. A. Wright, W. Aiken, H. Asemota, K. Foster, R. Delgoda;
University of the West Indies, Kingston, Jamaica

The Caribbean region accounts for the highest incidence and mortality rates of prostate cancer in the world. This warrants the need for targeted therapy as currently the most prevalent and effective option include chemotherapeutic drugs. Previous studies showed that an enriched sample extracted from the Jamaican Round Leaf yellow yam exhibited antiproliferative effects on DU145 prostate cancer cells. Based on the results obtained, this present study aims at exploring the underlying mechanism of action as well as the antimetastatic activities that the yam derived hexadecanoic acid may exhibit. Flow cytometry analysis was used to assess cell cycle arrest exhibited by hexadecanoic acid on the hormone insensitive DU145 prostate cancer cells. The western blot analysis was then utilized to determine the effects of the hexadecanoic acid enriched sample on cyclins in the cells. Transwell migration assays were then used to evaluate cell metastatic capabilities. Hexadecanoic acid enriched sample induced G1 S cell cycle arrest in the hormone insensitive prostate cancer cell line. Western blot assays also indicated that cell death was possibly induced through the cell cycle regulatory protein, cyclin D1 as its expression was downregulated in the treatment groups. Additionally, the observed metastatic inhibition of prostate cancer cells due to the action of the hexadecanoic acid in the wound healing assay may be attributed to a mechanism involving cyclin D1 as studies have indicated that abnormal Ccnd1 Cdk4 expression promotes tumor growth and metastasis. These results are substantial as it indicates a mechanistic pathway through which hexadecanoic acid is able to cause antiproliferative effects through a cell cycle arrest of hormone insensitive prostate cancer cell lines.

#1825 Synthesis and biological evaluation of novel 5-FU analogs against pancreatic cancer.

E. Frimpong[1], R. Bulusu[1], J. Okoro[1], A. Inkoom[1], N. Ndemazie[1], S. Rogers[2], X. Zhu[1], B. Han[3], E. Agyare[1];
[1]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL, [2]Department of Medicine, Division of Hematology and Oncology, University of Florida College of Medicine, Gainsville, FL, [3]Department of Surgery, Keck School of Medicine University of Southern California, Los Angeles, CA

Purpose: 5-Fluorouracil (5-FU) is one of the standard chemotherapy drugs used to treat pancreatic cancer. However, treatment only extends survival modestly, and disease recurrence is typical due to systemic instability, drug resistance, severe adverse effects, and limited benefits in patients with locally advanced tumors. These shortcomings have necessitated new strategies to develop safer and more effective anticancer agents. The study's objective was to synthesize, characterize, and evaluate the cytotoxic effects of novel 5-FU analogs in pancreatic cancer cells.

Methods: The analogs, XYZ-I-71 and XYZ-I-73, were synthesized by introducing a tetrahydrofuran ring on 5-fluorocytosine (a precursor of 5-FU) and conjugation with octanoyl chloride and lauroyl chloride, respectively. They were characterized by NMR, HPLC, micro-elemental analysis, and mass spectrometry. Cytotoxicity and cell migration studies were performed to determine the effectiveness of the analogs against MiaPaCa-2, PANC-1, and BxPC-3 pancreatic cancer cells. PARP apoptosis study was conducted in MiaPaca-2 cells using the analogs and 5-FU. The metabolic stability of analogs was determined by using human liver microsomes and quantified by HPLC.

Results: Analysis of the ^{1}H-NMR spectra displayed amide bonds at 7.80 ppm and 7.73 ppm, confirming the conjugation of octanoyl and lauroyl chloride to 5-fluorocutosine, respectively. The purity of both analogs was 99.6%. We found that the XYZ-I-73 (IC_{50} 3.6 ± 0.4μM) analog was most effective against MiaPaCa-2 cells compared to XYZ-I-71(IC_{50} 12.3±1.7μM), GemHCl (IC_{50} 24.2 ± 1.3 μM), Irinotecan (IC_{50} 10.1 ± 1.5 μM**)** and 5-FU (IC_{50} 13.2 ± 1.1 μM**)**. For PANC-1 cell growth inhibition, XYZ-I-73 (IC_{50} 3.9 ± 0.5) was again observed as the most effective agent compared to XYZ-I-71(IC_{50} 8.7±0.9 μM), GemHCl (IC_{50} 10.07±0.9), 5-FU (IC_{50} 20.43±1.2) and Irinotecan (IC_{50} 11.6 ±1.1). A similar pattern of XYZ-I-73 (IC_{50} 5.9±0.7) anticancer activity against BxPC-3 cells was found to be higher than XYZ-I-71(IC_{50} 7.7 ± 0.8), GemHCl (IC_{50} 10.95±0.9), 5-FU (IC_{50} 14±1.1) and Irinotecan (IC_{50} 9.5±1.0). For 24-hour MiaPaCa-2 cell migration studies, XYZ-I-73 (5μM) analog significantly reduced migration (# of migrated cells, 168±2.9) followed by XYZ-I-71(315±2.1), Gem-HCl (762±3.1) and 5-FU (710±3.2). PARP studies demonstrated significant inhibition of PARP expression of XYZ-I-73 treated cells compared to 5-FU and XYZ-I-71. Further, BAX and p53 expressions were significantly increased in cells treated with XYZ-I-73 compared to 5-FU and XYZ-I-71. Metabolic stability studies showed that 80 ± 5.9 % of XYZ-I-71 and XYZ-I-73 remained intact after 2-hour exposure in liver microsomal solution compared to 5-FU.

Conclusion: XYZ-I-73 demonstrated a remarkable cytotoxic effect and improved in vitro metabolic stability over the selected standard drugs and may have potential anticancer activity against pancreatic cancer.

#1826 New inhibitors of oncology targets discovered using the affinity-mediated selection of DNA-encoded chemical libraries followed by machine-learning.

A. D. Keefe, M. AbouZleikha, A. Baghaie, M. A. Clark, M.-A. Guie, J. P. Guilinger, R. Walsh, Y. Zhang;
X-Chem Inc., Waltham, MA

X-Chem's DNA-Encoded Chemical Library platform generates a large amount of binding data for each target it is screened against. Here, we report the application of machine learning to these large datasets with case studies that include the identification of novel inhibitors of two oncology targets. One, ERα, is an estrogen-activated receptor that controls transcription and stimulates breast cell proliferation including in breast cancer. The second, DCAF1, is the substrate-recognition component of an E3 ligase complex that is associated with the proliferation of colon cancer cells. Over 100 billion DNA-Encoded compounds were synthesized and screened for their affinity to each target. The selection output data was then featurized and used to train multiple machine-learned models. Models with demonstrated predictive power were then used to score virtual catalogue compounds which were subsequently acquired and tested. A range of successful data-science strategies will be described including those that lead to double-digit nM inhibitors of each of DCAF1 and ERα.

#1827 Exploring the feasibility and pharmacological mechanism of bufadienolides for the treatment of non-muscle invasive bladder cancer.

C.-C. Tu[1], M.-C. Chen[2], **C.-H. Chen**[1];

[1]College of Medicine, Taipei Medical University, Taipei, Taiwan, [2]College of Pharmacy, Taipei Medical University, Taipei, Taiwan

The majority of diagnosed bladder cancer (BC) patients is presenting with non-muscle-invasive bladder cancer (NMIBC). Although NMIBC generally exhibits a favorable prognosis, a considerable number of patients suffer from short-term recurrence, and high risks of progression to the more aggressive muscle-invasive bladder cancer (MIBC). Therefore, there is an urgent need for innovative treatments to improve outcomes for patients with NMIBC. For centuries, traditional Chinese medicine (TCM) has played a significant role in Asian society, with ongoing research to investigate the intricate relationship between TCM and treatment of cancers. Bufadienolides, the principal active components in Chansu, are derived from the aqueous extract of the parotoid glands and the dried secretion of the Asiatic toad. Bufadienolides have been reported to demonstrate significant antitumor and anti-inflammatory activities. This study aims to evaluate the feasibility and elucidate the pharmacological mechanisms that underlie the anticancer effects of bufadienolides in NMIBC. Our experiments show that bufadienolides significantly decrease cell viability, induce cell-cycle arrest at the sub-G1 phase, and activate apoptosis in NMIBC cells (RT112 and RT4). Protein analysis reveals the activation of apoptosis-related proteins (PARP, caspase-3, -8, -9) by bufadienolides in NMIBC cells. In conclusion, our findings suggest that bufadienolides present promising potential as therapeutic agents for NMIBC treatment.

#1828 Development and evaluation of novel gemcitabine analog for the treatment of pancreatic cancer.

J. Okoro[1], R. Bulusu[1], E. K. Frimpong[1], S. Rodgers[2], B. Han[3], X. Zhu[1], E. Agyare[1];
[1]Florida A&M University College of Pharmacy and Pharmaceutical Sciences, Tallahassee, FL, [2]Department of Medicine, Division of Hematology and Oncology, University of Florida College of Medicine, Gainesville, FL, [3]Department of Surgery, Keck School of Medicine University of Southern California, Los Angeles, CA

Purpose: Gemcitabine acts against pancreatic cancer and a wide range of solid tumors and it is known to be rapidly deaminated or metabolized in the blood to an inactive metabolite. To increase its therapeutic levels, gemcitabine is administered at high doses causing severe side effects. To improve its metabolic stability, increase cytotoxic activity, and limit the phenomena of resistance many alternatives have emerged, such as modifying gemcitabine. The purpose of this study was to develop and characterize a novel gemcitabine analog with improved stability and enhanced anticancer activity against pancreatic cancer.
Methods: A novel analog of gemcitabine (GemAGY) was designed and synthesized through chemical modification of gemcitabine hydrochloride (GemHCl) at position 4 with hydroxylamine. Gem AGY was characterized using nuclear magnetic resonance (NMR), micro-elemental analysis, and purity determined using High-Performance Liquid Chromatography (HPLC). Pancreatic cancer cell lines (MiaPaCa-2, BxPC3, and PANC-1) were treated with GemHCl and GemAGY. Cytotoxicity, cell migration, clonogenic assay, cell cycle, and apoptosis studies were performed to evaluate the effect of GemAGY against pancreatic cancer cell lines.
Results: The percent purity of GemAGY was over 99.6%. GemAGY demonstrated a higher cytotoxic effect against pancreatic cancer cells with a lower half-maximal inhibitory concentration (IC_{50}) value (2.5-fold high) compared with GemHCl. For MiaPaCa-2 cells, the IC_{50} value of GemAGY was found to be 1.63 ± 0.15 µm compared to GemHCl (4.0 ± 1.7 µm). GemAGY also exhibited higher cytotoxicity in PANC-1 (IC_{50}: 1.7 ± 0.2µm) compared to GemHCl (IC_{50}: 5.6 ±1.3 µm) and the IC_{50} value of GemAGY (3.2±1.1µm) in BxPC-3 cells was significantly better than GemHCl (5.5±1.0 µm). The cell cycle analysis indicated that GemAGY-treated MiaPaCa-2 cells at 1.50 µm concentration had a higher G_0/G_1 population (60.24%) compared to GemHCl-treated cells (55%). The cell migration studies showed that GemAGY-treated MiaPaCa-2 cells at 12.5 µm concentration significantly inhibited cell mobility towards the wound area with migrated cells found to be 65 ± 6 compared to Gem HCl (174.3 ± 4.0) (GemAGY vs GemHCl; $p<0.0001$). Similarly, GemAGY-treated PANC-1 cells at 12.5 µm concentration significantly inhibited cell mobility towards the wound area with (98 ± 5.1) compared to Gem HCl (254 ± 6.6). The quantitative analysis of apoptosis studies showed that GemAGY significantly induced higher apoptosis in a dose-dependent manner in MiaPaCa-2 cells compared to GemHCl as concentration increases (GemAGY vs GemHCl; $p <0.0001$).
Conclusion: This study demonstrates that GemAGY increases the anticancer activity of gemcitabine and may have the potential to improve the chemotherapeutic efficacy of gemcitabine in the treatment of pancreatic cancer.

#1829 Brusatol overcomes tyrosine kinase inhibitors resistance in myeloid leukemia cells by inhibiting translation of fast turnover protein cyclin D1 and Mcl-1.

H. Hua[1], Y. Yang[1], G. Lin[1], J. Zhang[1], S. Waxman[2], Y. Jing[1];

[1]Shenyang Pharmaceutical University, Shenyang, China, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Myeloid leukemia is characterized with fast proliferation and apoptosis evasion, which are controlled by mutant or activated tyrosine kinase signalings. Tyrosine kinase inhibitors (TKI) targeting BCR-ABL in chronic myeloid leukemia (CML) and FLT3-ITD in acute myeloid leukemia (AML) significantly improved the therapy, but not cure, due to the general resistance. Overactivated mTOR protein translation pathway is believed to be one of the mechanisms causing resistance and that targeting protein translation should be one effective approach to overcome resistance. Brusatol is a quassinoid extracted from the fruit of *Brucea javanica* and an inhibitor of protein translation. We tested its antiproliferation and apoptosis induction in a variety of AML and CML cell lines as well as in TKI resistant cell lines. Brusatol effectively inhibits the growth of seven leukemia cell lines with GI_{50} values less than 20 nM. Brusatol induces apoptosis in AML cell lines and induces G0/G1 phase arrest in CML cell lines. Brusatol decreases the levels of fast turnover protein cyclin D1 and Mcl-1. In FLT3-ITD inhibitor sorafenib resistant MOLM-13/Sor cell line brusatol exhibits similar growth inhibition and apoptosis induction with the parental MOLM-13 cells, associated with inhibition of Mcl-1 and FLT3-ITD proteins. In BCR-ABL inhibitor imatinib resistant K562/STI cell line brusatol is effective as in parental K562 cells, associated with inhibition of cyclin D1 and BCR-ABL proteins. Brusatol at 2 mg/kg effectively inhibit tumor growth of K562 xenografts without causing toxicity to normal organs. These data indicate that brusatol inhibits oncogenic protein translation and has potential to be used to treat TKI resistant leukemia.

#1830 Bergenin inhibits growth of human cervical cancer cells by decreasing galectin-3 and MMP-9 expression.

M. Singh[1], R. Chauhan[1], L. Malhotra[2], A. Gupta[1], G. Dagar[1], D. Das[3], S. Uddin[4], E. A. Samath[1], M. A. Macha[5], A. Akil[6], A. A. Bhat[6];
[1]All India Institute of Medical Sciences, Delhi, India, [2]Sri Venkateswara College, Delhi, India, [3]NYU Langone Health, New York, NY, [4]Hamad Medical Corporation, Doha, Qatar, [5]Watson Crick Center for Molecular Medicine, Islamic University of Science and Technology, Pulwama, India, [6]Sidra Medicine, Doha, Qatar

Cervical cancer is still the leading of cancer mortality worldwide, even after introducing a vaccine against Human papillomavirus (HPV), due to low vaccine coverage, especially in the developing world. Cervical cancer is primarily treated by Chemo/Radiotherapy, depending on the disease stage, with Carboplatin/Cisplatin-based drug regime. These drugs being non-specific, target rapidly dividing cells, including normal cells, so safer options are needed for more targeted therapy and lower off-target toxicity. Natural products offer an attractive option compared to synthetic drugs due to their well-established safety profile and capacity to target multiple oncogenic hallmarks of cancer like inflammation, angiogenesis, etc. In the current study, we investigated the effect of Bergenin (C-glycoside of 4-O-methylgallic acid), a natural polyphenol compound that is isolated from medicinal plants such as *Bergenia crassifolia*, *Caesalpinia digyna,* and *Flueggea leucopyrus*. Bergenin has been shown to have anti-inflammatory, anti-ulcerogenic, and wound healing properties. Still, its anticancer potential has been realized only recently. We performed a proteomic analysis of cervical carcinoma cells treated with bergenin and found it to influence multiple hallmarks of cancers, including apoptosis, angiogenesis, and tumor suppressor proteins. It was also involved in many different cellular processes unrelated to cancer, as shown by our proteomic analysis. Further analysis showed bergenin to be a potent -angiogenic agent by reducing key angiogenic proteins like Galectin 3 and MMP-9 (Matrix Metalloprotease 9) in cervical carcinoma cells at cellular level as shown by western blotting assay. Further understanding of this interaction was carried out using molecular docking analysis, which indicated MMP-9 has more affinity for Bergenin as compared to Galectin-3. Cumulatively, our data provide novel insight into the anti-angiogenic mechanism of Bergenin in cervical carcinoma cells by modulation of multiple angiogenic proteins like Galectin-3 and MMP-9 which warrant its further development as an anticancer agent in cervical cancer.

#1831 Reduction of PMN-MDSC level/activity following the consumption of white button mushroom in prostate cancer murine models and patients: A translational study to mitigate cancer progression.

X. Wang[1], S. Ma[1], P. Twardowski[2], C. Lau[1], Y. Chan[1], K. Wong[1], J. Wang[1], X. Wu[1], P. Frankel[1], T. G. Wilson[2], T. W. Synold[1], C. Presant[1], J. Yu[1], S. Chen[1]; [1]City of Hope National Medical Center, Duarte, CA, [2]Saint John's Cancer Institute, Santa Monica, CA

Frequent consumption of edible mushrooms, such as white button mushrooms (WBM), has been associated with a lower risk of prostate cancer [1]. Our laboratory at City of Hope has over 20 years of collective experience in defining the anticancer mechanisms of WBM [2, 3]. Previous studies have indicated that WBM consumption has anti-androgenic activities in prostate cancers in both preclinical models [4] and clinical trials [5]. In our first-in-human phase 1 trial on prostate cancer patients, we ensured the safety of consuming WBM in humans. In addition to observing a therapeutic-responsive decline in prostate-specific antigen (PSA), the levels of myeloid-derived suppressor cells (MDSCs) reduced in responders to WBM treatments [5]. These observations led us to hypothesize that WBM may mitigate the progression of prostate cancer in part by modulating the immune response. In the current study, we conducted translational research in syngeneic murine models and in prostate cancer patients from an ongoing phase 2 trial, aiming to define the immunomodulatory activity and mechanisms of WBM. We confirmed that WBM consumption in mouse models altered the number and function of immunosuppressive cells (MDSCs) and anti-tumor immune cells (T & NK cells), ultimately enhancing the intratumor and systemic immune responses. At a bulk-transcriptional level, we observed the elevated expression of programmed cell death protein 1 (PD-1) in xenograft tumors. In our single immune cell profiling of patients' blood specimens following 3 months of WBM consumption in freeze-dried tablets form, we investigated the transcriptional landscape of circulating immune cells in response to WBM interventions. The level of circulating neutrophil-associated PMN-MDSCs decreased, and the remaining cells showed transcriptional profiles associated with "neutrophil chemotaxis", "leukocyte aggregation", and "regulation of inflammatory response", as functions associated with enhanced anti-tumor activity. Lastly, we also showed in a mouse model that WBM consumption synergistically enhances the anticancer activity of anti-PD1 drugs, indicating that WBM may be used as adjuvant therapy with immune checkpoint inhibitors. In summary, our results from prostate cancer patients and murine models show the immunomodulatory effects of WBM consumption and provide a scientific foundation for the application of WBM in alleviating prostate cancer progression.

#1833 Antioxidant and antiproliferative activities of *Ipomoea cairica* extracts on three breast cancer cell lines.

A. M. Adegoke[1], D. Kyagaba[1], N. Hadebe[1], N. Mabaso[1], R. Lefojane[2], H. Baijnath[3], O. Odunola[4], M. Sekhoacha[1];
[1]University of the Free State, Bloemfontein, South Africa, [2]Central University of Technology, Bloemfontein, South Africa, [3]University of KwaZulu-Natal, Durban, South Africa, [4]University of Ibadan, Ibadan, Nigeria

Introduction: Breast cancer was the top cause of cancer deaths in 2020 with a death toll of 685 000 worldwide. Breast cancer treatments are based on drug specificity for unique receptors on the surface of some breast cancer types, there is a search for alternative treatments that are inclusive of different breast cancer types. Evidence suggests that antioxidants offer a protective effect against certain cancers. Studies on *Ipomoea cairica* have reported potential anticancer activity, hence this study aimed to assess the antioxidant and antiproliferative potentials of the extracts of *Ipomoea cairica* on three breast cancer cell lines.

Materials and Methods: The study protocol was approved by the University of the Free State Health Sciences Research Ethics Committee (HSREC), with approval number: UFS-HSD2022/0353/2607-0001. *Ipomoea cairica* stem and leaves were harvested and identified by Prof. H. Baijnath, Department of Conservation Science, School of Life Sciences, University of KwaZulu-Natal, Durban, South Africa, with specimen number 29 30 DD housed at the Ward Herbarium. The dried plant was extracted sequentially using organic solvents ranging from non-polar to polar and water. The extracts were filtered and concentrated using a rotary evaporator and then evaporated to dryness/lyophilized. Cells were cultured according to standard established procedure. The extracts were subjected to phytochemical analyses. FRAP, DPPH, and ABTS assays were done to examine antioxidant activity and MTT assays were used to evaluate the antiproliferative/cytotoxicity of the extracts against normal (Vero) and breast cancer cell lines (MCF-7, MDA-MB-231, and 4T1).

Results and Discussion: Extracts of *Ipomoea cairic*a possess alkaloids, saponins, phenols, flavonoids, phytosterols, tannins, triterpenoids, and anthraquinones. The results from the DPPH and ABTS assays revealed that the methanol and ethyl acetate fractions had significantly the highest antioxidant potentials while the methanol stem extract exhibited the most significant antioxidant activity in the FRAP assay. The DCM stem extract showed the highest antiproliferative activity against all tested cell lines.

Conclusion: Extracts of *I. cairica* possess significant antioxidant properties and antiproliferative activities against a wide array of breast cancer types including the most challenging triple-negative breast cancer. The plant would make for a strong herbal candidate for adjuvant therapy with breast cancer medication.

#1834 Discovery of a novel and highly selective PARP7 inhibitor for cancer immunotherapy.

X. Liu, Y. Wang, D. Xia, W. Zhang, S. Tian, Y. He, X. Feng, X. Yang, Q. Zhang, S. Jiang, M. Wu, J. Deng, Y. Wang, Y. Su, M. Yao, W. Yuan, X. You; Beijing Pharscin InnoBio Co., Ltd., Chongqing, China

Poly-ADP-ribose polymerase 7 (PARP7) is a member of the wider PARP enzyme family that modulate protein function by using nicotinamide adenine dinucleotide (NAD^+) as a substrate to transfer an ADP-ribose monomer onto specific amino acid acceptor residues of target proteins. PARP7 acts as a key repressor of type I interferon (IFN) signaling. Its inhibition combats tumor regression by enhancing antitumor immunity that depends on STING pathway. Therefore, PARP7 is emerging as a promising drug target for new immunotherapy. Using structure-based drug design and optimization, we discovered a novel PARP7 inhibitor, HSN002066, with high inhibitory potency (Enzyme assay IC50 = 0.96 nM) and high selectivity for PARP7 over PARP1/2/12/5A/5B/10 (IC50 =163.4/4.7/345.2/1790/110.2/>10000 nM, respectively). In addition, HSN002066 has excellent ADMET profiles with CYPs inhibition, IC_{50} >10 μM, human LMS $T_{1/2}$ > 60 min, hERG inhibition, IC_{50} > 30 μM,mouse oral bioavailability (F) 98.1%. Notably, HSN002066 and RBN-2397, the only PARP7 inhibitor currently in Ph 1/2 clinical development, displayed differentiated antiproliferative activities in cell line NCI-H1373 (IC_{50} are 387.8 nM and 15.2 nM, respectively). However, HSN002066 revealed remarkable antitumor effects as monotherapy (TGI 77% at 100 mg/kg) or combination with PD-1 antibody in CT-26 allograft model. The structure of HSN002066 was not presented and will not be disclosed at the time of presentation at AACR meeting.

#1835 Discovery of HSN003839, a highly potent inhibitor of ubiquitin-specific protease USP21 for cancer therapy.

X. Liu, Y. Wang, D. Xia, W. Zhang, Y. He, S. Tian, X. Feng, X. Yang, Q. Zhang, F. Liu, S. Jiang, R. Hu, M. Tang, X. Tang, Y. Liu, W. Yuan, X. You; Beijing Pharscin InnoBio Co., Ltd., Chongqing, China

USP21 belongs to the ubiquitin-specific protease (USP) subfamily of deubiquitinating enzymes (DUBs), which catalyze the removal of ubiquitin chain from targeted proteins. Numerous efforts over the last decade have identified a wide range of USP21 substrates and revealed the momentous and multifaceted role of USP21 in physiological and pathological states, especially in tumorigenesis, indicating that USP21 is an appealing target for the therapy of many correlative diseases. Nevertheless, progress in the development of potent USP21 inhibitors remains limited. Herein, we present the discovery of HSN003839, a highly potent and selective USP21 inhibitor with excellent anticancer activity and drug-like properties. Following screening tool compounds to identify hits and subsequent optimization, we discovered a series of compounds with strong enzymatic inhibition for USP21 with IC_{50} < 100 nM. Among them, HSN003839 displayed low nanomolar cancer cells proliferation inhibitions and excellent ADMET properties. The mouse oral bioavailability (F) is 76.5% at 10 mg/kg. In a preliminary mouse CDX model, monotherapy of HSN003839 showed 105% tumor growth inhibition (TGI) at 30 mg/kg with no obvious body weight reduction. Further biological characterization, efficacy and toxicity studies are ongoing.
The structure of HSN003839 was not presented and will not be disclosed at the time of presentation at AACR meeting.

#1838 Advancing cancer research with Next-Generation Protein Sequencing™ on Platinum™ by Quantum-Si .
K. D. Q. Nguyen;
Quantum-Si, San Diego, CA

Protein sequencing has the potential of playing a crucial role in advancing cancer research by providing insights into the specific proteins involved in cancer pathways. New discoveries from protein sequencing advance our understanding of cancer and potential targeted therapies. Here, we demonstrate the power of next-generation protein sequencing™ using the insight-generating Platinum™ platform. Individual peptides are digested from proteins and immobilized on a semiconductor chip and probed by dye-labeled N-terminal amino acid (NAA) recognizers, followed by subsequent aminopeptidase cleavage to expose each NAA in the peptide for recognition. By recording and analyzing fluorescent intensity, lifetime, and binding kinetics of each NAA binding event, we can decipher single amino acid substitutions and modifications.
To demonstrate the versatility of this methodology across proteins associated with cellular biology, we sequenced a series of interleukins: IL4, IL6, IL7, IL13, IL20, and IL34. Interleukins, a group of cytokines that play a vital role in cancer by modulating immune responses, promoting inflammation, and influencing tumor microenvironment, impacting tumor growth and the efficacy of treatments. We have successfully sequenced all the mentioned interleukins individually or within protein mixtures. Furthermore, we were able to sequence IL6 that was enriched through immunoprecipitation from human serum. Finally, we demonstrated the unique potential of Platinum in detecting post-translational modifications (PTMs) relevant to cancer, as exemplified by the successful identification of arginine citrullination in vimentin, an onco-protein that promotes cancer cell mobility and invasion into surround tissues.
These results demonstrate the transformative potential of next-generation protein sequencing using Platinum™ in enabling the identification of proteins in complex mixtures and biofluids, as well as the detection of critical PTMs implicated in human pathophysiology, offering valuable insights into cancer research.

#1839 Proteomic and glycoproteomic differences associated with prostate cancer in urine.

N. Shamsher[1], F. Garcia-Marques[1], A. Bermudez[1], M. R. Flory[2], S. J. Pitteri[1];

[1]Stanford University School of Medicine, Palo Alto, CA, [2]Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background and Aims: Prostate cancer is one of the most common cancers affecting men in the United States, with ~288,300 new cases and 34,700 deaths in 2023 alone. Prostate-specific antigen (PSA), the most widely used prostate cancer biomarker, lacks specificity and sensitivity, leading to unnecessary biopsies, overdiagnosis, and overtreatment. There is an urgent unmet clinical need to find new biomarkers that can distinguish patients with benign disease from those with prostate cancer. Urine is an attractive source for these biomarkers as prostate-derived proteins are more highly concentrated in urine than in blood. To better understand both global proteomic and glycoproteomic molecular signatures that could lead to improved diagnostics for prostate cancer, we analyzed urine samples from unaffected men, men with benign prostatic hyperplasia (BPH), and men with prostate cancer.

Methods: Urine samples (N = 58 total) were collected from unaffected men (N = 17), men with BPH (N = 24), and men with prostate cancer (N = 17). Samples were digested with trypsin and analyzed with high-resolution liquid chromatography-tandem mass spectrometry (LC-MS/MS) for shotgun proteomics analysis. Association with cancer was determined through supervised analysis using Pearson correlation. For glycoproteomics analysis, intact glycopeptides were enriched using strong anion exchange-electrostatic repulsion hydrophilic interaction chromatography, fractionated using high pH reversed-phase chromatography, and analyzed with LC-MS/MS. Association with the three conditions was determined through several rounds of supervised analysis using Pearson correlation.

Results: In total, 3542 human proteins were identified, and 78 proteins ($p < 0.01$) were significantly associated with prostate cancer. The glycolysis pathway and lysosome pathway were enriched in samples from men with prostate cancer. In the glycoproteomics analysis, 36 proteins ($p < 0.05$) had altered glycan diversity in one of the three conditions, and the complement and coagulation cascade pathway and the lysosome pathway were highly enriched. Six proteins ($p < 0.05$) had significantly increased glycan diversity in the cancerous samples than in the BPH and normal samples.

Conclusions: This study identifies a set of interesting proteomic and glycoproteomic differences in urine from men with prostate cancer compared to BPH and non-cancer samples, which warrant further investigation in additional sample cohorts as potential novel biomarkers.

#1840 MYBBP1A AMPylated by SELO to influence its function.

W. Li;
Tianjin Medical University, Tianjin, China

Introduction: MYBBP1A, named Myb-binding protein 1A, is a protein that mainly locates in nucleolar and shuttles between the nucleus and cytoplasm, nuclear import may be mediated by KPNA2, however export depend partially on XPO1/CRM1. It activates or represses transcription via interactions with sequence specific DNA-binding proteins. Repression may be mediated at least in part by histone deacetylase activity (HDAC activity). Acts as a corepressor and in concert with CRY1, represses the transcription of the core circadian clock component PER2. Preferentially binds to di-methylated histone H3 'Lys-9' (H3K9me2) on the PER2 promoter. MYBBP1A overexpressed in tumor than normal and have a significantly negative correlation with patient overall survival. We aim to explore the role of MYBBP1A in PDAC progression and underlying mechanism. In our research, we find and prove the novel AMPylating enzyme SELO-AMPylate MYBBP1A inhibits PDAC progression and modified site in S1353 and further influence downstream relative RNA, such as 18s rRNA, 28S rRNA.

Methods and Materials:

1. The function of MYBBP1A in tumorigenesis at the organismal and cellular levels.

MYBBP1A is widely expressed in different tissues. Firstly, we explored the correlation between MYBBP1A expression level and PDAC through TCGA database and Kaplan-Meier plotter. We then established MYBBP1A gene knockout mice mating with PDX/$P53^{K172H}$/$KRAS^{G12C}$ to induced a primary PDAC model to analyze the progression of pancreatic cancer. The effect of MYBBP1A on tumor cell growth and proliferation was explored through cell proliferation analysis and a nude mouse tumor xenograft model.

2. The MYBBP1A AMPylated by SELO influence MYBBP1A function in cell proliferation was investigated at the molecular and cellular levels.

AMPylation-specific antibodies were used to confirmed MYBBP1A AMPylated by SELO in both cell lysates and purified proteins through experiments such as CO-IP and WB. Stably expressed MYBBP1A WT/S1353A were constructed to verify the function in cell proliferation or migration by SELO. The signaling molecules were further explored through CO-IP and WB to identify the changed molecular by SELO-AMPylate-MYBBP1A, revealing the entire signaling pathways of AMPylation-mediated regulation of PDAC proliferation.

Conclusion: We have demonstrated the function of MYBBP1A in the formation of pancreatic cancer, and further revealed SELO-AMPylate-MYBBP1A importance in the process of reversing MYBBP1A's role, which has played a certain significance for the treatment of pancreatic cancer and the exploration of related therapeutic targets.

#1841 Investigating mechanisms of tumor eradication by blocking SIAH E3 ligase, a major tumor vulnerability, in EGFR/RAS-driven human cancer.

J. M. Baker[1], A. Howell[1], A. Hannah[1], J. Wulfkuhle[2], N. Stahr[1], R. Gallagher[2], E. Petricoin[2], A. Tang[1];
[1]Eastern Virginia Medical School, Norfolk, VA, [2]George Mason University, Manassas, VA

Introduction: Hyperactivation of the EGFR/RAS pathway is a major driver of tumorigenesis and metastasis. It has been difficult to design effective therapies contravening the compensatory EGFR/RAS downstream effector pathways to achieve curative antitumor efficacy. Seven in absentia homologues ($SIAH_1$ and $SIAH_2$) are RING-domain E3 ubiquitin ligases that function as the most downstream signaling gatekeeper of the EGFR/RAS pathway. Our prior studies demonstrated that SIAH inhibition led to tumor eradication of multiple malignant human cancers cell lines in xenograft models. We propose that SIAH is a major tumor vulnerability/actionable drug target for inhibiting persistent EGFR/RAS pathway activation; we aim to elucidate the molecular mechanisms underpinning antitumor efficacy of our SIAH inhibitor.

Methods: Reverse phase protein arrays (RPPAs) in conjunction with Principal Component Analysis (PCA) were used to quantify fold-changes of 300 proteins/phospho-proteins that were significantly up- or down-regulated in response to SIAH inhibition ($p < 0.001$). Independent RPPA assays were performed in triplicate on doxycycline (DOX)-inducible MiaPaCa, MDA-MB-231, MDA-MB-468, HeLa, and A459 cell lines in which our SIAH inhibitor, $SIAH_2^{PD}$, expression was induced by a Tet-ON/OFF system. Four experimental conditions were used: Tet-ON control cells without DOX (group A) and with DOX induction (group B), Tet-ON-$SIAH_2^{PD}$ cancer cells without DOX (no $SIAH_2^{PD}$ inhibitor expression in group C) and with DOX induction ($SIAH_2^{PD}$ inhibitor expression in group D). The ratios of D/C/B/A, D/C, D/B, C/A, and B/A were calculated in a pairwise comparison after normalization to GAPDH as an internal control. To validate identified targets of interest, immunoblotting of biological quadruplicate cell lysates for each respective cell line were performed for group C and D at 3-, 5-, and 7-days post DOX induction; target proteins' expression normalized to β-actin, α-Tubulin, or GAPDH respectively, and the pathway alterations induced by SIAH2 inhibition were standardized, quantified, and analyzed.

Results: RPPA analyses identified 6 proteins (NFκB, Caspase-7, PARP, Cofilin, PD-L1, and Collagens) exhibiting differential expression in response to SIAH2 blockade. Western blot analyses independently confirmed their altered expression patterns, further supporting their roles as the biological readout of $SIAH_2$ loss-of-function in human cancer cells.

Conclusion: The RPPA-based cancer pathway mapping provides valuable molecular insight into the antitumor efficacy and reveals a major tumor vulnerability in human cancer pathway/network rewiring when SIAH2 is blocked in late-stage malignant cells. The kinomic data support our innovative strategy to design anti-SIAH-based anti-EGFR/RAS target therapies to control and eradicate undruggable and incurable human cancers in the future.

#1842 Global proteomics reveals integrin signaling as a driver of infiltration in glioblastoma.

L. J. van Winden, R. S. Sajid, O. A. Borhani, E. R. Kamski-Hennekam, N. Gopal, A. Leon, P. Diamandis;
University of Toronto, Toronto, ON, Canada

Background: Glioblastoma (GBM), a notably aggressive brain cancer, presents significant treatment challenges due to its propensity for deep, diffuse infiltration into healthy brain tissue. This trait enables GBM to resist and survive following surgery and conventional adjuvant therapies. Emerging evidence suggests that signaling between GBM stem cells (GSCs) may be instrumental in this invasive behavior. Our study aimed to unravel the intricacies of these intercellular communication networks within glioblastoma by employing comprehensive proteomic profiling across a diverse array of patient-derived GSC lines.
Methods: We conducted our study using a sex-stratified cohort comprising 17 patient-derived GSC lines. Proteomic profiling encompassed analyses of both GSC lysates and conditioned media under various oxygen conditions (normoxia at 20% O_2, hypoxia at 1% and 0.2% O_2). Additionally, we incorporated the glioma cerebral organoid (GLICO) system, facilitating co-cultures of GSCs with human cerebral organoids. For in-depth proteomic analysis, we utilized advanced TMT-based liquid chromatography-tandem mass spectrometry (LC-MS/MS; Q-Exactive, Thermo Fisher).
Results: Our findings corroborate that GSCs adhere to the tripartite model of proliferation, invasion, and hypoxic response. A salient discovery was the consistent enrichment of integrin signaling pathways in GSCs under hypoxic conditions. Specifically, we observed a significant association between upregulation in integrin signaling (BIOCARTA_INTEGRIN_PATHWAY) and elevated KRAS activity (SWEET_KRAS_TARGETS_UP: $r=0.43$, $p<0.01$), as well as hypoxic responses (WINTER_HYPOXIA_UP: $r=0.76$, $p<0.0001$) in GSCs. Notably, in the GLICO model, both integrin signaling and KRAS pathways were markedly upregulated in the presence of GSCs compared to cerebral organoids alone ($p<0.05$).
Conclusions: This research highlights the pivotal role of integrin signaling in mediating the invasive attributes of glioblastoma. The data underscore the importance of further exploring key modulators within the integrin signaling pathway, presenting a promising avenue for the discovery of novel therapeutic targets in glioblastoma treatment.

#1843 Integrating machine learning with microfluidic technologies for proteomic profiling of extracellular vesicles in triple-negative breast cancer.

M. Kim[1], J. Kim[1], Y. Kim[1], S. Lee[1], S. Moon[1], J.-y. Hyon[2], K.-A. Hyun[3], Y. Yang[2], S. Ha[4], S. Park[4], H. Gawk[4], H. Lee[2], E. Han[2], J. Kim[2], H.-I. Jung[4], Y.-H. Chung[2], S. Kim[1];

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Korea Basic Science Institute, Cheongju, Korea, Republic of, [3]Korea Electronics Technology Institute (KETI), Seongnam, Korea, Republic of, [4]Yonsei University, Seoul, Korea, Republic of

Accurate diagnosis of breast cancer using circulating biomarkers present in plasma remains an important challenge. In particular, protein changes in tumor-derived extracellular vesicles (tdEVs) have emerged as potential biomarkers for breast cancer diagnosis because they accurately reflect dynamic changes in tumors. In this study, we compared the proteomes of extracellular vesicle (EV) isolated from the plasma of 100 breast cancer patients and 30 healthy individuals who visited Severance Hospital between Mar 2010 and Dec 2015. Microfluidic chip-based protocol that facilitates the removal of contaminants such as albumin and immunoglobulins was used for the extraction of enriched tdEVs with small amounts of plasma. Comparative analysis of the proteomes identified 26 significant biomarkers that could indicate differences between breast cancer patients and healthy individuals. Using the LsBoost-CNN-SVM hybrid machine learning algorithm, we especially identified key EV protein biomarkers for detecting triple-negative breast cancer (TNBC), a breast cancer subtype with a poor prognosis and a high recurrence rate, as well as lacking therapeutic and diagnostic targets. Remarkably, a signature consisting of three EV proteins, specifically extracellular matrix protein 1 (ECM1), mannose-binding lectin 2 (MBL2), and biotinidase (BTD), effectively distinguished TNBC patients from healthy individuals. In our proteomic analysis set (n=73), this signature exhibited impressive performance, achieving a sensitivity of 93.3% and specificity of 93% in the accurate discrimination of TNBC from the control group. The validation set (n=40) confirmed these findings, with 100% sensitivity and 80% specificity. This signature not only served as a diagnostic tool but also provided valuable insights into the risk of recurrence and patient prognosis. We found a novel diagnostic approach that holds the potential to revolutionize breast cancer diagnostics by enhancing the reliability of tumor-related information obtained from blood samples.

#1844 Proteomic characterization of decitabine resistance in acute myeloid leukemia reveals signaling pathway crosstalk dampens the effectiveness of combination therapy.

J. C. Pino[1], C. Posso[1], S. Sharzehi[2], S. Gosline[1], C. Hutchinson-Bunch[1], E. Traer[2], P. D. Piehowski[1], K. D. Rodland[1], J. W. Tyner[2], T. Liu[1], A. Agarwal[2]; [1]Pacific Northwest National Laboratory, Richland, WA, [2]OHSU, Portland, OR

Acute myeloid leukemia (AML) is a deadly form of blood cancer primarily characterized by genetic abnormalities that guide treatment strategies. In recent years, several new therapies have emerged to target these genetic abnormalities such as gilteritinib or quizartinib, which target an internal tandem duplication (ITD) of the FLT3 gene. Additional drugs have been developed to target core cellular processes, such as venetoclax and the decitabine. Despite initial positive responses to these treatments, patients eventually relapse as they develop resistance to the individual drugs. One common approach to drug resistance is to add an additional drug to the treatment protocol. However, patients then develop further resistance to not just a single drug but multiple. As such, understanding the origins of both single and multi-drug resistance is crucial for improving treatment efficacy and clinical outcomes. Here, we present a collection of cell lines that have developed resistance to single, double, and triple drug combinations of gilteritinib, venetoclax, and decitabine. Through comprehensive global and phospho proteomics analyses under multiple conditions together with computational pathway interrogation, we unravel the underlying molecular mechanisms responsible for resistance. Leveraging our previous model of early and late drug resistance, we investigate the emergence of resistance to drug combinations involving gilteritinib alone, gilteritinib with venetoclax, gilteritinib with decitabine, and gilteritinib with venetoclax and decitabine. Through the characterization of molecular signatures for each drug combination, we identify molecular signals that are specific to combination treatments. Specifically, we find that the emergences of decitabine resistance alters the cellular pathways to effectively downregulate targets of venetoclax and gilteritinib, ultimately dampening the response to these drugs, regardless of co-administration. These findings provide a potential explanation for the limited success of combination treatments involving hypomethylating agents, as observed in recent clinical trials. Our results underscore the importance of monitoring proteome-level changes in single and combination drug treatments and shed light on the simple and intuitive reasons behind the lack of synergy often observed in combination therapies. In conclusion, we establish cell line models of resistance to various combinations of venetoclax, gilteritinib, and decitabine. By integrating global and phospo proteomic measurements, we gain a comprehensive understanding of the intricate molecular mechanisms underlying resistance.

#1845 11,000-plex aptamer based proteomics of colorectal cancer stools for the discovery of novel disease biomarkers.

C. Mohan[1], K. Vanarsa[1], J. Castillo[1], R. Bresalier[2], N. Chia[3];
[1]University of Houston, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX, [3]Mayo Clinic, Rochester, TX

Given the morbidity and mortality associated with colorectal cancer, novel biomarkers are clearly warranted, especially for early detection, particularly for advanced adenomas. An earlier 1317-plex aptamer-based proteomic screen of stool proteins revealed 92 proteins to be significantly elevated in CRC stool, with the most discriminatory proteins being MMP9, haptoglobin, myeloperoxidase, fibrinogen, and adiponectin (PMID: 34117903). Results from a recent 2000-plex proteomic screen of CRC stools are detailed below, while a 11,000-plex aptamer based proteomic screen is in progress. Comprehensive proteomic screening revealed 116 proteins to be differentially expressed in CRC stool compared to control stool, with 45 being elevated 2-fold or higher. 37 of these proteins were ELISA validated in 3 independent cohorts. Stool MMP-8, MMP-9, Hemoglobin, PGRP-S, Haptoglobin, Myeloperoxidase and Fibrinogen emerged as being most discriminatory for distinguishing CRC from healthy controls (AUC: 0.91-0.95), while Stool Fibrinogen, MMP-9, Hemoglobin, MMP-8, and PGRP-S best distinguished advanced adenoma from healthy control (HC) stool, with stool Fibrinogen topping the list with an ROC AUC value of 0.86, as detailed in Table 1. Functional pathway analysis revealed a significant over-representation of pathways related to anti-oxidant activity, integrin/receptor binding, cytokines, blood coagulation, and lipoprotein biosynthesis in patients with CRC compared to HC. Nuclear Factor IC (NFIC) and IKZF2 were identified as key regulators of the molecular cascades over-represented in CRC. Stool Fibrinogen, MMP-8, MMP-9, PGRP-S, Haptoglobin, and Myeloperoxidase emerge as promising biomarkers for distinguishing CRC/advanced adenomas/healthy stools, outperforming Hemoglobin. Thus, comprehensive proteomics and independent ELISA validation have uncovered novel stool biomarkers for identifying CRC and advanced adenomas, that warrant further head to head comparison against current diagnostic tests.

#1846 Integrative histopathologic, proteomic, phosphoproteomic, genomic, and transcriptomic characterization of renal cell carcinoma.

W. Kwon[1], C. Kim[1], H. Koo[2], W. Bae[3], E. Hwang[3], W. Ham[1], N. Cho[1], J. Sa[4], J. Park[2], S. Rha[1];
[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]National Cancer Center, Goyang, Korea, Republic of, [3]Chonnam National University Medical School, Hwasun, Korea, Republic of, [4]Korea University College of Medicine,, Seoul, Korea, Republic of

Although histologically defined subtypes exist, renal cell carcinoma (RCC) is a heterogenous disease, resulting in various treatment outcomes and prognosis. Here, we conduct comprehensive profiling of RCC with histopathologic, proteomic, phosphoproteomic, genomic, and transcriptomic analyses on tumor and paired adjacent normal tissues from 113 patients. RCC tumors are distinctly separated from corresponding normal tissues through multi-omics clustering, a distinction further supported by pathway analysis. In addition, various hallmarks of cancer were differentially observed at the individual patient level, highlighting the intertumoral heterogeneity of RCC. Proteomic subtyping classifies RCC tumors into four subtypes (C1-4) with distinct phosphoproteomic, genomic, and transcriptomic characteristics with prognostic and predictive implications. Among these subtypes, C1-3 were almost composed of clear cell RCC (ccRCC; 96.8%), whereas C4 was composed of non-clear cell RCC (nccRCC) or other types of cancer (100.0%). Among each subtype, C1 (N=37) exhibits the strongest adaptive immune response and angiogenesis with favorable prognosis after surgical resection. C2 (N=39) was characterized with enrichment in DNA repair pathways and alteration in *VHL* (100.0%) along with *BAP1* (24.0%) genes. C3 (N=19) was associated with enrichment in inflammatory response with dismal prognosis and therapeutic resistance to tyrosine kinase inhibitors targeting vascular endothelial growth factor receptors. C4 (N=18) was exclusively enriched with nccRCC with active mitochondrial and oxidation phosphorylation. Transglutaminase 2 (*TGM2*), a crosslinking enzyme, is identified as a potential marker with therapeutic implication for ccRCC. Collectively, this study reports a large-scale multi-omics-based approach of RCC, providing insights into biologic underpinning and evidence for rational treatment selection as well as linking the multi-omics-derived phenotypes to clinical outcomes of ccRCC.

#1847 Human protein atlas: A resource for target expression across 19 tissues.

S. Schaer, M. Tognetti, R. Bruderer, P. Shichkova, **Y. Feng**, L. Reiter;
Biognosys AG, Schlieren, Switzerland

Proteins are the primary targets and off-targets of therapeutics such as small molecule and biologics. Thus, a thorough understanding of their expression profiles across various human tissues in health and disease is essential through all stages of drug development. However, generating such a comprehensive proteome profile for each tissue poses a major analytical challenge due to the large dynamic range of protein abundance within a tissue and the enormous complexity introduced by distinct proteoforms. These proteoforms may arise from genetic variations (e.g. mutations), posttranscriptional events (e.g. isoforms from alternative splicing) or posttranslational modifications, resulting in more than a million protein species from 20,000 protein-coding genes. Thanks to advancements in sensitivity and speed in the recent years, mass spectrometry (MS)-based proteomics can now be routinely applied to quantify ten thousand of proteins in biological samples. Taking advantage of MS being an unbiased and matrix-agnostic method, we pivoted the generation of a high quality and uniform protein expression atlas of 19 healthy human tissues and 3 cancerous tissues. We constructed the atlas in two parts aiming to address the following two aspects respectively: 1) a deep library providing evidence for protein/proteoform presence in each of the 22 tissues; 2) quantitative profiles for cross-comparison in all tissues. For the first part, each tissue sample was subjected to an extensive fractionation process followed by MS analysis of each of the fractions. In total, we identified 20’025 protein groups mapped to 17’715 protein-coding genes, providing protein-level evidence for > 90% of all protein-coding genes annotated in the neXtProt repository. Among all identified proteins, 10’755 were detectable across all tissues. Notably, we identified 37 proteins mapping to putative genes. In part two of the atlas, quantitative expression profiles were generated for 15’772 protein groups using TrueDiscovery DIA-MS across the 22 tissues. These data allow us to investigate ubiquitous vs. tissue-restricted protein expression of various protein classes such as surface receptors or kinases. Moreover, we performed correlation analysis between protein expression and mRNA abundance across 19 tissues, demonstrating that for a significant portion of the proteome, mRNA level-information is not an adequate proxy for protein expression. Collectively, this MS-based resource alleviates dependency on antibody-based reagents. We envision that the tissue atlas can be expanded to cover various disease indications, providing valuable insights for target discovery and assessment of target/off-target tissue distribution.

#1848 The Cellular Thermal Shift assay and its applications in Target ID, MoA determination and biomarker discovery.

T. Friman, A. Chernobrovkin, T. Tolvanen, E. Gilson, S. Lundgren, V. Brehmer, **D. Martinez Molina**;
Pelago Bioscience, Stockholm, Sweden

With the Cellular Thermal Shift Assay (CETSA) celebrating its first decade since the PoC publication, the method has gained much interest in the basic science field as well as become an industry standard in applied drug discovery setting. In the last few years it has become apparent that in addition to providing information about drug-protein interaction, CETSA based thermal profiling of cells can help describe additional aspects of cell biology as it gives insight into the activating and rewiring of protein-protein interaction networks inside the cell upon stimuli. In the work presented here, we have used CETSA coupled to high resolution mass spectrometric readout to profile the response patterns of about 8000 proteins to several hundred molecular probes and marketed drugs. The goal has been to provide a map of wanted and unwanted effects following treatment and to correlate it to alternative readouts, by for example cellular imaging and cell death assays.

We have applied the CETSA protocol for close to five hundred compounds, many in several cell-lines (HepG2, U87MG and K562). The experimental setup includes the step of treating the cells with a certain compound at a fixed concentration. After incubation for an hour, we heated the cells to a range of temperatures, followed by a lysis protocol and pooling of the samples. After this, the samples have been centrifuged to separate the soluble from insoluble fraction. The soluble fraction has then been prepared for MS acquisition using TMT based multiplexing.

Typically, this allowed us to monitor changes in thermal stability among more than 8,000 proteins, as a consequence of compound treatment. This data reveals specific compound “fingerprints” that can be used to decipher mode of action and identify biomarkers. Despite the short incubation time, proteins with compound-induced thermal stability shifts are not only targets/off-targets (direct binders), but also downstream, and sometimes upstream, pathway members and general cellular responses. All data combined makes the basis of the Target Engagement Atlas. Here we can see clusters of compounds, sharing similar protein binding profiles. Among the most prominent ones are mTOR inhibitors, NSAIDs, as well as tubulin binders. Alternatively, one can use this resource to reveal clusters of “pharmacologically” associated protein networks. We show that pharmacological perturbation allows identification of clusters representing tight protein complexes (for example ribosomes), known metabolic pathways (folate biosynthesis), molecular functions (kinases), as well as networks of proteins linked only by ligand binding specificity.

CETSA MS allows for unbiased, cellular, and molecular profiling of compound effects. Together with data from clinical settings, as well as in vivo/in vitro end point assays it is possible to correlate the CETSA patterns to wanted but also unwanted responses.

#1849 High throughput interactome profiling of small bioactive peptides.

C. D. Warren, N. Yardeny, J. B. Geri;
Weill Cornell Grad. School of Medical Sci., New York City, NY

Interactions between individual biomolecules give rise to emergent signaling and regulatory networks that govern complex and varied biological processes. Disruption of these finely tuned interactions can result in imbalanced cellular states that drive diseases; for example, many metastatic cancers become desensitized to checkpoints encoded by molecular contacts. Still, numerous interaction networks remain unmapped within the cell, namely those between cryptic endogenous peptides and their protein targets. This is primarily due to the lack of investigation around translation events that occur from “noncoding” genetic material and limited knowledge of how translated polypeptides can mature into functional proteolytic fragments. Moreover, technologies to map protein-peptide interactions in an efficient and reliable manner are limited, leaving a gap in knowledge of how many bioactive peptides regulate cellular homeostasis. We aim to map the interactions of short (30 > amino acid), bioactive peptides that are (1) translated from noncanonical open reading frames or (2) generated through proteolytic cleavage of nascent proteins. To achieve these goals, we are leveraging the recently developed MicroMap technology and label-free mass spectrometry-based proteomics. A scalable and reliable platform to discover peptide binding targets will uncover the elusive functional roles of understudied endogenous peptides in cell signaling and their part in driving cancer cell survival.

#1850 From proteomic analysis to early investigations of combining inhibitors targeting PCNA and histone deacetylase.

C. M. Li[1], K. Garcia-Mansfield[2], R. G. Lingeman[1], L. Gu[1], R. J. Hickey[1], P. Pirrotte[2], L. H. Malkas[1];
[1]Beckman Research Institute of City of Hope, Duarte, CA, [2]Translational Genomics Research Institute, Phoenix, AZ

Proteomic changes were investigated in a neuroblastoma cell line, SK-N-AS, treated with a small molecule inhibitor, AOH1996, designed to specifically bind proliferating cell nuclear antigen (PCNA) in cancer. PCNA is crucial to DNA replication, DNA repair, transcription, cell cycle control, and chromatin organization through interactions with different proteins. Pathway analysis of differential protein expressions between treated and untreated cells revealed less G2/M DNA damage checkpoint regulation and decreased assembly of RNA polymerase complex. Phosphoproteomic analysis by PTM Signature Enrichment Analysis (PTM-SEA) identified signatures of kinase activities, signaling pathways, and perturbations. Specifically, the histone deacetylase inhibitors belinostat and vorinostat were identified as enriched perturbation signatures. Both inhibitors were tested in combination with AOH1996 in SK-N-AS as well as cell lines derived from breast, lung, ovarian, and pancreatic cancer, revealing drug synergies at specific dose combinations. Western blot analysis showed that belinostat decreased protein expression of PCNA, suggestive of mechanistic synergies with AOH1996+belinostat combination therapies. Our proteomic analysis reveals a therapeutic potential of combining AOH1996 and histone deacetylase inhibitors for treating cancer with possibly lower drug dose and toxicities compared to single drug treatment.

#1851 Comprehensive multi-level proteomics characterization of gastric cancer.

Y. Wang, Clinical Proteomic Tumor Analysis Consortium (CPTAC);
Johns Hopkins University School of Medicine, Baltimore, MD

Gastric cancer is the leading cause of cancer related deaths worldwide, accounts for over 700,000 deaths each year. There is an urgent need for advancing therapeutic strategies for patients with gastric cancer. Addressing this need, the Clinical Proteomics Tumor Analysis Consortium (CPTAC) has conducted a comprehensive characterization of gastric cancer, aiming to elucidate the complex molecular mechanisms driving this cancer type, and to discover underlying cancer biology that will form the basis for developing new approaches for precision medicine. This comprehensive study includes an integrated multi-level proteomics analysis of 165 surgically resected gastric cancer and 41 normal adjacent tissues. We employed a multi-faceted approach, analyzing the proteome, phosphoproteome and glycoproteome, along with other protein modifications including ubiquitination, acetylation, and tyrosine phosphorylation. Furthermore, we extended our research to include 74 pairs of early-onset gastric cancer and normal adjacent tissues, analyzed using a proteomic approach. We can totally identify more than 12,000 protein groups with median identification of 9750 protein groups per sample. This expansive dataset helps constructing a comprehensive multi-omics atlas of gastric cancer, offering a deep understanding into the disease's molecular landscape. The depth of this study was enhanced by incorporating multi-level proteomics data across 6 tiers, facilitating an unprecedented multi-level proteomics analysis. Our integrated approach allows us to illustrate the changes in protein expression, protein modifications, signaling pathways, and protein networks during tumorigeneis. This analysis uncovers potential therapeutic targets for personalized treatments. Overall, our study provides a multi-omics atlas for gastric cancer, a profound insight into gastric cancer biology, contributing significantly to the understanding of its pathogenesis. It could pave the way for precise treatments for gastric cancer, underscoring the potential of multi-level proteomics analyses in advancing personalized medicine.

#1852 NCI's Clinical Proteomic Tumor Analysis Consortium: A proteogenomic cancer analysis program.

M. Mesri, E. An, X. Zhang, J. Bavarva, A. I. Robles, T. Hiltke, H. Rodriguez;
National Cancer Institute, Rockville, MD

The National Cancer Institute's Clinical Proteomic Tumor Analysis Consortium (NCI's CPTAC) is a national effort to accelerate the understanding of cancer biology through the integration of large-scale proteome and genome analysis, or proteogenomics. The program which is composed of a Tumor Characterization Program and a Translational Research Program (proteomics.cancer.gov) aims to leverage the investments made in cancer research by understanding the molecular changes by proteogenomically characterizing cancers and accelerating the basic discovery toward clinical impact. All data and analytical tools are made broadly available to the research community through public databases to maximize utility and public benefit.CPTAC teams have characterized a plethora of treatment-naïve tumor types, including colorectal, ovarian, breast, clear cell renal cell carcinoma, uterine corpus endometrial carcinoma, lung adenocarcinoma, lung squamous cell carcinoma, brain (including adult, pediatric, and adolescent and young adult), head and neck squamous cell carcinoma, and pancreatic ductal adenocarcinoma (proteomics.cancer.gov/resources/milestones-and-publications). Ongoing projects include acute myeloid leukemia (AML), cutaneous melanoma, sarcoma, oligodendroglioma, gastric, prostate, liver, and thyroid cancers. In the PTRC Program, CPTAC is partnering with NCI-sponsored clinical trials to support clinically relevant research projects that would elucidate biological mechanisms of therapeutic response, resistance, and/or toxicity in cancers including AML, multiple myeloma, melanoma, and lung cancers.

All mass spectrometry-based proteomic, genomic, and imaging data (histopathology and radiology) are made publicly available at the CPTAC Proteomic Data Commons (pdc.cancer.gov), Genomic Data Commons (gdc.cancer.gov), and the Cancer Imaging Archive (cancerimagingarchive.net) / Imaging Data Commons (imaging.datacommons.cancer.gov) respectively. CPTAC is also supporting development of new proteogenomic data analysis tools (proteomics.cancer.gov/resources/computational-tools). In addition, the CPTAC Assay Portal (assays.cancer.gov) is a public resource populated with mass spectrometry-based targeted proteomic assays developed by the consortium for quantitatively measuring proteins of interest, including those discovered through comprehensive tumor characterization. Lastly, well-characterized monoclonal antibodies targeting cancer-specific proteins and peptides are also made available at CPTAC's Antibody Portal (antibodies.cancer.gov).

#1853 Prostate specific membrane antigen (PSMA) glycoforms and prostate cancer progression.

S. Mackay, I. O. Oduor, T. C. Burch, D. A. Troyer, O. J. Semmes IV, **J. O. Nyalwidhe**;
Eastern Virginia Medical School, Norfolk, VA

Introduction: Prostate cancer (PCa) is the most common non-skin malignancy and the second leading cause of cancer related death in men. Prostate cancer is a heterogeneous disease with diverse clinical outcomes ranging from indolent asymptomatic cases to very aggressive and potentially lethal metastatic forms of the disease. Early detection of PCa is predominantly through determination of serum PSA levels and digital rectal examinations (DRE). Subsequently, biopsy based Gleason Grade Scores and TNM staging, tumor size or mpMRI are used to assess disease severity and progression. However, due to the low specificity of PSA concentration in diagnosis and prognosis, biopsy complications, and high mpMRI costs, there is still a critical need to identify and develop novel noninvasive biomarkers that discriminate indolent from aggressive PCa upon diagnosis. Our long-term objective is to discover biomarkers for aggressive PCa, develop and to implement them into robust clinical testing minimally invasive assays for PCa risk stratification at diagnosis. The current focus is on Prostate-Specific Membrane Antigen (PSMA), a membrane bound glycoprotein, that is significantly over-expressed in aggressive and metastatic prostate carcinomas and with poor patient prognosis. The role of its glycosylation status and composition in disease progression and its glycoforms on biomarker development and therapeutics is unknown. Aberrant glycosylation of glycoproteins occurs in many cancers, and it influences disease progression. We rationalize that differential glycosylation of PSMA correlate with progression to aggressive PCa and that PSMA glycopeptides and glycoforms can be used as diagnostics and prognosticators for aggressive disease.

Methods/Results: PSMA was isolated from risk Grade Group stratified post-DRE urines, seminal plasma and prostate cancer cell lines with different metastatic phenotypes cell line lysates. Intact glycopeptides were isolated, purified and analyzed by qualitative and quantitative mass spectrometry to identify site specific glycoforms. Our data demonstrate differential expression of unique PSMA glycoforms that correlate with disease risk and severity. Conclusions: Differential glycosylation of PSMA correlates with PCa disease progression to aggressive phenotypes and may have utility in disease stratification. Ongoing studies focus on determining if these qualitative and quantitative changes have diagnostic/prognostic value and if these be integrated with other PCa biomarkers to improve their prognostic power in discriminating aggressive PCa.

Acknowledgements: This work was supported by the DOD, USAMRAA, through the Prostate Cancer Research Program under Award No. W81XWH18-1-0228. Opinions, interpretations, and conclusions are those of the author and are not necessarily endorsed by the USAMRAA.

#1854 Plasma proteomic biomarkers identify non-responders and reveal biological insights about the tumor microenvironment in melanoma patients after PD1 blockade.

Samuel J. Wright[1], Deepika Yeramosu[1], Milan Parikh[1], Marijana Rucevic[2], Ngan Nguyen[3], Russell W. Jenkins[4], Keith T. Flaherty[4], Nir Hacohen[4], Genevieve M. Boland[4], Arnav Mehta[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Olink Proteomics, Watertown, MA,[3]Teiko.bio, Salt Lake City, UT,[4]Massachusetts General Hospital, Boston, MA

Most patients treated with immune checkpoint blockade (ICB) do not have durable treatment responses, stressing a critical need to identify early non-invasive biomarkers of response. Circulating biomarkers provide easy access for serial monitoring and can provide insight on the mechanisms of response to ICB. We performed plasma proteomics (~3000 proteins) on 250 metastatic melanoma patients before and on ICB treatment and performed analysis to identify response- and time point-associated peripheral protein biomarkers. We next generated patient-matched peripheral blood lymphocyte (PBL) surface proteomic data and tumor sample bulk transcriptomic data to build a multimodal dataset. We leveraged these data to train machine learning models for unsupervised analysis and to classify treatment responses and learned features predictive of survival and patient endotypes. Using univariate linear models to predict protein abundance based on time point, response and the interaction term for time point and response, we identified 343 time point-associated proteins, 141 response-associated proteins, and one interaction-associated protein. We further investigated response-related proteins by fitting multivariate logistic regression and cox proportional hazards regression models to further investigate the ability of these proteins to predict response, progression-free survival (PFS), and overall survival (OS) and identify those proteins that are most important in predicting response. We calculated covarying modules of proteins that were found to be either response-associated or time point-associated to discover underlying biological networks at different treatment time points and disease response states. Additionally, we leveraged these modules to endotype patients and identified trends in protein modules across patient subsets, including modules related to biological processes such as immune infiltration, apoptosis, metaplasia and cell adhesion. To understand the contribution of different compartments on plasma proteomic abundance, we studied correlations of plasma protein abundance with PBL surface protein abundance and tumor bulk mRNA-sequencing expression. Finally, we integrated our data modalities and fit various statistical models to evaluate the relative importance of plasma protein biomarkers in predicting response compared to PBL surface proteins and tumor bulk mRNA-sequencing expression. Together, these data represent one of the deepest peripheral biomarker studies using paired samples in melanoma patients treated with anti-PD1 therapy.

#1855 Proteomics driven biomarker discovery for high-grade serous ovarian carcinoma from archived tissue specimens.

A. Shenoy, **G. Arad**, D. Kovalerchik, A. Manor, N. Simchi, D. Daitchman, K. Pevzner, E. Seger;
Protai, Tel Aviv, Israel

High-Grade Serous Ovarian Carcinoma (HGSOC) is a highly aggressive and heterogeneous cancer with variable treatment responses. Current treatment strategies, including surgical resection and chemotherapy, are often ineffective due to a lack of molecular markers to predict drug sensitivity and patient prognosis. Mass spectrometry-based proteomics analysis is a powerful tool for biomarker discovery, but it is restricted by the availability and quality of archived clinical specimens.

In this study, we developed a proteomics-based biomarker discovery pipeline that optimizes the extraction and sample preparation from archived tissue specimens of HGSOC patients. Macrodissection of the tumor rich tissue areas of interest ensured sample purity and statistical power for comparative analysis. Using liquid chromatography-tandem mass spectrometry (LC-MS/MS), we conducted a comprehensive, global proteomics analysis of FF tissue specimens from 25 HGSOC patients to associate proteomic profiles with patient outcomes. Combining high-resolution mass spectrometry proteomics of clinical samples with advanced computational tools for clinical data mining, we were able to identify pathways associated with HGSOC that hold clinical significance.

Our unique biomarker discovery platform provides a novel strategy for detecting cancer vulnerabilities from archived tissue samples and identifying proteomic biomarkers linked with treatment response and patient prognosis beyond BRCA mutation status.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Based Technologies and New Inhibitors
Poster Session

#1857 Development of monoclonal antibodies against CD44v specifically expressed in cancers.

Yukinari Kato, Hiroyuki Suzuki, Mika K. Kaneko

Tohoku University Graduate School of Medicine, Sendai, Japan

CD44 is a transmembrane glycoprotein that binds to the extracellular matrix including hyaluronic acid. Human CD44 has 19 exons, 10 of which are commonly present in all isoforms. CD44 standard isoform (CD44s) is composed of the common exons, and is expressed in many cell types. CD44 variants (CD44v) are produced by alternative splicing, in which the remaining nine variant exons are inserted into the CD44 standard isoform in various combinations. The CD44 isoforms have overlapping and unique functions. Both CD44s and CD44v harbor hyaluronan-binding motifs that promote interaction with the tumor microenvironment, which activate various signaling pathways in tumor cells. CD44v is mainly expressed in epithelial cells and is involved in cell adhesion, proliferation, and survival. Overexpression of CD44v is observed in many solid tumors and plays an important role in invasion, metastasis, and acquisition of stemness. In this study, we employed the Cell-Based Immunization and Screening method (CBIS method), and established highly sensitive anti-CD44 monoclonal antibodies (mAbs) using CD44v3-10-overexpressed cell lines as immunogens. After that, we determined the epitopes by enzyme-linked immunosorbent assay and investigated their applications. As a result, we successfully established eight mAbs against each CD44v (v3 to v10), which can be used for flow cytometry, western blotting, and immunohistochemistry. Furthermore, some of them exhibited cancer specificity against pancreatic cancers, colorectal cancers, gastric cancers, or oral cancers, indicating that established anti-CD44v mAbs are useful for the antibody therapies.

#1858 Discovery of AT86474, a highly efficacious anti-ROR1 ADC utilizing a proprietary payload.

B. Tan, X. Zhang, Y. Wu, Y. Cheng, S. Liu, P. Du, C. Zhong, B. Zou;
Axcynsis Therapeutics, Singapore, Singapore

ROR1 is a pseudo kinase that is involved in the non-canonical Wnt signaling pathway and is highly expressed during early embryonic development. In adult tissues, ROR1 is expressed at very low levels but its increased expression is observed in hematological cancers and a broad range of solid tumors. AT86474 is a highly homogeneous antibody drug conjugate incorporating AxcynCYS^{TM} technology that allows reproducible site-specific conjugation with DAR4 composition greater than 97%. AT86474 utilizes a proprietary payload derived from an FDA approved drug that was optimized in-house for increased potency and with altered PK properties to limit systemic exposure. In vitro, the payload displays broad sub-nanomolar activity across multiple cancer cell lines, including those resistant to paclitaxel, DM1, MMAE and DXd. The payload is conjugated via an enzyme-cleavable linker optimized for solubility, stability, and high drug to antibody ratios. AT86474 uses a humanized and optimized monoclonal antibody that demonstrates selective binding to ROR1-positive cells and subsequent internalization, sub-nanomolar potency in vitro and strong bystander effects. AT86474 was evaluated in a preclinical CDX mouse model of ovarian cancer, where substantial tumor growth inhibition was observed with two weekly doses at as low as 1 mg/kg. As ROR1 over-expression is also observed in many solid tumors, such as pancreatic, gastric, breast and lung cancers, the use of AT86474 can be expanded to benefit a large patient population.

#1859 Diverse CD28-binding IgG and heavy chain-only antibodies for T-cell engager development.

K. Lam, S. Zhi, L. Kraft, E. Vigano, W. Wei, C. Faralla, E. Odekunle, K. Bullock, E. Marshall, M. Cid, G. Leung, **L. DeVorkin**, S. Duncan;
AbCellera, Vancouver, BC, Canada

Engagement of the CD28 co-receptor by T-cell engager (TCE) molecules can enhance activation, proliferation, and anti-tumor activities, particularly in immunosuppressive tumor microenvironments. In this study, we present data on a diverse panel of CD28-binding IgG and heavy chain-only (HCAb) antibodies for T-cell co-stimulation. Our diverse panel of CD28-binding antibodies add co-stimulatory building blocks to our TCE repertoire. Using single B cell-screening, we identified fully human IgG and HCAb binders to human and non-human primate CD28 with a high degree of sequence diversity. We selected a subset of antibodies for expression and assessed binding to both human and cynomolgus CD28-expressing cells. These antibodies displayed a wide range of binding avidities in the sub-nanomolar to micromolar range, and epitope binning analysis identified seven epitope communities. Co-stimulatory activity for a subset of molecules was assessed *in vitro*. Antibodies displayed a wide range of crosslinked T-cell activation with the majority showing no activation independent of crosslinking. Data presented here describe a diverse set of CD28-binding antibodies ready for engineering into co-stimulatory TCEs. Combining these molecules with our TCE platform or other T-cell activating strategies will enable development of novel TCE modalities with co-stimulatory function for diverse tumor targets.

#1860 The smallest antibody class: Cow ultralong CDR3 knobs as a new class of biomolecule for therapeutics and diagnostics.

V. Smider;
Applied Biomedical Science Institute, San Diego, CA

Engineered antibodies, including bispecifics and ADCs, are now a major drug class for oncology and other therapeutic areas. There are two fundamental antibody fragments: the Fv (heavy and light chain variable region fragments, derived from most species), and VHH (heavy chain 'only' V regions, derived from camelids and sharks). Cows produce antibodies with an unusually long VH CDR3 region, which can be up to seventy amino acids in length and is comprised of a β-ribbon "stalk" and disulfide-bonded "knob" minidomain which sits atop the stalk. The knob region is highly diverse and can bind cryptic epitopes with high affinity. We recently developed the technology to produce knob domains independently of the antibody, and at ~5 kDa are the smallest functional antibody fragment (https://doi.org/10.1073/pnas.2303455120). The high stability and small size could enable improved tissue penetration and development of novel therapeutics, including knob-drug conjugates or extremely small bispecific molecules.

#1862 ZW191 - a FRα-targeting antibody drug conjugate with strong preclinical activity across multiple FRα-expressing indications.

S. Lawn, A. Hernandez Rojas, R. Colombo, J. Wong, K. Wu, V. Fung, M. Lasalle, M. E. Petersen, L. Degefie, A. Sagoe-Wagner, D. Urosev, L. Yang, A. Wu, C. Kim, A. Chua, K. Stahl, G. C. Winters, J. C. H. Fann, J. Rich, S. Barnscher;
Zymeworks Inc., Vancouver, BC, Canada

Background: Folate Receptor alpha (FRα) is a validated cancer target that is prevalently expressed in multiple cancers with high unmet need, including ovarian cancer and other gynecological cancers, NSCLC, endometrial cancer and TNBC. Due to FRα's favorable expression profile, multiple antibody-drug conjugates (ADCs) are being explored in this setting. Here we present the preclinical characterization of a new anti-FRα ADC, ZW191. ZW191 is a bystander active antibody drug conjugate (ADC) comprised of a humanized IgG1 antibody conjugated to a novel camptothecin-based topoisomerase 1 inhibitor (TOPO1i) payload, ZD06519, via a maleimidocaproyl (MC) anchor and a glycyl glycyl phenylalanyl glycyl (GGFG)-aminomethyl (AM) cleavable linker at a drug-to-antibody ratio (DAR) of 8. ZW191 is projected to undergo IND submission in 2024.

Materials and Methods: The novel antibody and drug-linker components of ZW191 were generated, characterized, and optimally integrated. The apparent binding affinity and cellular internalization of the ZW191 antibody were determined in FRα-expressing cells. Tumor spheroid cancer cell cultures were utilized to determine ZW191's degree of tissue penetration and its cytotoxicity. The bystander activity of ZW191 was assessed using antigen positive and negative co-culture experiments. The anti-tumor activity of ZW191 was evaluated in a panel of ovarian cancer, NSCLC, endometrial cancer and TNBC patient-derived xenografts (PDX) spanning a range of FRα expression. ZW191 was evaluated in toxicology and pharmacokinetic (PK) studies performed in non-human primates (NHP).

Results: The antibody component of ZW191 features a favorable binding profile with strong binding to FRα, and drives superior tumor spheroid penetration, cellular internalization, and payload delivery compared to FRα targeted antibodies used in multiple other ADCs. ZW191 demonstrates potent activity in FRα expressing cell cultures and effective bystander activity. In a panel of PDX models representing a range of FRα expression, ZW191 demonstrates compelling anti-tumor activity across ovarian and endometrial cancers, NSCLC and TNBC. ZW191 demonstrates an encouraging tolerability profile in NHP, with favorable PK. The promising efficacy, tolerability, and PK support the potential of ZW191 as a novel therapeutic agent that may help address unmet need in patients with high and low FRα expressing cancers.

#1863 α-ABN501, a novel antibody targeting claudin-3, demonstrates the potential to be a new therapeutic option for small cell lung cancer.

J. Choi[1], S. Hong[1], H. Park[1], J. Kim[1], S. Lee[1], M.-R. Seo[2], S.-B. Bang[2], H.-J. Shin[2], K.-i. Jeong[1], H. Yang[3], S. Hong[4], J. Choi[1], N. Kim[1], Y. Shin[2], S. Lee[1]; [1]ABION Inc., Digital-ro, Guro-gu, Seoul, Korea, Republic of, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Republic of Korea, 1 Gwanak-ro, Gwanak-gu, Seoul, Korea, Republic of, [3]College of Pharmacy, Kyungsung University, 309, Suyeong-ro, Nam-gu, Busan, 48434, Republic of Korea., 309, Suyeong-ro, Nam-gu, Busan, Korea, Republic of, [4]College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul 08826, Republic of Korea, 1 Gwanak-ro, Gwanak-gu, Seoul, Korea, Republic of

Small Cell Lung Cancer (SCLC) is the most aggressive and lethal type of lung cancer, characterized by a poor prognosis, with a 5-year survival rate of only 7% for overall SCLC patients. Limited treatment options such as chemotherapy and immune-checkpoint inhibitor therapy are available for SCLC patients, very often followed by rapid recurrence and metastasis. Thus, new effective treatment options for SCLC remain high unmet medical needs. Overexpression of claudin-3 (CLDN3), one of the tight junction proteins, is observed in various types of cancers. The abnormal conformation of tumor cell growth leads to the external exposure of CLDN3, in contrast, the normal cells that maintain high polarity do not expose CLDN3 externally. Therefore, CLDN3 could be a potential therapeutic target and biomarker. Based on the analysis of the expression pattern of CLDN3 using a single-cell RNA sequencing dataset derived from SCLC patients, we found that CLDN3 could be a superior and unique target of SCLC compared to others (e.g., DLL3 and B7H3). Hence, we developed a fully human monoclonal antibody, afucosylated ABN501 (α-ABN501), which has high specificity and strong affinity to CLDN3-expressing cells. The α-ABN501 antibody showed CLDN3-dependent killing effects against the SCLC cells, expressing different levels of CLDN3, as assessed via the antibody-dependent cellular cytotoxicity (ADCC) assay wherein using NK cells expressing CD16a (NK-92MI-CD16a), peripheral blood mononuclear cells (PBMC), and primary NK cells. Further, the efficacy study in the CLDN3-expressing SCLC cell derived xenograft mouse model revealed that α-ABN501 was highly efficacious in inhibition of tumor growth. Collectively, we elucidated that the ADCC activity of α-ABN501 was dependent on the expression level of CLDN3 and especially specific to the SCLC cells, which underlines significant suppression of tumor growth. Present study data sets suggest that the α-ABN501 can be a potential new therapeutic option for SCLC. In addition, the α-ABN501 antibody is currently under way of development into new drug platforms for further applications.

#1864 New generation of fully human anti-progranulin monoclonal antibodies inhibiting migration and tumor formation of non-small cell carcinoma cells.

G. Serrero[1], J. Dong[1], B. Yue[1], M. Oshimura[2], C. Dong[3], J. Hayashi[3],
[1]A&G Pharmaceutical, Inc., Columbia, MD, [2]TransChromosomics, Inc, Yonago, Japan, [3]Precision Antibody, Columbia, MD

Advanced carcinomas of the lung or the breast are characterized by invasiveness and poor survival. Identifying novel targeted therapies to potentiate standard of care (SOC) therapy, remains an unmet need. In the past 4 years, numerous targeted therapies in Oncology have been approved by the Food and Drug Administration (FDA). However, the identification of targeted therapies against direct tumor biological drivers remains important. Progranulin (PGRN/GP88) is a biological driver of tumorigenesis, survival, and drug resistance in multiple cancers including breast and lung cancers. PGRN/GP88 tissue expression is an independent prognostic factor of recurrence and mortality while elevated serum PGRN/GP88 level is associated with poor outcomes such as progression of disease and shortened survival. The importance of inhibiting PGRN/GP88 expression or action effect on the proliferation and tumor growth of several cancers has been established by several laboratories including ours. In the current study, in association with Precision Antibody, we developed anti-PGRN/GP88 fully human monoclonal antibodies by immunizing TC transgenic humanized mice with recombinant human progranulin. Within 60 days following the start of immunization, several fully human anti-progranulin monoclonal antibodies were developed, characterized by several functional assays including neutralization, inhibition of PGRN/GP88 cell surface binding, proliferation, migration *in vitro* and tumor formation *in vivo*. Results: The inhibition of PGRN/GP88 action by fully human monoclonal antibodies inhibited cell proliferation and migration in a dose-and time-dependent fashion. Octet analysis determined Kd in the range of 10^{-11} M to 10^{-10} M. Transwell assay showed that anti-PGRN treatment inhibited migration of non-small cell lung cancer cells such as H1299 and A549 cells. In vivo xenograft studies with H1299 cells injected in athymic nude mice showed that fully human anti-PGRN antibodies inhibited tumor growth when compared to antibody control treated mice. Conclusion: PGRN/GP88 represents a therapeutic target for non-small cell carcinoma with two companion diagnostics (tissue test and ELISA to measure GP88 circulating levels). The use of the TC transgenic mice allows for the rapid development of fully human high affinity monoclonal antibodies bypassing the need for chimerization or humanization and affinity maturation of monoclonal antibodies raised in mice or other humanized systems.
This work is supported by SBIR grants R44 CA 224718 and R44CA162729 from the National Cancer Institute to GS.

#1865 HDP-102 - a CD37-targeting Amanitin-based-ADC for the treatment of NHL - non-clinical data package.

S.-J. Neuberth[1], K. Decker[2], C. Orlik[1], I. Dranova[1], A. Palfi[1], T. Hechler[1], A. Pahl[2], M. Kulke[2];
[1]Heidelberg Pharma Research GmbH, Ladenburg, Germany, [2]Heidelberg Pharma AG, Ladenburg, Germany

Background: Antibody-drug conjugates (ADC) are gaining importance as anti-cancer therapy. Most ADCs are based on cytotoxic warheads targeting only proliferating cells. In contrast, HDP´s proprietary ATAC platform utilizes amatoxins as payload. Amatoxins are specific inhibitors of eukaryotic RNA polymerase II, suppressing a key function in the protein metabolism not limiting their cytotoxicity to proliferating cells. Furthermore, there are no known resistance mechanisms against amatoxins in mammalian cells (i.e. multi drug resistance transporters), making ATACs a promising new class of anti-cancer ADCs. Here we present pre-clinical data on the anti-CD37 ATAC HDP-102. CD37 is a transmembrane protein expressed exclusively on immune cells, mainly mature B-cells, and in many B-cell malignancies, including Non-Hodgkin's Lymphoma (NHL).
Material and Methods: HDP-102: anti-CD37 ADC based on cysteine-reactive, site-specific amatoxin-linker constructs produced by HDP
Cytotoxicity assays: CellTiter Glo 2.0 (Promega) assays on $CD37^{pos}$ cell lines MEC-2, Raji-luc, Ramos and $CD37^{neg}$ Nalm-6 cells
Efficacy studies: Disseminated MEC-2 and Raji-Luc mouse xenograft tumor models in single dose experiments
Tolerability study in Cynomolgus monkeys: i.v. HDP-102 treatment on days 1 and 22; blood sampling for PK analysis; necropsy and histopathology on days 28 and 64
Results: HDP-102 showed full-blown cytotoxicity with EC_{50} values in the low nanomolar range in all $CD37^{pos}$ cell lines *in vitro* but no cytotoxicity on $CD37^{neg}$ cells. *In vivo*, the anti-tumor efficacy of HDP-102 was evaluated in disseminated CDX models of NHL. A single dose of 0.5 mg/kg HDP-102 already led to complete tumor remission in all animals in a Raji-luc model and 60% survival on day 100 in a MEC-2 model, demonstrating the high potency of HDP-102 in NHL models. In a tolerability study in Cynomolgus monkeys, i.v. administration of HDP-102 was well tolerated up to 2.5 mg/kg without clinical signs of toxicity. Microscopically, decreased cellularity in lymphoid tissue was the main finding, caused by the targeted effect of HDP-102 on $CD37^{pos}$ cells. The HNSTD of 2.5 mg/kg together with the potent anti-tumor efficacy of HDP-102 leads to a therapeutic window of ~200 for HDP-102.
Conclusion: CD37 is an ideal target for ADCs due to its high prevalence in B-cell malignancies and limited expression on healthy cells. We have demonstrated that the anti-CD37 ATAC HDP-102 is a promising drug candidate for the treatment of NHL. HDP-102 showed excellent anti-tumor efficacy in CDX models even after single doses. Pharmacological activity of HDP-102 was also seen in Cynomolgus monkeys as evidenced by depletion of B-cells in lymphoid organs. Furthermore, HDP-102 was well tolerated in monkeys. Taken together, based on pre-clinical data, HDP-102 is a promising new treatment option for NHL patients combining a good safety profile with strong anti-tumor efficacy.

#1866 Discovery of mutation-independent EGFR degrading bispecific antibodies that suppress tumor growth in preclinical tumor models.

J. Sitrin, L. Marshall, H. Tran, K. Ng, K. Hoi, J. Gramespacher, Z. Huang, A. Goodrich, F. Housley, M. Dayao, M.-T. Wang, K. Pance, A. Chen, K. Carlin, L. Zhang, J. Lee, R. Hannoush, K. Flanagan, M. Vinogradova, I. Rondon, S. Gardai;
EpiBiologics, San Mateo, CA

Extracellular targeted protein degradation (eTPD) has emerged as a promising new drug modality focused on targeted elimination of extracellular and transmembrane proteins. In contrast to intracellular protein degraders, such as proteolysis targeting chimeras (PROTACs) and molecular glues which require ubiquitin-proteosome cellular degradation pathways, extracellular protein degraders can additionally harness endosomal-lysosomal protein degradation. Two recently published examples of extracellular protein degraders include AbTACs (antibody-based PROTAC) which co-engage a protein of interest (POI) and transmembrane E3 ligases, and KineTACs (cytokine receptor-targeting chimeras) which utilize endogenous cytokine receptors to degrade extracellular POIs. These bispecific antibody degrader platforms not only have advantageous pharmacological and drug-like manufacturing properties, but can also be engineered for tissue-specificity and to address multiple complementary targets, with the goal of increased efficacy and decreased toxicity. To that end, we have greatly expanded the extracellular degrader repertoire beyond AbTACs and KineTACs, with a novel bispecific antibody degrader platform called TrainTACs (tissue receptor antigen internalization targeting chimeras). To demonstrate the potential of this novel extracellular degrading platform, we developed degraders for the canonical receptor tyrosine kinase epidermal growth factor receptor (EGFR). EGFR is an oncogenic driver, that has been clinically validated in lung, colorectal and head and neck cancers, but patient benefit has been limited by treatment-related acquired resistance mutations and on-target/off-tumor dose-limiting toxicities. The potential of our TrainTACs, AbTACs and KineTACs to overcome the limitations of current therapeutic modalities was assessed. Gene expression profiles from tumor and normal tissues were evaluated to identify potential degraders co-expressed with EGFR in tumors. More than 70 unique bispecific antibody constructs spanning 20 receptors were generated and screened in tumor cell-based assays to evaluate EGFR antagonism, internalization, and degradation. TrainTACs, AbTACs and KineTACs degraded EGFR in multiple tumor cell lines covering a range of EGFR mutations. Degradation of EGFR led to deep inhibition of EGFR signaling, robust inhibitory effects on tumor spheroids, and in xenograft mouse tumor models. In conclusion, eTPD represents a promising new drug modality, and TrainTACs, AbTACs and KineTACs have expanded the toolbox of extracellular targeted protein degraders that can be utilized in a target-, tissue- and disease-specific manner.

#1867 LBL-049: A novel neutralizing antibody against GDF15 for the treatment of cachexia.

Baohui Wang, Xiao Huang, Mi Ding, Jing Huang, Yurong Qin, Fengxia Li, Jing Guan, Jianming Sun, Guojin Wu, Xiaoxiao Liu, Jordan Zhu, Shoupeng Lai, Xiaoqiang Kang, **Hong Ling**

Nanjing Leads Biolabs Co.,Ltd., Nan Jing, China

Background: Cachexia is a disorder characterized by loss of body weight with specific losses of skeletal muscle and adipose tissue and occurs in the progression of many diseases, especially in cancer. Growth differentiation factor 15 (GDF15) belongs to the transforming growth factor β (TGFβ) superfamily. GDF15 can bind to the glial cell-derived neurotrophic factor (GDNF) family receptor α-like (GFRAL) protein, which is primarily expressed in the hindbrain. This interaction activates the GFRAL-RET signaling pathway, which transmits anorectic neural signals, leading to weight loss, affecting fat and muscle degradation, and inducing cachexia. Anti-GDF-15/GFRAL antibodies have the potential to reverse this response, making them vital therapeutic targets for cachexia. Herein, a novel humanized GDF-15 neutralizing antibody (LBL-049) was developed with higher efficacy and better specificity than ponsegromab, the same target antibody from Pfizer, in pre-clinical studies.

Methods: LBL-049 was generated from mouse hybridoma, humanized by CDR grafting, the Fc region was further engineered to silence Fc effector. The binding affinity and specificity were detected by Fortebio and ELISA respectively. The function of blocking GDF15/GFRAL/RET signaling was examined in the reporter-gene cell assays. The in vivo efficacy of restoring cachexia was demonstrated in both tumor-induced and cisplatin-induced mouse cachexia models, in which preliminary pharmacokinetics (PK) and pharmacodynamics (PD) studies were also conducted. And a single-dose PK study was conducted in rats.

Results: LBL-049 had high binding affinities to both human and cynomolgus GDF-15 proteins with high specificity, did not bind with other TGF family members as compared with ponsegromab. In reporter-gene cell assays, LBL-049 blocked GDF15/GFRAL signaling more potently than ponsegromab. In HT1080 tumor-induced or cisplatin-induced mouse cachexia model, LBL-049 prevented weight loss by neutralizing circulating GDF-15 in a dose dependent manner, at low dose of 1 mpk in HT1080 cachexia model, LBL-049 was more efficacious than ponsegromab to restore the body weight loss. The PK profile was excellent after single dosing of LBL-049 in rats. LBL-049 also showed good developability, i.e., low viscosity and good stability.

Conclusion: LBL-049, a novel GDF15 neutralizing antibody with high affinity and specificity, showed great potency to inhibit GDF15/GFRAL/RET signaling in vitro and prevent weight loss in various mouse cachexia models, which are encouraging for future development for the treatment of cachexia.

#1868 Target-dependent considerations for the design of bispecific T-cell engagers.

Matt Mai, Raffi Tonikian, Peter Bergqvist, **Michael Kennedy**, Alaa Amash, Nathalie Blamey, Gabrielle Conaghan, Valentine de Puyraimond, Patrick Farber, Allison Goodman, Ahn Lee, Jessica Fernandes Scortecci, Cindy-Lee Crichlow, Akram Khodabandehloo, Tova Pinsky, Kate Caldwell, Jessica Patterson, Philippe Pouliot, Davide Tortora, Oscar Urtatiz, Ping Xiang, Irene Yu, Kirstin Brown, Kelly Bullock, Andrea Chee, Stephanie K. Masterman, Neil Aubuchon, Lindsay Devorkin, Bryan C. Barnhart, Tim Jacobs

AbCellera, Vancouver, BC, Canada

In this study, we present data from four T-cell engager (TCE) programs in which we leveraged our highly diverse CD3-binding antibodies to generate functional bispecifics for each tumor target. By aggregating tumor-cell killing and cytokine data across four tumor targets with different properties and target expression levels, we have gained novel insights into target-specific considerations for the development of CD3 TCEs. TCEs recapitulate a synapse between T cells and target cells. T cell function downstream of this synapse is determined by the complex interplay between multiple independent factors. These include properties of the CD3- and tumor-binding arms, such as binding kinetics and epitope, as well as target-dependent factors such as cell type and target density. We used our diverse CD3 antibodies to engineer bispecific TCEs against four solid tumor targets: PSMA, B7-H4, 5T4, and the peptide-MHC target MAGE-A4. For each target, we engineered and characterized hundreds of bispecific molecules using high-throughput assays, including T-cell dependent tumor-cell killing, cytokine release, developability assessments, and structural studies. Here, we compare data from across these programs to elucidate the impact of target-dependent parameters on TCE function. These data provide important insights for the selection of appropriate TCE targets and efficient design of bispecific antibodies with high therapeutic potential.

#1869 The AI-powered KisoSeek™ platform identifies functional anti-TROP2 heavy-chain antibodies with potent anti-cancer activity.

S. E. Cousineau[1], A. Subedi[2], R. Wargachuk[1], J. The[1], X. Wang[2], W. Hou[1], A. Nair[1], W. Qiu[1], A. Zhou[2], T. Cheng[2], M. Babaie[3], B. Gojogh[3], M. Montero[1], H. Zahreddine[1], E. Undzys[2], L. Lai[1], G. Ngan[1], L. Da Cruz[1], D. Young[1];

[1]KisoJi Biotechnology Inc., Montreal, QC, Canada, [2]KisoJi Biotechnology Inc., Toronto, ON, Canada, [3]KisoJi Biotechnology Inc., Waterloo, ON, Canada

Functional heavy-chain antibodies (HCAbs) are promising therapeutic agents for targeted cancer therapy. Since they do not have a light chain, HCAbs have a small antigen-binding domain that can unlock new functionalities by reaching epitopes that are inaccessible to classical antibodies. HCAbs can be obtained by immunizing camelids, but this approach is expensive, time-consuming, and results in a limited antibody repertoire. Previously, we engineered the KisoMouse™- a transgenic mouse with multi-camelid species VHH/VH genes and the complete alpaca D and J gene segments integrated into the mouse IgH locus, along with a functional loss of the heavy chain CH1 domain to eliminate light chain pairing. KisoMouse™ are healthy and generate a robust serum HCAb response against a diverse range of immunogens.

Trophoblast cell surface antigen-2 (TROP2) is a membrane protein overexpressed in numerous solid tumor types such as breast, colon, and lung cancers. TROP2 is associated with tumor aggressiveness and decreased survival and has emerged as an attractive therapeutic target. An anti-TROP2 antibody-drug conjugate has been approved for breast and bladder cancer, but challenges related to payload toxicity and resistance highlight the need for alternative therapeutics.

We had previously identified an anti-TROP2 HCAb with high potency in *in vivo* preclinical models of human breast and colorectal cancer. Conventional antibody discovery approaches are resource-intensive and can fail to identify rare antibodies. To overcome such limitations, we developed the KisoSeek™ platform, a proprietary AI-powered toolkit that categorizes antibodies in an immune response based on their structural and biophysical features. With KisoSeek™, we analyzed the entire antibody repertoire generated from KisoMouse™ immunized with TROP2 and rapidly identified HCAbs with similar features as the high potency reference antibody described above. We selected three additional antibodies based on their *in vitro* TROP2 affinity, competitiveness for the reference antibody's epitope, and yield in CHO cells. These candidates showed comparable potent efficacy in inducing regression in human breast and colorectal xenograft models, akin to the original reference antibody.

In summary, the KisoSeek™ platform identified novel anti-TROP2 HCAbs out of the KisoMouse™ antibody repertoire that were similar to our original reference antibody. This demonstrates how KisoMouse™ and KisoSeek™ are two powerful complementary platforms for novel clinical antibody discovery. By categorizing the entire antibody repertoire and identifying antibodies with similar characteristics as known functional antibodies, KisoSeek™ has the potential to leverage existing discovery efforts to uncover many more rare yet potent therapeutic antibodies - the proverbial needles in a haystack.

#1870 LCB36, a bi-specific antibody drug conjugate (BsADC) utilizing ConjuAll conjugation technology and proprietary prodrug payload selectively activated in cancer cells for treating B-cell blood cancers expressing CD20 and/or CD22.

Wihak Kim, Namjeong Choi, Cul-Woong Chung, Hwanhee Oh

LegoChem Biosciences, Inc, Daejeon, Korea, Republic of

Although frontline chemoimmunotherapy elicits responses in many B-Cell malignancy patients, treatment options remain limited, and clinical outcomes are suboptimal for those with relapsed or refractory diseases. Minimal residual disease (MRD) can lead to disease relapse despite achieving complete remission through targeted therapy, and tumor heterogeneity is responsible for MRD and compromises the efficacy of targeted therapy, especially in B-cell malignancies. Antibody-drug conjugates (ADCs) play a crucial role in oncology indications, and bispecific antibodies (BsAbs) represent one of the fastest-growing classes of next generation antibody therapeutics for cancer therapy. Several advantages of targeting dual tumor-associated antigens (TAAs) with BsAbs and bi-specific antibody drug conjugates (BsADCs) have been proposed, including improved efficacy, heightened tumor cell specificity, and reduced side effects in normal tissues. Notably, the ability of BsADCs to bind to cancer cells expressing even just one antigen has prompted further investigation into their efficacy in heterogeneous cancer models. LCB36 is a BsADC composed of a BsAb targeting both clinically validated CD20 and CD22, which are expressed in B-Cell malignancy, and a proprietary DNA cross-linking PBD prodrug that is site-specifically conjugated to the BsAb using ConjuAll technology. We assessed the expression levels of CD20 and CD22 in the cancer cell lines. While most cells expressed both antigens, some populations showed a low expression level of CD20 and a high expression level of CD22, while others exhibited the opposite pattern, suggesting heterogeneous expression of the two antigens within the same cell line. To confirm the heterogeneity of the two antigens in blood cancer patients, we analyzed single-cell sequencing data [GSE132509]. Each patient had CD20 and CD22 double-positive cells along with CD20 or CD22 single-positive cells, suggesting the possibility of relapse due to MRD following CD20 or CD22 single-targeted therapy. LCB36 demonstrated superior efficacy in CD20 and CD22 double-positive cell lines and cell-line derived xenografts (CDXs) models compared to ADCs targeting either CD20 or CD22, while showing comparable efficacy to single-target ADCs in CD20 or CD22 single-positive cancer cell lines and CDXs. Pharmacokinetic and toxicokinetic studies of LCB36 were analyzed in rats and Cynomolgus monkeys, respectively, using LC-MS/MS bioanalysis. Preliminary toxicity studies in rats and Cynomolgus monkeys demonstrated that LCB36 is well tolerated. In conclusion, LCB36, composed of a BsAb that binds to two clinically validated targets, showed efficacy at well-tolerated doses and has the potential to increase event-free survival periods by reducing MRD.

#1871 Discovery and characterization of NXV01c, an EGFR×cMET bispecific nanobody drug conjugate with potent anti-tumor activity.

R. Wu[1], P. Yuan[1], **Y. Xie**[2], J. Guo[1], F. Zhang[1], F. Liu[1], T. B. Guo[3];
[1]neoX Biotech, Beijing, China, [2]neoX Biotech, Boston, MA, [3]neoX Biotech, Shanghai, China

EGFR and cMET are proven cancer targets co-expressed in diverse tumor types. EGFR×cMET bispecific antibody has been approved for the treatment of NSCLC, supporting a simultaneous targeting strategy. In addition to this dual targeting benefit, bispecific antibody drug conjugates (ADCs) targeting EGFR and cMET have also been developed to further improve anti-tumor activity and tissue selectivity. Sufficient target affinity, good cellular internalization and high tumor infiltration are critical for an ADC to mediate therapeutic activity. To this end, we developed the first EGFR×cMET bispecific nanobody conjugated with monomethyl auristatin E (MMAE) as payload (NXV01c). Lead nanobodies against EGFR and cMET were respectively selected from immune libraries by phage display, followed by highly efficient humanization and optimization by neoX's computation platform. The bispecific nanobody with Fc (NXV01) was constructed by "knobs-into-holes" heterodimerization and then homogeneously conjugated with MMAE via a lysosomal cleavable valine-citrulline dipeptide linker. The resulting bispecific nanobody drug conjugate (NDC), NXV01c, was evaluated in multiple tumor cell lines and tumor xenograft models. NXV01, the pre-conjugate bispecific nanobody, bound EGFR and cMET with nanomolar potency (BLI) and inhibited the phosphorylation of cellular EGFR and cMET with nanomolar IC50 (ELISA). Moreover, it did not activate cellular cMET. Importantly, the NDC NXV01c is highly homogeneous: it has an average DAR of 3.87 and >95% of NXV01c has a DAR of 4. To examine stability of conjugation, NXV01C was incubated in human plasma (37℃) for 14 days, the maximum free drug release rate (by LC/MS/MS) is 0.68%, which is much lower than that of DS8201. In vitro, NXV01c was rapidly internalized into H1975 cells which co-expressed EGFR and cMET. It inhibited the growth of H1975 (lung) and SNU5 (gastric) cancer cells with picomolar activity but spared normal keratinocytes. NXV01c also inhibited the proliferation of additional cell lines derived from lung, gastric, esophageal, and liver cancer, and the level of inhibition positively associated with the expression density of both targets. In an H1975 cell line-derived xenograft model, NXV01C exhibited potent and dose-dependent anti-tumor activity. Treatments at 3 and 10 mg/kg once per week for 2 weeks led to shrinkage and complete regression of tumor, respectively. In patient-derived xenograft models of NSCLC and esophageal cancer, NXV01C led to tumor regression and elimination without noticeable toxic effects. EGFR×cMET bispecific nanobody drug conjugate NXV01c has favorable drug-like properties and demonstrated superior anti-tumor effect in vitro and in vivo. The results suggest NXV01C can be an effective solution for EGFR/cMET bearing tumors commonly found in diverse malignancies.

#1872 A next generation treatment for Nectin-4 positive cancers - Preclinical characterization of LY4052031, an anti-Nectin-4 antibody, conjugated to a novel camptothecin payload.

D. Sagar[1], M. Srinivasan[2], K. Lindquist[2], Q. Guo[1], W. Wong[1], M. B. Lebron[1], R. Sattler[1], J. Zhou[2], W. Helms[3], J. Boyles[4], P. Verdino[5], X. Zhao[2], Y. Mak[2], J. Park[2], R. Holmgaard[1], K. Driscoll[1], O. Duramad[2], K. Bedard[2];
[1]Loxo@Lilly, New York, NY, [2]Loxo@Lilly, South San Francisco, CA, [3]Loxo@Lilly, Silver Springs, MD, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly and Company, San Diego, CA

Nectin-4 is an immunoglobulin-like antigen overexpressed in a variety of cancers including bladder, breast, NSCLC, and gastric. Normal tissues including skin, salivary glands, bladder and esophagus express only low to medium levels of Nectin-4 making the protein an attractive target for cancer therapies. The approval of enfortumab vedotin-ejfv, an anti-Nectin-4 based antibody-drug conjugate (ADC) with a microtubule inhibitor payload, either as a single agent or in combination with pembrolizumab has been a significant advancement in the treatment of metastatic urothelial cancer. We have developed a novel anti-Nectin-4 ADC with a novel topoisomerase I (TOPO 1) inhibitor drug payload. Topoisomerase inhibitor payload-based ADCs offer potential advantages compared to microtubule payload-based ADCs including a different toxicity profile and the differentiated susceptibility to resistance mechanisms, such as P-gp mediated drug efflux. LY4052031 is a fully human monoclonal anti-Nectin-4 antibody conjugated to a novel TOPO 1 inhibitor by a cleavable peptide linker at a homogeneous drug antibody ratio (DAR) of 8:1. *In vitro*, both LY4052031 and its unconjugated parental antibody specifically bind to Nectin-4 expressing cell lines and are quickly and efficiently internalized. LY4052031 demonstrated potent cytotoxicity on tumor cells with high and low Nectin-4 expression. Additionally, bystander activity exerted by LY4052031 on antigen negative cells co-cultured with antigen positive cells was greater than that observed with the clinical benchmark enfortumab vedotin-ejfv. *In vivo* studies in xenografts expressing low to high levels of Nectin-4 showed significant tumor growth inhibition following treatment with LY4052031 as monotherapy. Overall, LY4052031 exhibits specificity, selectivity, potency, and effectiveness as a next generation therapy to treat Nectin-4 positive tumors. An IND submission is planned for 2024.

#1873 AST-05X: A novel GCN2 inhibitor as a promising anti-cancer approach for sarcoma.

Y. Choi[1], J. Lim[1], H.-H. Park[1], J. Kang[1], H. Kim[2], K. Yun[2], H. Jung[1];
[1]Aston Sci., Seoul, Korea, Republic of, [2]Yonsei Cancer Center, Seoul, Korea, Republic of

Background Integrated stress response (ISR) is an adaptive signaling pathway that responds to stress and plays an important role in cell fate determination. This pathway enables cellular adaptation and survival under stress conditions by activating specific genes that reduce protein synthesis. Tumors exist in a state characterized by heightened intrinsic and extrinsic stress, heavily relying on a balanced ISR to manage the metabolic demands for rapid growth. ISR (Integrated Stress Response) consists of four major kinases: GCN2, PERK, HRI, and PKR. GCN2 is activated by stress due to amino acid deprivation. Amino acids are crucial for cell survival, and cancer cells, require higher amounts than normal cells, particularly depending on conditionally essential amino acids like glutamine, asparagine, and arginine. GCN2 activation acts as a key mechanism for cancer cells to overcome amino acid deficiencies, making GCN2 a potential target, especially in conjunction with anticancer drugs like asparaginase. In this study, we aimed to identify a potential GCN2 inhibitor to explore a promising anti-cancer approach in sarcoma, a rare cancer with no new therapeutic alternatives.
Method The activity verification of ISR kinases was characterized using *in-vitro* enzyme assays. *In-vitro* panel assays were employed to determine the selectivity profiling for oncology kinases. The modulation of the ISR pathway was validated using a sarcoma cell line (HT-1080) and a cell line derived from sarcoma patients. Western blot or ELISA assays were employed to measure phospho-GCN2, ATF4, phospho-eIF2a, and CHOP under both basal conditions and amino acid starvation conditions. Gene expression profiling (GEP) of sarcoma patient tissue samples(n=17) was conducted through RNA sequencing (RNAseq) analysis.
Results AST-05X is a selective and potent GCN2 inhibitor. AST-05X inhibits the expression of GCN2 and ISR downstream factors (p-eIF2a, ATF, CHOP) in vitro cell-based experiments under amino acid deprivation. In addition, based on the results of ISR-related gene expression profiling GEP analysis, we identified potential CDx biomarkers for evaluating the diagnosis and treatment response of sarcoma.
Conclusion This study is currently investigating the efficacy of the drug in sarcoma patient-derived xenograft models. AST-05X is a GCN2 inhibitor that has the potential to validate the inhibition of GCN2 as a promising anti-cancer approach for sarcoma, a rare cancer with limited therapeutic alternatives.

#1874 Common vulnerabilities of stem cells along the Barrett's-dysplasia-adenocarcinoma sequence.

Wa Xian[1], Frank McKeon[1], Christopher Crum[2], Jaffer Ajani[3], Peter Davies[4], Matthew Vincent[5], William Bachovchin[6], Hung-Sen Lai[6], Shuang Pan[6], Amber Su[1], Ashley Hoffman[1], Raul Caballero Montes[1], Melina Khorrami[1], Melika Khorrami[1], Yusuke Yamamoto[7]

[1]University of Houston, Houston, TX,[2]Harvard University, Boston, MA,[3]MD Anderson Cancer Center, Houston, TX,[4]Texas A&M, Houston, TX,[5]Tract Pharmaceuticals, Inc., Houston, TX,[6]Tufts University, Boston, MA,[7]National Cancer Institute, Tokyo, Japan

Barrett's esophagus (BE) is an early precursor of esophageal adenocarcinoma and therefore a relevant target of preemptive therapeutics. Using robust stem cell cloning technologies, we have cloned stem cells from patient-matched biopsies of BE, low-grade dysplasia (LGD), high-grade dysplasia (HGD), and esophageal adenocarcinoma (EAC) from multiple patients. Whole exome sequencing of these stem cells reveals the mutational maturation along the sequence of BE, LGD, HGD, and EAC at unprecedented resolution of both copy number and single nucleotide variation. In vitro differentiation and xenografting of these clones recapitulates their original histology and shows that only the EAC stem cells yield robust tumors in immunodeficient mice. Leveraging the intrinsic immortality of these stem cells, we have performed high-throughput screens for small molecules that selectively kill BE stem cells without harming patient-matched normal esophageal stem cells. These screening efforts evolved into synthetic lethal strategies that identified drug combinations that selectively eliminate, in vitro, BE stem cells from 20 of 23 cases. Remarkably, this same synthetic lethal drug combination also eliminated in vitro stem cells of LGD, HGD, and EAC that were not components of the original screens. We have used synthetic chemistry to generate a series of novel molecules based on the identified drug combination that significantly improved the in vitro efficacy to sub-nanomolar levels. These novel molecules directed to the stem cell component of BE, LGD, HGD, and EAC also show potent effects against tumors generated from EAC stem cells in immunodeficient mice. We anticipate that these synthetically lethal drug combinations will have potential utility against precursor lesions to preempt EAC as well as against EAC itself.

#1875 Enhanced lung cancer treatment using AOH1996, a potent PCNA inhibitor.

R. G. Lingeman, R. J. Hickey, L. H. Malkas;
Beckman Research Institute of the City of Hope, Duarte, CA

AOH1996 targets a cancer-associated form of PCNA (caPCNA) by altering the protein-protein interface between caPCNA and its many binding partners. AOH1996 does this by inserting into the PCNA-interacting protein-box (PIP-box) pocket that is, in part, defined by the interdomain connecting loop (IDCL), the site of interaction between PCNA and most of its many binding partners. As a result, AOH1996 inhibits PCNA functions such as DNA replication, DNA repair, and transcription-replication conflict (TRC) resolution leading to cell cycle arrest and apoptosis. These effects are cancer specific and AOH1996 has little effect on non-cancerous cells even at 6-fold the effective dose in cancer cells. AOH1996 was developed in our lab and is currently in Phase I human clinical trials. Six patients have been enrolled in the trial and have not experienced AOH1996-related toxicities as the doses have been escalated to levels found to be efficacious in preclinical animal studies. Resistance to EGFR tyrosine kinase inhibitors (TKIs) poses a significant challenge in the treatment of non-small cell lung cancer (NSCLC) patients harboring EGFR activating mutations. Initially, EGFR TKIs like gefitinib, erlotinib, afatinib and osimertinib deliver remarkable responses, inducing tumor regression and improving overall survival. However, the emergence of resistance mechanisms, such as secondary EGFR mutations and bypass signaling pathway activation, hampers the efficacy of these drugs over time. The functional relationship between PCNA and EGFR has implications for the treatment of lung cancer patients with activating EGFR mutations. Membrane-localized EGFR modulates the PCNA-centric process of DNA replication through signaling pathways such as the Ras-Raf-Mek-Erk, PI3K/AKT, and PLCγ1/PKC signaling pathways. Nucleus-localized EGFR enhances PCNA stability by phosphorylating PCNA on tyrosine 211 (Y211), which prevents its degradation. In addition, phosphorylation at Y211 by EGFR results in decreased association of PCNA with MutS, which results in reduced mismatch repair (MMR). In this study, we combine AOH1996 and osimertinib as an innovative approach to treating NSCLC cancers with activating EGFR mutations and find that the drug combination: 1.) enhances the killing of NSCLC cell lines with activating EGFR mutations and acquired resistance to TKIs; 2.) enhances the destabilization of PCNA on chromatin; and 3.) causes changes in the localization and colocalization of PCNA and EGFR. We conclude that the combination of AOH1996 and osimertinib holds much potential as an improved treatment regimen for lung cancer patients with activating EGFR mutations.

#1876 Development of therapeutic antibodies targeting the GLUT-1 transporter to restrict cancer cell growth.

S. Tahk[1], K. Virumae[1], K. Anton[1], P. Hermet[1], R. Pau[1], M. Plaas[2], M. Abel[1], D. Belitskin[1], L. Galdieri[3], S. Garner[3], J. Krings[3], K. Collver[3], E. Schultz[3], K. Powers[3], A. King[3], F. Neethling[3], A. Planken[4], M. Ustav[1], J. Terya[1], A. Mannik[1], M. Ustav, Jr.[1];

[1]Icosagen Cell Factory OU, Tartu maakond, Estonia, [2]University of Tartu, Tartu, Estonia, [3]Eurofins Discovery, St. Charles, MO, [4]North-Estonian Medical Centre, Tallinn, Estonia

Background: Upregulated glucose metabolism is one of the strategies cancer cells use to fuel their abnormal cell growth and division. Targeting the cancer-specific glucose transporter GLUT-1 is a promising approach to restrict glucose uptake and challenge the metabolic needs of tumor cells. Antibodies, as opposed to small molecule inhibitors, are an attractive modality to therapeutically target complex muti-pass membrane transporters. Here we report the development of antibodies that very specifically block the function of only GLUT-1.

Methods: Monoclonal antibodies against GLUT-1 were generated using virus-like particles. For immunization, chickens were used as they are evolutionarily distant from mammals and can produce antibodies with prolonged CDR3-s in VH, which could facilitate their binding to the limited extracellular region of GLUT-1. Antibody discovery was performed with HybriFree B cell cloning technology followed by functional screens with 2-deoxyglucose uptake interference or cell proliferation measurements.

Results: The discovered antibodies specifically bind to GLUT-1 with low nanomolar EC50 values and do not target other glucose transporters. The lead candidate, ICO-33, inhibits glucose uptake and rewires the metabolism of GLUT-1-dependent cancer cells to rely on oxidative phosphorylation. This results in a significantly synergistic cancer proliferation inhibition with ICO-33 and OXPHOS inhibitor combinations in doses that do not inhibit proliferation as single agents. ICO-33 and OXPHOS inhibitor treatment is well-tolerated and demonstrates a drastic tumor growth inhibition in *in vivo* colorectal and pancreatic cancer models.

Conclusions: We describe the discovery of highly specific monoclonal antibodies targeting GLUT-1. We further demonstrate that the restriction of the much-needed glucose uptake by ICO-33 makes cancer cells highly susceptible to OXPHOS inhibitor co-therapy both *in vitro* and *in vivo*, validating the antibody as a promising candidate for clinical development.

#1878 CTPS1: An unexplored vulnerability in breast and ovarian cancer.

X. Wang[1], M. Emch[1], L. Voll[1], R. Russell[1], E. Rodman[1], N. Pearson[1], X. Hou[1], S. Kaufmann[1], S. Weroha[1], P. Beer[2], J. Hawse[1];
[1]Mayo Clinic, Rochester, MN, [2]Step Pharma, Saint-Genis-Pouilly, France

Breast and ovarian cancer represent the most common cancer types in women worldwide and are among the top fatal cancers. Despite the use of cytotoxic chemotherapy and targeted agents, recurrence is frequent and survival rates for patients with advanced metastatic disease are dismal. These realities highlight the need to identify novel biomarkers and therapeutic vulnerabilities in such tumors and to develop alternative treatment strategies. We took an unbiased approach to tackle this problem in which we leveraged publically available (DepMap) and in-house generated genome-wide CRISPR screens conducted in over 1000 cancer cell lines. We initially focused on the identification of essential genes that were unique to triple-negative breast cancer (TNBC) cells and whose expression levels were associated with worse patient outcomes. This interrogation revealed six genes (CTPS1, RHOA, PRKRA, RAD9A, HUS1, and RAD1) meeting these initial criteria. The essentiality of these genes was validated using gene-specific siRNAs in a panel of TNBC cells and knockdown of CTPS1 was shown to elicit the most inhibitory effect. CTPS1 depletion resulted in a rapid S-phase cell cycle arrest followed by apoptosis, not only in TNBC cells but also in highly aggressive ovarian cancer cells which share many molecular features with TNBC. CTPS1 converts uridine triphosphate to cytidine triphosphate, forming an essential nucleic acid required for multiple cellular processes. CTPS1 mRNA expression was substantially elevated in tumor vs. normal tissue, for both breast and ovarian cancer. Using over 40 breast and ovarian cancer cell lines, RT-PCR analyses confirmed increased expression of CTPS1 in TNBC and most ovarian cancer cell lines compared to other disease sub-types and “normal” cell line/tissue controls. Interestingly, chemoresistant and PARP inhibitor-resistant models exhibited the highest levels of CTPS1 among all cells analyzed. We subsequently identified and acquired STP938, a first-in-class highly selective CTPS1 inhibitor being developed by Step-Pharma. STP938 was found to elicit potent anti-cancer effects at nM concentrations across many cell line and patient-derived models, in both 2D and 3D culture systems. RNAseq analysis in aggressive cell line models following STP938 treatment or CTPS1 knockdown revealed significant regulation of genes related to DNA replication and the cell cycle pathways suggesting that combinatorial/sequential treatments of STP938 with replication stress/DNA damage response related drugs may be synergistic. STP938 is currently being developed for the treatment of lymphoma, and our findings support the repurposing of STP938 for breast and ovarian cancer, an avenue that we are currently developing.

#1879 A novel therapeutics accelerator for the brain cancer community: Early lessons learned.

Charlotte Kate Aitken[1], Katie Bushby[1], Petra Hamerlik[2], Nicky Huskens[1], Edward Kaye[3], Dione Kobayashi[4], **Juanita Lopez**[5], Ryan Mathew[6], John McCall[7], Javad Nazarian[8], Ruth Plummer[9], Steven Pollard[10], Ruman Rahman[11]

[1]Tessa Jowell Brain Cancer Mission C.I.C., London, United Kingdom,[2]University of Manchester, Manchester, United Kingdom,[3]Stoke Therapeutics, Bedford, MA,[4]Mass General Brigham, Boston, MA,[5]The Royal Marsden NHS Foundation Trust, London, United Kingdom,[6]University of Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom,[7]University of Wisconsin, Madison, WI,[8]University Children's Hospital,, Zurich, Switzerland,[9]Newcastle University, Newcastle upon Tyne, United Kingdom,[10]University of Edinburgh, Edinburgh, United Kingdom,[11]University of Nottingham, Nottingham, United Kingdom

Developing a comprehensive translational program for brain tumors is a complex task that involves numerous challenges. These challenges include significant obstacles surrounding the delivery of pre-clinical studies, safety, clinical trial design, and routes to commercialization. Recognizing that this journey is difficult, in 2023 the Tessa Jowell Brain Cancer Mission launched the Brain Tumor Research Novel Therapeutics Accelerator (BTR-NTA). The BTR-NTA is a new international accelerator program that provides independent and comprehensive expert guidance to de-risk therapeutic development through systematic, multidisciplinary evaluation and feedback for academic or industry researchers who are developing a therapeutic or technology for brain tumors. The BTR-NTA was modeled on the TREAT-NMD Advisory Committee for Therapeutics, which has yielded impressive results in the neuromuscular disease field. The ultimate goal of the BTR-NTA program is to enable researchers with a potential therapy or technology for brain tumors to navigate the development journey and successfully make it to the clinic in an efficient and timely way. The international, multidisciplinary BTR-NTA Expert Committee spans the entire therapeutic development pathway to avoid a siloed approach to research. Thanks to charitable funding, the BTR-NTA is free for academics and available at low cost for industry. Researchers at any stage of pre-clinical or clinical work can apply to the BTR-NTA, and, if accepted, their application will proceed as follows: 1. The applicant completes an application form covering work to date and future plans under a strict confidentiality agreement that protects the applicant; 2. Depending on the types of applicants, additional experts are recruited to ensure that each applicant gets a robust and tailored review 3. The applicant’s work is reviewed by an international, multidisciplinary committee 4. The applicant and BTR-NTA Expert Committee meet in-person to further discuss the applicant’s work; and 5. The applicant receives a comprehensive written report from the BTR-NTA Expert Committee, with feedback on strengths and weaknesses and guidance on next steps. The BTR-NTA Expert Committee dedicates half a day to review the applicant’s work in-person, and extensive time pre- and post-meeting. This is a low cost to applicant, high impact process designed to provide valuable feedback and support. The BTR-NTA aims to help overcome barriers for applicants by highlighting potential pitfalls or risks, providing multi-disciplinary feedback on work to date and constructive guidance on next steps, and by strengthening international collaboration in the brain tumor field. Following the launch of the BTR-NTA program in 2023 and review of the first group of therapeutics and technologies, we report on our early learnings, impact, and how we hope to grow the program to help accelerate new brain tumor therapies globally.

#1880 Ecubectedin and PM54 demonstrate antitumor activity in patient-derived xenograft models of soft tissue sarcoma.

D. Gorgels[1], A. Wozniak[1], C.-C. Wang[1], P. M. Aviles[2], M. J. Guillen[2], C. Cuevas[2], P. Schoffski[3];
[1]KU Leuven, Leuven Cancer Institute, Leuven, Belgium, [2]PharmaMar, Madrid, Spain, [3]University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium

Objective: Soft tissue sarcoma (STS) is a heterogenous group of rare, malignant tumors arising from mesenchymal tissue. Doxorubicin (DOX)-based chemotherapy is the standard for advanced or metastatic STS, despite low response rates and poor disease control. We explored the antitumor activity of two novel compounds, ecubectedin (ECU; PM14) and PM54 (PharmaMar), in two patient-derived xenograft (PDX) models of STS, leiomyosarcoma (LMS) and *CIC*-rearranged sarcoma (CRS). Mode of action of ECU and PM54 is similar to lurbinectedin (LUR), inhibiting oncogenic transcription by eviction of oncogenic transcription factors from gene promotors' recognition sequences, while inducing the generation of double strand breaks through DNA adduct formation.
Methods: Female NMRI *nu/nu* mice (n=104) were transplanted bilaterally with STS PDX: UZLX-STS134 (CRS) and UZLX-STS22_2 (LMS). Xenografted mice were randomized to six treatment groups: 1) vehicle (VEH) (5% dextrose) 5 mL/kg once weekly (QW) intravenously (IV); 2) DOX 5 mg/kg QW IV; 3) trabectedin (TRA) 0.15 mg/kg QW IV; 4) LUR 0.18 mg/kg QW IV; 5) ECU 1.2 mg/kg QW IV; 6) PM54 1.2 mg/kg QW IV. Treatment lasted 16 days and antitumor activity was assessed by tumor volume (TV) analysis, histopathology and western blot. The Mann-Whitney U test was used to compare groups, the Wilcoxon test to compare to baseline.
Results: ECU and PM54 caused TV shrinkage in UZLX-STS134, while TV in other groups grew significantly on day 16 (Table 1). VEH treatment led to the largest TV increase on day 16, compared to any treatment. PM54 treatment showed TV stabilization in UZLX-STS22_2, and significantly smaller tumors than VEH and TRA treated tumors ($p<0.05$ and $p<0.01$, respectively). Histopathological evaluation corroborate the results from the relative TV analysis.

Table 1: TV change on day 16 versus baseline, and comparison of proliferative and apoptotic activity

	Tumor volume change		Proliferative activity (pHH3)		Apoptotic activity (cPARP)	
Subtypes	**UZLX-STS134**	**UZLX-STS22_2**	**UZLX-STS134**	**UZLX-STS22_2**	**UZLX-STS134**	**UZLX-STS22_2**
VEH(5 ML/kg)	387%***	349%**	n/a	n/a	n/a	n/a
DOX (5 mg/kg/QW IV)	177%***	243%**	↓***	↓	↑**	↑
TRA(0.15 mg/kg/QW IV)	230%**	254%***	↓**	↓**	↑**	↑***
LUR(0.18 mg/kg/QW IV)	202%**	232%**	↓***	↓***	↑***	↑**
ECU(1.2 mg/kg/QW IV)	41%***	181%**	↓***	↓***	↑***	↑***
PM54 (1.2 mg/kg/QW IV)	76%***	162%	↓***	↓***	↑***	↑

Conclusion: Novel drugs exhibit promising results in the PDX models tested, supporting ongoing exploration in additional PDX models of synovial sarcoma and dedifferentiated liposarcoma.

#1881 Screening of Rac1 and Cdc42 inhibitors as anti-metastatic compounds.

J. Colon Gonzalez[1], M. C. Santa Maria Fuentes[2], C. Vlaar[1], S. Dharmawardhane[1];
[1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Puerto Rico Rio Piedras Campus, San Juan, PR

Metastasis is responsible for >90% of cancer-related deaths and is a key cause of failure of cancer therapy. The development of effective targeted therapy to prevent and treat metastasis has been challenging. Homologous Rho GTPases Rac and Cdc42 are viable metastasis targets because they have a crucial role in the signaling pathways that regulate cell survival, proliferation, and migration, so dysregulation of these proteins leads to cancer progression and metastasis of diverse cancer types. Therefore, targeting these regulatory proteins results in anticancer and antimetastatic activity, as observed with our dual Rac/Cdc42 inhibitor, MBQ-167, in triple-negative breast cancer. MBQ-167 has an IC_{50} of ~100nM for Rac and Cdc42 activation inhibition and a GI_{50} of 130nM. MBQ-167 inhibits the binding of guanine nucleotides to Rac and Cdc42 with similar efficacy. The purpose of this study was to identify MBQ-167 derivatives with similar or greater efficacy and specificity, with a range of inhibitory mechanisms, that may be specific to the different guanine nucleotide exchange factors expressed in distinct cancer cell types. Currently, over 30 different compounds with potential Rac1 and Cdc42 inhibitory activity are being evaluated. So far, some of the evaluated compounds have shown comparable GI_{50} values to MBQ-167 in metastatic breast cancer cell lines. From this screening, CPV-337 was selected as a compound with a GI_{50} of ~55nM and ~70% Rac activation inhibition at 50nM, therefore being 2X more effective than our leading compound MBQ-167. However, evaluation of CPV-337 in the viability of the MCF-10 non-tumorigenic epithelial cell line demonstrated a GI_{50} of ~63nM, which is similar to that of breast cancer cells. Therefore, CPV-337 may have cytotoxic effects on breast cancer. We are continuing to screen the library of MBQ-167 derivatives in breast, pancreatic, lung, and prostate cancer cell lines.

#1882 DXC024, a novel anti-TROP2/EGFR bispecific antibody and tubulysin conjugate, for targeted treatment of highly TROP2- or EGFR-expressing tumors.

Jingjing Zhu, Junxiang Jia, Huihui Guo, Xiangfei Kong, Yong Du, Zhicang Ye, Lingli Zhang, Yongxiang Chen, Lu Bai, Yunxia Zheng, Wei Zheng, Jun Zheng, Juan Wang, Wenjun Li, Yuanyuan Huang, Zhongliang Fan, Mengmeng Liu, Binbin Chen, Meng Dai, Fang Du, Miaomiao Chen, Zhixiang Guo, Qingliang Yang, **Robert Y. Zhao**

Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Antibody drug conjugates (ADCs) which combine the precision of targeted therapy with the cytotoxic effects of chemotherapy have become a promising drug class in cancer therapy. Epidermal growth factor receptor (EGFR) is overexpressed in a wide diversity of epithelial tumors, promoting cell proliferation and survival pathways. Tumor-associated calcium signal transducer 2 (Trop2) is also expressed in a wide range of solid tumors and has been used as a transport gate for cytotoxic agents into cells in antibody-drug conjugate constructions for clinic applications. However, the approved Trop2 ADC, sacituzumab govitecan, only showed an objective response rate (ORR) of 17% and median OS of 9.5 months for lung cancers. In addition, both EGFR-ADC and Trop2-ADC had exhibited strong side effects in clinical trials due to their expression on some normal tissues, such as skin, mouth, eyes, etc. We generated bispecific Fab/scFv antibodies targeting both TROP2 and EGFR using the knob-into-hole technology, which presumably have wider efficacy, less on-target toxicity in comparison to the ADCs constructed based on the fully individual EGFR and Trop2 IgG antibodies having strong affinity to either EGFR or Trop2 antigens. Indeed, many of generated anti-TROP2/EGFR BsAbs showed strong binding activity in $TROP2^{high}EGFR^{high}$ cells and demonstrated over 60% internalization rate within 60 min in vitro. The selected BsAbs were subsequently conjugated with tubulysin B analogs with varieties of peptidyl linkers to generate bispecific ADC (DXC024) candidates, two of which exhibited strong killing activity in A431, MDA-MB-468, Calu3, MCF-7 cells with IC_{50} of single to ten digital pM. In vivo, they showed very good durable antitumor response at dose as low as 4.6 mg/Kg for one injection in Calu3 ($TROP2^{high}EGFR^{moderate}$) xenograft model, and demonstrated enhanced anti-tumor efficacy in comparison to those of the same payload conjugated to the monoclonal TROP2 or EGFR ADCs. These results indicated that DXC024 would be a promising ADC candidate for targeted treatment of highly either TROP2- or EGFR-expressing tumors.

#1883 A MUC1 antibody-conjugated with a tubulysin B analog, DXC005, demonstrates excellent synergistic effect in combination with gemcitabine for treatment of pancreatic tumors.

X. Cai, M. Cao, H. Guo, Q. Yang, Y. Chen, X. Kong, Y. Du, Z. Ye, Z. Guo, L. Zhang, L. Bai, J. Jia, Y. Zheng, W. Zheng, J. Zheng, W. Li, Y. Huang, Z. Fan, B. Chen, Y. Yang, M. Dai, **R. Y. Zhao**;
Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

Pancreatic cancer is a malignant tumor with high incidence and mortality. It is difficult to diagnose and detect in the early stage, with low surgical resection rate and high recurrence and metastasis rate after surgery. At present, the clinical therapeutic strategy is extremely limited. The first-line Standard of Care (SOC) for unresectable pancreatic cancer is chemotherapy. The preferred regimen includes gemcitabine combined with albumin paclitaxel or FOLFIRINOX (5-FU+Oxaliplatin+Irinotecan). Due to the limited long-term benefits and toxic side effects of chemotherapy, targeted therapy combined with chemotherapy has become a new therapeutic strategy. MUC1 is a highly glycosylated transmembrane mucin located on the lumen surface of epithelial cells. It can protect cells from extreme factors and plays an important role in tumor cell metabolism, apoptosis, epithelial-mesenchymal transition (EMT) and metastasis. Previous studies have confirmed that MUC1 is highly expressed in a variety of tumors, including pancreatic cancer, and is closely related to poor prognosis. DXC005 is a novel MUC1-targeting antibody-drug conjugate (ADC), generated by conjugating a Tubulysin B analogue to a recombinant humanized anti-Muc1 monoclonal antibody. DXC005 is the first MUC1-ADC IND in China, and is currently in phase I clinical trials. Preclinical studies have confirmed the efficacy of DXC005 monotherapy (2.5 mg/kg, 5 mg/kg, 10 mg/kg in one administration) in the HuPrime ® pancreatic cancer PDX model (PA1194). The tumor growth inhibition (TGI) was 42.53 %, 70.77 %, and 95.58 %, respectively. We want to further clarify whether DXC005 combined with chemotherapeutic drug Gemcitabine can ensure or even improve the efficacy while reducing the dosage of Gemcitabine. In PA1194 xenograft model, DXC005 (3 mg/kg or 6 mg/kg) in combination with Gemcitabine (10 mg/kg) showed significant anti-tumor efficacy with 58.77% and 93.17% TGIs, respectively. In contrast, the treatment with 10 mg/kg of Gemcitabine alone exhibited much less TGI. Furthermore, complete response (CR) was observed in some animals after treatment with DXC005 (6 mg/kg) plus Gemcitabine (10 mg/kg). All groups of treatment are tolerated well, no abnormal animal behavior and body weight loss were observed in the study. The above results concluded that DXC005 combined with Gemcitabine can achieve synergistic effect even with reduced dose of Gemcitabine, which will serve as a support for synergistic application in clinical studies.

#1884 DXC006, Anti-CD56-CPT113 ADC displays favorable anti-tumor efficacy, pharmacokinetic and safety profiles in preclinical studies.

X. Kong, H. Guo, Y. Du, Z. Ye, Y. Chen, Z. Guo, L. Zhang, L. Bai, J. Jia, Y. Zheng, W. Zheng, J. Zheng, W. Li, Y. Huang, Z. Fan, M. Liu, B. Chen, M. Dai, J. Wang, F. Du, M. Chen, Q. Yang, **R. Y. Zhao**;
Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

CD56, also known as neural cell adhesion molecule 1 (NCAM1), is a type I plasma membrane glycoprotein involved in cell-cell and cell-matrix adhesion. It is overexpressed in almost all neuroblastomas, 95% of small cell lung cancers and 78% of multiple myeloma patients[1], whereas CD56 is less frequently or less abundantly expressed in normal tissues, making it a potential target for tumor therapy. So far, no CD56-targeting ADCs have entered late-stage clinical trials.DXC006 is an antibody-drug conjugate of a humanized anti-CD56 antibody (DXA006) linked to the topoisomerase I inhibitor CPT113 through a cleavable peptidyl linker and CROSSCONJU™ technology. The pharmacologic activity and mechanism of action of DXC006 were investigated in several human cancer cell lines and xenograft mouse models. Pharmacokinetic and safety profiles were also assessed in rats and cynomolgus monkeys.DXC006 binds specifically to CD56 and internalizes into tumor cells, after intracellular trafficking to lysosome and CPT113 releasing, induces DNA damage. In vitro cell based assays showed that DXC006 remarkably inhibited the cell growth of CD56-positive cell lines of IMR-32 (neuroblastoma), NCI-H526 (small cell lung cancer), and NCI-H929 (multiple myeloma), with IC_{50} of 0.0046~0.061 nmol/L. Although DXC006 also binds to CD56 expressed NK cells, we found that the inhibition of DXC006 to human NK cells was much less effective, with IC_{50} higher than 675 nmol/L, which is ten thousand-folds less potent than that of targeted abnormal cells. In vivo, DXC006 demonstrated good durable antitumor activities in three CD56-positive xenograft models of IMR-32, NCI-H526 and NCI-H929 cell lines, with a single dose of 2 mg/Kg, 3 mg/Kg, and 5 mg/Kg, respectively. No animal death or moribund outcome was observed in two months during preclinical safety studies in 150 mg/Kg Q2W dosed rats. For cynomolgus monkeys, the highest non-severely toxic dose (HNSTD) of DXC006 was 20 mg/Kg, in Q2W, four times of administration. PK profiles of both DXC006 the naked antibody DXA006 were comparable in both rats and monkeys. In summary, DXC006 demonstrated strong antitumor activity in various types of cancer cells both in vitro and in vivo, and good pharmacokinetic and safety profiles in rat and monkeys, a potential to be explored in clinical applications.

[1] Yang Feng, Yanping Wang, Zhongyu Zhu, et al. Differential killing of CD56-expressing cells by drug-conjugated human antibodies targeting membrane-distal and membrane-proximal nonoverlapping epitopes. mAbs 2016; 799-810.

#1885 Developing a biparatopic anti-ROR1 antibody drug conjugate BR111 for hematological and solid tumor treatment.

X. Zhao[1], J. Zhu[1], z. Wu[2], Y. Li[1], J. Li[1], Y. Zhou[2], L. Nie[2], H. Wang[2], G. Chen[1];
[1]BioRay Pharmaceutical Corp., San Diego, CA, [2]BioRay Pharmaceutical Ltd., San Diego, CA

ROR1 is a type I transmembrane protein that belongs to the ROR family. It is a receptor for Wnt family signaling molecules Wnt5a, and plays a critical role in various cellular processes, such as cell proliferation, survival, and migration. Being an oncofetal protein, ROR1 exhibits limited expression in most normal tissues. However, it is abnormally expressed in various hematological and solid cancers, contributing to the development and progression of many types of cancer. Due to its overexpression in cancer, ROR1 presents as a highly attractive target for antibody-drug conjugate (ADC) therapy. The current clinical results of ROR1 ADCs have been promising in treating patients with relapsed and/or refractory (R/R) hematologic malignancies.
BR111 is anti-ROR1 ADC that consists of a biparatopic antibody, stably conjugated to an antimitotic agent. The biparatopic antibodies demonstrate superior binding affinity to ROR1-expressing cancer cells compared to single epitope antibodies. Notably, our unique and innovative conjugation platform CysX™, not only prevents payload detachment during circulation and reducing the off-target toxicity, but also enables a uniformed drug-to-antibody ratio (DAR) of 4.
Both *in vitro* and *In vivo* studies have highlighted the remarkable antitumor activity of BR111. Preclinical data have shown great safety profile in cynomolgus monkeys. BR111 demonstrated a wider therapeutic window for cancer treatment, outperforming the lead anti-ROR1 ADC currently in phase II/III trial. The promising outcome holds great potential as a therapeutic treatment for hematological and solid cancers, offering a better safety profile. BR111 has great potential in further clinical evaluations.

#1886 BRY812, an anti-LIV-1 antibody drug conjugate with novel conjugation method for cancer therapeutics.

X. Zhao[1], J. Zhu[1], Y. Zhou[2], J. Li[1], L. Nie[2], H. Wang[2], G. Chen[1];

[1]BioRay Pharmaceutical Corp., San Diego, CA, [2]BioRay Pharmaceutical Ltd., Hangzhou, China

LIV-1, also known as SLC39A6 or ZIP6, belongs to the zinc transporter family and was initially identified as an estrogen-inducible gene in breast cancer. Immunohistochemical (IHC) analysis have revealed escalated LIV-1 expression in estrogen receptor-positive (ER+), hormone-treated tumors (both primary and metastatic sites) as well as ER-/PR-/Her2- (triple-negative) breast cancers. Notably, healthy human tissues exhibit limited LIV-1 expression, primarily in hormone regulated organs (prostate, uterus, and breast). The escalated expression of LIV-1 in breast and prostate cancer, as well as melanoma and other tumors, positions LIV-1 as an excellent target for ADC therapeutics.

BRY812 is a monomethyl auristatin E (MMAE)-conjugated humanized IgG1 ADC against LIV-1. With Bioray's irreversible conjugation method CysLink™, BRY812 enables superior *in vivo* stability and eliminates off-target payload migration. The PK studies in rat and monkey demonstrated that the free MMAE released from ADC is 1 to 2 logs lower compared with approved ADCs prepared by the standard conjugation method. BRY812 is well tolerated in cynomolgus monkeys with repeated doses. With best-in-class anti-tumor efficacy in various models, BRY812 demonstrated a wider therapeutic window for cancer treatment. BRY812 is currently in Phase Ia dose escalation stage clinical trial to explore the maximum tolerate dosage (MTD) from 0.25 to 3.6 mg/kg Q3W in patients with advanced malignancies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Drug Conjugates and Bispectific Antibodies
Poster Session

#1890 HMA800067, a novel CD38-targeting antibody-drug conjugate (ADC), demonstrated superior anti-tumor activity to daratumumab in preclinical B-cell malignancies models.

Y. Xu, J. Liang, S. Jiang, H. Yang, H. Zhang, F. Mao, J. Zhu, J. He, N. Yang, J. Wang, W. Zhang, Y. Ren, W. Su;
HUTCHMED, Shanghai, China

Introduction: Daratumumab (Dara), an anti-CD38 monoclonal antibody, has been widely used in the treatment of multiple myeloma (MM). However, some of MM patients exhibit primary or acquired resistance to Dara therapy. A CD38 targeting antibody-drug conjugate (ADC) HMA800067 is developed, in which Dara was conjugated with cytotoxic payload via a novel linker, aiming to have superior anti-tumor efficacy to Dara, even in the subjects with resistance to Dara treatment.
Methods: HMA800067 was characterized by ELISA-based binding assay, cell internalization assay, antibody-dependent cell-mediated cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP) assays. The *in vitro* anti-tumor potency was assessed against a panel of 24 MM and B cell lymphoma cell lines with various CD38 expressions. Bystander effect of HMA800067 was evaluated in co-culture of $CD38^-$ SU-DHL-2 cells with $CD38^\pm$ Ramos cells. *In vivo* anti-tumor efficacy was investigated in the multiple MM and Diffuse Large B-cell Lymphoma (DLBCL) subcutaneous xenograft models, including some non-responsive to Dara.
Results: HMA800067 displayed comparable binding affinity and internalization capability to Dara in $CD38^\pm$ Ramos cells. And HMA800067 maintained the ability of Dara to induce the death of $CD38^\pm$ Daudi cells by ADCC and ADCP, which indicated that conjugation did not change the property of Dara in the ADC upon antigen binding. HMA800067 exhibited a CD38-dependent cytotoxic activity with median IC_{50} of 0.46 nM against a panel of tumor cell lines, with a trend that the higher CD38 expression, the stronger potency could be seen. Bystander killing effect of HMA800067 was observed in $CD38^-$ cells when co-cultured with $CD38^\pm$ cells *in vitro*. Furthermore, with the low release of payload in plasma and sustainable high exposure of payload in the tumor, HMA800067 demonstrated dose-dependent and superior anti-tumor efficacy to Dara in all tested models, and 10 mg/kg induced complete tumor regression in MM RPMI-8226, DLBCL SU-DHL-6 and SU-DHL-10 models. For example, in SU-DHL-6 xenograft model, the treatment of intravenous injection of HMA800067 at 10 mg/kg single dose induced complete tumor regression in all the animals within 10 days of administration, which was maintained until the end of study (day 49), while 10 mg/kg Dara twice a week for 2 weeks inhibited tumor growth within 20%-40% without any tumor regression during a four-week observation post initial dosing.
Conclusion: HMA800067 demonstrated potent anti-tumor activities *in vitro* and *in vivo* in multiple B-cell malignant tumor lines, including those with poor response to Dara. These results supported further development of HMA800067, as a superior therapeutic option for treatment of patients with $CD38^\pm$ B cell malignancies.

#1891 Preclinical characterization of ADRX-0706: A next-generation anti-Nectin-4 antibody-drug conjugate with improved therapeutic window.

A. M. Hau[1], M. Shahmoradgoli[1], D. Lee[1], W. Sisson[1], A. Wang[1], P. P. Challita[1], E. Nye[1], M. M. -. Kuo[1], A. Mahloch[1], M. Leung[1], O. Betancourt[1], A. Chu-Kung[1], M. Guo[2], H. Li[1], S. Rottmann[1], P. M. Challita-Eid[1];

[1]Adcentrx Therapeutics, Inc., San Diego, CA, [2]Adcentrx Therapeutics, Inc., Shanghai, China

Nectin-4 is a well validated tumor target, which is highly expressed in several solid cancers such as urothelial, head-and-neck, breast, lung, pancreatic, ovarian, and cervical cancer, while expression in normal tissues is limited. A first-generation antibody-drug conjugate targeting Nectin-4, called enfortumab vedotin-ejfv (EV), was granted accelerated FDA approval in 2019 for urothelial cancers, and is currently approved for frontline therapy in cisplatin-ineligible patients with locally advanced or metastatic urothelial carcinoma, providing groundbreaking improvement in patient survival. However, clinical use of EV has also revealed safety-driven limitations, which result in reduced and/or interrupted drug exposures impacting efficacy. To overcome these limitations in therapeutic window and to maximize on the potential of Nectin-4 as a tumor target beyond urothelial cancers, Adcentrx has developed ADRX-0706, a Nectin-4-targeting next-generation ADC with a drug-antibody ratio of 8. ADRX-0706 is comprised of a novel fully human IgG1k monoclonal antibody linked to an optimized tubulin inhibitor payload AP052 through a proprietary cleavable linker. ADRX-0706 has strong binding affinity and selectively induces cytotoxicity in Nectin-4-expressing tumor cells. Importantly, ADRX-0706 is designed to have improved bystander effect, which allows tumor regression even in cases of heterogeneous Nectin-4 expression. This translates to superior in vivo efficacy of ADRX-0706 over EV in multiple mouse xenograft models of other indications beyond bladder cancer. In a mouse clinical trial of patient-derived cervical cancers with a range of Nectin-4 expression levels, ADRX-0706 reaches a 73% ORR. Since peripheral neuropathy is a main platform toxicity for this payload class, ADRX-0706 is assessed in an in vitro co-culture model to evaluate its neurotoxic potential. While EV displays a 75% decrease in neurite outgrowth, ADRX-0706 strikingly has no impact at concentrations up to 1mg/ml, suggesting a lower risk of peripheral neuropathy in humans for ADRX-0706. In preclinical repeat dose toxicology study, ADRX-0706 reaches an HNSTD of 18mg/kg in NHPs well above therapeutic exposures in mouse pharmacology studies, indicating a tremendous increase in the therapeutic index compared to EV. In summary, the highly selective and potent anti-tumor activity in multiple tumor types and wide preclinical therapeutic index of ADRX-0706 support clinical evaluation of this next generation anti-Nectin-4 ADC. ADRX-0706 is currently in a phase 1a/b study (NCT06036121).

#1892 KK2260: A fully human tetravalent bispecific antibody targeting TfR1 and EGFR for the treatment of EGFR-expressing tumors.

K. Mitamura[1], H. Otsuki[2], K. Nakahashi[2], A. Kitagawa[2], M. Kamigaki[1], Y. Kurio[1], M. Inoue[1], Y. Uemura[1];
[1]Kyowa Kirin Co., Ltd., Machida-Shi, Tokyo, Japan, [2]Kyowa Kirin Co., Ltd., Sunto-gun, Shizuoka, Japan

Background: TfR1 is a transmembrane glycoprotein involved in iron uptake and regulation of cell growth. High TfR1 expression has been reported in different types of cancers, therefore recognized as a target molecule for cancer therapy. Despite the promise of potent efficacy of TfR1-targeted agents, there is a risk of side effects (*i.e.*, severe anemia), since TfR1 is also highly expressed in certain normal cells (*e.g.*, reticulocytes). KK2260 is a fully human tetravalent bispecific antibody (bsAb) based on REGULGENT™ technology targeting TfR1 and EGFR. This bsAb was designed for EGFR-expressing cell selective anti-cancer drug which could not be achieved by conventional monospecific Ab. In this study, we evaluated the mechanism of action (MOA), anti-cancer effect, and toxicity of KK2260.

Methods: Binding activity of KK2260 to TfR1 and EGFR was evaluated by surface plasmon resonance method. Ligand blocking activity was evaluated by binding competition on esophageal squamous cell carcinoma (ESCC) OE21 cells. Growth inhibitory activity of KK2260 on cancer cells or hematopoietic progenitor cells was evaluated by proliferation inhibition assay. In some studies, excessive iron or anti-EGFR parent Ab was added. Effect on the cell surface target expression levels was evaluated by flow cytometry. The intracellular iron level was evaluated by cell imaging. Effect on EGF induced EGFR phosphorylation was evaluated by Western blotting. The *in vivo* efficacy of KK2260 was evaluated in cell line-derived and patient-derived xenograft (PDX) models of ESCC selected for high EGFR expression level. The toxicity of KK2260 was evaluated in cynomolgus monkeys.

Results: KK2260 bound to TfR1 and EGFR with no ligand binding inhibition. KK2260 inhibited cell growth of moderate to high EGFR-expressing cancer cells, but not against EGFR-negative cancer cells or hematopoietic progenitor cells. KK2260 downregulated TfR1 expression on OE21 cells and the intracellular iron level decreased, but no effect was observed on EGFR phosphorylation. The growth inhibitory activity of KK2260 was abolished by adding excessive amounts of iron or reduced by inhibiting the binding to EGFR. Potent anti-tumor activity was observed in the ESCC PDX models with tumor regression. In the intermittent-dose toxicity study of cynomolgus monkeys, KK2260 was well-tolerated.

Conclusions: KK2260 demonstrated potent anti-cancer effect both *in vitro* and *in vivo*. Intriguingly, KK2260 did not inhibit EGFR phosphorylation while EGFR-binding dependent TfR1 downregulation resulted in intracellular iron deficiency, which was considered as the MOA of KK2260. KK2260 was well tolerated in non-human primates. These preclinical data suggest the unique property of KK2260 is expected to provide significant benefit to patients with advanced ESCC and other EGFR-expressing tumors and Phase 1 study is currently on going in Japan (jRCT2031230372).

#1893 OBI-992, a novel TROP2 targeting antibody-drug conjugate, displayed excellent antitumor efficacy in various animal models.

W.-F. Li, M.-F. Chiang, H.-C. Weng, J.-J. Yang, H.-S. Wu, C.-J. Lin, P.-T. Chiu, M.-T. Lai;
OBI Pharma, Inc., Taipei, Taiwan

Background: TROP2 is a validated therapeutic target for cancer treatment. OBI-992 is an antibody-drug conjugate (ADC) derived from a novel TROP2 antibody linked with a topoisomerase 1 inhibitor payload, exatecan, through conjugation with an enzyme-cleavable linker. Upon binding to TROP2 on the surface of cancer cells, OBI-992 is internalized into the cell and trafficked to lysosomes where the linker is cleaved by cathepsin B, releasing the payload exatecan to kill the cancer cells. This study aims to evaluate the antitumor efficacy of OBI-992 *in vitro* and *in vivo*, including cell-based cytotoxicity, cell line-derived xenografts (CDX), and patient-derived xenografts (PDX) models.

Methods: The cytotoxicity of OBI-992 was evaluated in cell lines with different levels of TROP2 expression. *In vivo* efficacy was evaluated using CDX and PDX models of various cancer types. Bystander killing effect of OBI-992 was examined in a xenograft model containing a premixture of TROP2 positive and TROP2 negative cancer cells. Moreover, the impact of overexpression of P-glycoprotein (Pgp) or breast cancer resistance protein (BCRP) on the antitumor efficacy of TROP-2 ADCs was evaluated. OBI-992 in combination with PARP inhibitors such as olaparib and talazoparib was examined for potential synergistic effects in a homologous recombination deficiency (HRD) xenograft model.

Results: The cytotoxicity of OBI-992 was positively associated with the TROP2 RNA levels in different cell lines. In various CDX and PDX models, a single dose of OBI-992 at 3 or 10 mg/kg exhibited remarkable tumor growth inhibition. Notably, the antitumor efficacy of OBI-992 surpassed that of datopotamab deruxtecan (Dato-DXd) across different CDX and PDX models. OBI-992 demonstrated a bystander killing effect as OBI-992 was able to kill TROP2-negative xenografts in the presence of nearby TROP2-positive cells. OBI-992 showed superior efficacy to Dato-DXd in the CDX model overexpressing Pgp or BCRP. These findings suggest that OBI-992 was not affected by the Pgp- and BCRP-mediated multidrug resistance. In the HRD CDX model at suboptimal doses, combination of OBI-992 with olaparib or talazoparib displayed remarkable synergistic effects.

Conclusions: OBI-992 exhibited excellent antitumor efficacy and outperformed the benchmark Dato-DXd in CDX and PDX models of various cancer types. A strong bystander killing effect indicated that OBI-992 will be effective for tumors with heterogenous expression of target antigen. OBI-992 retained its antitumor effect upon overexpression of Pgp and BCRP, suggesting that OBI-992 may overcome the multidrug resistance. Outstanding synergistic effect with the combination of OBI-992 with PARP inhibitors was observed. These results warrant further studies of OBI-992 in the clinical setting.

#1894 Preclinical development of YL205, a novel NaPi2b-targeting antibody-drug conjugate (ADC) with novel topoisomerase I inhibitor-based linker-payload for treatment of solid tumors.

L. Xiao[1], W. Lian[1], Q. Liu[1], Q. Zong[1], S. Song[1], S. Stann[2], J. Cai[1], T. Xue[1];
[1]MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China, [2]MediLink Therapeutics USA, INC., Boston, MA

MediLink's TMALIN (Tumor Microenvironment Activable LINker-payload) platform incorporates the proprietary protease-cleavable tripeptide linker and novel DNA topoisomerase I inhibitor, enables the release payload both in the tumor cell intracellularly and in the tumor microenvironment extracellularly. YL205 is built on the TMALIN platform, which is comprised of an anti-NaPi2b humanized monoclonal antibody and conjugated in a site-specific manner to yield a uniform DAR 8 product. NaPi2b, encoded by the SLC34A2 gene, is a cell surface sodium-dependent phosphate transporter that is highly expressed in certain cancers, including ovarian, lung, thyroid, and breast cancers, with limited expression in normal tissues. This study evaluated the drug properties, efficacy, safety and pharmacokinetic profiles of YL205 in nonclinical studies. YL205 achieved a high drug-to-antibody ratio through homogeneous conjugation with hydrophilic TMALIN linker-payload, which showed limited impact on the hydrophilicity of the antibody, prolonged the retention time *in vivo* and eventually enhanced the *in vivo* potency of ADC. Additionally, YL205 exhibited strong potency, high internalization, potent cytotoxicity and bystander-mediated cell killing toward tumor cells. Significant dose-dependent antitumor activities, including complete tumor regressions with no observable toxicity, were noted in NaPi2b low to high expression ovarian and NSCLC tumor xenograft mouse models. YL205 showed a favorable PK profile evidenced by the overlapping ADC and TAb curves in SD rat and cynomolgus monkey studies. Despite high levels of expression in normal lungs of non-human primates, YL205 exhibited a good safety profile with toxic findings unrelated to normal tissue target expression. Toxicity studies using cynomolgus monkeys showed that YL205 is well tolerated with calculated therapeutic index (TI, HNSTD versus MED) of >80 for repeat dosing. No drug-related adverse findings were found in the lungs, liver or kidneys when tested in all doses. The highly stable nature of TMALIN linker, together with the high potency of the payload, likely mitigates the potential liability of this normal tissue expression. Based on these results, it demonstrates that YL205's advanced ADC design results in an increased therapeutic margin, and YL205 may help address unmet medical need in patients with NaPi2b-expressing tumors.

#1896 Therapeutic potential of TORL-4-500, an antibody-drug conjugate directed against delta like non-canonical notch ligand 1 (DLK1).

M. S. J. McDermott, N. A. O'Brien, M. Lu, J. Zhang, K. Gong, B. Hoffstrom, T. Luo, M. Liang, W. Jia, K. Chau, L. Presta, J. Glaspy, D. J. Slamon;
UCLA David Geffen School of Medicine, Los Angeles, CA

Delta like non-canonical Notch ligand 1 (DLK1) is a transmembrane protein that belongs to the NOTCH non-canonical ligand family. It has been implicated in adipogenesis, the regulation of stem cell pools, tissue differentiation during development, cancer differentiation, and cancer stem-like cell maintenance. DLK1 is highly expressed in adrenocortical, uterine, and testicular cancers as well as in a large portion of pancreatic, sarcoma, liver and squamous lung cancer patient samples. In contrast there is limited normal tissue expression beyond the normal adrenal gland, pituitary, and ovarian tissue samples. This expression profile makes DLK1 an attractive target for development of a therapeutic antibody-drug conjugate (ADC). This study describes the generation and preclinical characterization of TORL-4-500, an ADC consisting of a humanized anti-DLK1 monoclonal antibody coupled to monomethyl auristatin E (MMAE) via a cleavable linker.

TORL-4-500 showed strong binding to DLK1 by flow cytometry in DLK1 native and artificial overexpressing cell lines. In contrast no binding was observed in DLK1 non-expressing cell lines. TORL-4-500 exhibits nanomolar binding affinity for both human and cynomolgus monkey DLK1 and is rapidly internalized in DLK1 expressing cells. TORL-4-500 exhibited selective efficacy in cell line xenograft models of DLK1 positive human cancers. Treatment with TORL-4-500 induced significant regressions in four DLK1 expressing human cancer cell line xenograft studies encompassing liver, small cell lung cancer (SCLC) and sarcoma cancer. Furthermore, anti-tumor responses were sustained in each of the DLK1 expressing models for several weeks post-final dose. In the case of the two SCLC cell lines, complete regressions of xenograft tumors were measured out past 100 days in the TORL-4-500 treated animals. No significant impact on xenograft tumor growth was observed in either a DLK1 non-expressing colon cell line xenograft or in a DLK1 non-expressing melanoma xenograft study. Each of the doses tested in this study was well tolerated in mice with no dose-limiting toxicity observed. The nonclinical pharmacokinetics and toxicokinetics of TORL-4-500 were characterized in mice and monkeys and results support dosing in humans.

In summary, TORL-4-500 is a novel therapeutic for DLK1 positive cancers and on the basis of these promising preclinical efficacy results, a first in human trial to evaluate safety, tolerability, pharmacokinetics, and antitumor activity of TORL-4-500 has been launched in patients with advanced cancer and is currently ongoing (NCT06005740).

#1897 Preclinical development of MGC028, an ADAM9-targeted, glycan-linked, exatecan-based antibody-drug conjugate for the treatment of solid cancers.

J. A. Scribner[1], J. G. Brown[2], T. Son[2], L. Jin[2], C. McKenzie[2], V. Nam[2], C. Bush[2], D. Quinonez[2], D. Ford[2], V. Gonzalez[2], J. Tamura[2], S. Gorlatov[2], H. Li[2], S. Butler[2], E. Bonvini[2], D. Loo[1];

[1]MacroGenics, Inc., San Mateo, CA, [2]MacroGenics, Inc., Rockville, MD

Introduction: Antibody-drug conjugates (ADCs) seek to increase the therapeutic window of potent cytotoxic agents by linking them with monoclonal antibodies (mAbs) to selectively deliver cytotoxic payloads to tumor cells. The effectiveness and safety of ADCs rely on both the mAb specificity, and the linker-payload employed. Several approved ADCs using microtubule inhibitor payloads are impacted by ocular adverse events that have been observed both preclinically and in patients. A class of linker-payloads incorporating topoisomerase 1 inhibitors (TOP1i) has emerged recently as an effective alternative to tubulin inhibitor-based ADCs. To date, TOP1i ADCs have not been associated with dose-limiting ocular toxicity seen with microtubule inhibitor payloads. Here we report the preclinical development of an ADAM9 (a disintegrin and metalloprotease domain 9)-targeted ADC that incorporates a novel glycan-linked TOP1i. ADAM9, a member of the ADAM family of multifunctional type 1 transmembrane proteins, plays a role in tumorigenesis and cancer progression and is overexpressed in multiple cancers, making it an attractive target for cancer treatment.

Methods: MGC028 incorporates the cleavable linker-payload, bicyclononyne carbamoyl sulfamide Val-Ala-PABC exatecan (SYNtecan E™), site-specifically conjugated at asparagine 297 of the heavy chain through enzymatic glycan remodeling and metal-free click chemistry using Synaffix's GlycoConnect™ technology. *In vivo* efficacy studies were performed in immunodeficient mice with ADAM9-expressing human tumor cell-line (CDX) or patient-derived (PDX) xenografts. A non-human primate toxicology study was conducted in which MGC028 was administered by 15-minute IV infusion every two weeks at dose levels of 22.5 and 55 mg/kg for a total of two doses.

Results: MGC028 exhibited specific, dose-dependent *in vivo* antitumor activity toward ADAM9-positive CDX models representing gastric, lung, pancreatic and colorectal cancer, and head and neck squamous cell carcinoma. Furthermore, MGC028 demonstrated antitumor activity toward ADAM9-positive PDX models of lung and pancreatic cancer, and cholangiocarcinoma. MGC028 was well tolerated in a repeat-dose non-human primate toxicology study, up to 55 mg/kg, the highest dose level tested. Observations were limited to mild, reversible increases in liver enzymes, without microscopic correlates, and decreased lymphoid cellularity in the thymus. In particular, ocular toxicities were not observed.

Conclusions: MGC028 exhibited potent antitumor activity in *in vivo* models representing various solid cancer indications and was well tolerated in non-human primates at exposure levels exceeding those required for antitumor activity. Our findings support continued investigation of MGC028 as an ADC therapeutic for the treatment of ADAM9-expressing solid cancers.

#1898 LNCB74 is a potent and safe next-generation antibody-drug-conjugate utilizing a cancer selective linker for the treatment of B7-H4 expressing cancers.

Daniel P. Fitzgerald[1], Duc N. Doan[1], Riley B. Peacock[1], Shannon M. Kahan[1], Suvendu Lomash[1], Stephen Slocum[2], Kwang Hwa Jung[3], Hwanhee Oh[3], Ingrid Meza[1], Yanira Manzanarez[1], Shanmugam Selvam[1], Dallas B. Flies[1], Chul-Woong Chung[3], **Sol Langermann**[1]

[1]NextCure, Inc., Beltsville, MD,[2]AntibodyChem Biosciences, Boston, MA,[3]LegoChem Biosciences, Daejeon, Korea, Republic of

The B7 family protein B7-H4 is highly expressed on a range of solid tumors including breast, ovarian, and endometrial cancers, where it may play a role in immune evasion. In non-cancerous tissues, B7-H4 expression is limited, suggesting it may be a potential target for an antibody drug conjugate (ADC). LNCB74 is a human IgG1 antibody conjugated to the potent microtubule disrupting payload monomethyl auristatin E (MMAE) with a drug-to-antibody ratio of 4 (DAR4). The ADC employs a highly selective B7-H4 antibody based upon NextCure's expertise in B7-H4 tumor biology coupled with a glucuronidase-cleavable, site-specific linkage to an engineered cysteine in the antibody light chain via LegoChem Biosciences' ConjuAll™ technology. This improves the safety profile and therapeutic index of the agent by a) increasing stability in circulation, b) selectively releasing payload in tumor cells, and c) reducing payload release in off-target cells. LNCB74 was further engineered with a "LALA"-mutant Fc region to minimize uptake and toxicity to immune cells. In a nonhuman primate (NHP) toxicity study, LNCB74 was well tolerated for repeat dosing and provides evidence for a superior safety profile without noticeable side effects. LNCB74 is rapidly internalized by B7-H4-expressing tumor cells, and demonstrates potent, target-specific cytotoxicity on multiple cancer cell lines. *In vivo* studies demonstrate a strong bystander effect following a single dose administration of LNCB74. A rapid and durable anti-tumor response has been demonstrated in multiple cell-line derived (CDX) and patient-derived xenograft (PDX) tumor models. In summary, LNCB74 is a promising ADC enabling specific targeting of B7-H4 positive cancers across a spectrum of indications.

#1899 Novel combinations of aplitabart, a DR5 agonist IgM antibody, with ADCs or chemotherapeutic agents lead to robust anti-tumor responses in solid tumor models.

M. Desbois[1], S. E. Calhoun[1], K. C. Hart[1], C. R. Denson[1], P. Yakkundi[1], T. J. Matthew[1], M. K. Leabman[1], S. Bilic[2], G. Hernandez[1], E. W. Humke[1], A. F. Candia[1], B. Keyt[1], A. M. Sinclair[1], M. F. Kotturi[1], **B. T. Wang**[1];
[1]IGM Biosciences, Inc., Mountain View, CA, [2]Vanadro, West Des Moines, IA

Agonism of death receptor 5 (DR5), a tumor necrosis factor receptor superfamily member, induces the killing of tumor cells via the extrinsic apoptotic pathway upon receptor multimerization. We have engineered a multivalent IgM DR5 agonist antibody, aplitabart (IGM-8444), that induces robust anti-tumor activity in both in vitro and in vivo preclinical models. We also demonstrated potent synergistic in vitro activity of aplitabart with different classes of chemotherapeutic agents including microtubule inhibitors, nucleoside analogs and topoisomerase inhibitors in a range of solid cancer cell lines. Preliminary results from an ongoing phase 1a/ab clinical study show that aplitabart has an encouraging safety profile and promising activity in combination with FOLFIRI ± bevacizumab in heavily pretreated metastatic colorectal cancer patients. To further explore the combination therapies for aplitabart in lung and breast cancers, we evaluated standard of care chemotherapies, such as paclitaxel, carboplatin, and antibody drug conjugates (ADCs) *in vitro* on a range of human lung and breast cancer cell lines. We observed dose-dependent synergistic cytotoxic effects of aplitabart on tumor cells when combined with these agents. Additionally, these agents increased the expression of DR5 on tumor cells and could explain their synergistic combinatorial activity with aplitabart. Representative cancer cell lines were selected to evaluate these combinations *in vivo* using xenograft mouse models where robust anti-tumor responses were demonstrated in the xenograft lung and breast cancer models, resulting in enhanced tumor growth inhibition and extended survival. Our findings demonstrate potent in vitro synergistic cytotoxicity and enhanced anti-tumor response in preclinical models *in vivo* by combining aplitabart with ADCs, or carboplatin and paclitaxel. These results support the combination of DR5 agonist IgM antibodies with agents known to upregulate DR5 expression on solid tumors. Aplitabart is currently under evaluation in a randomized clinical study in combination with FOLFIRI + bevacizumab in comparison with FOLFIRI + bevacizumab in patients with colorectal cancer (NCT04553692).

#1900 TORL-3-600, a novel antibody drug conjugate directed against cadherin 17 (CDH17), has preclinical efficacy in colorectal, gastric, and pancreatic cancer.

N. A. O'Brien, M. S. McDermott, J. Zhang, M. Lu, K. Gong, B. Hoffstrom, W. Jia, T. Luo, A. M. Madrid, M. Liang, J. A. Glaspy, D. J. Slamon;
UCLA - University of California Los Angeles, Los Angeles, CA

Cadherin 17 (CDH17) is a cell-to-cell adhesion protein that is a member of the cadherin superfamily. In normal tissues, expression of this single pass transmembrane protein is restricted to the lateral surfaces of intestinal and pancreatic ductal epithelial cells. However, in cancer, CDH17 is frequently overexpressed in tumors of the colon, stomach, and pancreas. The selective expression of this cell surface protein in these hard-to-treat cancer makes it an attractive target for the development of antibody-based therapeutics. Here, we describe the preclinical development of TORL-3-600, a novel CDH17-targeting antibody drug conjugate (ADC). CDH17 specific monoclonal antibodies were generated using traditional hybridoma technology and splenocytes isolated from mice immunized with cocktails of NIH3T3 cells overexpressing full length hCHD17 plus purified mammalian expressed hCDH17 extracellular domain protein (aa 23-787). Selective mAb binding was confirmed by flow cytometry and mAb internalization rate was assessed by immunofluorescence (IF). TORL-3-600 was generated from a fully humanized CDH17 mAb by MMAE conjugation with a cleavable linker. Cell membrane staining of CDH17 in patient tumor microarrays (TMAs), cell line (CDX) and patient derived xenografts (PDX) was evaluated by IHC assay. Selective binding of the TORL-3-600 to CDH17 was confirmed in human cancer cell lines and cells engineered to overexpress CDH17. Binding of TORL-3-600 to cell surface CDH17 induced Internalization and translocation to the lysosome of the protein-ADC complex for release of the MMAE payload. Treatment with TORL-3-600 induced significant regressions and tumor growth inhibition (TGI) in four CDH17-positive (CDH17+) human colorectal cancer (CRC) CDXs (103.6 - 140.4% TGI) and three CDH17+ CRC PDXs (63.3 - 102.2% TGI). Responses in these models were sustained for up to nine-weeks following cessation of treatment. Sustained inhibition of xenograft tumor progression was also observed in a cell line model of CDH17+ pancreatic cancer (85.8% TGI). In contrast, greatly reduced responses (37.3 - 58.2% TGI) to TORL-3-600 were observed in the CDH17- human colon cancer CDX and PDX models. Each of the doses tested in this study were well tolerated in mice with no dose-limiting toxicities observed. Analyses of large human patient TMAs by CDH17 IHC assay demonstrated detectable expression of CDH17 in 90.1% (173/193) of CRC, 51.8% (86/166) of gastric and 20.4% (69/331) of pancreatic cancers. These numbers suggest that an ADC directed against CDH17 could provide benefit to a significant number of patients diagnosed with these cancers. These data support the clinical development of TORL-3-600 for the treatment of CDH17+ cancers. TORL-3-600 has completed IND enabling toxicity studies with acceptable PK and toxicity profiles and is now in phase 1 clinical testing (NCT05948826).

#1901 Disitamab vedotin, a clinical stage HER2-directed antibody-drug conjugate, shows potent antitumor activity as a monotherapy in preclinical urothelial cancer models.

Renee Hein, Kelsi Willis, Gina LoMastro, Suhas Vasaikar, Vinita Gupta, Katie Snead, Sharsti Sandall, Anita Kulukian

Seagen, Bothell, WA

Disitamab vedotin (DV, RC48-ADC) is an antibody-drug conjugate (ADC) that selectively delivers cytotoxic drug to HER2-expressing cancer cells. DV is composed of disitamab, a HER2-directed monoclonal antibody, and a vedotin linker-payload system, which enables conjugation of the microtubule-disrupting agent monomethyl auristatin E (MMAE) to the antibody via a protease-cleavable linker. The proposed mechanism of action (MOA) of DV occurs through direct cytotoxicity of HER2-expressing tumor cells following internalization of DV and intracellular release of MMAE. DV may also induce antitumor activity through bystander-mediated cytotoxicity of neighboring cells and via the inhibition of HER2 signaling pathways. Moreover, cellular response to MMAE includes the induction of immunogenic cell death and recruitment of immune cells to the tumor site. DV is currently being evaluated globally in subjects with HER2-expressing locally advanced or metastatic urothelial carcinoma (la/mUC) and has gained conditional approval in China following an overall response rate of 50.5% (pooled analysis from studies NCT03507166 and NCT03809013). RNA sequencing data from a large cohort of urothelial cancer patient tumors revealed expression of HER2 in many urothelial tumors; however, the relationship between HER2 expression and efficacy of DV is not well understood. Here, we sought to evaluate the antitumor activity of DV monotherapy in preclinical urothelial cancer models with varying levels of HER2 expression. Multiple patient-derived xenografts (PDX) and patient-derived 3D *in vitro* urothelial cancer models showed potent antitumor response to DV monotherapy in tumors with varying HER2 expression levels including HER2-low tumors. Overall, these findings support ongoing clinical trials in subjects with HER2-expressing la/mUC and provide scientific rationale to further explore DV monotherapy in HER2-positive and HER2-low urothelial cancer clinical settings.

#1902 ADRX-0706 Nectin-4 antibody-drug conjugate PK/PD characterization elucidates its widened therapeutic window.

M. Shahmoradgoli, A. Hau, D. Lee, A. Wang, P. P. Challita, O. Betancourt, W. Sisson, M. M. -. Kuo, K. Zhang, A. Goldson, S. Janssen, P. Datta, F. Acosta, A. Chu-Kung, H. Li, P. M. Challita-Eid, S. Rottmann;
Adcentrx Therapeutics, Inc., San Diego, CA

Nectin-4 is a well validated tumor target, which is highly expressed in several solid cancers, while expression in normal tissues is limited. A first-generation antibody-drug conjugate targeting Nectin-4, called enfortumab vedotin-ejfv (EV), was granted accelerated FDA approval in 2019 for urothelial cancers, and is currently approved for frontline therapy in cisplatin-ineligible patients with locally advanced or metastatic urothelial carcinoma, providing groundbreaking improvement in patient survival. However, clinical use of EV has also revealed safety-driven limitations, which result in reduced and/or interrupted drug exposures impacting efficacy. To overcome these limitations in therapeutic window, Adcentrx has developed ADRX-0706, a Nectin-4-targeting next-generation ADC with a drug-antibody ratio (DAR) of 8. ADRX-0706 utilizes a novel tubulin inhibitor payload AP052 with a proprietary cleavable linker utilizing Adcentrx' proprietary i-ConjugationTM technology, which results in excellent biophysical features. Most noteworthy, ADRX-0706 displays a very stable PK profile with overlapping curves for total antibody and ADC as well as full DAR retention in circulation as determined by mass spectrometry. This translates to superior efficacy of ADRX-0706 over EV in multiple in vivo cancer cell line- and patient-derived xenograft mouse models across indications. Detailed PK/PD characterization of ADRX-0706 validates the mechanism of action as an anti-mitotic agent inducing cell cycle arrest and apoptosis. In addition, ADRX-0706 treatment leads to increased PD-L1 expression in mouse pharmacology models, which is a consequence of immunogenic cell death as described for this payload class. These findings are in line with emerging data on EV and provide rationale for combination regimens with checkpoint inhibitors. Besides the improvement in efficacy, ADRX-0706 was also designed for superior safety. A payload distribution study in tumor-bearing mice reveals a preferential and increased delivery of payload to tumors and lower payload delivery to normal tissues as well as lower free payload levels in plasma for ADRX-0706 compared to EV. Taken together, these data provide association of the improved drug-linker stability of ADRX-0706 to an improved Nectin-4 directed delivery of AP052 payload to the tumor and lower exposure in normal tissues, which may translate to an improved therapeutic window. In summary, the preclinical efficacy and safety properties of ADRX-0706 support clinical evaluation of this next generation anti-Nectin-4 ADC. ADRX-0706 is currently in a phase 1a/b study (NCT06036121).

#1903 Zenocutuzumab, a HER2xHER3 bispecific antibody, is effective in cancer models with high NRG1 expression.

M. N. O'Connor[1], R. C. J. Schackmann[2], I. Odintsov[3], S. Fatrai[1], A. B. Brinkman[1], S. Walker[1], J. J. Lammerts van Bueren[1], C. A. W. Geuijen[1];
[1]Merus N.V., Utrecht, Netherlands, [2]Genmab B.V., Utrecht, Netherlands, [3]Memorial Sloan Kettering Cancer Center, New York, NY

Neuregulin 1 (NRG1) is a ligand that binds to HER3, promotes HER2/HER3 dimerization and PI3K/AKT/mTOR signaling, and causes malignant transformation. Zenocutuzumab (Zeno, MCLA-128) is a humanized IgG1 bispecific antibody that docks on HER2, preventing heterodimerization with HER3, while also blocking NRG1 interaction with HER3, and potently inhibiting NRG1-induced HER2:HER3 proliferation and survival signaling of cancer cells. High NRG1 expression arising from autocrine signaling or gene amplification is associated with poor prognosis in certain cancers, and resistance to standard therapies. The clinical efficacy and safety of Zeno in patients with NRG1 fusion-driven cancer who were enrolled in the ongoing global multicenter eNRGy study and Early Access Program were recently presented. Treatment with Zeno led to durable responses across multiple different previously treated NRG1 fusion tumor types. Zeno utilizes the Merus Dock & Block® mechanism to inhibit HER2/HER3 dimerization and the NRG1/HER3 tumor-signaling pathway and is effective at high NRG1 concentrations. Here, we examined the efficacy of Zeno in preclinical models representing different tumor types expressing high NRG1 levels. Zeno treatment of the lung cancer cell line HCC95, which harbors an NRG1 gene amplification, effectively inhibited signaling pathways involved in the regulation of proliferation and survival, including the PI3K/AKT/mTOR pathway and inhibited cell proliferation. The anti-tumor efficacy of Zeno in vivo against a panel of 28 patient-derived xenograft (PDX) models representing different tumor types was examined. Zeno significantly inhibited tumor growth in seven high-NRG1-expressing PDX models. These results show that Zeno is effective in tumor cell killing in vitro and in vivo in high NRG1-expressing cancer models representing multiple different tumor types.

#1904 Preclinical development of MGC026, a glycan-linked, exatecan-based antibody-drug conjugate (ADC) targeting B7-H3 for solid cancer.

J. A. Scribner[1], J. G. Brown[2], T. Son[2], L. Jin[2], C. McKenzie[2], V. Nam[2], C. Bush[2], D. Quinonez[2], J. Tamura[2], S. Gorlatov[2], H. Li[2], S. Butler[2], E. Bonvini[2], **D. Loo**[1];

[1]MacroGenics, Inc., San Mateo, CA, [2]MacroGenics, Inc., Rockville, MD

Introduction: Antibody-drug conjugates (ADCs) have emerged as an important class of therapeutic agents for the treatment of cancer. A duocarmycin-based B7-H3-targeted DNA-alkylating ADC, vobramitamab duocarmazine (vobra duo), has shown encouraging clinical activity in the treatment of metastatic castration-resistant prostate cancer. Given the broad spectrum of tumor indications addressable by targeting B7-H3, we developed MGC026, an ADC incorporating a B7-H3-targeting antibody and a novel glycan-linked topoisomerase 1 inhibitor (TOP1i). With distinct mechanisms of action, vobra duo and MGC026 can address different cancers, tumor stages, or be used in combination with alternate agents to enhance their clinical utility.

Methods: MGC026 is comprised of the cleavable linker-payload, bicyclononyne carbamoyl sulfamide Val-Ala-PABC exatecan (SYNtecan E™) site-specifically conjugated at asparagine 297 of the heavy chain through enzymatic glycan remodeling and metal-free click chemistry, using Synaffix's GlycoConnect™ technology. In vivo efficacy studies were conducted in immunodeficient mice with human tumor cell-line or patient-derived xenografts to identify the spectrum of MGC026-sensitive tumors and the relationship between exposure and antitumor activity. A toxicology study was conducted in cynomolgus monkeys in which MGC026 was administered by 15-minute IV infusion once every three weeks. Pharmacokinetic (PK) analysis and detailed toxicology evaluation was performed.

Results: MGC026 demonstrated specific, dose-dependent in vivo antitumor activity toward B7-H3-positive tumor xenografts representing lung, pancreatic, and prostate cancers, head and neck squamous cell carcinoma, and melanoma. Additionally, MGC026 demonstrated antitumor activity toward B7-H3-positive patient-derived xenograft models of lung and prostate cancer, with additional indications under investigation. MGC026, administered to cynomolgus monkeys at dose levels of 10, 30, and 50 mg/kg every 3 weeks for a total of 3 doses, exhibited approximate dose-proportional PK and high stability in circulation. MGC026 was well tolerated, with no lung toxicity observed, and the highest dose level tested (50 mg/kg) was declared as the highest non-severely toxic dose.

Conclusions: MGC026 exhibited a favorable preclinical profile, with potent in vivo activity toward B7-H3-expressing tumor xenografts representing a range of cancer indications. MGC026 was tolerated in cynomolgus monkeys, a relevant toxicology model, at exposure levels exceeding those required for antitumor activity. These data support clinical development of MGC026 for the treatment of B7-H3-expressing solid cancers.

#1905 The ROR1 antibody-drug conjugate, MK-2140, enhances the efficacy of established drugs in preclinical models of pediatric acute lymphoblastic leukemia.

R. B. Lock[1], K. Evans[1], B. Watts[1], E. P. Bowman[2], S. Neuhauser[3], T. Stearns[3], J. H. Chuang[3], V. M. Phillip[3], K. A. Jessen[4], E. L. Jocoy[5], C. J. Bult[3], B. A. Teicher[6], M. A. Smith[6],

[1]UNSW Medicine & Health, UNSW Centre for Childhood Cancer Research, UNSW Sydney, Sydney, Australia, [2]Merck & Co., Rahway, NJ, [3]The Jackson Laboratory, Bar Harbor, ME, [4]Formerly VelosBio, Inc., San Diego, CA, [5]The Jackson Laboratory, Sacramento, CA, [6]National Cancer Institute, Bethesda, MD

Introduction: Children diagnosed with acute lymphoblastic leukemia (ALL) experience ~90% likelihood of cure. However, the outcome for high-risk ALL and children who relapse remains poor. Receptor tyrosine kinase like orphan 1 receptor (ROR1) is a cell surface antigen primarily expressed in embryonic tissue, but also overexpressed in hematological malignancies. UC961 is a humanized IgG monoclonal antibody with high affinity for ROR1. MK-2140 (Zilovertamab vedotin/VLS-101) and VLS-211 are antibody-drug conjugates (ADCs) of UC961 with monomethyl auristatin-E or PNU payloads, respectively. This study evaluated the in vivo efficacy of MK-2140 and VLS211 against pediatric ALL patient derived xenografts (PDXs).

Methods: PDXs were selected based on ROR1 mRNA (RNA-seq) and cell surface (flow cytometry) expression and grown as orthotopic disease in immune-deficient NSG mice. Engraftment and drug responses were assessed by flow cytometric enumeration of the proportion of human versus mouse $CD45^{\pm}$ cells in peripheral blood (%$huCD45^{\pm}$). Events were defined a priori as the %$huCD45^{\pm}$ exceeding 25% or leukemia-related morbidity. MK-2140 (2.5 and 5.0 mg/kg) and VLS-211 (0.25 and 0.5 mg/kg) were administered intravenously, weekly x 3 weeks. Vincristine (0.15 mg/kg once weekly), dexamethasone (5 mg/kg daily x 5) and Lasparaginase (1,250 U/kg daily x 5) (VXL) were administered intraperitoneally for 3 weeks, followed by MK-2140 (5 mg/kg weekly x 3 weeks). Drug efficacy was assessed by event-free survival of treated (T) and control (C) groups and by stringent objective response criteria. In receptor occupancy/pharmacokinetic studies, a single dose of MK-2140 was administered and samples collected for analysis at discrete timepoints thereafter.

Results: ROR1 mRNA and cell surface expression showed a significant correlation (R=0.83, P=0.021). MK-2140 significantly delayed disease progression in 4/7 PDXs compared to vehicle control (T-C, -2.6 to 20.0 days). At the highest dose, MK-2140 elicited objective responses (remissions) in two PDXs. VLS-211 significantly delayed disease progression in 5/7 PDXs (TC, -1.8 to 70.5 days), including 3 objective responses. Prior treatment with VXL followed by MK-2140 significantly delayed disease progression compared to VXL alone (T-C, 56.8 versus 35.2 days). MK-2140 bound to $ROR1^{\pm}$ cells with near 100% occupancy within two hours of treatment, which was sustained for up to 96 h. Consistent with the receptor occupancy data, plasma levels of MK-2140 were maintained at ≥100 nM for at least 96 h after a single dose (5 mg/kg).

Conclusions: MK-2140 and VLS-211 exerted significant single-agent *in vivo* activity against a panel of pediatric ALL PDXs. MK-2140 significantly enhanced the efficacy of an induction-type regimen and should be considered for further evaluation in a minimal residual disease setting.

#1906 UNO-A001 (A001), a clinical candidate CD38 x CD3 bispecific with a novel structure, potently kills multiple myeloma cells *in vitro* and is highly effective *in vivo*.

M. Anderson[1], Y. Ling[1], M. L. Chiu[2], P. Cheung[1];
[1]Unogen Biotech Limited, Harrisburg, PA, [2]Tavotek Biotherapeutics, Spring House, PA

CD38 is a validated target for the treatment of multiple myeloma (MM) as evidenced by the important clinical activity of CD38 targeting monoclonal antibodies. Bispecific T Cell Engagers (TCEs) kill cancer cells by distinct mechanisms as compared to standard format antibody therapeutics and several TCEs have demonstrated impressive clinical activity, and have been approved for clinical use, in hematologic malignancies. Here we describe a novel bispecific leveraging the potent killing mechanism of TCEs to target CD38 bearing cancer cells. UNO-A001 is a TCE binding the cell surface receptor CD38 on target human cancer cells and CD3 on T cells. The molecule has a differentiated format, binding CD38 with a high affinity humanized camelid VHH moiety and CD3 on T cells through a unique antibody Fab arm. The affinities of each arm were optimized so that the CD38 arm bound with high affinity and the CD3 arm with much lower relative binding affinity. This configuration was designed to engage CD38 bearing target cells with multiple TCE molecules at lower doses and concentrations while minimizing T cell binding in the periphery, and in the absence of cell surface CD38. A001 potently and specifically killed human CD38 bearing multiple myeloma cell lines in T cell killing assays in vitro with EC50s in the 2.7-6.6 pM range. This potency, despite the designed lower affinity to CD3, may be due to the unique structure of A001 enabling a productive immunologic synapse between T cells and the target cancer cells, and an optimal TAA/CD3 binding affinity ratio. A001 was also highly effective in inhibiting tumor growth in H929 xenograft models. In a flank model of H929 tumor growth A001 dose dependently inhibited tumor growth with complete growth inhibition of established tumors at the highest dose level tested. In a systemic disease model with NCI-H929-luc cells A001 was also highly effective and improved survival relative to control treated animals. In preparation for clinical studies a robust and high yield production cell line was created and characterized. It achieved high expression levels of quality monodisperse UNO-A001 product that was stable in all relevant storage conditions. A001 has similar affinities for human and cynomolgus macaque CD38 and CD3. Dose ranging studies in cynomolgus macaques demonstrated tolerability consistent with clinically approved TCEs, and the expected dose dependent pharmacodynamic effects on CD38 expressing myeloid and lymphoid cell populations. These data support planned clinical testing of A001 in multiple myeloma and other CD38 bearing hematologic malignancies, including mantle cell lymphoma, T cell lymphoma, and acute myelogenous leukemia.

#1907 MYTX-011: A pH-dependent anti-cMET ADC with increased payload delivery in vivo and potent activity against cMET-expressing tumors of various epithelial origins.

D. Kanojia, W. Comb, W. Israelsen, F. Colombo, L. Nie, N. Gera, T. Chittenden, B. Fiske;
Mythic Therapeutics, Waltham, MA

cMET is an oncogenic receptor tyrosine kinase overexpressed in multiple types of solid tumors, including non-small cell lung cancer (NSCLC), gastric, head and neck, liver cancer and others. Several cMET-directed therapies including antibody-drug conjugates (ADCs) have been developed that may benefit a subset of patients with tumors that have high cMET expression, *MET* amplification, or dependency on cMET signaling. MYTX-011 is an investigational, pH-sensitive, vcMMAE-based ADC that is designed to potentially benefit not only patients whose tumors express high levels of cMET, but also a broader set of patients whose tumors express low to moderate levels of cMET. MYTX-011 is engineered to rapidly dissociate from cMET only at the acidic pH of endolysosomes. We have previously demonstrated that MYTX-011 drives increased internalization and cytotoxicity in tumor cells expressing moderate cMET levels compared to a matched parent non-pH sensitive ADC. MYTX-011 also demonstrated markedly superior efficacy in NSCLC xenografts with moderate cMET expression as compared to either the parent ADC or benchmark ADCs representing clinical-stage anti-cMET ADCs with vcMMAE and maytansinoid payloads. MYTX-011 was efficacious in NSCLC PDX models with moderate cMET expression of adenocarcinoma/squamous histology and in heterogeneous cMET-expressing EGFR mutant models. In these studies, we demonstrate that MYTX-011 exerts enhanced efficacy by delivering increased levels of payload to cMET+ tumors compared to the parent ADC. MYTX-011 treatment induced significantly increased levels of phospho-histone H3 (pHH3), a pharmacodynamic marker of MMAE cytotoxicity, in moderate cMET expressing NCI-H1975 NSCLC xenograft tumors compared to the parent ADC. Further, increased levels of free MMAE were detected in tumors from mice treated with MYTX-011 compared to a matched dose of the parent ADC, indicating that the pH dependent binding engineered into MYTX-011 translated to increased payload delivery to tumors in vivo. To explore the potential efficacy of MYTX-011 in other cMET-expressing tumor types, we tested the activity of MYTX-011 in a panel of cell lines derived from gastric and head and neck cancers. MYTX-011 demonstrated increased cMET-dependent cytotoxicity compared to the parent ADC. MYTX-011 was also highly active in cMET+ xenograft models derived from gastric (non-*MET* amplified), esophageal, and head and neck cancers. Together, these findings highlight the potential of MYTX-011 as a therapeutic candidate for treating a broader range of cMET-expressing malignancies.

#1909 Advancing a novel tubulin-inhibitor ADC technology: The Adcentrx auristatin platform offers enhanced efficacy and safety profiles compared to vedotin technology.

D. Lee[1], S. Rottmann[1], A. Wang[1], P. P. Challita[1], A. M. Hau[1], W. Sisson[1], M. M. -. Kuo[1], K. Zhang[1], M. Leung[1], A. Mahloch[1], E. Nye[1], P. Datta[1], S. Janssen[1], F. Acosta[1], O. Betancourt[1], M. Shahmoradgoli[1], A. Chu-Kung[1], M. Guo[2], P. M. Challita-Eid[1], H. Li[1];
[1]Adcentrx Therapeutics, Inc., San Diego, CA, [2]Adcentrx Therapeutics, Inc., Shanghai, China

Auristatins represent an important class of anti-mitotic antibody-drug conjugate (ADC) payloads with potent cytotoxic effects on rapidly dividing cancer cells. Most notably, monomethyl auristatin E (MMAE) stands as the most extensively validated compound, laying the foundation for the vcMMAE (vedotin) linker-payload technology that has contributed to the approval of several ADCs, including brentuximab vedotin, polatuzumab vedotin-piiq, tisotumab vedotin-tftv, and enfortumab vedotin-ejfv. However, while these first-generation ADCs have paved the way for a paradigm shift in cancer treatment away from traditional chemotherapy, there remains a discernible opportunity for improvement in both efficacy and safety. In this context, we introduce the Adcentrx auristatin platform, which substantially expands the therapeutic window of auristatin-ADCs beyond the vedotin technology. Through systematic exploration, we have synthesized >100 proprietary auristatin analogues with a range of distinctive properties. We identified optimized linker-payloads by strategically pairing lead payload candidates with our proprietary i-ConjugationTM, an irreversible, stable cysteine conjugation technology, and fine-tuned linkers. The resulting ADCs with a drug-to-antibody ratio (DAR) of 8 were extremely hydrophilic with excellent in vivo pharmacokinetics, and sustained DAR retention for a period of 21-days. Comparative assessments against vedotin-ADCs revealed that Adcentrx-ADCs demonstrated superior efficacy across multiple targets and indications in various mouse xenograft models. In Sprague-Dawley rats, Adcentrx-ADCs exhibited remarkable tolerability, albeit their high drug loading of 8. In summary, our preclinical studies underscore the significant enhancement in the therapeutic index achieved by the Adcentrx auristatin platform. Furthermore, this technology presents a promising alternative mode of action to camptothecins, exhibiting tolerance to targets expressed in non-proliferative normal tissues but without the burden of severe dose-limiting toxicities such as interstitial lung disease.

#1910 Advancing therapeutic interventions for NUT carcinoma: Orchestrating the precision of CRISPR/Cas9-mediated NUTM1 suppression and synergistic ADC strategies.

J. Choi[1], H. Yi[1], H. Park[2], M. Lee[3], D. Kim[1], S. Hong[2], Y. Shin[2], Y.-I. Choi[3];
[1]Sungkyunkwan University, Seoul, Korea, Republic of, [2]Seoul National University, Seoul, Korea, Republic of, [3]Samsung Medical Center, Seoul, Korea, Republic of

Purpose: NUT carcinoma (NC) is aggressive carcinoma defined by translocations involving the *NUTM1* and frequent squamous differentiation. *NUTM1* gene encodes a testicular nuclear protein (NUT), exclusively expressed in the testis. The fusion of *NUTM1* leads to abnormal cell growth, resulting in the development of NC. This study aims to discover advanced approaches for inducing the death of cancer cells, specifically targeting those expressing NUT proteins.
Methods: Spatial Transcriptome analysis and RNA sequencing were applied to formalin-fixed paraffin-embedded *NUTM1* fusion-positive cancer tissues. Virus-like particles were used to introduce CRISPR/Cas9 into cells expressing the *NUTM1* fusion oncoprotein. The inhibitory effect was confirmed through multiple in vitro assays. The effectiveness of Anti-Trophoblastic cell-surface antigen (TROP-2) Antibody-Drug Conjugate (ADC) was demonstrated in vivo and in vitro in cells with increased TROP2 expression subsequent to NUT suppression.
Results: NCs revealed a relatively uniform pattern of gene expression, forming six unique groups. Notably, the NUT protein predominantly located in the inner regions of the tumor tissues. We employed CRISPR/Cas9 technology to specifically target cells harboring the NUTM1 fusion gene. The precise genetic editing was remarkably effective, achieving up to 90% success in the targeted area. This led to a notable decrease in both RNA and protein levels of NUT expression, effectively disrupting associated downstream pathways. The cell growth rate was reduced in several NC cell lines, and differentiation, accompanied by morphological changes, was observed in most edited cells. RNA sequencing analysis of these edited cells uncovered a substantial increase in expression of cytosolic molecules, with a marked increase in TACSTD2 expression. Interestingly, when we combined this genetic editing approach with a targeted therapy - the TROP2-ADC loaded with interferon-beta - the results were even more striking. Cells treated with this combination showed almost double the rate of growth inhibition compared to those receiving only a single form of treatment.
Conclusion: This study provides valuable insights into identifying novel therapeutic targets and elucidating potential mechanisms by analyzing NUT cancer tissues using various assays. Our results support that CRISPR/Cas9-mediated targeting of *NUTM1* could be a useful approach for NUT oncoprotein ablation, especially when used in combination with other therapies such as ADCs. Further studies are needed to investigate the efficacy of NUT inhibition in preclinical and clinical settings. the elimination of tumor cells facilitated by CRISPR/Cas9, along with additional tumor markers targeted by ADCs, holds potential for developing treatment strategies against incurable cancers driven by genetic alterations.

#1911 Dato-DXd mediates anti-tumor activity in preclinical TROP2-expressing intracranial tumor model.

K. Jones, M. Suksomboon, S. rosenthal, J. Gordon, C. Reimer, M. Sung, **C. Rane**;
AstraZeneca, Waltham, MA

Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) consisting of a humanized anti-TROP2 monoclonal antibody linked to a potent DNA topoisomerase I (TOP1) inhibitor payload via a plasma-stable, tumor-selective, tetrapeptide-based cleavable linker. Dato-DXd is currently under clinical investigation for the treatment of patients with solid tumors including non-small cell lung cancer (NSCLC), hormone receptor positive (HR+ BC) and triple negative breast cancer (TNBC). Pharmacotherapy of brain tumors can be limiting due to restricted drug delivery across blood brain and blood tumor barrier. Enhertu®, that uses the same DXd ADC technology, has reported clinical activity in patients with brain metastases from HER2+ breast cancer, but very little information is available on what drives ADC biodistribution and activity in CNS-involved cancers. Here, we investigated whether systemically administered ADCs can penetrate the brain microenvironment and mediate anti-tumor activity in a preclinical model. Luciferase-tagged H1373 (TROP2-expressing NSCLC) tumor cells were intracranially implanted into NSG mice. Tumor-bearing mice were dosed with Dato-DXd or matched isotype Control IgG-ADC (DAR4) at 10mpk 7 days or 14 days post intracranial tumor implant. Dato-DXd inhibited intracranial tumor growth better than Control ADC (Day 7: 105% TGI vs 38% TGI; Day 14: 65% TGI vs <10% TGI, respectively, compared to Vehicle). Immunohistochemistry analysis of brain tissue validated localization of Dato-DXd in the tumor, suggesting Dato-DXd can distribute into the local tumor microenvironment in this preclinical tumor model. Additionally, treatment with Dato-DXd provided a significant survival benefit over Control ADC (Median survival of 63 days vs 43 days, P=0.0002). This preclinical study supports the inclusion of Dato-DXd in treatment of patients with CNS-involved tumors. Understanding the pharmacological determinants of Dato-DXd activity in the CNS will help outline strategies to implement Dato-DXd-based treatment of patients with CNS-involved tumors.

#1912 Targeting Trop-2 with sacituzumab govitecan (IMMU-132) suppresses the tumor growth in diffuse large B cell lymphoma.

J. Ting, M.-F. Wei, H.-W. Lee, K.-H. Lan, A.-L. Cheng, S.-H. Kuo;
National Taiwan University College of Medicine, Taipei City, Taiwan

Introduction: Sacituzumab govitecan (SG), also termed IMMU-132, is an antibody-drug conjugate, linking an anti-Trop-2 antibody and the topoisomerase I inhibitor, SN-38. Clinically, SG has shown promising therapeutic effects in patients with human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer. However, the efficacy of SG in diffuse large B-cell lymphoma (DLBCL) remains unexplored. In this study, we sought to determine whether SG can efficiently inhibit cell proliferation and tumor growth of DLBCL by using both *in vitro* and *in vivo* models.

Methods: We examined the cytotoxicity of SG in the activated B-cell like (ABC)-subtype-DLBCL cell lines, Riva (Ri-1), HBL-1, and SU-DHL-2, and the germinal center B-cell (GCB)-subtype-DLBCL cell lines, SU-DHL-4, SU-DHL-5, and SU-DHL-6 by MTT assay. We assessed the distributions of cell cycle phase and apoptosis in the aforementioned DLBCL cell lines treated with SG for 24 h or 48 h using flow cytometry and Annexin V staining. We confirmed apoptosis (cleavage of poly ADP-ribose polymerase [PARP] and caspase-3) and detected DNA damage (γH2AX and 53BP1)-related protein expression in SU-DHL-2 and SU-DHL-6 cell lines treated with SG at various concentrations for 48 h using western blotting, compared to untreated cells. To examine the anti-tumor effect of SG *in vivo*, NOD-SCID nude mice of Riva-xenograft mouse models were randomized into a control group and an SG-treated group.

Results: Flow cytometry and western blotting revealed overexpression of Trop-2 on the surface of untreated ABC-DLBCL and GCB-DLBCL cell lines. In this study, we showed that SG treatment reduced cell viability in all six DLBCL cell lines with nanomolar IC_{50} values. Exposing SG to DLBCL cells significantly increased cell cycle arrest at the G2/M and sub-G1 phases of all six DLBCL cell lines. Annexin V staining revealed that SG induced apoptosis in all six DLBCL cell lines. Western blotting confirmed apoptosis induction by showing a dose-dependent upregulation of cleaved PARP and cleaved caspases-3 by SG treatment, along with decreased expression of survivin in both SU-DHL-2 and SU-DHL-6 cells. SG also upregulated the expression of γH2AX and 53BP1 in both SU-DHL-2 and SU-DHL-6 cells. Furthermore, we found that tumor growth of Riva cells *in vivo* was significantly reduced by treatment with SG when compared with untreated control.

Conclusion: SG suppresses tumor growth of ABC-DLBCL and GCB-DLBCL cells in both *in vitro* and *in vivo* models by inducing cell cycle arrest, apoptosis, and DNA damage. These findings provide a rationale for transitioning SG to clinical trials for treating patients with relapsed or refractory DLBCL.

#1913 KD5005: HER-2 dependent strong potent anti-tumor activity of an anti-HER-2 mAb-TNFaimmunocytokine.

Y. CHEN[1], P. LI[2], G. FANG[2], H. WU[2], C. ZHANG[2], Z. CAI[2];

[1]Shanghai Kanda Biotechnology Co. Ltd., Shanghai, China, [2]Shanghai Celgen Bio-Pharmaceutical Co. Ltd., Shanghai, China

Tumor necrosis factor alpha (TNFα) is a pleiotropic cytokine with diverse biological functions, including apoptosis, cell survival, inflammation, and immunity. While recombinant human TNFα has demonstrated therapeutic efficacy in isolated limb perfusion for soft tissue sarcoma and melanoma, its systemic administration is limited by severe toxicities, including hypotension. Tumor-specific targeting and enhancement of TNFα's tumor cell killing activity hold promise for improving its therapeutic index. To address these challenges, we developed KD5005, a novel HER-2-targeted immunocytokine fusion protein comprising an anti-HER-2 IgG1 monoclonal antibody (trastuzumab) and human TNFα. Tissue distribution studies revealed that KD5005 specifically accumulated in HER-2-expressing tumors, demonstrating its tumor-targeting capability. In vitro, KD5005 exhibited reduced TNFα-mediated apoptosis in L929 cells compared to recombinant TNFα, indicating its lower non-specific toxicity. Notably, KD5005 induced apoptosis of HER-2-positive human gastric cancer NCI-N87 cells at significantly lower concentrations than trastuzumab, TNFα, or their combination, demonstrating its enhanced tumor cell killing activity. The potent apoptotic activity of KD5005 was HER-2-dependent, as it did not show increased apoptotic activity in WT mouse forestomach carcinoma (MFC) cells and had similar apoptotic activity compared to the combination of trastuzumab and TNFα. This HER-2 dependency further supports the tumor-specific targeting of KD5005.In vivo, KD5005 demonstrated superior anti-tumor efficacy compared to the combination of trastuzumab and TNFα in syngeneic tumor models using CT26 tumor cells transfected with the human HER-2 gene. KD5005 induced robust tumor regression and durable cure in 7 of 8 mice, while the combination of trastuzumab and TNFα elicited weaker therapeutic responses, resulting in tumor rejection in only 3 of 8 mice. Pharmacokinetic and toxicity studies of KD5005 were conducted in cynomolgus monkeys. KD5005 exhibited a significantly prolonged in vivo half-life compared to TNFα, indicating its improved pharmacokinetic profile. KD5005 was administered intravenously every two weeks to the same animal in a dose-escalation study at 0.3 mg/kg, 1.0 mg/kg, 3 mg/kg, 10 mg/kg, and 30 mg/kg. The toxicity study results showed that the maximum tolerated dose for KD5005 in cynomolgus monkeys is 10 mg/kg, indicating its favorable toxicity profile. In summary, we have developed KD5005, a HER-2-targeted immunocytokine fusion protein with enhanced tumor-killing activity, improved pharmacokinetic properties, and a favorable toxicity profile. These preclinical findings support the further clinical development of KD5005 as a promising therapeutic agent for HER-2-positive cancers.

#1914 Amivantamab efficacy in wildtype EGFR NSCLC tumors correlates with levels of ligand expression.

R. Rivera-Soto[1], B. Henley[1], M. Pulgar[1], S. Lehman-Tenuto[1], H. Gupta[1], M. Weindorfer[1], S. Vijayaraghavan[1], T.-W. Yao[2], S. Laquerre[1], S. Moores[1];
[1]Johnson & Johnson Innovative Medicine, Spring House, PA, [2]Johnson & Johnson Innovative Medicine, La Jolla, CA

Amivantamab (RYBREVANT™) is an FDA-approved, low-fucose IgG1 bispecific antibody targeting EGF and Met receptor tyrosine kinases, with proven clinical activity against EGFR mutant non-small cell lung cancer (NSCLC). Preclinical studies demonstrated that three context-dependent mechanisms of action (MOA) contribute to amivantamab efficacy: immune cell-mediated killing by antibody-dependent cellular cytotoxicity and trogocytosis, receptor internalization and degradation, and inhibition of ligand binding to both EGF and Met receptors. In tumors lacking known cancer-driver genetic aberrations, ligand binding to wildtype EGFR ($EGFR^{WT}$) and/or Met^{WT} may activate downstream signaling pathways, inducing pro-tumorigenic processes. Among the EGFR ligands, we demonstrated that amphiregulin (AREG) is highly expressed in $EGFR^{WT}$ NSCLC primary tumors, with significantly higher circulating protein levels in NSCLC patients than in healthy volunteers, and induces EGFR phosphorylation, promoting downstream signaling and increasing cell proliferation. Importantly, treatment of AREG-stimulated $EGFR^{WT}$ cells/tumors with amivantamab, or an AREG-targeting antibody, inhibits ligand-induced signaling and cell/tumor proliferation/growth. Across 10 $EGFR^{WT}$ NSCLC patient-derived xenograft mouse models, amivantamab efficacy correlated with *AREG* RNA levels, suggesting AREG as a potential predictive marker for amivantamab activity in this population. Interestingly, in these xenograft models, amivantamab anti-tumor activity was independent of amivantamab's Fc engagement with immune cells, suggesting that, in this context, the amivantamab's ligand-blocking function is sufficient for its efficacy. Juxtaposedly, we previously demonstrated that low fucose amivantamab, active Fc domain, was necessary for maximal anti-tumor activity against tumors with EGFR or Met activating mutations. Altogether, these results demonstrated amivantamab context-dependent MOA for efficacy. In conclusion, these data 1) highlight EGFR ligand AREG as a driver of tumor growth in some $EGFR^{WT}$ NSCLC models, 2) illustrate the preclinical efficacy of amivantamab in ligand-driven $EGFR^{WT}$ NSCLC, and 3) identify AREG as a potential predictive biomarker for amivantamab against anti-$EGFR^{WT}$ therapies.

#1915 A scalable pancancer antigen target discovery platform for precision oncology.

E. Fox, G. Appe, A. Behdenna, L. Meunier, A. Nordor, S. Weill, **C. Marijon**;
Epigene Labs, Paris, France

With the emergence of precision oncology as a new paradigm in cancer care, there is an urgent need to develop tools capable of mining the massive amounts of rich omic data generated every year. To support target discovery programs at scale, we developed a pan-cancer bioinformatics platform combining patient data with extensive biological and pharmaceutical knowledge for the identification and prioritization of novel antigen targets. Our pipeline was first validated with the discovery of new antigen targets amenable to CAR-T therapy for relapsed/refractory multiple myeloma. Here, we are exploring AML, a type of leukemia with several unmet needs.

First, we identified and integrated 36 relevant microarray datasets from the GEO database using a proprietary data identification and integration pipeline. The clinical data was curated using our proprietary oncology ontology, machine learning models, and domain expert quality control processes. The molecular data was normalized and the datasets aggregated into a virtual patient cohort of unprecedented size and quality, comprising 2,995 AML patients and 220 healthy controls. To both find a clinically relevant patient sub-population and reduce the cohort heterogeneity, AML patients were stratified based on their transcriptomic profile using a consensus clustering analysis, which we interpreted thanks to the curated clinical data. Among multiple others, we identified a highly stable cluster enriched in AML-M3 patients, a very distinct and aggressive subtype of AML caused by a t(15;17) translocation. A differential gene expression analysis was performed comparing this cluster with the control group and 574 genes were found to be overexpressed. We then applied proteomic filters to exclusively focus on cell surface-bound protein targets demonstrating an acceptable level of anticipated cytotoxicity. Finally, the 23 short-listed antigen targets were prioritized with additional multi-omic patient and cell line data to optimize their safety and efficacy profiles as well as expression robustness. Interestingly, well-known targets, such as CD96 and ABCC1, were found in the top targets.

Developing scalable pipelines will be instrumental in the advent of precision oncology. Combining unbiased data-driven tools with cancer biology-driven approaches, our state-of-the-art pipeline can be used for any cancer type and antigen-targeting modality, including CAR-T and antibody-based therapies. The present study illustrates the potential of our platform when applied to AML, one of the most heterogeneous groups of neoplastic disorders. Leveraging our large and unique AML patient cohort, we were not only able to detect a relevant subgroup of patients, but also identified novel antigen target candidates for this specific population, which were then prioritized based on domain expertise. A broader study addressing other cancer indications, including solid tumors, is underway.

#1916 Discovery of a novel Nectin4 IPSC-derived cell therapy for the treatment of solid tumors.

J. M. Carton, **C. Dower**, M. Miller, J. Wheeler, S. Heron, H. J. Millar, D. Walker, D. J. Perry, A. Lebid, L. Cocka, D. Kim, B. Morse, B. Gurung, M. Harris, A. Jethon, M. Naso, H. Levitsky;
Century Therapeutics LLC, Philadelphia, PA

Century Therapeutics is developing a Nectin4-targeting IPSC-derived cell therapy for the treatment of Nectin4 expressing solid tumors. The Nectin proteins (Nectin1, Nectin2, Nectin3 and Nectin4) are members of the calcium independent immunoglobulin superfamily of cell adhesion molecules (CAMs) involved in adhesive processes that help in the growth and development of tissues. Nectin 1, 2 and 3 are normally found in adult tissue whereas Nectin4 is mainly found in normal placental and embryonic tissue. Nectin4 is also expressed in different types of cancer including urothelial, ovarian, lung and head/neck cancers. Nectin4 is established as a biomarker for worse prognosis in cancers and is linked with carcinogenesis and disease severity. These features establish Nectin4 as a promising target for anti-tumor drug development. Enfortumab vedotin, an antibody drug conjugate targeting Nectin4 positive tumors, has demonstrated benefit in clinical trials and is FDA approved for treatment of advanced bladder cancer. We have identified novel single-domain antibodies (VHH) that bind to multiple epitopes on Nectin4 extracellular domain. The VHH antibodies were engineered into chimeric antigen receptor (CAR) formats and characterized for expression, cell activation through antigen engagement, and cytotoxicity activity in primary T-cells. Selected binders demonstrated efficacy in multiple CAR formats in primary T-cells in a mouse xenograft model using OVCar-3 tumor cells. The lead CARs engineered into primary T-cells demonstrated tumor inhibition similar to a reference CAR using the ASG-5ME antibody (Enfortumab) as the Nectin4 binder. The CARs were engineered into our IPSC-derived iNK and iT cells and demonstrated cytotoxicity activity against a panel of cell lines with a range of cell surface expression of Nectin4. Based on these studies, Century Therapeutics is advancing the lead Nectin4 binder for development of an IPSC-derived cell therapy to treat Nectin4 positive solid tumors.

#1917 HER2-FGFR1 interaction induced by bispecific molecules: A novel strategy for treating breast cancer.

M. A. Krzyscik, K. Hristova;
Johns Hopkins University, Baltimore, MD

Breast cancer poses a significant global health challenge, demanding effective therapies targeting specific receptors. In our prior study, we engineered molecules capable of binding to both HER2 and FGFR1, pivotal receptors in breast cancer progression. By combining the high-affinity Affibody $Z_{HER2:2891}$ for HER2 with a modified, stable form of FGF2 binding to FGFR1, we created the bispecific protein (Af_{HER2}-lFGF2). This innovative molecule could simultaneously recognize HER2 and FGFR1, exhibiting enhanced cell penetration. When coupled with the potent cytotoxic agent monomethyl auristatin E (MMAE), it demonstrated exceptional efficacy in eliminating cancer cells expressing HER2, FGFR, or both receptors. Our current investigation focused on quantifying the interaction between HER2 and FGFR1 receptors on the cell surface upon treatment with these bispecific molecules. Leveraging fully quantified spectral imaging FRET (FSI-FRET), a technique utilizing spectrally resolved two-photon microscopy. We directly monitor the association of HER2 and FGFR1 in the plasma membrane. Our findings revealed that the bispecific Af_{HER2}-lFGF2 molecule forces interaction between HER2 and FGFR1 on the cell surface. Furthermore, we analyzed the activation of the HER2-FGFR1 complex and subsequent downstream signaling pathways using western blotting. In summary, our research uncovers the ability of the Af_{HER2}-lFGF2 bispecific protein to foster direct interaction between HER2 and FGFR receptors on the cell membrane. By employing state-of-the-art techniques like FSI-FRET, we elucidated the mechanisms governing this interaction and, by western blotting, downstream signaling pathways. These insights emphasize the potential of A_{fHER2}-lFGF2 as a promising therapeutic agent for targeting HER2, FGFRs, and HER2/FGFRs-positive cancers. This approach paves the way for targeted therapies in addressing the prevalent global health challenge of breast cancer.

#1918 LX-101, a novel, clinical stage, payload-bearing targeted therapy directed to the insulin-like growth factor receptor (IGF-1R), demonstrates potent preclinical anti-tumor activity against multiple cancer types with well-established ties to the IGF-1/IGF-1R pathway.

M. Hoberman[1], A. Z. Dudek[2];

[1]Lirum Therapeutics, New York, NY, [2]Mayo Clinic, Rochester, MN

Objective: LX-101 is a next-generation, targeted therapy directed to the insulin-like growth factor 1 receptor (IGF-1R). LX-101 consists of a proprietary IGF-1 variant coupled to a cytotoxic methotrexate payload. LX-101 was previously evaluated in Phase 1 trials of adult patients with advanced, pretreated cancers, where it was well-tolerated and demonstrated single agent activity. Neither a dose limiting toxicity, nor a maximum tolerated dose was reached, leaving potential room for additional dose escalation and schedule optimization. Multiple aggressive cancers of unmet need have genetic alterations affecting the IGF-1R pathway and/or high IGF-1R expression that correlates with poor outcomes, including certain cancers of the breast, head and neck, Ewing's sarcoma, osteosarcoma, and others. Prior attempts at inhibiting IGF-1R with non-payload bearing naked monoclonal antibodies or small molecules produced a range of clinical outcomes including some partial and complete responses. None of these agents, however, were ultimately approved, potentially due to suboptimal potency that allowed for escape mechanisms, including redundant signaling pathways, and the lack of enrichment for select tumor types with strong ties to the IGF-1/IGF-1R pathway. Herein, we investigated the anti-tumor activity of the payload-bearing agent LX-101 against IGF-1R-involved cancer cell lines.

Methods: Cell lines were incubated with LX-101 (~1.6 - 2500nM). Cell viability was assessed by CellTiter-Glo after 4 days. IC_{50}s were calculated using GraphPad PRISM software.

Results: LX-101 displayed potency against head and neck cancer (FaDu, IC_{50} = 9 nM), triple negative breast cancer (BT-20, IC_{50} = 17 nM), Ewing's sarcoma, including EWSR1-FLI1 gene fusion-positive cell lines RD-ES (IC_{50} = 10 nM), A-673 (IC_{50} = 14 nM), and SK-ES-1 (IC_{50} = 29 nM) and EWSR1-ERG gene fusion-positive cell line CADO-ES1 (IC_{50} = 14 nM). LX-101 was also potent against PAX3-FOXO1 gene fusion positive alveolar rhabdomyosarcoma (SJCRH30, IC_{50} = 23 nM), osteosarcoma (143B, IC_{50} = 6 nM; HOS, IC_{50} = 7 nM; U2OS, IC_{50} = 32 nM), and neuroblastoma (SK-N-AS, IC_{50} = 16 nM; IMR-32, IC_{50} = 20 nM; SH-SY5Y, IC_{50} = 30 nM).

Conclusion: These results demonstrate that LX-101 has potent preclinical anti-tumor activity against multiple cancer cell lines with well-established ties to the IGF-1/IGF-1R pathway, including with different genetic and epigenetic alterations. These data support further clinical development of LX-101 in IGF-1R-involved cancers. New clinical trials are planned.

#1919 Activity and affinity tuning next-generation immunotoxins for targeted therapy.

H. Liang[1], G. L. Beilhartz[2], S. Cao[1], R. A. Melnyk[2];
[1]University of Toronto, Toronto, ON, Canada, [2]Hospital for Sick Children, Toronto, ON, Canada

Classic cancer-associated receptors, such as EGFR and Her2, are often overexpressed on malignant cells relative to healthy cells. Numerous molecules have been developed to leverage this differential expression with the goal of developing specific and safe targeted therapies, including antibody-drug-conjugates and immunotoxins. The general schematic of these molecules is to fuse toxic payloads -either small molecules or proteins - with a targeting moiety that binds to the cancer-specific receptor. Despite the general success of this approach, even low levels of these receptors on healthy tissues result in on-target/off-tumor toxicity thus limiting the dose of therapeutic molecules available to tumors. Targeted therapies with greater on-tumor efficacy and reduced toxicity are urgently needed in order to further advance therapeutic outcomes. To achieve this, we set out to exploit the unique features of bacterial toxins as highly modular protein delivery systems to design next-generation targeted therapies. We demonstrate the capacity of the immunotoxin platform to deliver various therapeutic proteins, with distinct activities from inhibiting protein synthesis to degrading oncogenic signaling pathways, such as the RAS/MAPK pathway. Further, we show how modifying the affinity, valency, and specificity of the receptor-binding moieties, as well as tuning the enzymatic activity of the toxic enzyme payloads interact to affect the on-target efficacy and off-target toxicity of the targeted molecules. Altogether, these data demonstrate the potential of immunotoxins as highly flexible and tunable platforms for the development of a new class of anti-cancer therapeutics.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance 2: Ras GTPase
Poster Session

#1923 Cytoplasmic localization of KRAS in Her2-amplified colorectal cancer induces an altered dependency of the oncogenic signaling pathway from RAS/MAPK to PI3K/AKT.

K. Maruyama, S. Nagayama, R. Katayama;
Japanese Foundation for Cancer Research, Tokyo, Japan

Nowadays, KRAS-G12C specific inhibitor has been used for the treatment of patients with KRAS mutated non-small cell lung cancer, but not for colorectal cancer (CRC) patients. Recent clinical trials have shown that the efficacy of a single KRAS inhibitor treatment was limited for CRC due to multiple primary/adaptive resistance mechanisms. In the CRC, clinical trial with dual inhibition of KRAS-G12C and EGFR has demonstrated that combination therapy had improved partial response rate, suggesting that primary resistance to KRAS inhibitor is mainly caused by EGFR-mediated adaptation. Meanwhile, more than half of the primary resistance mechanisms are still unknown. To understand the intrinsic resistance mechanisms to KRAS inhibitors in CRC, KRAS G12C- or G12D-positive CRC patient-derived cells (PDCs) were established from surgically resected tumor specimens. Analysis of cell proliferation under KRAS inhibitor treatment or KRAS knockdown revealed these PDCs were not solely dependent on KRAS mediated growth signaling. To clarify the compensatory activated pathways in KRAS inhibitor, inhibitor library screening and sequencing analysis were performed among 8 KRAS-mutated PDCs. As a result, PDCs were categorized into EGFR inhibitor with KRAS inhibitor sensitive group and PI3K pathway activating group harboring PIK3CA mutation or/and ERBB2 amplification with KRAS mutation. To explore the novel intrinsic resistance mechanisms, we deeply analyzed one of the PDC named JC261, harboring PIK3CA, ERBB2, and KRAS alterations. We observed that PI3K pathway was highly activated in JC261 cells, and cell proliferation was mainly dependent on PI3K/AKT/mTOR pathway regardless the existence of KRAS-G12C mutation. To examine whether Her2 amplification contributes to the PI3K pathway dependency, we established Her2 knockout JC261 cells. Notably, *Her2* knockout suppressed Her2-Her3-PI3K signaling and restored KRAS-MAPK dependency. To analyze the mechanism of how KRAS-MAPK pathway was activated in Her2 knockout cells, we focused on KRAS localization, since the MAPK activation is known to initiate from plasma membrane localization of KRAS after appropriate modifications. Remarkably, immunofluorescence staining of KRAS revealed that KRAS was aberrantly localized in the cytoplasm in JC261, while KRAS localization was changed to the plasm membrane in Her2 knockout JC261 cells. In addition, the cytoplasmic KRAS localization was also observed in Her2-amplified, KRAS-WT PDC (JC69). These results suggest that Her2 amplification may induce aberrant KRAS localization, resulting in low dependence on the KRAS-MAPK pathway. Thus, KRAS localization may regulate the balance between MAPK and PI3K signaling intensity.

#1924 RTK signaling and WT RAS activity as vulnerabilities in tumors with acquired resistance to GDP-state selective KRAS^{G12C} inhibitors in preclinical models.

H. S. Solanki[1], H. Shah[2], D. Imbody[1], B. Desai[1], P. A. Stewart[1], B. Fang[1], Y. Stern[1], L. N. Darville[1], J. M. Koomen[1], A. Marusyk[1], E. Ahler[2], I. Aronchik[2], M. Singh[2], E. B. Haura[1];

[1]Moffitt Cancer Center, Tampa, FL, [2]Revolution Medicines, Inc. (RVMD), Redwood City, CA

Background: KRAS^{G12C}-GDP Inhibitors such as sotorasib and adagrasib have demonstrated clinical benefit in lung cancer patients harboring an oncogenic *KRAS^{G12C}* mutation. However, the durability of monotherapy benefit is limited by the development of resistance. Hence, identification of novel treatment approaches to overcome resistance and extend duration of benefit becomes necessary to address this unmet clinical need.

Experimental Design: We generated two NSCLC models of KRAS^{G12C}-GDP inhibitor acquired resistance, named sotorasib-R LU65 (cell-line derived, *in vitro*) and adagrasib-R LUN156 (PDX-derived, *in vivo*) following extended treatment with sotorasib and adagrasib, respectively. We then performed transcriptomic and mass spectrometry-based phosphoproteomics analyses on baseline and KRAS^{G12C}-GDP inhibitor-resistant samples to determine resistance and escape mechanisms.

Results: In the sotorasib-R LU65 cells, we discovered upregulation of various RTKs including HER2, HER3, and AXL using a mass spectrometry-based proteomics approach and Immunoblot analysis. Simultaneously, from a transcriptome analysis, we observed activation of RAS and PI3K/AKT signaling in these cells. In the adagrasib-R LUN156 model, increased phosphorylation of MET was observed via phospho-RTK array and by immunoblotting. Transcriptomic analysis revealed an enrichment for RAS pathway dependency in the adagrasib-R tumor models. RAS GTP-binding assessed by RAF-RBD pulldown and multiple reactions monitoring mass-spectrometry suggest increased GTP-bound RAS isoforms in sotorasib-R LU65 cells and active RAS signaling in adagrasib-R LUN156. Given the convergence of our findings on re-activation/maintenance of wild-type RAS signaling as a means of resistance to KRAS^{G12C}-GDP-state inhibitors, we hypothesized that RMC-7977, a tri-complex RAS^{MULTI}-GTP inhibitor, which inhibits signaling via mutant and wild-type RAS, had the potential to counteract these mechanisms. We tested RMC-7977 monotherapy, which drove complete tumor regressions in the adagrasib-R LUN156 model. Additionally, RMC-7977 attenuated tumor growth in sotorasib-R cell derived LU65 xenograft model wherein we observed co-activation of PI3K/AKT signaling. Thus, we tested a combination with the pan-PI3K inhibitor pictilisib and observed combinatorial activity consistent with our findings.

Conclusions: These data suggest that in KRAS^{G12C}-GDP inhibitor-resistant models RTK activation maintains MAPK dependency and in the case of one model, PI3K signaling. Consistent with these mechanisms, RMC-7977 as a single agent or in combination with pictilisib drove significant tumor regressions in these models. These preclinical results indicate RAS^{MULTI}-GTP inhibition alone or combination with PI3K inhibition has the potential to address KRAS^{G12C}-GDP inhibitor resistance.

#1925 Wild-type RAS signaling is an essential therapeutic target in *RAS*-mutated cancers.

Nancy E. Sealover, Bridget Finniff, Jacob Hughes, Hyun Lee, Robert L. Kortum

Uniformed Services University, Bethesda, MD

Single-agent targeting of RAS-mutated cancers using RAF/MEK/ERK or PI3K/AKT pathway inhibitors is ineffective; blocking one pathway relieves negative feedback control of RTK signaling and hyperactivates parallel effector pathways. While combined MEK and PI3K inhibition is effective in preclinical models, toxicity of this combination prevents its clinical use. Alternative strategies for treating RAS-mutated cancers are essential. Therapeutics directly targeting mutated RAS proteins have the potential to spare normal cellular function thereby lessening overall toxicity. Unfortunately, direct RAS inhibition as a monotherapy does not fully block RAS effector signaling. RAS proteins show differential activation of RAF and PI3K pathways: KRAS potently activates RAF but poorly activates PI3K, whereas HRAS effectively activates PI3K but poorly activates RAF. Further, mutant RAS inhibition relieves negative feedback controls leading to rapid hyperactivation of RTK−WT RAS signaling. A more comprehensive understanding of the interplay between mutant RAS and RTK−WT RAS signaling is essential to developing rational therapeutic approaches to treat RAS-mutated cancers. We found that WT RAS enhanced mutant RAS-driven transformation by activating RAS effectors poorly engaged by mutated RAS. Further, inhibition of RAS effectors activated poorly by mutant RAS synergized with and limited resistance to mutant HRAS and KRAS inhibitors. The mutant HRAS inhibitor tipifarnib blocked PI3K signaling and synergized with MEK inhibitors in HRAS-mutated cancer cell lines; covalent KRASG12C inhibitors blocked MEK signaling and synergized with PI3K inhibitors in KRASG12C- mutated cell lines. Synergy between inhibitors of mutant RAS and RAS effectors was dependent on intact RTK/WT RAS signaling and was lost in both RASless or SOSless MEFs. Dual knock-out of WT RAS isoforms in *KRAS*- and *HRAS*-mutated cancer cell lines reduced PI3K signaling in *KRAS*-mutant cell lines and MAPK signaling in *HRAS*-mutant cell lines and reduced proliferation, confirming our findings in MEF cells. Overall, our data highlight the critical role of WT RAS isoforms in supporting mutant RAS signaling and should be considered when designing combination therapies in *RAS*-mutated cancers.

#1926 MRAS the forgotten member of the GTPase superfamily plays a role in KRASG12Ci resistance.

V. Thatikonda, K. Kostyrko, S. Jurado, S. Lieb, M. Hinkel, D. Alpar, O. Bergner, A. Jeschko, M. Pearson, **M. H. Hofmann**;
Boehringer Ingelheim RCV GmbH & Co. KG, Vienna, Austria

$KRAS^{G12C}$ inhibitors have achieved impressive results in the clinic. However, intrinsic or acquired resistance to therapy invariably develops leading to disease progression in most treated patients. Emerging pre-clinical and clinical evidence points to multiple mechanisms being responsible for resistance to $KRAS^{G12C}$ inhibitors, including receptor tyrosine kinase (RTK) activation, $KRAS^{G12C}$ amplification, activation of alternative signaling pathways including PI3K, mTOR, YAP/TAZ, acquisition of KRAS mutations that would preclude compound binding (e.g. R68S, Y96C/D, H95D/Q/R), conversion of the G12C codon mutation, and additional activating KRAS mutations (G13D, Q61H). In the clinic, many of the described mutations were detected at low frequency, some patients displayed multiple mutations and in 40% of patients no potential driving mutations were identified. It is therefore likely that other non-genetic alterations are also involved in resistance to $KRAS^{G12C}$i monotherapy.

Here, we used preclinical models of $KRAS^{G12C}$ non-small cell lung cancer (NSCLC) and colorectal cancer (CRC) to study intrinsic and acquired resistance to $KRAS^{G12C}$ inhibitors. Increased expression of the RAS superfamily gene MRAS was observed in most $KRAS^{G12C}$-naïve tumor cells upon treatment with a $KRAS^{G12C}$ inhibitors. In line with this, we observed an increase of MRAS-GTP levels in cells treated with $KRAS^{G12C}$i *in vitro*. Interestingly, the increase in active MRAS did not lead to concomitant upregulation of MAPK signaling.

Long term treatment with adagrasib was used for generating in vitro and in vivo $KRAS^{G12C}$ models with acquired resistance to $KRAS^{G12C}$i . A strong increase in MRAS expression was observed under these conditions, that surpassed the levels seen with short term treatment in naïve models. This data suggests that activation of MRAS-SHOC2-PP1C complex may play a role in compensating for the $KRAS^{G12C}$-driven signaling in both the intrinsic and acquired resistance setting. Knockdown of SHOC2 to baseline levels resulted in re-sensitization to $KRAS^{G12C}$i monotherapy and to the effects of combinations in adagrasib-resistant NCI-H358 NSCLC cells. Pathway suppression was deepened by combining adagrasib with either a SOS1i (e.g. BI-3406) or SHP2i (e.g. TNO155) resulting in enhanced anti-tumor effects observed in the $KRAS^{G12C}$i-resistant models. Our findings underscore the role of MRAS in acquired resistance in KRASG12Ci and the potential to overcome this with vertical pathway combinations, such as SOS1i or SHP2i.

#1927 Resistance to RAS-GTP inhibition in models of pancreatic ductal adenocarcinoma arises downstream of RAS effectors.

U. N. Wasko[1], J. Jiang[2], Y. Wang[2], L. Tomassoni[1], L. Jiang[2], M. Menard[2], A. Curiel-Garcia[1], T. C. Dalton[1], M. Orlen[3], C. Edwards[4], C. Stalnecker[4], J. Dilly[5], S. Chang[2], S. A. Sastra[1], C. F. Palermo[1], T. Baslan[6], S. Tian[6], M. Holderfield[2], E. Quintana[2], Z. Wang[2], J. A. M. Smith[2], A. Califano[1], D. Wildes[2], A. J. Aguirre[5], R. H. Vonderheide[3], B. Z. Stanger[3], S. W. Lowe[6], C. J. Der[4], M. Singh[2], K. P. Olive[1],

[1]Vagelos College of Physicians and Surgeons, Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY, [2]Revolution Medicines, Redwood City, CA, [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [4]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Dana-Farber Cancer Institute, Boston, MA, [6]Sloan Kettering Institute, Memorial Sloan Kettering Cancer Center, New York, NY

More than 90% of pancreatic ductal adenocarcinoma (PDAC) cases are driven by activating mutations in KRAS that drive it into an active, GTP-bound state (KRAS(ON)), producing excessive signaling via MAPK and other effector pathways. RMC-7977 is a potent inhibitor of GTP-bound RAS proteins (RAS(ON)), including both wild type and mutant variants of KRAS, NRAS, and HRAS. The related investigational agent, RMC-6236, is a first-in-class, potent, orally bioavailable, RAS^{MULTI}(ON) inhibitor currently in Phase 1/1b clinical trials (NCT05379985). Exposure to RMC-7977 suppressed the MAPK biomarker p-ERK, reduced cell growth, and induced apoptosis in multiple human RAS-addicted cancer cell lines. Assessment of RMC-7977 in a series of PDAC preclinical model systems revealed broad anti-tumor activity and treatment was well tolerated at translatable doses. The K-$ras^{LSL.G12D/+}$, $p53^{LSL.R172H/+}$, $Pdx1Cre^{tg/+}$ (KPC) autochthonous mouse model was utilized to study the effects of Ras-GTP inhibition in both tumor and normal tissues. At doses that drove anti-tumor activity, RMC-7977 dosing produced a metronomic effect on RAS signaling in tumor and normal tissue, with full pathway inhibition at 4 h post treatment that was restored by 24 h. This pattern yielded tumor-selective effects on apoptosis and proliferation, consistent with RAS oncogene addition in PDAC. RMC-7977 treatment drove regressions and an unprecedented ~3-fold extension of overall survival in KPC mice. After an initial response, all tumors eventually developed resistance on treatment, affording the opportunity to study acquired resistance mechanisms to RAS-GTP inhibition. Strikingly, in all resistant tumors, acute inhibition of MAPK and PI3K signaling was still apparent following treatment. These results indicate that RAS signaling re-activation mechanisms that have been reported as clinical mechanisms of resistance to mutant-selective $KRAS^{G12C}$ inhibitors (e.g. second-site mutations or upregulation of upstream RTK) may be insufficient to confer resistance to a compound that inhibits all RAS isoforms. Rather, in this model we observed activation of alternative oncogenic mechanisms downstream of RAS effector signaling, including frequent focal amplification of Myc, focal amplification of Jun, and/or activation of Yap/Taz/Tead signaling in most resistant KPC tumors. Together these results demonstrate preclinical activity of RMC-7977 at tolerable doses, producing unprecedented responses even in highly chemoresistant PDAC models such as the KPC mouse. The observed range of potential resistance mechanisms suggests that RAS-GTP inhibition imposes a narrow evolutionary path to the development of acquired resistance in this context. These preclinical findings may help inform the ongoing development of investigational RAS inhibitors and the design of potential combinatorial treatment strategies to forestall resistance.

#1928 Targeting FAK to improve the therapy of KRAS G12C mutant cancers.

S. Liu, J. Shi, C. Lu, M. Zhang, Y. Xin, Y. Zhu, J. Li, **H. Luo**, Y. Sun;
Shouyao Holding (Beijing) Co., Ltd., beijing, China

Despite the pivotal role of KRAS G12C in tumor initiation and progression, currently available KRAS G12C inhibitors have relatively modest activity compared to other approved therapies targeting other classic oncogenic drivers. Fortunately, efforts to improve the anti-tumor response to KRAS G12C targeted therapy have benefited from the use of combination approaches. Here, we found that treatment with KRAS G12C inhibitors induces sustained activation of focal adhesion kinase (FAK) in KRAS G12C mutant cell lines from various cancer types, including non-small cell lung cancer, colorectal cancer, and pancreatic cancer. These results suggest a potential role for FAK in adaptive resistance to KRAS G12C inhibition and encourage us to explore the anticancer effects of combining the KRAS G12C inhibitor SY-5933 with a FAK inhibitor, CT-707. The cell viability and clonogenic assays using various KRAS G12C mutant cancer cell lines showed that the combination of SY-5933 and CT-707 synergistically inhibited cell growth. Mechanistically, this enhanced anti-proliferative effect is associated with a significant decrease in FAK activity and a more pronounced induction of cell cycle arrest and apoptosis. In vivo efficacy studies in multiple cell line derived xenograft (CDX) models, the combination of SY-5933 plus CT-707 consistently induced a more potent anti-tumor response than either monotherapy alone. In conclusion, our results demonstrate that CT-707 has the potential to enhance the efficacy of SY-5933 by suppressing adaptive FAK activation under KRAS G12C inhibition. This provides a rationale for an innovative combination therapy to improve outcomes in patients with KRAS G12C mutated cancers.

#1929 Acquired resistance to sotorasib in KRAS^{G12C} mutant NSCLC is vulnerable to PI3K-mTOR pathway inhibition and regulated by 4E-BP1.

I. M. Meraz[1], S. Wu[1], M. Majidi[1], C. Ren[1], Y. Xu[1], F. Meng[1], L. Gao[1], R. Song[1], R. Zhang[1], B. Fang[1], Q. Wang[1], Y. Xi[1], J. Wang[1], S. Jung[2], J. A. Roth[1]; [1]UT MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX

Up to 40% of NSCLC patients with KRAS^{G12C} mutation respond to sotorasib. However, acquired resistance (AR) develops rapidly in all patients. The majority of AR is associated with unknown mechanisms. Twelve KRAS^{G12C} mutant NSCLC PDXs were developed from patient samples and characterized with WES, RNAseq, and RPPA analyses. Three PDXs treated with sotorasib showed complete tumor regression, and one showed growth inhibition. PDXs, PDX derived organoids (PDXO), and cell line derived xenografts (CDX) were with AR to sotorasib were generated. TC303AR and TC314AR PDXs were generated by prolonged continuous in-vivo treatment with sotorasib. Two isogeneic AR PDXOs from TC303 and TC314 PDXs were generated through continuous incremental dosing of sotorasib in organoid cultures. Both TC303AR and TC314AR PDXOs showed >100-fold resistance than sensitive counterparts. Over 100-fold resistance were also measured in two sotorasib resistant isogenic H23AR and H358AR cell lines. Both resistant PDXOs and cell lines showed resistance to adagrasib, another selective, KRAS^{G12C} inhibitor. H358AR CDXs were generated through continuous in-vivo treatment with sotorasib and multiple passages of CDX tissues. WES was performed for AR PDXs, CDX, PDXOs and cell lines and all retained the KRAS^{G12C} mutation, and no additional KRAS mutations were found. We performed RNAseq, RPPA, and mass spectrometry (MS) on TC303AR and TC314AR PDXs. Heatmaps showed significant sets of differentially regulated RNA and protein in AR vs. parental. Enrichment analysis found a significant upregulation of MTORC1 signaling in AR PDXs. Proteins involved in PI3K-AKT-mTOR pathway were significantly upregulated in AR. PI3K and AKT expression were also increased in H23AR and H358AR. Inhibition of PI3K, AKT and mTOR by copanlisib, MK2206 and everolimus respectively was synergistic with sotorasib in AR cells and PDXOs, with copanlisib being the most effective. Copanlisib significantly inhibited colony formation in AR cells. Downstream molecules in PI3K-AKT-mTOR pathway showed marked downregulation of pAKT, pmTOR, p70S6, pS6, pGSK3b, and pPRAS40 by copanlisib. The downstream 4E-BP1 and p4E-BP1 were remarkably high in AR cells, which was downregulated by copanlisib. To verify the role of PI3K, PI3Kα CRISPR-Cas9 knock-out clones were generated in both H23AR and H358AR cells. Absence of p4E-BP1 was associated with restoration of sotorasib sensitivity while high levels of p4E-BP1 phosphorylated by an mTOR independent pathway restored sotorasib resistance in the knock-out clones. When copanlisib was combined with sotorasib in treating the resistant TC303AR, TC314AR PDXs, H358AR CDX and H23AR xenograft tumors, antitumor effects were observed in every model. Inhibition of the PI3K pathway at different nodes is a vulnerability in KRAS^{G12C} mutant NSCLC with sotorasib AR and p4E-BP1 is a mediator of sotorasib resistance

#1930 Combination of KRASG12C and FGFR1 inhibitors as a resistance-overcoming therapeutic strategy for maximizing therapeutic impact of KRASG12C inhibitors.

A. Santos, P. Plaza, M. Jimenez, D. Gomez-Sanchez, L. Paz-Ares, I. Ferrer;
Fundacion Investigacion Biomedica Hospital 12 de Octubre, Madrid, Spain

INTRODUCTION: Lung cancer is the leading cause of cancer-related deaths worldwide. KRAS is the most frequent mutated driver gen in lung adenocarcinoma (LUAD). KRASG12C inhibitors (G12Ci) have revealed promising results in the clinic, having being approved two G12Ci for the treatment of LUAD patients, which marks the first approved targeted therapy for KRAS-mutant tumors. Nevertheless, these therapies face the same limitation as other targeted therapies, the therapeutic potential of these inhibitors can be impaired by resistance mechanisms. Deciphering resistance mechanisms to G12Ci is of prime relevance to predict which patients may benefit from these therapies and to propose resistance-overcoming therapeutic strategies for maximizing therapeutic impact of these inhibitors.

MATERIAL AND METHODS: We generated 10 acquired resistant LUAD cell lines to G12Ci (Sotorasib and Adagrasib), exposing sensitive cells to increasing concentrations of drugs. All the acquired resistant models were characterized at the proteomic (phospho-Array and Western Blot) and transcriptomic (WTS) levels to find signatures that define the resistance.The efficacy of G12Ci was tested *in vitro* in a panel of 8 cell lines and 7 PDX-derived organoids (PDXDO) models and *in vivo* in 7 patient-derived xenografts (PDX) models to classify them as resistant, sensitive or partially sensitive. The efficacy of the combination of FGFR1 and G12Ci was tested *in vitro* in the panel of 10 acquired resistant cell lines but also in the parental cell lines and PDXDOs (sensitive and intrinsic resistant) and *in vivo* in the intrinsic resistant PDXs.

RESULTS AND DISCUSSION: The characterization of 10 acquired resistant cell lines at the proteomic and transcriptomic levels showed differences in the expression and/or activation of Fibroblast Growth Factor Receptors (FGFRs) in more than 50% of them. The combination of KRASG12C and FGFR1 inhibitors in all acquired resistant cell lines showed efficacy, regardless of whether acquired resistance was mediated or not by FGFR1 overexpression/overactivation.In addition, the combination of KRASG12C and FGFR1 inhibitors showed more efficacy than the monotherapies in most intrinsically resistant cell lines, PDXDOs and PDXs models. Finally, we tested the combination with FGFR1i in sensitive or partially responsive models, observing an improvement in efficacy compared to monotherapy with G12Ci.

CONCLUSIONS: The activation or overexpression of FGFR1 acts as a mechanism of acquired resistance to KRASG12C inhibitors.-The combination of FGFR and KRASG12C inhibitors is effective as an acquired/intrinsic resistance-overcoming therapeutic strategy in cell lines, PDXDOs and PDXs models.-The combination of FGFR and KRASG12C inhibitors is also synergistic for sensitive models, which could maximize therapeutic impact of KRASG12C inhibitors.

#1931 Targeting YAP1/TEAD signaling re-sensitizes MAPK/ERK pathway inhibitors in KRAS- driven cancer cells.

X. Yang, G. Li, P. Ren, X. Shi, Y. Yu, B. Hao, P. Wang, M. Cheng, G. Dai;
HUTCHMED, Shanghai, China

Many TEAD small-molecule inhibitors (SMIs) have recently reported initial clinical evaluations on Hippo-mutated cancer types. Several studies have demonstrated that activation of the YAP1/TEAD transcriptional complex via a Hippo-independent manner can drive resistance to MAPK/ERK pathway inhibitors. Here, we elucidated the potential mechanism of TEAD inhibition overcoming MAPK/ERK pathway resistance with a TEAD SMI (hereafter abbreviated as TEADi). Firstly, the MoA of TEADi was validated in Hippo-mutated cells. TEADi inhibited cell growth of Hippo-mutated cancer cell lines NCI-H226 and NCI-H2052 but not that of MKN45, a YAP1-deletion cell line. Co-IP and qRT-PCR results demonstrated that TEADi disrupted the interaction between YAP1 and TEAD, and thus markedly repressed the expression of *CTGF* and *CYR61*, two downstream targets of YAP1/TEAD, in NCI-H226 cells. Secondly, we hypothesized that hyper-activation of TEAD confers resistance to KRAS mutant cancer types. To test this hypothesis, we generated two resistant cell lines. One is KARS G12C inhibitor Sotorasib-resistant NCI-H358 (NCI-H358-R). The other is MEK inhibitor Trametinib-resistant HCT116 (HCT116-R). Immunofluoresence assay showed that YAP1 nucleus translocation was enhanced in both resistant cells (NCI-H358-R and HCT116-R), but not in their parental counterparts (NCI-H358-P and HCT116-P). The enhanced YAP1 nucleus translocation resulted in increased transcription activities of TEAD in both resistant cells, as illustrated by luciferase reporter assay. Accordingly, *CTGF* and *CYR61* were observed upregulated in both resistant cells. The above data indicate that YAP1/TEAD mediated-transactivation plays a role in MAPK pathway resistance. Indeed, TEADi treatment alone displayed substantial difference in cell growth inhibition between parental and resistant cell lines in both NCI-H358 and HCT116, further confirming that the resistant cells are more dependent on YAP1/TEAD signaling. Finally, we evaluated the combinational efficacies of TEADi and MAPK/ERK pathway inhibitors in the resistant cells. It was observed that addition of TEADi could significantly restore the response of NCI-H358-R and HCT116-R to Sotorasib and Trametinib, respectively. Mechanistically, TEADi efficiently suppressed TEAD transcriptional activities and subsequently the expression of *CTGF* and *CYR61* in both resistant cells. Moreover, TEADi had almost no impact on ERK phosphorylation in either of the resistant cells, suggesting that re-sensitization of MAPK/ERK pathway inhibitors by TEADi is independent of primary onco-genetic signaling pathway. Taken together, our study demonstrates that inhibition of YAP1/TEAD signaling would be an efficient approach to overcome resistance to MAPK/ERK pathway inhibitors in the patients carrying KRAS mutations, and provides the scientific basis for development of combination therapy strategies.

#1932 Overcoming acquired resistance to KRAS(G12D) inhibition using a KRAS-HSP90 hetero-bifunctional small molecule therapeutic agent.

KRAS mutations are highly prevalent across many different cancer types. Recent advancements in KRAS-targeted drugs, such as the FDA-approved KRAS(G12C) inhibitors sotorasib and adagrasib for NSCLC patients, have shown great promise in the clinic. Nonetheless, these new agents fail to address other mutations, such as KRAS(G12D), which overall is the most common KRAS mutation in cancers, being found in 37% of pancreatic ductal adenocarcinomas, 12.5% of colorectal cancers and 4.9% of lung adenocarcinomas. Recently, MRTX1133 has been described as a selective, non-covalent inhibitor of KRAS(G12D) that shows promising preclinical efficacy and is undergoing clinical testing. However, based on prior clinical experience with sotorasib and adagrasib, acquired resistance to MRTX1133 may reasonably be anticipated. In fact, we find that KRAS(G12D)-mutated cell lines and a patient-derived organoid model exhibit varying degrees of inherent resistance to MRTX1133. To examine the consequences of blocking KRAS signaling, we employed a KRAS(G12D)-specific PROTAC, which simulated the effects of *KRAS* deletion. This demonstrated that receptor tyrosine kinase (RTK) activation could compensate for loss of KRAS signaling and was a key de novo resistance mechanism. This suggests that combination therapies may need to be individually tailored to treat patients resistant to KRAS(G12D)-targeted therapies. Additionally, we developed MRTX1133 resistant cells by culturing sensitive AsPC-1 pancreatic cancer cells in gradually increasing concentrations of the inhibitor. The resulting resistant cells displayed a complex RTK activation profile compared to parental cells. To counteract this, we employed KRAS(G12D)-CHAMP RNK08179, a hetero-bifunctional small molecule agent that simultaneously targets both KRAS(G12D) and HSP90, an RTK-regulating chaperone protein. RNK08179 effectively suppressed both KRAS signaling and RTK activation in MRTX1133-resistant cancer models, overcoming the compensatory resistance mechanisms observed with MRTX1133 alone. These findings highlight the potential of KRAS-CHAMPs as a novel, effective treatment strategy for KRAS-driven cancers, particularly those resistant to KRAS(G12D) inhibitors.

#1933 Dissecting acquired resistance to KRAS^{G12D} inhibition in a mouse model of pancreatic ductal adenocarcinoma.

J. Dilly[1], L. Abbassi[2], C. J. Hennessey[3], G. A. Uribe[3], B. Parent[3], A. Yang[3], K. S. Kapner[3], Z. Li[2], K. E. Evans[1], S. Dasgupta[3], M. T. Hoffman[2], L. Qiang[2], F. P. Hambitzer[2], S. Chugh[2], A. K. Shalek[4], S. K. Dougan[2], B. M. Wolpin[5], J. A. Nowak[6], S. Raghavan[7], P. S. Winter[8], A. J. Aguirre[9];

KRAS is a major oncogenic driver in pancreatic ductal adenocarcinoma (PDAC) and is mutationally activated in approximately 90% of cases, with the glycine-to-aspartic acid substitution at position 12 (p.G12D) being the most prevalent alteration. Mutations in this oncogene have been associated with more aggressive disease and poorer outcomes and have remained “undruggable” for more than three decades. However, the recent development of mutant-specific small molecule inhibitors of KRAS has given hope for the treatment of this highly lethal and treatment-refractory malignancy. Here we evaluated the genomic and transcriptional mechanisms of resistance to MRTX1133, a first-in-class inhibitor of KRAS^{G12D}, in an autochthonous mouse model of PDAC. We leveraged single-nucleus RNA sequencing and whole-exome sequencing on 17 tumors from KPC mouse specimens (LSL-Kras$^{G12D/+}$; LSL-Trp53$^{R172H/+}$; p48-Cre) that were treated with either MRTX1133 or the vehicle, including 6 samples from mice that developed acquired resistance to KRAS^{G12D} inhibition. Our analysis has uncovered that resistance is multifaceted and characterized by both emergent genomic and transcriptional features. Genetically, resistant tumors harbored clonal and subclonal amplifications in the HIPPO pathway, cell cycle regulators, and ABC transporters. Transcriptionally, we employed non-negative matrix factorization and identified recurrent gene expression programs in resistant and vehicle samples. Using this approach, we uncovered the existence of an intermediate phenotype between classical and mesenchymal cell states that is enriched in tumors with evolved resistance to MRTX1133. In summary, our study provides a high-resolution genomic and transcriptional landscape of resistance to KRAS targeting in a preclinical *in vivo* model of PDAC, highlighting the complexity of treatment resistance and identifying various pathways and effectors that may serve as potential new targets for combination therapy.

#1934 The PLK1 inhibitor, onvansertib, is active as monotherapy and in combination with cetuximab in RAS wild-type colorectal cancer patient-derived xenografts.

M. Ridinger[1], P. Kanikarla Marie[2], F. Gao[2], Z. Liu[2], G. Maddalena[2], D. Menter[2], A. Sorokin[2], T. Smeal[1], S. Kopetz[2];
[1]Cardiff Oncology, San Diego, CA, [2]UT MD Anderson Cancer Center, Houston, TX

Background: Cetuximab and panitumumab are monoclonal antibodies targeting the epidermal growth factor receptor (EGFR), that provide clinical benefit to metastatic colorectal cancer (mCRC) patients with RAS wild-type (RAS^{WT}) tumors. Unfortunately, intrinsic or acquired resistance to these therapies limits their clinical effectiveness, necessitating the development of more efficient therapeutic strategies. Onvansertib is an oral, small molecule, selective inhibitor of the PLK1 kinase, currently in clinical development for KRAS-mutant mCRC. The aim of this study was to assess the anti-tumor activity of onvansertib monotherapy and in combination with cetuximab in RAS^{WT} CRC patient-derived xenograft (PDX) models.

Methods: Twenty RAS^{WT} CRC PDXs were selected and engrafted in nude mice. Once tumors reached 200-350-mm^3, mice were treated with vehicle, onvansertib (60mg/kg, QD), cetuximab (20mg/kg, BIW) or the combination for 18 days. PDX models were chosen based on their sensitivity to cetuximab, resulting in a selection of 7 cetuximab-sensitive (CetuxS) and 13 cetuximab-resistant (CetuxR) PDXs, including 7 with intrinsic resistance and 6 with acquired-resistance. Tumor volume change from baseline (TVC) was calculated as 100%x(Vt-Vo)/Vo and tumor growth inhibition (TGI) as 100%x(TVCcontrol-TVCtreated)/TVCcontrol. Tumor regression was defined as $TVC_{D18}<0$ and tumor stasis $0\leq TVC_{D18}<100$.

Results: Cetuximab sensitivity was confirmed in the selected models, cetuximab induced tumor regression in all the CetuxS PDXs, while no or limited activity was observed in the resistant models (median TGI=29%, IQR 16-61). Onvansertib exhibited potent anti-tumor activity in 17 (85%) PDXs, resulting in tumor regression (n=11) or tumor stasis (n=6). Onvansertib TGI at Day 18 was not significantly different in CetuxS PDXs (median TGI 102, IQR 76-103) compared to CetuxR PDXs (median TGI 108, IQR 74-124), supporting that onvansertib anti-tumor activity is independent of the sensitivity/resistance to cetuximab. The combination of onvansertib and cetuximab induced tumor regression in 18 (90%) PDXs. The combination showed significantly improved efficacy compared to individual therapies in some of the models.

Conclusions: Onvansertib monotherapy displayed potent anti-tumor activity in RAS^{WT} CRC PDX models, independently of their sensitivity to cetuximab. Additionally, onvansertib combined with cetuximab exhibited either comparable or superior anti-tumor activity than the monotherapies. Collectively, this data supports the clinical development of the PLK1 inhibitor onvansertib for RAS^{WT} mCRC.

#1935 The FAK/SRC axis mediates resistance to KRAS G12C inhibitors and its blockade can overcome KRAS inhibitor resistance.

Y. Shibata, H. Udagawa, M. B. Nilsson, J. Robichaux, A. Galan-Cobo, M. Negrao, D. P. Molkentine, J. He, A. Poteete, Y. Qian, Q. Huang, F. Skoulidis, J. V. Heymach;
UT MD Anderson Cancer Center, Houston, TX

Activating mutations in KRAS are found in approximately 30% of non-small cell lung cancer (NSCLC), and among all KRAS mutations, KRAS G12C is the most frequent variant in NSCLC, with a prevalence of approximately 14%. KRAS G12C inhibitors, sotorasib and adagrasib are FDA approved for locally advanced or metastatic KRAS G12C-positive NSCLC. However, clinical evidence suggests that there are various factors limiting the efficacy of KRAS G12C inhibitors in patients with KRAS G12C-positive NSCLC, highlighting the urgent need for novel treatment strategies or combinations to improve efficacy. Therefore, we sought to identify effective combinations to enhance the efficacy of KRAS G12C inhibitors using in vitro and in vivo models of KRAS G12C-positive NSCLC. Employing a high throughput in vitro drug screening effort using KRAS mutant NSCLC cell lines, we observed that Focal Adhesion Kinase (FAK) and Steroid Receptor Coactivator (SRC) inhibitors produced a synergistic effect when combined with KRAS G12C inhibitors adagrasib or sotorasib. As determined by reverse phase array and Western blotting, in H358, H23, HCC44, and H2122 cells, KRAS inhibitor treatment alone resulted in an initial suppression of RAS/MAPK and AKT pathway activation which was followed by upregulation of multiple receptor tyrosine kinases and integrins which contributed to the re-activation of the RAS/MAPK and AKT pathways after 24-48 hours. We identified FAK as a key downstream mediator of these bypass pathways. FAK/SRC inhibitors enhanced the efficacy of KRAS G12C inhibitors by preventing this feedback activation. Moreover, we observed increased FAK activation in H358 NSCLC cell lines with acquired resistance to adagrasib or sotorasib as compared to parental cells, and FAK/SRC inhibitors re-sensitized resistant cells to KRAS G12C inhibitors. Using a xenograft model of human KRAS mutant NSCLC, we determined that the combination of repotrectinib, a FAK/SRC inhibitor, and a KRAS G12C inhibitor significantly suppressed tumor growth as compared to KRAS G12C inhibitors alone, and this combination was well tolerated. Overall, our findings indicate that activation of FAK is a key mechanism of adaptive feedback and acquired resistance to KRAS G12C inhibitors in KRAS G12C-positive NSCLC and highlight the therapeutic potential of FAK/SRC inhibitors in combination with KRAS G12C inhibitors. These data support the clinical testing of the combination of FAK/SRC inhibitors and KRAS G12C inhibitors in patients with KRAS G12C-positive NSCLC.

#1936 KEAP1-NRF2 mediated resistance against KRAS^{G12D} inhibitor in pancreatic ductal adenocarcinoma.

W.-H. Chang[1], A. G. Stamey[1], A. M. Waters[2], K. L. Bryant[1], A. D. Cox[1], C. J. Der[1];
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Cincinnati, Cincinnati, OH

Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer deaths in the US. Mutational activation of the KRAS oncogene is associated with 95% of PDAC and is essential for maintaining PDAC tumorigenic growth. Although inhibitors (sotorasib and adagrasib) targeting one KRAS mutation (G12C) have been approved for the treatment of KRAS^{G12C}-mutant lung cancer, the G12C mutation comprises less than 2% of KRAS mutations in PDAC. Recently, the clinical candidate KRAS^{G12D}-selective inhibitor MRTX1133 (G12Di) has been shown to potently suppress both activation of the RAF-MEK-ERK signaling pathway downstream of KRAS and tumorigenic growth of KRAS^{G12D}-mutant PDAC in vitro and in vivo. Since KRAS^{G12D} represents 40% of KRAS-mutant PDAC, G12D-selective inhibitors hold promise as an effective therapy for a significant fraction of PDAC patients. However, the efficacy of these inhibitors is hindered by persistent challenges related to both primary (innate) and acquired treatment-associated resistance, which curtails the long-term effectiveness of likely all KRAS inhibitors. Here, our studies focus on unraveling the mechanism of primary and acquired resistance to G12Di treatment in PDAC. We applied a loss-of-function CRISPR screen targeting the druggable genome on KRAS^{G12D}-mutant PDAC cells treated with a sublethal concentration of G12Di to identify genes that modulate G12Di sensitivity. We identified loss of genes (e.g., *CBL*, *RB1*, and *PTEN*) found previously in patients who relapsed on G12Ci treatment, providing validation of the screen. One gene also identified was *KEAP1*. KEAP1 is known as a substrate-specific adapter of an E3 ubiquitin ligase complex that promotes the degradation of NRF2, and the loss of KEAP1 is commonly associated with increased stability of NRF2, a transcription factor that promotes the transcription of many anti-oxidative stress and pro-cell survival genes. We found that knockout of *KEAP1* significantly compromised the ability of G12Di to inhibit PDAC cell proliferation in vitro. KEAP1 loss was associated with upregulated expression of NRF2, and concurrent CRISPR knockout of *NRF2* restored sensitivity of G12Di in PDAC. Interestingly, we determined that G12Di-resistant KEAP1-deficient PDAC cells exhibited high dependence on glutaminase (GLS), which converts glutamine to glutamate. We further discovered that combination treatment with a glutaminase inhibitor (CB-839) synergistically enhanced G12Di growth suppression not only of KEAP1-knockout but also of parental PDAC cells. In summary, our study establishes a role for KEAP1 loss as a mechanism that drives PDAC resistance to KRAS inhibitors and identifies GLS inhibition as a possible approach to overcome NRF2-driven resistance.

#1937 YAP-TAZ-TEAD transcriptional program is a prominent driver of acquired resistance to KRAS^{G12C}-based therapies in patients with metastatic colorectal cancer.

O. Coker[1], A. Sorokin[1], N. Akhave[1], K. Pan[1], F. Gao[1], Z. Liu[1], P. Kanikarla[1], H. Lee[1], O. Villarreal[1], J. Alshenaifi[1], G. Maddalena[1], A. Mohamed[1], D. Prescod[1], D. Menter[1], S. Chowdury[1], R. Corcoran[2], K. Rai[1], D. Hong[1], S. Kopetz[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Harvard Medical School, Houston, TX

Background: KRAS mutations are present in 50% of patients with metastatic colorectal cancer (mCRC) and play a critical role in mCRC tumor biology. KRAS^{G12C} mutations are present in 6% of patients with mCRC. While KRAS^{G12C} inhibitors (G12Ci) have entered the clinic, clinical responses to G12Ci are transient even when combined with EGFRi, highlighting the need to optimize therapeutic interventions. We have characterized our KRAS^{G12C} mCRC patient-derived xenograft (PDX) models and paired biopsies from progressing patients that have acquired resistance to G12Ci/G12Ci+EGFRi through an integrative multi-omics approach and have validated them through wet-lab experiments.

Experimental Procedures: qPCR analysis was performed on 13 PDX models that were established from paired tumor biopsies from patients pre and at progression of treatment. We also treated 5 KRAS^{G12C} mCRC PDX models with G12Ci +/- EGFRi until acquired resistance was achieved. Tumors were harvested post-treatment and whole-exome, RNAseq, and RPPA were performed on them. In parallel, 3 paired parental and G12Ci/EGFRi-resistant 2D/3D *in vitro* models were established and treated with G12Ci +/- EGFRi +/- pan-TEADi. Expression and response profiles were assessed through cell viability assays, western blot, qPCR, and IncuCyte analyses. We simultaneously re-established *in vivo* acquired resistance to G12Ci + EGFRi in 2 PDX models and treated them with pan-TEADi triple combo. Finally, we performed spatial transcriptomics (Xenium) from 6 paired pre-/post-treatment patient samples to characterize transcriptomic profiles at the single-cell resolution.

Results: In our PDX models, the acquisition of a new NRAS mutation and KRAS amplification in response to therapy were found, which are commonly known genomic resistance mechanisms to MAPK targeted therapies. 3 of the 5 PDX models ($p < 0.05$, $p < 0.001$) and 2 of 4 patients ($p < 0.01$, $p < 0.001$) from the PDX models established from paired tumor biopsies from patients pre and at progression of treatment exhibited YAP1-TEAD signaling as an acquired response to G12Ci-based therapies. In our *in vitro* work, pan-TEADi triple combo provided efficacy over G12Ci/therapy in 3D *in vitro* models while both 2D/3D *in vitro* resistant models were sensitized to pan-TEADi monotherapy, suggesting the combination drives a state change to be YAP dependent where YAP-TEAD signaling may now be driving MAPK signaling. Detailed spatial transcriptomic data will be presented.

Conclusion: Clinical responses to G12Ci are transient and require optimizing therapeutic modalities. In patients, where genomic mechanisms are not found, YAP-TAZ-TEAD signaling was found to be a common feature of resistance to inhibitors targeting the KRAS pathway. This work suggests that pan-TEADi may provide patients with improved therapeutic options.

#1938 WEE1 inhibition prevents and overcomes resistance to KRAS inhibitors in lung cancer by enhancing MCL1-mediated apoptosis.

G. Yamamoto, K. Tanaka, R. Kamata, T. Nakao, S. Mori, J. Liu, S. S. Kobayashi, A. Ohashi;
National Cancer Center Japan, Kashiwa, Chiba, Japan

Background: While novel covalent inhibitors of KRAS G12C have been approved in non-small-cell lung cancer (NSCLC), their efficacies are known to be limited. To enhance the therapeutic potential of KRAS inhibitors, combination strategies need to be developed. In this study, we conducted a large-scale screening to identify novel combination partners that induced synergistic efficacy with KRAS inhibitors. Additionally, mechanistic analyses were conducted to clarify the synergistic effects in combination and their role in conferring resistance to KRAS inhibitors.
Methods: To identify novel combination partners of KRAS inhibitors, we conducted high-throughput screening (HTS) using a chemical library composed of 1,400 kinase inhibitors. Sotorasib was used as a KRAS inhibitor. Anti-proliferative and apoptotic effects in vitro were assessed by ATP-based cell viability assay, and caspase 3/7 assay and/or Annexin V assay, respectively. Protein expression levels were assessed by immunoblotting. In vivo studies were performed using a H358 xenograft nude mouse model and a patient-derived xenograft model (PDX). PDX samples were provided by the National Cancer Center J-PDX library, Japan.
Results: HTS identified the WEE1 inhibitor AZD1775, a G2/M checkpoint abrogator in clinical-stage development, as a promising combination partner of KRAS inhibitors in KRAS G12C mutant NSCLC. Synergistic effects of KRAS and WEE1 inhibitors were confirmed across multiple KRAS G12C mutant NSCLC cell lines, independently of their co-occurring oncogenic mutation profiles. The combination treatment enhanced apoptotic cell death, being upregulated pro-apoptotic protein BIM, while downregulated anti-apoptotic protein MCL1. In vivo efficacy studies in combination with sotorasib and AZD1775 also demonstrated remarkable tumor regression and durable response in both CDX and PDX models. We also generated sotorasib-resistant H23 (H23-SR) cells, confirming upregulation of both WEE1 and MCL1 in the resistant cells. Ectopic overexpression of WEE1 in H23, on the contrary, conferred resistance to sotorasib. Furthermore, WEE1 inhibition re-sensitized H23-SR cells to KRAS inhibitors.
Conclusion: Our results suggest that the WEE1-MCL1 axis plays an important role in both the initial therapeutic efficacy and the acquired resistance to KRAS inhibitors. These findings could pave the way for a novel therapeutic strategy for KRAS G12C mutant NSCLC.

#1939 NT219, a dual inhibitor of IRS1/2 and STAT3, suppresses cancer stem cell mediated resistance to $KRAS^{G12C}$ and $KRAS^{G12D}$ inhibitors in solid tumors.

H. Reuveni[1], M. N. Al-Hallak[2], S. Motorwala[3], E. Beal[2], S. Kim[2], R. Beydoun[2], G. Dyson[2], B. El-Rayes[4], H. Chen[4], P. Philip[5], A. Shields[2], B. Pasche[2], K. Sigalov[1], H. Ben-David[1], D. Miron[1], A. Azmi[2],

[1]Purple Biotech Ltd., Rehovot, Israel, [2]Karmanos Cancer Institute Wayne State University, Detroit, MI, [3]Michigan State University, Detroit, MI, [4]University of Alabama, Birmingham, AL, [5]Henry Ford Health, Detroit, MI

Background NT219 is a novel small molecule, a dual inhibitor which uniquely triggers the degradation of Insulin Receptor Substrates 1/2 (IRS) and the dephosphorylation and suppression of STAT3, two major oncogenic targets that play a key role in drug resistance. Mutated KRAS (mKRAS) has long been referred to as undruggable until recently when $KRAS^{G12C}$ inhibitors were approved. While $KRAS^{G12C}$ is the most common oncogenic driver in NCSLC, $KRAS^{G12D}$ is found in 42% of pancreatic tumors. We present NT219 suppressive effect on mKRASi resistant and sensitive cells of both PDAC and NSCLC, as well as on cancer stem cells (CSC) known to contribute to disease recurrence.

Method The inhibitory effects of NT219 as a monotherapy or in combination with either $KRAS^{G12C}$ inhibitors (sotorasib/adagrasib) or $KRAS^{G12D}$ inhibitor (MTRX1133) were tested in 2D cell growth and colony formation assays using mKRAS inhibitor sensitive and resistant cancer cell lines. The effect of NT219 and mKRASi on cancer stem cells was assessed using 3D spheroid assay evaluating spheroid size (microscopic measurements), cell viability (CellTiterGlo) and stemness marker expression (FACS analysis).

Results NT219 in combination with either sotorasib or MTRX1133 suppressed established spheroids of NSCLC($KRAS^{G12C}$) and PDAC($KRAS^{G12D}$) respectively, in terms of size, disintegration and viability. In NSCLC H358, spheroid satellites appeared following treatment with sotorasib, while the combination with NT219 suppressed it. CSC marker ALDH increased 7-fold in NSCLC spheroids as compared to 2D grown cells, while NT219 and sotorasib suppressed it. The expression of SOX2 stemness marker was reduced by NT219 alone (5 fold), unexpectedly induced by sotorasib (4 fold) and suppressed by NT219+sotorasib (15 fold vs sotorasib alone). In addition, significant induction of STAT3, was observed following sotorasib treatment and completely reversed by the addition of NT219. We also demonstrate that NT219 induces growth inhibition in both $KRASi^{G12C}$ resistant PDAC and NSCLC, and $KRASi^{G12D}$ resistant PDAC cells. NT219 exhibited synergistic effects with adagrasib and MTRX1133, in suppressing the proliferation of $KRAS^{G12C}$ PDAC and NSCLC cells and $KRAS^{G12D}$ PDAC cells, respectively. This combination showed a synergistic effect in xenograft model.

Conclusion We first showed the effect of NT219 in suppressing cancer stem cells, known to promote resistance and tumor recurrence. Synergistic effect of NT219 and mKRAS inhibitors, G12Cand G12D, in NSCLC and PDAC respectively, was demonstrated. Initial results suggest involvement of NT219 target proteins in resistance to $mKRAS^{G12C/D}$ inhibitors. Treatment with sotorasib induced enhancement in stemness potential of $mKRAS^{G12C}$ NSCLC, which NT219 efficiently suppressed, suggesting a novel therapy for this unmet need and a novel mechanism to combat resistance to mKRAS inhibitors

#1940 Identifying resistant mechanisms to direct KRAS inhibitors in NSCLC.

S. T. Kundu, D. H. Peng, B. L. Rodriguez, E. L. McCarthy, D. L. Gibbons;
UT MD Anderson Cancer Center, Houston, TX

Mutations in the KRAS oncogenic driver gene are frequently found in malignancies such as pancreatic, colorectal, and lung cancers. The replacement of the amino acid glycine at position 12 (e.g., G12C, G12D, G12V) is a frequent mutation that traps the protein in an active state and promotes uncontrolled cell proliferation. KRAS was regarded as "undruggable" for many years due to insufficient drug-binding pockets on the protein's surface. Recent breakthroughs, however, have resulted in the development of covalent inhibitors capable of selectively targeting the KRAS G12C mutation, like Sotorasib (AMG510) and Adagrasib (MRTX849) which are approved by the FDA due to their encouraging effects in clinical trials. The identification of selective inhibitors of other oncogenic KRAS alleles, such as the noncovalent KRAS-G12D inhibitor, MRTX1133, and a pan-KRAS-inhibitor drug (BI2865) is also a promising next step in the treatment of KRAS-dependent malignancies. While these inhibitors have shown initial success, their use frequently leads to resistance, the mechanisms of which largely remain unknown. To fill this essential research gap, we are employing our pre-clinical syngeneic mouse models and KRAS mutant allele-specific cell lines to investigate the underlying molecular processes of acquired resistance to direct KRAS allele-specific inhibitors. Using these murine syngeneic cell lines and human NSCLC cell lines, we have generated a panel of cell lines with acquired resistance to these direct KRAS inhibitors. To elucidate the molecular underpinnings of acquired resistance to direct KRAS inhibitors, we performed proteomic profiling of the sensitive and resistant cells by RPPA analysis. Among the several proteins whose expressions were altered in the KRAS-inhibitor-resistant cells, we identified the YAP/TEAD1 pathway that was commonly upregulated in the cells resistant to MRTX849 (G12Ci) or MRTX1133 (G12Di). We also observed significant re-sensitization of the resistant cells to the specific KRAS inhibitors upon genetic or pharmacological inhibition of TEAD using siRNA or a TEAD-inhibitor, *in vitro.* Tumors from syngeneic mice that were implanted with KRAS inhibitor-resistant cells or their sensitive versions and treated with the specific KRAS inhibitors for 3-4 weeks, also exhibited increased nuclear YAP1 localization in the resistant tumors. We are currently performing *in vitro* and *in vivo* studies to understand the therapeutic efficacy of a TEAD inhibitor in combination with KRASi (MRTX849 or MRTX1133) to either reverse or prevent resistance to these direct KRAS inhibitors. We are also trying to identify alterations in the tumor immune microenvironment upon combination therapy targeting KRAS and TEAD. Successful completion of this research will help address the urgent need to understand ways to overcome resistance to KRAS inhibitors and increase their clinical efficacy.

#1941 AXL activation promotes adaptive resistance to KRAS-G12C inhibitors in KRAS-G12C-mutated non-small cell lung cancer.

K. Morimoto[1], T. Yamada[1], S. Hirai[1], Y. Katayama[1], K. Kunimasa[2], T. Sasaki[3], M. Nishida[4], S. Watanabe[5], S. Shiotsu[6], H. Uehara[7], K. Takayama[1]; [1]Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Osaka International Cancer Institute, Osaka, Japan, [3]Asahikawa Medical University Hospital, Hokkaido, Japan, [4]St. Marianna University School of Medicine, Kanagawa, Japan, [5]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, [6]Japanese Red Cross Kyoto Daiichi Hospital, Kyoto, Japan, [7]Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, Japan

Background: KRAS is the most frequent targetable oncogene in non-small cell lung cancer (NSCLC). Recently, novel KRAS inhibitor have been clinically developed for treatment of KRAS G12C-mutated NSCLC patients. However, it is difficult to achieve complete remission of tumor. Therefore, the optimal combined therapeutic intervention with KRAS G12C inhibitors has a potentially crucial role in the clinical outcomes of patients. In this study, we focused on the mechanisms underlying adaptive resistance to KRAS G12C inhibitors and therapeutic strategies required to overcome them.
Methods: We used KRAS G12C-mutated NSCLC cell lines to evaluate the adaptive response to KRAS G12C inhibitors in vitro and in vivo. We also investigated the correlation between AXL expression in pre-treated tumors and clinical outcomes with sotorasib for KRAS G12C-mutated NSCLC patients.
Results: We revealed that AXL signaling leads to the adaptive resistance to KRAS G12C inhibitors in KRAS-G12C mutated NSCLC, activation of which is induced by GAS6 production via transcriptional coactivator YAP. AXL inhibition reduced the viability of AXL-overexpressing KRAS G12C-mutated lung cancer cells by enhancing KRAS G12C inhibition-induced apoptosis. In xenograft models of AXL-overexpressing KRAS G12C-mutated lung cancer treated with KRAS G12C inhibitors, initial combination therapy with AXL inhibitor markedly delayed tumor regrowth compared with KRAS G12C inhibitor alone or the combination after acquired resistance to KRAS G12C inhibitor. AXL was highly expressed in clinical specimens of KRAS G12C-mutated lung cancers and its high expression was associated with a low treatment response to sotorasib.
Conclusions: These results indicated pivotal roles for AXL activation and its inhibition in the intrinsic resistance to KRAS G12C inhibitor.

#1942 Characterization of a panel of CRISPR/Cas9 engineered KRAS G12C inhibitor-resistant tumor models.

J. Zhou[1], L. Hua[1], J. Feng[1], N. Bao[1], D. Zhang[1], J. Wang[1], M. Putker[2], L. Bourre[1];
[1]Crown Bioscience, Inc., San Diego, CA, [2]Crown Bioscience, Inc., Leiden, Netherlands

Introduction: KRAS is one of the most frequent mutated oncogenes and has been recognized as undruggable for many years. AMG510, the first therapy to directly target KRAS, was approved by the FDA to treat non-small cell lung cancer (NSCLC) bearing KRAS G12C mutation. However, the emergence of resistance in patients remains a challenge and limits its clinical benefits, which calls for next-generation targeted therapy or combination strategies to overcome the resistance to KRAS G12C inhibitors. A variety of secondary mutations in KRAS attributing to the resistance have been identified, which requires robust *in vitro* and *in vivo* preclinical models to validate potential therapeutics targeting these mutations. Therefore, we generated a panel of KRAS G12C inhibitor-resistant tumor models to facilitate the development of possible strategies to overcome such resistance.

Methods: First, a secondary KRAS mutation, including H95D, H95Q, H95R, Q61H and R68S, was introduced by using CRISPR/Cas9 technology in MIA PaCa cell line, which harbors a homozygous KRAS G12C mutation in addition to Y96D, Y96C and Y96S previously published by us. Point mutation knock-in was validated by sanger sequencing, and cell identity was confirmed by SNP assay. *In vitro*, the parental and mutated cells were treated with either AMG510 and MRTX849 and cell viability was measured by CellTiter-Glo. *In vivo* efficacy of KRAS G12C inhibitors, AMG510 and MRTX849, SOS1 inhibitor, BI-3406 and MEK inhibitor, Trametinib were evaluated in the Y96D mutated MIA PaCa subcutaneous xenograft.

Results: Homozygous secondary point mutation knock-in in MIA PaCa cells was confirmed by sanger sequencing. Similar growth rate and morphology was observed in selected clones compared to the parental line. Similar to Y96D mutation previously published, R68S mutation was highly resistant to both KRAS G12C inhibitors, with IC_{50} increased more than 100 fold for both MRTX849 and AMG510, whereas H95D, H95Q and H95R mutation was more resistant to MRTX849, while Q61H had a minimal effect on either one of the inhibitors. In addition, cells expressing KRAS G12C/Y96D were also resistant to AMG510 and MRTX849 in *in vivo* study, whereas combination of BI-3406 (single treatment: TGI of 27%) and Trametinib (single treatment: TGI of 76%) suppressed tumor growth significantly with TGI of 93% on day 17 after randomization compared to control group ($p<0.001$). Also, the combination showed significant improvement compared to BI-3406 single treatment ($p<0.001$) whereas no significant improvement was observed compared to Trametinib single treatment ($p>0.05$).

Conclusion: CRISPR/Cas9 engineered second site KRAS mutations in cells harboring KRAS G12C mutation displayed a differentially resistant profile to KRAS G12C inhibitors. Thus, H95D/Q/R, R68S and Y96D can be used as preclinical inhibitor-resistant models to evaluate clinical strategies to overcome resistance to KRAS-targeted therapies.

#1943 Discovery and characterization of potential drivers of resistance to the KRAS G12D inhibitor, MRTX1133, in cancer cell line models.

X. M. Helu[1], E. Griffiths[1], A. Calinisan[1], A. Hebbert[1], L. Yan[1], N. Hoffman[1], D. Trinh[1], L. Hover[2], J. Fernandez-Banet[2], D. M. Briere[1], E. Lifset[1], P. Olson[1], J. G. Christensen[1], **J. Hallin**[1];

[1]Mirati Therapeutics, San Diego, CA, [2]Monoceros Biosystems LLC, San Diego, CA

Introduction: *KRAS*^{G12D} is the most common *KRAS* mutation and is present in approximately 34% of pancreatic cancer, 10-12% of colorectal cancer, 4% of lung adenocarcinoma and in a number of other cancer types. We previously identified MRTX1133, a potent, selective, and non-covalent KRAS^{G12D} inhibitor. The advancement of MRTX1133 to clinical trials warrants continued study of the role of the *KRAS*^{G12D} mutation in cancer pathogenesis and progression.

Methods: Previous pharmacodynamic and pharmacogenomic profiling in sensitive and partially resistant models identified mechanisms implicated in limiting the anti-tumor response including signaling pathways that induce feedback reactivation and/or bypass KRAS dependence. Thus, cell lines (GP2D and SNU-1033, colorectal cancer; HPAC and AsPC-1, pancreatic cancer) were utilized to study acquired resistance to MRTX1133 following continuous treatment at increasing concentrations over time. These cell lines were confirmed to be stably resistant as determined by evaluation of response to MRTX1133 in vitro and in vivo. These cell lines were extensively profiled to determine underlying mechanisms of resistance utilizing molecular profiling strategies as well as drug combination screens to interrogate pathways that could circumvent resistance.

Results: In one of the four generated cell lines with acquired resistance, evidence of secondary *KRAS* mutations Y96N and H95Q were confirmed by RNAseq and are likely drivers of resistance in this cell line and are consistent with known mechanisms of KRAS^{G12C} inhibitor resistance. The three other MRTX1133 resistant cell lines did not show evidence of secondary *KRAS* mutations and were further evaluated for mechanisms that bypass KRAS dependence. Combinations of MRTX1133 with therapies that target pathways including upstream RTK signaling, mTOR, or AKT broadly enhanced the anti-tumor activity of MRTX1133 in both in vitro cell viability and in vivo efficacy studies in the resistant cell lines. Conclusion: Collectively, these data provide early insight onto potential mechanisms of resistance to selective KRAS^{G12D} inhibitors and demonstrate the importance of developing rational combination strategies designed to address drug resistance. In addition, these studies provide a catalogue of potentially druggable vulnerabilities that complement KRAS blockade.

#1944 Using patient-derived cancer organoids to determine the effects of the anti-EGFR therapy panitumumab in the presence or absence of *KRAS* mutation.

J. N. Stoecker, S. Udgata, A. A. Gillette, C. A. Pasch, M. C. Skala, D. A. Deming;
UW Madison, Madison, WI

Introduction: Tumor heterogeneity is a major cause of resistance to therapies in colorectal cancer (CRC). The anti-EGFR (epidermal growth factor receptor) therapies panitumumab (pani) and cetuximab, are now being investigated for the retreatment of patients when resistant subclones could be more abundant in a previously wild-type cancer. Here we utilize patient-derived cancer organoids (PDCOs) to investigate the potential implications of the abundance of resistant subclones on treatment and duration of response.

Methods: Two CRC PDCO lines, one pani sensitive (PS) and one pani resistant (PR), were cultured separately and then mixed to determine how different combinations of mutations altered the time for the overall culture to be resistant to pani. NGS was performed on these cells to determine the mutation profile. The two PDCO lines were cultured together with the following concentrations (v/v) of 100% PS; 20% PR+80% PS; 10% PR+90% PS, 5% PR+95% PS, 1% PR+99% PS, and 100% PR using Matrigel and fed with previously published CRC organoid media. Widefield imaging was performed for diameter change analysis at day 0 and day 4 using ImageJ. Upon a median growth of >20% at baseline/untreated, all mixed populations were treated at increments of 20% physiologic Cmax of pani each week. Once select mixed populations reached 100% Cmax and maintained a median growth of >20% for two consecutive weeks, they were determined to have reached complete resistance to the treatment.

Results: DNA sequencing of PDCOs showed PR has mutations associated with pani resistance (KRASG12V, PIK3CAH1047R) and the PS line did not. All the conditions except for 100% PS escalated to ≥40% Cmax within 7 weeks and reached complete resistance to pani by week 22. 100% PS remained at 20% Cmax through week 22. The 100% PR population reached complete resistance to pani the quickest at 100% Cmax at week 8. The conditions with the lowest percentages of PR (5% PR+95% PS and 1% PR+99% PS already started to show resistance above the PS line by 8 weeks and reached complete resistance to pani at week 12.

Conclusion: PDCO lines containing low concentrations of resistant clones can quickly lead to resistance to pani treatment, even below the typical level for clinical NGS detection. All KRAS mutant conditions (PR) reached resistance quicker than 100% PS condition. Further studies will evaluate even low concentrations of resistance clones across further CRC PDCO models and will evaluate the mechanism by which these clones are leading to resistance.

#1945 Mechanisms of acquired resistance to EGFR tyrosine kinase inhibitor osimertinib and KRAS-G12C inhibitor sotorasib in lung cancer..

Y. Yagami[1], T. Sato[1], H. Yamamoto, Sr.[1], M. Shirasawa[1], Y. Nakahara[1], W. Hideo[2], N. Katsuhiko[1];
[1]Kitasato Univ. School of Medicine, kanagawa, Japan, [2]Mount Sainai, New York, NY

A series of molecular targeted drugs have been developed for the treatment of non-small cell lung cancer (NSCLC) harboring driver gene alterations. Although the use of these drugs has substantially improved the clinical outcomes of patients with the genetically altered NSCLC, these patients ultimately develop resistance to the drugs. Various molecular mechanisms of resistance to the molecular target therapies have been reported, it is still a crucial challenge to overcome the drug resistance. Osimertinib, the most used third-generation EGFR tyrosine kinase inhibitor to target both common *EGFR* mutations and secondary T790M mutation, and sotorasib, a recently developed KRAS inhibitor to target *KRAS* G12C mutation, are no exception. In this study, we aimed to investigate the mechanisms of acquired resistance to osimertinib and sotorasib in NSCLC by profiling drug-resistant lung cancer cell lines, which were established from *EGFR*-mutant HCC827(del E756_A750) and *KRAS* G12C-mutant H23 through exposure to each of the molecular targeted drugs. Phospho-RTK array and western blot analyses revealed MET overexpression and phosphorylation in the osimertinib-resistant HCC827 (HCC827OR) as previous studies reported. Notably in our study, HCC827OR cells were incompletely sensitive to a selective MET inhibitor savolitinib without osimertinib, suggesting that HCC827OR partially lost its dependency on mutant EGFR and got addiction to MET signaling. When sotolasib was administered to the sotolasib-resistant H23 (H23SR) cells, KRAS-GTP, and the downstream ERK and AKT phosphorylation were suppressed. To identify novel mechanisms of the resistance, we performed epigenomic profiling of active enhancer in those cells and found a candidate transcription factor, at whose gene locus H3K27 acetylation signal was increased in H23SR cells compared to parent H23 cells. Immunoblotting showed that protein expression of the gene was indeed higher in H23SR cells than the parent cells. To confirm the involvement of this gene to the resistance, further investigation is warranted.

#1946 Elucidating the mechanisms of acquired resistance to AMG510 in cancer models harboring KRAS G12C mutations.

T. Ni, T. Huo, Y. Zhang, J. Wang, G. Liu, W. Shi, Q. Gu;
WuXi AppTec, Suzhou, China

GTPase KRas (KRAS), a critical oncogene, is known for its frequent mutations across a wide array of human cancers, most notably in pancreatic, lung, and colorectal cancers. Recent advancements in the field have led to the successful development of numerous inhibitors targeting the mutant KRAS. Clinical application of KRAS G12C inhibitors, such as AMG510 and MTRX849, represents major breakthroughs in addressing previously 'undruggable' cancer targets. Nevertheless, a subset of patients initially responsive to these inhibitors eventually exhibit treatment resistance. Uncovering the underlying mechanism would help to develop novel therapies that overcome the acquired drug resistance.

To elucidate the underlying mechanisms, we generated AMG510-resistant tumor models, namely AMG510-R-MIA PaCa-2 and AMG510-R CT26 KRAS G12C, by continuous administration of AMG510 to tumor-bearing mice. Upon comparison of sensitive parental tumors and resistant tumors, we found that highly expressed KRAS and constant activation of RAS-MAPK signaling pathway are critical for resistant tumor progression following AMG510 treatment. In addition, resistant tumor cells are responsible for the elevated secretion of CXCL2/3/5, which dramatically reconditions the tumor immune microenvironment and recruits immunosuppressive cells.

In summary, the exploration of the resistance mechanism in AMG510-induced resistant models provides insight into the development of new-generation KRAS-G12C inhibitors and novel combinatorial therapies.

#1947 Studies on pMEK inhibitors for the treatment of RAS-mutant cancers as a single agent or combinations.

X. Lv, M. Xu, Y. Hu, L. Zhao, X. Chen, Y. Chen, C. Yang, J. Li, C. Chen;
ABM Therapeutics, San Diego, CA

RAS mutations are the most common oncogene in human cancers and KRAS has the highest frequency in non-small cell lung cancer (NSCLC) and pancreatic cancer (PDAC). KRAS G12C inhibitors have been approved to treat NSCLC patients. However, drug-resistance is eventually developed for these treatments. Preclinical studies suggested MAPK pathway reactivation is one possible mechanism. Among many MEK inhibitors in clinical development, CH5126766 binds to MEK1 inactive conformation and blocks its phosphorylation and activation. We believe this compound should prevent MAPK “paradoxical activation” commonly observed in most RAF and MEK inhibitors such as vemurafenib and cobimetinib. We studied this compound in various in vitro assays and found its potential in combating the paradoxical activation, which might be the cause of drug-resistance for MAPK signal pathway inhibitors, including RAS-, RAF- MEK- and ERK-inhibitors, as a single agent or in combination with above-mentioned inhibitors. In addition, we are developing a series of compounds based on CH5126766, by improving the inhibition of MEK1/2 kinase activity in addition to its activation. In summary, studies on the pMEK inhibitor demonstrated that this class of compounds might mitigate the MAPK pathway reactivation and prolong drug efficacies in clinical. Detailed research results will be discussed.

#1948 Resistance to RAS inhibition promotes remodeling of the immunosuppressive microenvironment of pancreatic cancer.

H. Tiriac;
UC San Diego, San Diego, CA

Background: Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal malignancies, largely due to acquired chemotherapy resistance. MRTX-1133, a promising KRAS-G12D inhibitor, has demonstrated initial efficacy; however, resistance analogous to that seen with KRAS-G12C inhibitors is an emerging challenge. The tumor microenvironment (TME) is increasingly recognized as a contributor to resistance, often fostering tumor survival and immune evasion.
Methods: To elucidate the resistance mechanisms to KRAS-G12D inhibition, we established resistant mouse and human PDAC cell lines derived from mouse and human models. These models were analyzed using flow cytometry and single cell RNA sequencing to define TME dynamics as resistant is acquired and after is has been established. We also analyzed cytokines released by resistant tumor cells using protein arrays and RNA sequencing.
Results: Our investigation revealed significant TME alterations associated with acquired resistance. Notably, there was a marked increase in the population CD4+ Tregs and neutrophil while activated CD8+ T cells are decreased in the resistant tumors. Concurrently, an increased secretion of chemokines such as CXCL1 and CXCL2 was observed in resistant tumor cells relative to their parental counterparts.
Conclusions: The adaptation of PDAC to circumvent KRAS inhibition involves a distinct reprogramming of the TME, attenuating immune surveillance and potentially facilitating tumor progression. Current efforts are directed towards delineating the key pathways implicated in these TME modifications to pioneer new therapeutic approaches for managing KRAS inhibitor resistant PDAC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Kinase and Phosphatase Inhibitors 2
Poster Session

#1952 Co-alterations in *PIK3CA* and ARID1A lead to enhanced sensitivity to PI3K inhibition.
S. Udgata, J. N. Stoecker, A. L. Lippert, C. A. Pasch, D. A. Deming;
University of Wisconsin-Madison, Madison, WI

Background: There is increasing interest in developing precision medicine strategies for cancers with *PIK3CA* mutations. Co-alterations in *PIK3CA* and ARID1A (AD) occur in ~1% of all cancers. Previously, patients with co-alterations in *PIK3CA* and AD have shown both an improved objective response rate and improved progression free survival following copanlisib (cop) treatment compared to cancers with *PIK3CA* mutations and wild-type AD. Here we evaluate potential mechanisms for this enhanced clinical benefit.
Methods: AD was knocked out in SW48 and SW48$^{PIK3CA\text{-}H1047R}$ (SW48PK) human 2D colorectal cancer cell lines using CRISPR (SW48AD; SW48PKAD). Knockouts were confirmed using PCR genotyping, amplicon sequencing, and western blot (WB). A cell proliferation assay (WST-1) was performed at increasing doses of cop for 48hrs to determine cell viability. WBs were performed at 6hrs and 24hrs after cop treatment to determine levels of phosphorylation of AKT, S6, and 4EBP1 and levels of apoptosis-related proteins (MCL-1, BCL-xL, BCL-2, PARP). Athymic nude mice were flank injected with SW48PK and SW48PKAD and treated with cop (10mg/kg in PEG400/acidified water (0.1N HCl, pH 3.5; 20/80, v/v) or vehicle for 25 days or until moribund.
Results: WST-1 assay showed highest sensitivity to cop in SW48PKAD cells compared to SW48, SW48PK and SW48AD. At 10nM ($p=0.01$), there was a significant difference in cell viability between SW48PK and SW48PKAD. No significant difference was seen in the phosphorylation (p) of AKT, S6, or 4EBP1 between SW48PK and SW48PKAD. Expression of MCL-1 protein decreased in SW48PKAD compared to SW48PK. No difference was seen in levels of BCL-xL and BCL-2. On treatment with cop, there was a greater reduction in pS6 in SW48PKAD at 24 hours compared to SW48PK, but no significant difference in pAKT and p4EBP1. There was a gradual increase in MCL-1, BCL-xL, and cleaved PARP in SW48PKAD overtime following cop treatment compared to SW48PK. *In vivo,* untreated SW48PKAD tumors grew more quickly than the SW48PK tumors (8-fold increase in tumor size in SW48PKAD compared to 5-fold increase in SW48PK by day 25, $p=0.06$). SW48PKAD mice had significant tumor reduction ($p=0.002$) on cop treatment by day 25; however, SW48PK mice did not.
Conclusions: ARID1A loss along with *PIK3CA* mutation leads to greater PI3K inhibition response most likely due to enhanced induction of apoptosis. Further confirmation of this enhanced sensitivity is required with better *in vitro* models such as patient-derived cancer organoids.

#1953 Posttranslational modification in glucocorticoid receptor in treatment resistant prostate cancers.

S. Gulla[1], E. Gardner[1], S. Sundar[1], P. Jaiswal[2], N. Gao[2], L. Bennet[2], S. Conzen[2], R. Adelaiye-Ogala[1];
[1]SUNY at Buffalo, Buffalo, NY, [2]University of Texas Southwestern Medical Center, Dallas, TX

Prostate Cancer (PCa) remains the most common cancer in men in the United States and the second leading cause of cancer-related death in men. An evolving concept that contributes to our understanding of resistance to androgen deprivation therapy (ADT) and AR antagonists in advanced PCa is the ability of cells to turn on compensatory hormone receptor signaling for survival. Preclinical and clinical studies demonstrate that induction of glucocorticoid receptor (GR) expression confers resistance to AR-targeted therapy. Previous studies from our lab demonstrated that the inhibition of AKT signaling blocks pro-oncogenic GR activity and overcomes resistance to AR-targeted therapy. AKT1 is predicted to phosphorylate GR at s134, however, the implications of pGR(s134) in advanced PCa remains unclear. Although ligands (e.g., Dex) activates GR, we have found GR activation modulated by post-translational modification (PTM) and persistent in treatment resistant PCa. Therefore, we hypothesize pro-oncogenic GR activation through AKT1-induced PTM. The rationale is that by inhibiting AKT signaling, we block residual GR signaling that can potentially drive lethal prostate cancers and consequently be re-sensitized to the standard of care. We validated our findings by Western blot analysis, we used an AKT1-specific inhibitor (AKT1i) and observed decreased AKT1 activity and decreased pGR(s134) without affecting total GR protein expression. Functional studies using shRNA against AKT1 showed reduced pGR(s134) expression without affecting the total GR expression Our preliminary data suggests that pro-oncogenic GR activity is modulated through the phosphorylation of GR on s134 by AKT1.

#1954 Development of highly potent, covalent, and selective inhibitors to target PI3Kα in cancer.

L. Raguz, T. A. Constantin, L. Bissegger, E. Keleş, C. Orbegozo, T. Schafer, R. Sriramaratnam, C. Borsari, M. P. Wymann;
University of Basel, Basel, Switzerland

Aberrant PI3K signaling is linked to various forms of cancer and proliferative disease. Approved clinical therapies targeting overactive PI3K are scarce and often accompanied by severe adverse effects due to lack of PI3K isoform selectivity. We recently reported a proprietary covalent proximity scanning (CoPS) approach to selectively target distant cysteines outside of the ATP-binding pocket in kinases. Using CoPS, we developed isoform specific, irreversible covalent PI3Kα inhibitors (cPI3Kαi) with outstanding target engagement profiles. Here, we report structure-guided scaffold and linker-optimizations resulting in cPI3Kαi with long-term and rapid inhibition of PI3Kα. Cellular activity was improved exploiting additional protein-inhibitor interactions inspired by X-ray crystallographic data, and introduction of structural elements to increase cell permeability. The cPI3Kαi series showed enhanced cellular potency and excellent on-target engagement. Kinetic parameters and covalent bond formation were determined using TR-FRET, nanoBRET tracer displacement assays, and LCMS/MS based proteomics. With our new cPI3Kαi, IC_{50}s of PKB/Akt phosphorylation, pPKB/Akt recovery after drug washout, and growth inhibition experiments were performed in cancer cell lines harboring activating PIK3CA or inactivating PTEN mutations. Efficient and long-lasting inhibition of PKB/Akt phosphorylation was observed in PIK3CA mutant cell lines, while loss of PTEN was associated with partial responses, consistent with contributions of other class I PI3K isoforms to signal reactivation. A dynamic FOXO cytosolic/nuclear translocation assay was used to monitor distal PI3K signaling: cPI3Kαi blunted PI3K signaling rapidly with rates identical to the reversible BYL719/alpelisib. After drug washout, inhibition by BYL719/alpelisib was relieved within minutes, while a complete and prolonged shutdown of downstream signaling events was observed in PIK3CA mutant cell lines but not in cell lines where PTEN function was lost. This relapse in downstream signaling explains the lack of efficacy of PI3Kα selective inhibitors in models with PTEN loss and demonstrates that persistent inhibition across the PI3K pathway is required for efficacy. In summary, the new cPI3Kαi display outstanding specificity and cellular activity in PIK3CA-mutated cancer cells, and support the further development of cPI3Kαi as future clinical candidates and an alternative to established reversible inhibitors.

#1955 Novel long-acting covalent PI3Kα inhibitors boost potential action in cancer.

T. A. Constantin[1], L. Bissegger[1], E. Keleş[1], L. Raguz[1], C. Orbegozo[1], T. Schaefer[1], I. Barlow-Busch[2], J. E. Burke[3], C. Borsari[1], M. P. Wymann[1];

Phosphoinositide 3-kinase (PI3K) is a key regulator of cell proliferation, survival, and metabolism. Hotspot mutations in the *PIK3CA* gene constitutively activate the catalytic subunit of the PI3Kα isoform and are found in 10-30% of solid tumors. The development of PI3K pathway inhibitors has been hampered by poor drug tolerance and release of negative feedback loops, leading to rapid reactivation of signaling in response to reversible inhibitors. To remedy these challenges, we developed highly selective covalent PI3Kα inhibitors that irreversibly bind to a non-conserved cysteine (C862) located 11 Å outside the ATP-binding site. Here we present the properties of an optimized drug-like covalent lead, dubbed compound 9, and describe the generation of a biotinylated probe developed to be used in conjunction with compound 9 to monitor PI3Kα target occupancy in relation to downstream PI3K signaling outputs. Biochemical investigations of compound 9 using TR-FRET assays showed high affinity binding (K_i), high reaction rates (k_{inact}) for covalent bond formation with PI3Kα, and negligible off-target reactivity. Cellular NanoBRET assays revealed that compound 9 diffuses three times more rapidly into cells as compared to BYL719 (alpelisib), and leads to rapid and potent on-target engagement. Covalent bond formation to residue C862 of PI3Kα was further confirmed by X-ray crystallography. In *PIK3CA* mutant cancer cell lines, covalent binding of PI3Kα occurred at low nanomolar concentrations and led to persistent inhibition of Akt/PKB phosphorylation for more than 72 hours after drug removal. Notably, investigation of PI3Kα re-synthesis after labeling with compound 9 showed a negligible reappearance in cancer cell lines, which indicates that persistent suppression of PI3Kα signaling by compound 9 results in a much longer half-life for PI3Kα than previously reported. The irreversible inactivation of PI3Kα by compound 9 provides a marked gain in growth inhibition potency (10-600-fold) in *PIK3CA* mutant cancer cell lines in comparison to clinical reversible PI3Kα inhibitors and allows for intermittent dosing without compromising efficacy. These data collectively demonstrate that compound 9 enables precise and selective targeting of PI3Kα with high potency and long-lasting efficacy in cancer models. The new class of irreversible PI3Kα inhibitors have a unique pharmacology among PI3K inhibitors characterized by strong decoupling of drug exposure from efficacy which may provide opportunities to lower treatment burden in patients.

#1956 Discovery of a novel and potent mutant-selective inhibitor of PI3Kα.

M. Gao, C. Qi, Z. Li, Q. Fan, L. Wang, F. Zhou, L. You, H. Zheng, Y. Li, L. Wu, W. Yao, P. C. C. Liu;
Synnovation Therapeutics, Inc., Wilmington, DE

Gain-of-function mutations in hotspots of PI3Kα including H1047R, E545K, and E542K are well-recognized oncogenic drivers in human cancers. Prevalence of these mutations is enriched in many human malignancies, particularly in hormone receptor-positive/human epidermal growth factor receptor 2-negative (HR+/HER2−) breast cancer. PI3Kα inhibition showed clear clinical benefit in treating HR+/HER2− breast cancer and has been approved in combination with fulvestrant. First generation PI3Kα inhibitors such as alpelisib and inavolisib, however, have limited selectivity against wild-type (WT) PI3Kα; therefore, are associated with a variety of on-target adverse effects including grade 3 hyperglycemia, skin rash, and gastrointestinal toxicities. Discovery of a highly-selective inhibitor of mutant PI3Kα could enable deeper target coverage while reducing undesired effects of inhibiting WT PI3Kα. SNV-002 is a novel, proprietary, and mutant-selective inhibitor of PI3Kα. In cellular assays, SNV-002 inhibited Ser473 phosphorylation of AKT (pAKT) with single digit nanomolar potency in PI3Kα H1047R-mutant T47D cells and displayed greater than 50-fold selectivity over SKBR3 WT control. Similar inhibition of pAKT was also observed in other cell lines carrying PI3Kα hotspot mutations, such as CAL33, NCI-H1048, EFM19, and HCC1954. SNV-002 maintained selectivity in helical domain E545K-mutant cell lines including MCF7 and MDA-MB-361. This selectivity was further confirmed using MCF10A isogenic cell lines carrying either WT or mutant PI3Kα (H1047R and E545K). In cellular assays to assess inhibition of other isoforms of PI3K (PI3Kβ, PI3Kγ, and PI3Kδ), the IC50 of SNV-002 was over 10,000 nM. Similarly, a broad kinome screen showed no inhibition of activity of 371 kinases. Compared with alpelisib, SNV-002 showed improved potency and prolonged residence time in T47D breast cancer cells. Importantly, assays using H1047R-mutant cells in the presence of human whole blood showed SNV-002 potency to be less than 100 nM, which was over 10-fold more potent than that of alpelisib. Treatment of breast cancer cells with SNV-002 suppressed PI3K-AKT-mTOR pathway, as evidenced by reduced levels of phospho-S6 ribosomal protein and associated with loss of cell viability in mutant lines. The pharmacokinetic profile of SNV-002 was excellent across multiple species. Oral administration of HCC1954 tumor-bearing mice with SNV-002 resulted in dose-proportional exposure and >90% pharmacodynamic inhibition of pAKT in the tumor with doses of 10 mg/kg, and no sign of glucose dysregulation in contrast to alpelisib. Together, these data show that SNV-002 is a highly-selective and potent inhibitor of mutant PI3Kα with good drug-like properties that support further development of SNV-002 for treatment of cancers driven by oncogenic PI3Kα mutations.

#1957 OPM-116, a highly potent and specific PI3Kγ inhibitor to enhance antitumor immunity.

K. Shoji, P. Blom, M. E. Riveiro, J. Hoflack;
Oncodesign Precision Medicine, Dijon, France

Tumor-associated macrophages are an integral part of the tumor microenvironment. They play a crucial role in cancer initiation and progression by orchestrating tumor proliferation, angiogenesis, extracellular matrix remodeling, metastasis, immunosuppression, and resistance to checkpoint blockade immunotherapy and chemotherapy (Gao J, 2022). On the other hand, when properly stimulated, macrophages can effectively interact with the innate and adaptive immune systems arms, promoting cancer cell phagocytosis and tumor destruction by T cell-mediated cytotoxicity (Mantovani A, 2022). PI3Kγ has a unique pattern of expression and biological function, and it has been investigated for a long time as a therapeutic target for different disorders, including cancer. Inhibition of PI3Kγ reprograms M2 macrophages into M1 cells in the tumor microenvironment which translates into the expansion of activated T cells by relieving macrophage suppression. Recent clinical data indicates the compelling role of PI3Kγ in combination with PDL1 in anti-tumor activity, irrespective of PDL1 status (Hamilton E, 2021). PI3Kγ selectivity has been difficult to achieve due to the high sequence homology across the class 1 PI3K isoforms (Drew SL, 2020). Macrocyclization of small molecules with a linear structure strongly reduces their conformational flexibility and alters a variety of their physicochemical and biological characteristics. The unexpected selectivity these compounds can exhibit, even amongst closely similar target molecules, is explained by the conformationally limited structure (Ma J, 2022). Here, we describe the discovery of a potent and selective, ATP-competitive inhibitor of PI3Kγ. OPM-116, macrocyclic compound display >300-fold selectivity for PI3Kγ over the other class I isoforms. Its selectivity in biochemical and cellular assays as well as in human PBMC assays is presented. In vitro, OPM-116 can inhibit the IL-4-induced polarization of M2 macrophages. Pharmacodynamic analysis performed in animals that received oral compound administration confirmed the absolute selectivity and good PK profiles of the drug. OPM-116 is a highly selective, PI3Kγ inhibitor that displays high potency and specificity and represents a promising step toward the identification of a clinical candidate.

#1958 EGFR and mTOR signaling facilitate RET-independent resistance to selective RET-TKIs.

T. Takehara[1], M. B. Nilsson[1], X. Liu[1], H. Udagawa[2], N. Morikawa[3], A. Poteete[1], J. He[1], X. Yu[1], T. Arumugam[1], K. Goto[2], J. V. Heymach[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]National Cancer Center Hospital East, Kashiwa, Japan, [3]Tohoku Rosai Hospital, Sendai, Japan

RET fusions are an oncogenic driver mutation occurring in 1-2% non-small cell lung cancer (NSCLC). Currently, RET-selective tyrosine kinase inhibitors (TKIs) selpercatinib and pralsetinib are approved for this patient population, demonstrating favorable antitumor activity and safety profiles in advanced RET fusion-positive NSCLC. However, tumors eventually become refractory to selective RET inhibitor monotherapy. We sought to identify signaling pathways which mediate RET-independent acquired resistance to RET inhibitors and effective therapeutic combinations to overcome resistance. Using LC-2/ad (CCDC6-RET) NSCLC cells, we assessed the expression and activation of critical signaling pathways at a proteomic level following RET knockdown using reverse-phase protein array. RET knockdown resulted in rapidly increased adaptive upregulation of EGFR, HER2, MET, mTOR and MEK pathway signaling; observations were confirmed by Western Blotting. To determine whether EGFR or MET signaling facilitate RET inhibitor resistance, LC-2/ad and NCCE-TH1101 (KIF5B-RET) NSCLC cells were treated with increasing concentrations of selpercatinib or pralsetinib with or without ligands for these receptors, EGF or HGF respectively, and after five days cell viability was measured by CellTiter Glo. EGFR and MET signaling promoted RET TKI resistance in both cell lines. Next, to evaluate whether blockade of EGFR or MET signaling could enhance the activity of RET inhibitors, we treated LC-2/ad and NCCE-TH1101 cells with RET TKIs alone or in combination with the EGFR TKI erlotinib or poziotinib, or the MET inhibitor SU11274. We observed an additive effect with EGFR but not MET inhibitors when combined with RET TKIs. Western blot analysis revealed that EGFR signaling could reactivate mTOR and MAPK signaling after RET TKI treatment. Therefore, we next tested whether inhibition of these downstream pathways might enhance RET TKI sensitivity. We observed that treatment of LC-2/ad and NCCE-TH1101 cells with an mTOR inhibitor (everolimus) or a MEK inhibitor (trametinib) in combination with RET TKIs increased the anti-tumor activity or RET inhibitors. Finally, we established cells with acquired resistance to selpercatinib and pralsetinib. RET TKI resistant cells did not harbor secondary RET fusion mutations but underwent epithelial to mesenchymal transition and exhibited pan-RET inhibitor resistance. Moreover, RET TKI resistant cells showed increased cell surface expression of EGFR and MET by flow cytometry. RET TKI resistant cells were sensitive to mTOR or MEK inhibitors in combination with RET TKIs. Collectively, our findings indicate that in RET-fusion positive NSCLC tumor cells, activation of bypass pathways including the EGFR, MAPK, mTOR pathways may facilitate RET inhibitor resistance and that blockade of bypass pathways may enhance the efficacy of selective RET inhibitors and overcome acquired RET TKI resistance.

#1959 BLU-222, a potent and highly selective CDK2 inhibitor, demonstrates antitumor activity as monotherapy and as combination treatment in *CCNE1*-aberrant endometrial cancer models.

N. House, V. Brown, L. Yuan, M. Chen, S. Lee, R. Wu, L. Muthuswamy, S. Ribich, P. Ramsden, K. Faia;
Blueprint Medicines Corporation, Cambridge, MA

Background: Many cyclin-dependent kinases (CDK) bind regulatory cyclins to control cell cycle progression. Aberrant CDK2 activation occurs in selected cancers (*e.g.*, ovarian cancer, endometrial cancer) through *CCNE1* amplification, leading to Rb phosphorylation, inactivation, and cell cycle checkpoint dysregulation. *CCNE1* amplification and subsequent cyclin E overexpression are associated with chemotherapy resistance and shorter progression-free and overall survival. Therefore, novel therapies are needed to inhibit aberrant CDK2 activation and elicit positive clinical benefit in these patients. BLU-222 is a potent, highly selective, orally bioavailable, investigational CDK2 inhibitor with demonstrated activity in preclinical *CCNE1*-amplified ovarian cancer models. Here, we explored additional, specific biomarkers to predict BLU-222 sensitivity in ovarian and endometrial cancer as monotherapy or in novel combination treatment strategies.

Methods: *In vitro* antiproliferative effect of BLU-222 was assessed by CyQuant in a panel of *CCNE1*-aberrant or *CCNE1*-normal ovarian and endometrial cell lines. Combination of BLU-222 and paclitaxel was evaluated by dosing matrix; synergy was calculated using SynergyFinder. *In vivo* antitumor activity of BLU-222 as a single agent or combined with paclitaxel was measured in *CCNE1*-aberrant endometrial cancer patient-derived xenograft (PDX) models (XenoSTART).

Results: In ovarian and endometrial cell lines, *CCNE1* amplification (copy number ≥ 6) predicted strong antiproliferative response to BLU-222. Using multivariate biomarker analysis, high p16 protein expression and wild-type Rb protein were identified as additional predictive markers for response to BLU-222 in *CCNE1*-aberrant cell lines. BLU-222 with paclitaxel was broadly active in endometrial cancer cell lines, with the strongest combination effect in cells with high *CCNE1* expression, wild-type Rb protein, and low p16 protein expression. *In vivo*, BLU-222 elicited strong monotherapy antitumor response in *CCNE1* copy number-aberrant endometrial cancer PDX models, and this effect was strengthened with the combination of paclitaxel.

Conclusions: In preclinical models of *CCNE1*-aberrant endometrial cancer, BLU-222 demonstrated enhanced activity in combination with paclitaxel. Furthermore, Rb and p16 protein expression can be used in conjunction with *CCNE1* copy number to predict response to both BLU-222 monotherapy and combination treatment. These data provide a rationale for using BLU-222 in combination with paclitaxel and demonstrate the potential benefit of using specific biomarkers to predict response.

#1960 CFON-026 is a potent non-covalent BTK inhibitor suitable for combination therapy with covalent BTK inhibitors for early eradication of resistance mutations.

J. de Man, M. Muller, J. Uitdehaag, F. van Cauter, S. van Gemert, M. Hoffmann, Y. van Mil, W. Mulder, M. Prinsen, J. Sterrenburg, D. Vu, J. de Wit, E. Ensing, R. Buijsman;
Crossfire Oncology B.V., Oss, Netherlands

Bruton's Tyrosine Kinase (BTK) inhibitor drugs are a mainstay in the treatment of CLL, WM and MCL. They are not curative because of the emergence of BTK inhibitor resistance mutations in as much as 67% of relapsed patients (in CLL) [1]. Frequently observed mutations include BTK^{C481S}, which abrogates covalent binding of irreversible drugs such as acalabrutinib, ibrutinib and zanubrutinib, and BTK^{T474I} and BTK^{V416L} which both abrogate binding of the non-covalent inhibitor drug pirtobrutinib [1, 2]. To combat resistance, third generation BTK inhibitors are needed, which must 1. bind to unique regions in the tumor driving kinases that are not marred by resistance mutations, 2. have sufficient potency for sustained inhibition of BTK signaling, and 3. be sufficiently selective to afford efficacious doses and suitable for a combination regimen. We have developed a platform called Energetically Privileged Ligands (EPriLs), based on a macrocycle scaffold that binds non-covalently in the kinase ATP pocket. Their unique binding mode involves connecting the N-terminal and C-terminal lobes of the general kinase fold in a continuous β-sheet, in this way avoiding hotspots for kinase inhibitor resistance mutations. The potent binding of the macrocycle ensures a very long residence time. Using the EPriL platform, we have developed CFON-026, a next generation non-covalent BTK inhibitor with a covalent-like residence time as demonstrated by surface plasmon resonance (SPR) and cellular washout experiments. The biochemical binding K_D to BTK^{WT}, determined by SPR, is 0.14 nM. CFON-026 binds mutants with K_Ds of 0.4 nM (BTK^{C481S}) and and 1.8 nM (BTK^{T474I}). X-ray crystal structures of CFON-026 bound to BTK^{WT} and BTK^{T474I} confirm the unique binding mode and water network around the active site. CFON-026 inhibits the growth of the BTK dependent cell lines TMD8 and Rec-1 with IC_{50}s of 0.45 nM and 1.7 nM, respectively. CFON-026 is very active on TMD8 variants containing endogenous BTK inhibitor resistance mutations (BTK^{C481S}, BTK^{V416L}, BTK^{T474I} and BTK^{L528W}, IC_{50} range 1-100 nM). CFON-026 has favorable metabolic stability, pharmacokinetic properties, and safety characteristics, and induces complete tumor regression in a TMD8 xenograft model. Since BTK resistance mutations can be detected diagnostically 12-18 months before clinical relapse, CFON-026 could be applied as combination partner to prolong progression free survival on first line BTK inhibitor therapy. Experiments with mixed populations of BTK mutant cell lines, to model a heterogenous tumor, show that CFON-026 can deepen the efficacy of ibrutinib, acalabrutinib and zanubrutinib. In conclusion, CFON-026 is a novel EPriL-based non-covalent BTK inhibitor that could enhance and prolong responses of existing covalent BTK inhibitor therapy. [1] Woyach *et al.*, J Clin Oncol (2017). [2] Wang *et al.*, N. Eng J Med (2022).

#1961 Discovery of a highly potent and brain penetrant fourth generation EGFR tyrosine kinase inhibitor.

s. kumar, j. wang, w. li, w. pan, z. wen, K.-L. yu, G. Zhao, t. yin;
Acerand Therapeutics US, Carmel, IN

Third generation EGFR tyrosine kinase inhibitors (TKIs) such as Osimertinib have emerged as first-line standard of care therapy to treat non-small cell lung cancer (NSCLC) patients with activating EGFR mutations (del19, L858R or T790M). However, within 12 to 18 months following treatment, 15-20% of the patients develop C797S mutation, which drives resistance to these drugs; with the progression of disease brain metastasis is observed in 40-70% of the EGFRm+ NSCLC patients. Here, we report a highly potent and brain penetrant fourth generation EGFR-TKI ACE-34237307, designed to overcome C797S mutation (del19/C797S and L858R/C797S), and common single point mutations (del19 and L858R). ACE-34237307 is also designed to potently inhibit the more prevalent non-canonical EGFR mutations such as G719S and L861Q. ACE-34237307 showed robust anti-proliferative activity against EGFR double mutations in Ba/F3 (EGFR-del19/C797S and EGFR-L858R/C797S) cell lines with IC_{50} values of 0.1 and 0.23 nM, respectively. In phospho-EGFR assay, ACE-34237307 demonstrates over 79-fold selectivity against A431 (EGFR-WT) cell line when compared to PC-9 (EGFR-del 19) cell line. ACE-34237307 is highly brain penetrant with B/P ratio of 2.3 in rat and 1.2 in mouse. It has an excellent pharmacokinetic profile in rat, mouse and dog with good bioavailability, a flat PK curve and reduced C_{max}, which will translate to a better safety profile. The *in vivo* anti-tumor efficacy was evaluated in Osimertinib resistant double mutant Ba/F3-EGFR-del19/C797S and L858R/C797S as well as del19 and L858R single mutant xenograft models. It has been shown that ACE-34237307 at doses of ≥ 0.6 mg/kg induces complete tumor regression or eradication in all tumor models tested. In brain tumor models with Ba/F3 (EGFR-del19/C797S) and PC-9 (EGFR-del19), ACE-34237307 showed complete inhibition or eradication of brain tumors and drastically extended animal survival at ≥ 0.6 mg/kg. In summary, ACE-34237307 is a potent fourth generation EGFR-TKI with high WT selectivity, excellent brain penetration, highly favorable DMPK profile, outstanding *in vivo* efficacy in subcutaneous and brain tumor models and low projected human dose amenable to QD dosing.

#1962 PH009-1, a highly potent, selective and brain-penetrable fourth-generation EGFR-TKI that overcome classic and resistant EGFR mutations in NSCLC.

F. Gao[1], J. Wang[1], B. Liu[1], Y. Wu[2], L. Jing[2], P. Zhang[1], Y. Gao[1], Z. Li[3], Y. Guo[1];
[1]Puhe Biopharma, Beijing, China, [2]Gongkang Bio, Suzhou, China, [3]Shiyu Children Foundation, Beijing, China

Background: Epidermal growth factor receptor (EGFR) inhibitors, especially 3rd Gen inhibitor such as osimertinib (Osi), have become the first line therapy for non-small cell lung cancer (NSCLC) patients with EGFR activating mutations. However, treatments with 3rd Gen EGFR inhibitors lead to occurrence of acquired C797S mutation in 10-24% of patients. Though studies showed that double mutations 19Del/C797S (DC) and L858R/C797S (LC) could be inhibited by 1st Gen EGFR TKIs, appearance of triple mutations 19Del/T790M/C797S (DTC) and L858R/T790M/C797S (LTC) always leads to treatment failure. In recent years, 4th Gen EGFR inhibitors have been developed such as BLU-945 and PH009-1. PH009-1 had been reported on AACR annual meeting 2023.
Methods: Cell activity and selectivity were determined in engineered Ba/F3 cell lines carrying EGFR wild type (WT, stimulated with EGF), 19Del (D), L858R (L), 19Del/T790M (DT), L858R/T790M (LT), DC, LC, DTC and LTC. The *in vivo* anti-tumor efficacy and PK-PD studies were performed in cell or patient derived xenograft (CDX or PDX) cancer models (HCC827, D; Ba/F3, LC; PDX, DTC). Brain penetration capability was tested in mice orally treated with PH009-1 for 7 days. Systemic safety of PH009-1 was evaluated in 28-day repeated dosing toxicity studies in rats and dogs following GLP guidelines.
Results: PH009-1 displayed potent anti-proliferation activity against Ba/F3 cells harboring EGFR mutations (L, D, LC, DC, LT, DT, LTC, DTC) with IC_{50} of 2.4, 1.3, 5.2, 1.2, 1.1, 1.5, 2.8, 1.9 nM, respectively, but had very weak effect on EGFR WT Ba/F3 cells (IC_{50}, 1135 nM), suggesting excellent potency and selectivity. In contrast, though BLU-945 potently inhibited DT, LT, DTC, LTC with IC_{50} less than 5 nM, but its activities on L, D, LC, DC were not strong with IC_{50} of 31.6, 81.2, 46.2, and 52.0 nM. In *in vivo* efficacy studies, PH009-1 at a dose of 20 mg/kg BID led to potent inhibition on tumor growth and EGFR phosphorylation, and tumor regression was observed at higher doses in all tested models. In HCC827 model with 19Del (first line therapy setting), mice were treated for more than 200 days, and one tumor relapsed in BLU-945 group but not in PH009-1 or Osi group. Also, deaths were observed in Osi group, but not with PH009-1. After treated mice with PH009-1 at efficacious dose for 7 days, concentrations in cerebrospinal fluids (CSF) at 0-8 h post final dose were more than enough (≥1.5 fold) to cover IC80 on all tested mutations. In GLP toxicity studies, no unexpected toxicity was observed. In dogs. the highest tested dose was determined as highest non-severely toxic dose (HNSTD) and based on high plasma exposure, wide safety margin was confirmed with PH009-1.
Conclusion: Our data suggested that PH009-1 overcome T790M/C797S resistant mutations, and also have potential to become a potent and safe approach for first line therapy of NSCLC with EGFR mutations.

#1963 BB102, a highly selective and potent reversible-covalent FGFR4 inhibitor effective in multiple xenograft tumor models.

Q. Wang, G. Duan, W. Hua, X. Wei, M. Li, J. Wang, X. Zhang;
BroadenBio Co., Ltd., Beijing, China

Introduction: Fibroblast growth factor receptor 4 (FGFR4) belongs to the FGFR family which interact with fibroblast growth factors (FGFs) to regulate cell proliferation, differentiation and apoptosis. Due to unique structural domain, FGFR4 is specifically bound by FGF19 with high affinity in the presence of co-receptor β-Klotho. Hyperactivated FGF19/FGFR4 signaling, induced by FGF19/FGFR4 overexpression and FGFR4 mutation, was reported to be associated with the growth, metastasis and invasion of various cancer. Thus, FGFR4 is considered as a novel target to treat cancer with hyperactivated FGF19/FGFR4 signaling. Here we report BB102 as a highly selective and potent reversible-covalent FGFR4 inhibitor.

Methods: BB102 was developed through structure-based drug design, and optimized by SAR analysis and medicinal chemistry iteration. Biochemical and cell assays were applied in evaluation of BB102 inhibitory activity. Preclinical studies including pharmacokinetic (PK) and toxicity were performed in rats and dogs. Xenograft tumor models in mice were conducted to demonstrate the *in vivo* efficacy of BB102.

Results: As a reversible-covalent FGFR4 inhibitor, about half compound of BB102 dissociated from FGFR4 kinase within 24 h, which was conducive to overcome the fast re-synthesis rate of FGFR4 (< 2 h) in hepatocellular carcinoma cells. BB102 only inhibited kinase activity of $FGFR4^{WT}$, $FGFR4^{N535K}$ and $FGFR4^{V550L}$ at nanomolar levels in 207 kinase panel screening. BB102 completely blocked the phosphorylation of the downstream protein ERK at 16.7 nM. BB102 exhibited strong inhibitory effects on the cell proliferation *in vitro* and tumor growth in mouse models inoculated with the high expression of both FGF19 and FGFR4, or FGFR4 mutated tumor cells. PK profile of BB102 showed good oral bioavailability (F>70%) with a nearly linear dose-dependent exposure. The compound had no effects on the respiratory and central nervous systems in rats, cardiovascular system in Beagle dogs or hERG liability *in vitro*. In comprehensive safety evaluation, the Severely Toxic Dose in 10% (STD_{10}) in rats was 300 mg/kg/day and the Highest Non-Severely Toxic Dose (HNSTD) in dogs were 100 mg/kg/day.

Conclusion: BB102 is a highly selective and potent reversible-covalent FGFR4 inhibitor with promising efficacy in high expression of both FGF19 and FGFR4, and/or FGFR4 mutated tumor models and good safety in preclinical studies. The phase I study of BB102 is in progress.

#1964 Furmonertinib is a brain-penetrant EGFR TKI highly active in uncommon EGFR mutations, including PACC and exon 20 insertions.

Monique B. Nilsson[1], Zineb Mounir[2], Luna Musib[2], Junqin He[1], Xiaoxing Yu[1], Qing Li[3], Huibing Luo[3], John V. Heymach[1], Jerry Y. Hsu[2], Stuart Lutzker[2], **Xiuning Le**[1], Marcin Kowanetz[2]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]ArriVent Biopharma, Inc., Burlingame, CA,[3]Allist Pharmaceuticals Co., Ltd., Shanghai, China

Background: Furmonertinib (AST2818, furmo) is an oral, highly brain-penetrant, and broadly active mutation-selective EGFR inhibitor against both classical and uncommon EGFR mutations (mts). Furmo has demonstrated promising interim efficacy and safety in non-small cell lung cancer (NSCLC) patients (pts) with EGFR exon 20 insertion (ex20ins) mts (Han et al., 2023). Furmo is currently being studied in a global Phase 3 trial for 1st line pts with ex20ins in NSCLC (FURVENT; NCT05607550) and has received FDA Breakthrough Designation in this pt population. P-loop and αC-helix Compressing (PACC) mts represent another subset of uncommon EGFR mts (Robichaux et al., 2021) that are similar to ex20ins in narrowing the drug binding pocket; include e.g. G719X, S768I, E709X, L747X, V774M; and are found as single or compound EGFR mts. Treatment options for pts with PACC mts remain limited. In this study, we further characterized PACC mts as cancer drivers in NSCLC and evaluated the pre-clinical activity and binding mechanisms of furmo in PACC and ex20ins mts.
Methods: AACR Project GENIE and TEMPUS databases were used for mutation analysis. In vitro potency was determined in Ba/F3 cell lines for 33 PACC and 16 ex20ins mts. In vivo efficacy was conducted in pt-derived xenografts (PDXs). Molecular modeling was performed using MOE software.
Results: PACC prevalence was 2.4% vs. 1.6% for ex20ins and 14% for classical EGFR mts in all NSCLC, corresponding to 10.4% PACC and 7% ex20ins of all EGFR mts. Co-mutation analysis revealed that other oncogenes, such as p53, co-occurred alongside PACC to a similar rate as with ex20ins and classical EGFR mts which further supports the role of PACC mts as a similar cancer driver as other EGFR mts in NSCLC. Ba/F3 cell lines harboring PACC mts were highly sensitive to furmo which showed overall superior potency vs. osimertinib and similar activity to afatinib. When comparing the mutant/wild-type IC50 ratio, furmo showed promising and high activity against single (e.g. G719X) and compound (e.g. ex19del+L718V) PACC mts. IC50 values were similar for PACC as compared to ex20ins mts. Therefore, furmo is predicted to be broadly active across both PACC and ex20ins mutant pt populations at clinically achievable drug levels. Molecular modelling revealed that furmo's interaction with ex20ins and PACC mts is stabilized through hydrogen bonds with specific sites and its proximity to hydrophobic residues including L792 and P794 in the drug binding pocket. To further characterize furmo sensitivity in vivo against PACC mts, studies in PDXs are ongoing to evaluate efficacy, pharmacokinetics and pharmacodynamics and will be presented.
Conclusions: PACC mts are important and prevalent cancer drivers in NSCLC and furmo is similarly active preclinically against both PACC and ex20ins mts. The activity of furmo in EGFR PACC mutant NSCLC is currently being evaluated in a global study FURTHER (NCT05364073).

#1965 3HP-2827-high selective inhibitor of FGFR2, a best-in-class therapy for FGFR2-driven solid tumors.

S. S. Liu-Chen, J. Lin, J. Hu, Y. Liu, W. Zhang, Z. Zhang, Y. Ding, J. Liu, K. Chen, S. Hu;
3H Pharmaceuticals Co., Limited, Shanghai, China

FDA-approved pan-FGFR inhibitors bring encouraging results in solid tumors. However, resistance mechanisms and side effect profiles may limit their clinical utility. We designed 3HP-2827, a highly selective and potent small molecule inhibitor of FGFR2, to treat solid tumors harboring FGFR2 alterations, including amplifications, mutations, and fusions to overcome these limitations. 3HP-2827 inhibits FGFR2 enzyme activity with more than 1623-fold selectivity over FGFR1 and FGFR3. 3HP-2827 inhibits cell proliferation with IC50 <10 nM and 30 nM in FGFR2 amplified and FGFR2-mutant cancer cell lines, respectively. 3HP-2827 demonstrates high kinome selectivity for FGFR2 against a panel of 485 human kinases, resulting in 90.1% inhibition of FGFR2, and no other kinases showed greater than 75% inhibition. 3HP-2827 leads only modest activity at 10 μM against PDE4D2 and LCK in 44 distinct common adverse drug reaction targets, supporting its high degree of safety. 3HP-2827 also demonstrates a dose-dependent inhibition of phosphorylation of FGFR2 and FGFR2 signaling pathway nodes, including ERK and AKT, in the FGFR2-dependent cancer cell line. In vivo, 3HP-2827 demonstrates potent antitumor activity in cell- and patient-derived xenograft mouse models, including FGFR2-amplified gastric cancer, FGFR2-mutant (N549K) endometrial cancer, FGFR2 fusion ICC and gastric cancers. Strikingly, 3HP-2827 demonstrates superior activity in patient-derived ICC and gastric cancer, cell-derived endometrial cancer (CDX) in tumor and pFGFR2 inhibitions. In the ICC PDX model, 3HP-2827 also induces the regression of pemigatinib-resistant tumors. 3HP-2827 is well tolerated in the toxicology studies, and no hyperphosphatemia or tissue mineralization is observed at 150 mg/kg/kg/day in rats and 120 mg/kg/day in dogs. The data support that 3HP-2827, a potential to be a best-in-class selective FGFR2 inhibitor, will be studying clinically at the beginning of 2024.

#1966 The FLT3 tyrosine kinase receptor ITD mutation controls its expression and drug resistance in acute myeloid leukemia.

T. Alqahtani[1], D. MacEwan[2];

[1]King Khalid University, Abha, Saudi Arabia, [2]University of Liverpool, Liverpool, United Kingdom

In approximately 23% of AML patients, Fms-like tyrosine kinase 3 (FLT3) contains a gain-of-function, internal tandem duplication (ITD) mutation that is associated with an unfavourable prognosis. FLT3 is therefore seen as a promising therapeutic avenue for AML and as a result, a more complete understanding of its function and signalling may lead to additional targets and resistance mechanisms being identified. To date, several FLT3 inhibitors including Quizartinib (AC220), a second-generation ITD-selective tyrosine kinase inhibitor, have been developed, but single-agent clinical trials have not been overwhelmingly successful. In most preclinical studies, the inhibitory effects of FLT3 inhibitors are mainly evaluated using mutant-expressing models, however, most AML patients harbour both a wild-type and mutant FLT3 allele as well as presenting with high plasma levels of FLT3 ligand (FLT3L). We hypothesized that FLT3L could act through WT-FLT3 to influence the efficacy of FLT3 inhibitors in cells with heterozygous mutations. In this study, we have examined the role of FLT3 inhibition and FLT3L activation on the cellular localisation and downstream signalling in several AML cell lines, some of which express ITD mutations. We also looked at mechanisms by which FLT3L could impair the efficacy of FLT3 inhibitors. Our results revealed that the majority of FLT3 in the MV4-11 and MOLM-13 cells was intracellular. Inhibition of ITD-FLT3 with quizartinib led to a dramatic relocalisation of FLT3 to the cell surface. This effect was more pronounced in MV4-11 (FLT3ITD/ITD) than the heterozygous MOLM-13 (FLT3ITD/WT) cells that also express WT. This was accompanied by inhibition of ERK, AKT and STAT5 signalling pathways and resulted in cell death. Quizartinib induced cell death only in AML lines expressing FLT3-ITD mutations (MOLM-13 and MV4-11), and this could be antagonised by FLT3 ligand (FLT3L). The largest inhibitory effects were seen in heterozygous cells expressing a mutated and wild-type allele. FLT3 inhibition was associated with downregulation of the anti-apoptotic protein Mcl1 and upregulation of the pro-apoptotic BH3-only protein, Bim. Our experiments indicated that both of these proteins were regulated by both WT and ITD-FLT3 through the MAPK pathway. These results suggest that activation of FLT3 signalling by FLT3L confers resistance to quizartinib through upregulation of Mcl-1 and suppression of Bim expression. Taken together, our data suggest that FLT3 cell surface localisation and expression are controlled by ITD mutations and are key components of drug resistance. The data also suggests a novel therapeutic approach in patients with high plasma FLT3L levels, especially when using type II inhibitors such as quizartinib, is to co-target the MAPK/ERK pathway to abrogate the FLT3Lmediated resistance in FLT3-ITD AML.

#1967 IN-119873, the next-generation allosteric EGFR TKI, a potent and highly selective EGFR L858R for the treatment of osimertinib-resistant NSCLC.

J. Choi, D. Yoon, S. Kim, D. Kim, S. Kang, S.-I. Choi, S. Park, H. Lee, D. Kim, J. Lee, H.-J. Kim, B. Kim;
HK inno.N, Icheon-si, Korea, Republic of

EGFR mutations occur in approximately 50% of Asian patients and 20% of Caucasian patients with non-small cell lung cancer (NSCLC). The EGFR L858R mutation constitutes approximately half of the EGFR-mutated patients, and despite receiving first-line or second-line treatment with the 3rd generation EGFR TKI osimertinib, they continue to exhibit a poor prognosis. According to real-world analysis, the leading resistance mechanism to osimertinib is identified as EGFR C797S mutation. Furthermore, osimertinib is still associated with gastrointestinal and skin toxicity, despite its improved selectivity for EGFR WT compared to 1st-generation EGFR TKIs. Here, we show that IN-119873 can overcome C797S-mediated acquired resistance based on the results obtained by various in vitro and in vivo NSCLC models. IN-119873 binds to an EGFR allosteric site separate from the ATP-binding site with a remarkable preference for highly mutant-selective inhibition. It effectively targets EGFR L858R activating mutations while sparing the inhibition of EGFR WT, which sets it apart from ATP competitive inhibitors. Moreover, oral administration of IN-119873 showed excellent anti-tumor efficacy in a dose-dependent manner in a diverse of osimertinib-resistant CDX and PDX models. IN-119873 also demonstrated favorable blood-brain-barrier penetration with promising intracranial efficacy in the H1975-luc brain metastasis model both mono or in combination with osimertinib. As a selective, orally available, and CNS-penetrable next-generation allosteric EGFR-TKI, IN-119873 is currently undergoing IND-enabling studies and has the potential to demonstrate activity in both first-line and resistance settings, either as a monotherapy or in combination with 3rd generation EGFR TKI.

#1968 Discovery of a highly potent and selective FGFR2 inhibitor for FGFR2-driven cancers.

W. Li, B. Liu, J. Wang, T. Yin, K.-L. Yu, S. Kumar, Z. Wen, G. Zhao, W. Pan;
Acerand Therapeutics US, Carmel, IN

Fibroblast growth factor receptor 2 (FGFR2) is a clinically validated target and frequently altered in many solid tumors. The resulting oncogenic driver alterations often drive multiple solid tumors. Therefore, targeting FGFR2 has broad therapeutic potential. Currently, only pan-FGFR inhibitors are approved for FGFR2-driven intrahepatic cholangiocarcinoma, but not for other FGFR2-driven cancers. Due to the severe on-target toxicity associated with inhibition of FGFR1 and FGFR4, the use of the pan-FGFR inhibitors has been very limited. Thus, developing a selective FGFR2 inhibitor addresses the unmet medical need as the treatment options for FGFR2-altered cancers remain limited. Here we report the discovery and characterization of a highly selective FGFR2 inhibitor, ACE-16229210. This molecule potently inhibits FGFR2 (IC_{50} = 6.2 nM) and exhibits excellent selectivity (>133-fold) over other FGFR1 and FGFR4 in biochemical assays. It also potently (IC_{50} <1 nM) and selectively (≥500-fold) inhibits FGFR2-induced ERK phosphorylation in multiple cancer cell lines harboring FGFR2 fusions, amplification, and mutations, but not those harboring FGFR1, FGFR3, or FGFR4 genetic alterations (IC_{50} > 460 nM). Furthermore, this molecule, when evaluated in a panel of 24 cell lines, demonstrates potent anti-proliferative activity against the cell lines harboring FGFR2, but not FGFR3, and especially FGFR1, or FGFR4 genetic alterations. Thus, ACE-16229210 is a potent and selective FGFR2 inhibitor. Interestingly, it exhibits the most potent activity against gatekeeper and molecular brake mutations followed by fusions, amplification, and activation loop mutations. This molecule shows a robust broad spectrum of antitumor activity with significant tumor regression at low doses (1-10 mg/kg) in several tumor xenograft and PDX models representing the major FGFR2 relevant tumor histologies including gastric, breast, ovarian, and endometrial cancers harboring clinically important FGFR2 driver alterations with a well-defined pharmacokinetic/pharmacodynamic relationship. This molecule also demonstrates strong synergistic effects when combined with irinotecan and fulvestrant in a gastric tumor model and a breast cancer PDX model harboring FGFR2 amplification, respectively. Finally, ACE-16229210 did not significantly affect serum phosphorus levels in animals at the exposure levels that are >100-fold higher than the efficacious AUC, further confirming its excellent selectivity over FGFR1. Taken together, these *in vitro* and *in vivo* studies show that ACE-16229210 is a potent and selective FGFR2 inhibitor with the potential to be developed into a more effective treatment option for multiple cancers harboring FGFR2 oncogenic driver alterations.

#1969 Off-target autophagy inhibition by SHP2 allosteric inhibitors and therapeutic implications for aberrant RAS-driven cancers.

Yiming Miao[1], Yunpeng Bai[1], Jinmin Miao[1], Allison A. Murray[1], Jianping Lin[1], Jiajun Dong[1], Zihan Qu[1], Ruo-Yu Zhang[1], Quyen Nguyen[1], Shaomeng Wang[2], Zhong-Yin Zhang[1]

[1]Purdue University, West Lafayette, IN,[2]The University of Michigan, Ann Arbor, MI

Aberrant activation of RAS-MAPK signaling is common in cancer, and efforts to inhibit pathway components have yielded drugs with promising clinical activities. Unfortunately, treatment-provoked adaptive resistance mechanisms inevitably develop, limiting their therapeutic potential. As a central node essential for receptor tyrosine kinase mediated RAS activation, SHP2 has emerged as an attractive cancer target. Consequently, many SHP2 allosteric inhibitors are now in clinical testing. Here we discovered a previously unrecognized off-target effect associated with SHP2 allosteric inhibitors. We found that these inhibitors accumulate in the lysosome and block autophagic flux in a SHP2-independent manner. We showed that off-target autophagy inhibition by SHP2 allosteric inhibitors contributes to their anti-tumor activity. We also demonstrated that SHP2 allosteric inhibitors harboring this off-target activity not only suppress oncogenic RAS signaling but also overcome drug resistance such as MAPK rebound and protective autophagy in response to RAS-MAPK pathway blockage. Finally, we exemplified a new therapeutic framework that harnesses both the on- and off-target activities of SHP2 allosteric inhibitors for improved treatment of mutant RAS driven and drug resistant malignancies such as pancreatic and colorectal cancers.

#1970 Discovery and characterization of potent and selective HER2 exon20 insertion mutant inhibitors.

H. Nam, S. Jang, J. Jeon, H. Yoo, J. Byun, G. Lee, Y. Lee, Y.-Y. Kim, S. Jeon, Y. Ahn;
Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

Non-small cell lung cancer (NSCLC) is the most common type of lung cancer, accounting for over 85% of all cases. Among NSCLC, approximately 2-4% of patients have mutations in the HER2, a member of the ErbB family of receptor tyrosine kinases and key proliferation driver, with exon 20 insertions making up about 90% of these mutations. HER2 exon mutations can have various alterations, and among them, the most common HER2 mutation is in-frame insertions in exon 20, especially the A775_G776insYVMA insertion/duplication. These mutations can affect the structure and function of the HER2 protein and may contribute to tumor development and growth. HER2 mutations have often shown resistance to EGFR tyrosine kinase inhibitors (TKIs), further highlighting the need for HER2-specific treatments. Also, inhibitors targeting HER2 mutations are selective, meaning they specifically target HER2 alterations without causing toxicities or affecting $EGFR^{WT}$. Therefore, there is a need for the development of selective HER2 exon20 insertion mutant inhibitors. Herein, Hanmi has identified selective HER2 exon20 insertion mutant small molecule inhibitors, designed based on affinity and binding mode starting from a known crystal structure using GLIDE (Schrödinger), and the screening for the viability of cell lines including $HER2^{A775\_G776insYVMA}$, $HER2^{G776delinsVC}$, $HER2^{WT}$ and $EGFR^{WT}$ was investigated. Hanmi's HER2 exon20 insertion mutant inhibitors selectively target mutant HER2 receptor tyrosine domains through shared binding, sparing $EGFR^{WT}$ and minimizing EGFR-related toxicities. With highly selectivity against $EGFR^{WT}$ and desirable pharmacokinetic properties, the Hanmi compounds inhibit HER2 mutant cells and HER2 mutant enzymes. Additionally, the compounds have an oral administration-compatible DMPK profile and demonstrated anti-tumor activity in HER2 mutant and $HER2^{WT}$ tumor xenograft mice. In conclusion, based on our study, Hanmi compounds, a novel HER2 exon20 insertion mutant inhibitors could be suggested as an appropriate therapeutic agent for inhibitory activity against HER2 exon20 insertion mutant NSCLC.

#1971 Olverembatinib, a novel multikinase inhibitor, demonstrates superior antitumor activity in succinate dehydrogenase (SDH)-deficient neoplasms.

Yan Xiong[1], Eric Liang[2], Ping Min[1], Huidan Yu[1], Bingxing Wu[1], Jing Yang[3], Guoqin Zhai[1], Dajun Yang[1], Yifan Zhai[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD,[3]Department of Experimental Research, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China Collaborative Innovation Center for Cancer Medicine, Guangzhou, China

SDH deficiency, characterized by loss of SDHB, occurs in many tumors including paraganglioma, pheochromocytoma, renal, and gastrointestinal stromal tumor (GIST). Olverembatinib, a novel multikinase inhibitor, targets a broad spectrum of kinases and has promising efficacy in SDH-deficient GIST (Qiu H et al. *J Clin Oncol*. 2023). Here, we assessed antitumor effects of olverembatinib in preclinical models of SDH-deficient cancers and explored potential mechanisms of action (MOA). Antiproliferation assays were conducted using CellTiter-Glo®. MOA analyses were performed using western blotting. *In vivo* activity was evaluated using an SDHB knock-out [KO]-derived mouse xenograft model. Olverembatinib had superior antiproliferative activity (vs other approved TKIs) in SDH-deficient cell lines (IC_{50}, 0.129-5.132 μM), including Jurkat clone E6-1 (*SDHB* mutation [mut]), OS-RC-2 (*SDHA* and *SDHB* mut), RKO (*SDHA* mut), and rat pheochromocytoma PC12 cells with SDHB KO (PC12$^{\#}$5F7) (Table 1). In PC12$^{\#}$5F7 cells, olverembatinib decreased HIF-1α, HIF-2α, VEGFA, and FGFR1 protein levels and inhibited phosphorylation of FGFR1, IGF-1R, SRC, AKT, and ERK1/2. Increased cleavage of caspase-3 and PARP-1 was observed, suggesting induction of apoptosis. In PC12$^{\#}$5F7 (SDHB KO)-derived xenograft models, olverembatinib demonstrated dose-dependent antitumor activity at 10 and 20 mg/kg (QOD), with tumor growth inhibition rates of 27.4% and 52.2%, respectively. At 20 mg/kg, olverembatinib showed superior efficacy vs ponatinib (10 mg/kg) and rogaratinib (50 mg/kg). Results from western blot analyses were similar in both tumor tissues and cell lines. Olverembatinib exerts promising antitumor effects in SDH-deficient neoplasms and can modulate multiple signal pathways involved in angiogenesis, apoptosis, proliferation, and survival. The results provide a preclinical rationale for future development of olverembatinib in SDH-deficient cancers.

#1972 Preclinical activity of the type II RAF inhibitor tovorafenib in tumor models harboring either a *BRAF* fusion or a *NF1*-LOF mutation.

S. Rastogi, S. Perino, M. Lal-Nag, Y. Wang, S. C. Blackman, E. Venetsanakos;
Day One Biopharmaceuticals, Brisbane, CA

Genomic alterations and dysregulation of the MAPK pathway have been described in many different types of cancers. BRAF V600 point mutations and *BRAF* fusions, which are found in both pediatric and adult cancers, are oncogenic drivers that drive constitutive activation of the RAF pathway (Jones 2009, Yaeger 2019). Neurofibromatosis 1 (*NF1*) loss-of-function (LOF) mutations, which occur in many cancer types, result in decreased neurofibromin GAP function, thus activating RAS (Basu 1992). Tovorafenib is an investigational, selective, CNS-penetrant, small molecule type II RAF inhibitor which inhibits both RAF monomers and dimers and has been shown preclinically to impact the *KIAA1549*::*BRAF* fusion (Sun 2017). In this study, the impact of tovorafenib alone or in combination with MEK inhibitor, pimasertib, was explored in adult or pediatric tumor models harboring *BRAF* fusions or *NF1*-LOF mutations. At clinically relevant doses, tovorafenib treatment resulted in tumor regression in an *AGK*::*BRAF* fusion melanoma patient-derived xenograft (PDX) model *in vivo*. In contrast, little anti-tumor activity was observed in response to tovorafenib *in vivo* in two tumor models harboring *NF1*-LOF mutations. Ongoing PK-PD studies in both the *AGK*::*BRAF* fusion model and the *NF1*-LOF models will assess the extent and duration of target inhibition. *In vitro*, anti-proliferative activity of tovorafenib was also evaluated in *NF1*-LOF mutant tumor cell lines or PDX models of different tumor types, including melanoma, lung and malignant peripheral nerve sheath tumor (MPNST). While tovorafenib was potent in the BRAF V600E tumor cell line, little activity was observed in the *NF1*-LOF tumor cell lines. Modulation of phosphorylated-ERK (pERK) was also assessed. At very low concentrations, modest induction of pERK was observed in the *NF1*-LOF tumor cell lines, with inhibition at higher concentrations. *In vitro* combination studies were conducted using pimasertib and tovorafenib, or a tool compound. Synergy was observed in a *NF1*-LOF embryonal rhabdomyosarcoma PDX model *ex vivo* and a *NF1*-LOF MPNST cell line *in vitro*, suggesting that vertical pathway inhibition is impactful in the *NF1*-LOF mutant setting. Tovorafenib is currently being evaluated as a monotherapy in relapsed or progressive pediatric low-grade glioma (pLGG) harboring *RAF* alterations (NCT04775485) and in combination with pimasertib in patients ≥12 years of age with recurrent, progressive, or refractory solid tumors harboring MAPK pathway alterations (NCT04985604). Ongoing preclinical translational work will continue to explore potential biomarker-defined tumor indications for these agents.

#1973 Discovery of the first-in-class SHP1 covalent inhibitor for cancer immunotherapy.

Z. Qu, F. Nguele Meke, Z. Zhang, Y. Bai, A. D. Krabill, C. S. Muli, B. A. Jassim, J. Dong, J. Li, N. Yuyen, A. W. Tao, D. T. Trader, Z.-Y. Zhang;
Purdue University, West Lafayette, IN

Cancer immunotherapy refers to the approach leveraging patients' immune system against tumor, which has gained tremendous progress hallmarked by immune checkpoint blockade and adoptive cell therapies. However, contemporary strategies suffer from limited responses, adverse side effects, and low tissue penetration due to utilization of macromolecules, calling for more efficacious and safer alternative strategies. SHP1 is a protein tyrosine phosphatase (PTP) primarily expressed in hematopoietic cells and has been shown to negatively regulate immune responses in T cells and natural killer (NK) cells, and SHP1 deletion in these cells has shown to promote their anti-tumor functions. Recent studies also demonstrated that inducible SHP1 knockout inhibited tumor growth *in vivo* through immune activation. Although presented as an attractive target, no high-quality small molecule inhibitors have been reported for SHP1 due to its undruggable nature. Through high-throughput screening and extensive medicinal chemistry, we have acquired the first-in-class SHP1 covalent inhibitor M029, which shows >25-fold selectivity against SHP2, its closest analogues and >60-fold selectivity against other PTPs and cysteine-based proteins. Further proteomics studies reveal that M029 is superiorly selective for SHP1 *in cellulo*. Additionally, M029 is stable in 100-fold excessive glutathione with a half-life of ≥35 hours and non-toxic up to 100 μM to healthy cells, such high stability was also reflected by its oral bioavailability with a F% of 10%. M029 treatment significantly activated T cell receptor signaling in T cells and NK cells killing effects *in vitro*. Furthermore, oral dosage of M029 significantly delayed tumor progression in mice bearing MC38 tumors through enhanced T cell and NK cell infiltration and activation and prolonging of T cell exhaustion. To validate that the compound acted through immune activation, we dosed the mice with anti-$CD8^{\pm}$ or anti-NK1.1 during M029 treatment, both of which abolished the compound efficacy, corroborating with its mechanism of action. Meanwhile, to assess the compound safety, we dosed the mice up to 100 mg/kg for 8 days, where no significant body weight change or cytokine storm were observed. Collectively, we have developed the first SHP1 covalent inhibitor with high selectivity and strong anti-tumor efficacy. This study is the first characterization of pharmacological SHP1 inhibition as cancer immunotherapy and solidified its potential as an immunotherapeutic target. The development of M029 will also enlighten drug discovery strategies against SHP1 or other undruggable PTPs.

#1974 Discovery of TRX-211-399, a potent, CNS-penetrant, highly selective inhibitor of EGFR exon 20 insertion mutations.

K. Chun, S. Lim, J. Lee, S. Choi, S. Kim, Y. Choi, A. Park, B. Kim, Y. Park, E. Choi, S. Lee, K. Lee;
Therapex, Seoul, Korea, Republic of

Lung cancer is the leading cause of cancer-related deaths worldwide, accounting for approximately 2 million new cases and 1.8 million deaths annually. Various types of EGFR-activating mutations are one of the most important oncogenic drivers in non-small cell lung cancer (NSCLC). Among NSCLC patients with EGFR mutations, 5-10% of patients have EGFR exon 20 insertion (ex20ins) mutations that are insensitive to clinically available EGFR tyrosine kinase inhibitors (TKIs). Recently, as mobocertinib (EXKIVITY®) failed to improve progression-free survival in Phase 3 clinical trial, there remains a high unmet medical need to develop new drugs with wider therapeutic window to treat NSCLC harboring EGFR ex20ins mutations. Herein, we report a novel EGFR-TKI, TRX-211-399, specifically designed to target ex20ins mutations. TRX-211-399 potently inhibited the proliferation of not only Ba/F3 cells overexpressing near-loop (A767dupASV, S768dupSVD) and far-loop (H773insNPH, H773dupH) mutations but also patient-derived NSCLC cell line. In particular, TRX-211-399 demonstrated high selectivity against wild-type EGFR. With favorable DMPK profiles, once-daily oral administration of TRX-211-399 showed significant tumor regression in multiple Ba/F3 xenograft models carrying different EGFR exon20ins mutations. Furthermore, in a PC-9-luc cell intracranial xenograft model, TRX-211-399 induced substantial anti-tumor effects and prolonged survival without body weight loss. TRX-211-399 is currently undergoing further preclinical evaluation as a potential candidate for clinical development for patients with EGFR exon20ins mutations.

#1975 Discovery of I-1000233, a potent, selective and brain permeable SHP2 allosteric inhibitor.

Francesca Puca, Danilo Fabbrini, Alina Ciammaichella, Antonino Missineo, Monica Bisbocci, Martina Nibbio, Annalise Di Marco, Claudia Apicella, Fabrizio Colaceci, Romina Sasso, Daniela Natale, Francesco Scalabri, Cristina Alli, Vincenzo Pucci, Christian Montalbetti, Alessia Petrocchi, Alessandro Carugo, Carlo Toniatti

IRBM Spa, Pomezia (RM), Italy

Background: SHP2 (Src homology region 2-containing protein tyrosine phosphatase 2) is a target of interest for cancer therapy due to its key role in the regulation of RAS/MAPK signal transduction downstream of Receptor Tyrosine Kinases (RTKs). We report here the identification of I-1000233, a novel, highly potent, orally available and brain permeable SHP2 allosteric inhibitor, with potential for the treatment of tumors with dysregulated RTK/RAS/ERK signaling pathways.

Material and Methods: High-throughput biological, biochemical and pharmacodynamic (PD) assays were used to inform Structure Activity Relationship studies which led to the identification of a chemical series of potent SHP2 inhibitors. Iterative optimization of physicochemical and pharmacological properties resulted in the identification of I-1000233, an orally available SHP2 inhibitor that showed excellent drug-like properties in preclinical studies.

Results: I-1000233 is a potent inhibitor of the SHP2 enzyme in vitro (IC_{50} = 2 nM) with an exceptionally long residence time on the target. When tested in cell lines, it exhibits significant anti-proliferation activity against brain tumor cells and multiple RAS or EGFR mutant models. It strongly inhibits pERK, a downstream marker of MAPK pathway activity, in a dose dependent manner. Further, in vivo preclinical data confirmed that I-1000233 penetrates the BBB and shows anti-tumor activity, supporting its potential in the treatment of CNS and brain-metastasized tumors.

Conclusions: I-1000233 is a potent, selective and orally available SHP2 inhibitor with potential for once-a-day dosing and its brain permeability in humans makes it a promising therapeutic agent against SHP2i responsive brain tumors and metastases.

#1976 Targeting metabolism in non-small cell lung cancer (NSCLC) with the novel multitarget small molecule PI3K-CDK4/6-CDK9 inhibitor LCI139.

Cody C. McHale[1], Anna V. Ivanina Foureau[2], Hailey L. Dryden[1], Krishnaiah Maddeboina[1], Dhananjaya Pal[1], Bharath Yada[1], Page Mangum Arditti[1], Fei Guo[2], Kathryn F. Mileham[3], David M. Foureau[2], Donald L. Durden[1]

[1]Molecular Targeted Therapeutics Laboratory, Atrium Health Levine Cancer, Charlotte, NC, [2]Translational Research, Atrium Health Levine Cancer, Charlotte, NC, [3]Section of Thoracic Medical Oncology, Atrium Health Levine Cancer, Charlotte, NC

Introduction: NSCLC is a heterogenous disease estimated to cause the majority of all 2023 United States cancer-related deaths. There is no broadly applicable targeted therapy to treat lung cancer and those FDA-approved drugs target patient-specific biomarker mutations such as *EGFR*, *ALK*, *ROS1*, etc. Targeting multiple oncogenic pathways to induce synthetic lethality is an attractive strategy for anticancer therapeutic development. Here, we describe the effects of novel multitarget small molecule PI3K-CDK4/6-CDK9 inhibitor LCI139 on a panel of human NSCLC cells of mixed histologic and mutational backgrounds.

Methods: LCI139 specific target inhibition was assessed by cell-free kinase hotspot/lipid kinase assay and KINOMEscan. LCI139 (0.001-10μM) was screened against NCI-H1975, NCI-H1703, NCI-H1373, NCI-H1781 and NCI-H226 human cell lines; IC_{50} values determined by CellTiter-Glo/WST-8 Assay and apoptotic rate by flow cytometry (Annexin V/7-AAD). Metabolomic profile of representative LCI139 sensitive ($LCI139^S$) and resistant ($LCI139^R$) NSCLC cells was evaluated by western blot.

Results: LCI139 is a highly potent inhibitor of PI3K-CDK4/6-CDK9: 0.070μM (PI3Kα), 0.461μM (PI3Kγ), 0.214μM (PI3Kδ), 0.0015μM (CDK4), 0.0036μM (CDK6), 0.000039μM (CDK9). NCI-H1703, NCI-H226, NCI-H1373 and NCI-H1975 were highly sensitive to LCI139 (0.68, 3.2, 35.27 and 342.4nM IC_{50}), while NCI-H1781 remained insensitive up to 10μM. Confirming those findings, LCI139 promoted robust apoptotic cell death in NCI-H1703, NCI-H226, NCI-H1373 and NCI-H1975 but not NCI-H1781. $LCI139^S$ H1703 cells displayed increased bioenergetic reliance on oxidative phosphorylation (OXPHOS), compared with the $LCI139^R$ H1781 cells. In the $LCI139^S$ H1703 cells, LCI139 treatment decreased expression of all mitochondrial complexes (I-IV) and glycolytic enzymes (HK2, GAPDH, LDHA). Conversely, LCI139 treatment of $LCI139^R$ H1781 cells only inhibited expression of mitochondrial complexes II and III, but increased glucose uptake (Glut1) and retained expression of other glycolytic enzymes.

Conclusions: Triple PI3K-CDK4/6-CDK9 inhibitor LCI139 is nanomolar potent against several NSCLC cells lines of mixed histologic and mutational backgrounds. NSCLC cells that are most reliant on OXPHOS to generate ATP, a classic metabolic adaptation to chemotherapy, appear to be most sensitive to LCI139. Taken together, these data support further drug characterization and mechanistic dissection to assess LCI139's potential clinical utility in treating advanced stage and recurrent NSCLC.

#1977 ACR-2316: A potentially first-in-class, potent, selective WEE1/PKMYT1 inhibitor rationally designed for superior single agent activity through synergistic disruption of cell cycle checkpoints.

C. Wigerup[1], H. Nilsson[1], L. Shi[2], J. Jung[2], J. Baddour-Sousounis[2], R. Cornelius[1], N. Lipjankic[1], U. Muralitharan[1], V. Siino[1], I. Arribas Diez[1], Z. Best[2], M. Pasetto[1], W. Dahlberg[2], S. Rafiei[2], P. Lombardo[2], M. E. Jakobsson[1], R. Improgo[2], C. Scherer[2], J. van Duzer[2], D. A. Proia[2], K. Masson[2], P. Blume-Jensen[2]; [1]Acrivon Therapeutics, Lund, Sweden, [2]Acrivon Therapeutics, Watertown, MA

WEE1 and PKMYT1 kinases play essential roles in cell cycle checkpoints and DNA damage response. Genetic interaction has been documented between WEE1 and PKMYT1, and clinical trials have reported clinical activity with inhibitors of WEE1 (adavosertib, azenosertib) and PKMYT1 (lunresertib). Here, we report the discovery and characterization of ACR-2316, a dual inhibitor of WEE1 and PKMYT1 specifically designed for optimal selectivity through co-crystallography and superior single agent activity uniquely enabled by Acrivon Predictive Precision Proteomics (AP3). Mass spectrometry-based AP3 profiling was conducted across several novel WEE1 and PKMYT1 inhibitor leads generated through co-crystallography-based rational drug design. Selective leads originating from one series were further optimized using AP3 for biological structure-activity relationship analysis. AP3 profiling revealed WEE1 inhibitor-upregulated phosphorylation sites across a subset of phosphoproteins that were oppositely regulated (quenched) by PKMYT1 inhibitors. Consensus sites for these included CDK1 T14, a direct PKMYT1 phosphorylation site, as well as CHK1 S296. A particular lead compound, ACR-2316, demonstrated a desirable potent, balanced ratio of cellular WEE1 (IC50 = 2 nM, IC90 = 10 nM) and PKMYT1 (IC20 = 44 nM) inhibition resulting in superior activation of the mitotic kinases CDK1, CDK2, and PLK1 compared to adavosertib and lunresertib, based on annotated kinase substrate relationships. ACR-2316 is more selective than adavosertib, azenosertib, and lunresertib based on >200 kinases profiled by AP3 and 468 kinases assessed by KINOMEscan. Cell cycle analyses demonstrated a drastic ACR-2316-induced S-G2/M accumulation qualitatively distinct from adavosertib or lunresertib. In a 19-cancer cell line proliferation assay (CellTiter-Glo), ACR-2316 demonstrated greater potency in all cell lines tested compared to adavosertib and lunresertib (mean IC50 = 70, 252 and 364 nM, respectively). Superior anti-cancer activity of ACR-2316 was observed in 12 ovarian cancer patient-derived xenograft models tested ex vivo (CellTiter-Glo 3D) compared to azenosertib and lunresertib (mean IC50 = 9, 248 and 1620 nM, respectively). Across human tumor xenograft mouse models, oral administration of ACR-2316 demonstrated superior, durable, dose-dependent efficacy compared to azenosertib and lunresertib and was well tolerated at all doses. Complete responses observed with ACR-2316 were associated with strong WEE1 and intermediate PKMYT1 inhibition in tumors. In conclusion, ACR-2316 is a potent, selective dual WEE1/PKMYT1 inhibitor with superior single-agent activity compared to clinical WEE1 or PKMYT1 inhibitors. ACR-2316 is progressing through IND-enabling studies in preparation for clinical monotherapy development.

#1978 The combination of neratinib with sotorasib is synergistic in models of HER2-amplified and KRAS^{G12C}-mutated cancer.

M. E. Castel[1], N. T. Conlon[1], N. Walsh[1], G. F. Bischof[2], J. P. Crown[3], D. M. Collins[1];
[1]Dublin City University, Dublin, Ireland, [2]Puma Biotechnology, Inc., Los Angeles, CA, [3]St Vincent's University Hospital, Dublin, Ireland

Introduction: Constitutive activation of KRAS through gain-of-function mutations, such as KRAS^{G12C}, is thought to reduce sensitivity to HER-targeted TKIs like neratinib (N), lapatinib (L) and tucatinib (T). Sotorasib (S) is a KRAS^{G12C} specific inhibitor clinically approved for the treatment of advanced KRAS^{G12C}-mutated non-small cell lung cancer. One identified resistance mechanism to sotorasib is the increase of multiple phosphorylated receptor tyrosine kinases, including EGFR and HER2. The objective of this study was to assess the *in vitro* efficacy of the single agents N, L, T and S, and the combination of N and S in HER2-amplified, KRAS^{G12C}-mutated cancer cell lines.

Methods: The antiproliferative effects of N, L, T and S were assessed in the HER2-amplified and KRAS^{G12C}-mutated KYSE-410 (esophageal) and NCI-H2030 (lung) cancer cell lines, and KRAS^{G12C}-mutated MiaPaca-2 (pancreatic) cell line by 5-day acid phosphatase assay. IC_{50} values were calculated using CalcuSyn software. To assess the synergy between N and S, matrix assays were performed and analyzed using Combenefit software. To further determine the efficacy of the drugs, changes in signaling pathways were assessed by Western blotting.

Results: N displayed nanomolar IC_{50} values (< 100 nM) in all three cell lines, while nanomolar IC_{50} values with L and T were only achieved in KYSE-410 (IC_{50} = 426.84 nM and IC_{50} = 363.38 nM respectively). S was most potent in MiaPaca-2 (IC_{50} = 6.04 nM), followed by NCI-H2030 (IC_{50} = 270.60 nM) and KYSE-410 (IC_{50} = 5.46 µM). Matrix assays showed that NS was broadly additive in MiaPaca-2 cells, and synergistic in both NCI-H2030 and KYSE-410 cell lines. N and NS numerically decreased HER2 levels compared to control in NCI-H2030 after 24h of treatment (6.4-fold, $p = 0.58$ and 2.5-fold, $p = 0.79$ respectively) but not in KYSE-410. KRAS levels were significantly increased (1.89-fold, $p \leq 0.05$) after treatment with NS in NCI-H2030. No significant effects were observed on the activation of HER2 and EGFR in either cell line at 24h. In NCI-H2030, NS had a significantly stronger inhibitory effect on pERK compared to N ($p \leq 0.0001$) and S ($p = 0.012$) alone. In KYSE-410, pERK levels were also slightly decreased with NS, but not significantly different from N ($p = 0.12$). However, pAkt levels in KYSE-410 were significantly reduced by N (1.3-fold, $p = 0.009$) and NS (1.7-fold, $p \leq 0.0001$) compared to control, with NS showing a significantly greater decrease than N ($p = 0.026$). It thus appears that the synergy between N and S occurs through a stronger inhibition of ERK activity in NCI-H2030, while it occurs through a stronger inhibition of Akt activity in KYSE-410.

Conclusion: NS is additive or synergistic in the three KRAS^{G12C}-mutated cancer cell lines examined. Further work is planned to investigate the basis of the synergy observed.

#1979 Preclinical characterization of NVL-330, a selective and brain penetrant HER2 tyrosine kinase inhibitor with broad activity on HER2 oncogenic alterations.

Y. Sun[1], K. L. Andrews[1], A. Tangpeerachaikul[1], T. M. Nguyen[1], B. Gerard[1], N. E. Kohl[2], J. C. Horan[1], H. E. Pelish[1];
[1]Nuvalent, Cambridge, MA, [2]Kohl consulting, Wellesley, MA

Background: Oncogenic mutations and gene amplifications in the HER2 receptor tyrosine kinase are detected in approximately 2 - 4% and 1 - 5%, respectively, of non-small cell lung cancers (NSCLC) in the US. Exon 20 insertion mutations (exon20ins) are the predominant HER2 mutations in NSCLC, and ~50% of HER2-mutant metastatic NSCLC patients develop brain metastases. The antibody drug conjugate trastuzumab deruxtecan (T-DXd) has received FDA accelerated approval for HER2-mutant NSCLC, but currently there are no approved tyrosine kinase inhibitors (TKIs) for this indication. NVL-330 is a novel, brain-penetrant, HER2-selective TKI, designed to address the combined medical need of treating HER2-mutant tumors, avoiding treatment related adverse events due to off-target inhibition of wild-type EGFR, and treating brain metastases. Here we characterized the preclinical pharmacological profile of NVL-330 in comparison to other investigational HER2-targeting TKIs and T-DXd.
Methods: TKIs were profiled in cellular phospho-HER2, phospho-EGFR, and viability assays. *In vivo* antitumor studies were performed in nude mice with HER2-altered subcutaneous or intracranial tumors. T-DXd concentration was measured in an ELISA assay. The unbound brain-to-plasma partitioning ratio (Kp,uu) was determined at one hour after oral 10 mg/kg dosing in Wistar Han rats.
Results: NVL-330 broadly inhibited HER2 oncogenic alterations, including amplified wild-type HER2, HER2 exon20ins and non-exon20ins mutants, with potency and selectivity over wild-type EGFR comparable to investigational HER2-selective TKI zongertinib. By contrast, NVL-330 had a higher Kp,uu than zongertinib in rats. In a patient-derived xenograft model harboring HER2 exon20ins, treatment with NVL-330 suppressed phospho-HER2 and downstream signaling, increased total HER2 and caused dose-dependent tumor regression at well tolerated doses. In the $HER2^{amp}$ NCI-N87 subcutaneous xenograft model, oral administration of 30 mg/kg NVL-330 twice per day induced tumor regression, similar to that achieved by intravenous administration of 10 mg/kg T-DXd once every three weeks, a human-relevant dose in mice. By comparison, in the intracranial setting with the same tumor model and dosing regimens, NVL-330 induced tumor regression, whereas T-DXd provided tumor stasis. Pharmacokinetic analysis in these intracranial tumor bearing mice indicated that NVL-330 had significantly higher brain penetrance than T-DXd.
Conclusions: NVL-330 was broadly and selectively active against HER2 oncogenic alterations *in vitro* and *in vivo*, and demonstrated brain penetrance in rodents exceeding that of HER2 investigational TKI zongertinib and T-DXd. This preclinical profile supports the potential for NVL-330 to address a medical need for patients with HER2-driven cancers, including those with brain metastases.

#1980 Validation of a novel Type II HER2 inhibitor through preclinical studies across various cancer models.

L. Kulyk, K. Chen, I. Botrous, C. Zhao, C. Zhao, M. Maestre, S. Wright, J. Dennis, J. Park, A. Adams, W. Derricotte, S. Yost, M. L. Anderson, F. Manby, T. Miller, C. Zhang, L. Gomez, Z. Huang;
Iambic Therapeutics, Inc., San Diego, CA

HER2 activation through amplification, overexpression or mutation drives many types of human cancers, and has been the target of several therapeutic approaches. The demonstration of clinical benefit of available pan-ERBB and HER2 inhibitors has been hampered by the dose-limiting side effects from their collateral or residual EGFR inhibition. Here we present IAM1363 (also known as ENT-H1), a highly potent and selective irreversible inhibitor of both HER2 wild-type and HER2 oncogenic mutants. IAM1363 binds to HER2 in a type II DFG-out conformation, the only example reported to date for this target. This binding mechanism underlies its strong interactions with HER2, including N-terminally truncated HER2 (p95HER2) and HER2 kinase domain mutants, with cellular IC50s in the low nanomolar range, while sparing WT EGFR. Oral administration of IAM1363 in mice led to tumor regression (TR) in a diverse set of HER2-driven tumor models at levels well below the maximum tolerated dose (MTD). Importantly, strong in vivo efficacy was observed in tumor models that exhibited resistance to the existing HER2-targeting agents. For example, in a p95HER2 xenograft model, IAM1363 caused significant TR, including complete responses, at 100 mg/kg dose, whereas tucatinib achieved at best tumor stasis at MTD and T-DXd showed marginal effect. Besides HER2 truncation, co-occurring EGFR and other receptor tyrosine kinase (RTK) amplification or overexpression can also lead to resistance to HER2-directed treatments. IAM1363 was tested in xenograft models using HER2-amplified/EGFR-high cell lines HCC1954 and SKOV3, and demonstrated robust TRs. Even more strikingly, IAM1363 led to TR in the HCC827 human lung cancer xenograft model with mid-level HER2, and high levels of EGFR and MET expression. The resistance combatting effect of IAM1363 goes beyond co-occurring RTK-mediated mechanism as IAM1363 also showed dose-dependent TR in KYSE410, a human esophageal squamous cancer xenograft model that harbors the KRAS G12C mutation and HER2 amplification. Taken together, IAM1363 represents a promising clinical candidate for the treatment of HER2-driven tumors. Its unique binding mechanism and potent pan-HER2 activity overcome multiple resistance mechanisms, and its strong EGFR avoidance widens the safety margin. Additionally, IAM1363 was found to be consistently enriched in xenograft tumors that had moderate to high HER2 expression levels, and those with HER2 activating mutations. This distinctive pharmacokinetic property facilitates optimal target engagement in tumors, including those occurring in the brain, while minimizing potential systemic side effects.

#1981 Profiling of protein interactome with cysteine-reactive libraries led to the discovery of EML4ALK dimerizers.

Diane Yang, Stefan Harry, Elizabeth Codd, Stefan T. Kaluziak, Alexander D. Carlin, Edwin Zhang, Zavontae Oppong-Holmes, Wenxin Yang, Abigail Smith, Dawn Mitchell, Mariko Hara, Siwen Zhang, Maristela Onozato, Liron Bar-Peled, Anthony J. Iafrate

Massachusetts General Hospital, Boston, MA

Cysteine covalent binders enable direct interactions with previously deemed undruggable protein targets, revolutionizing cancer therapeutics development. The primary focus has been on tailoring single-warhead compounds to target specific cysteine residues within the functional domains of target proteins. However, the biochemical properties including dimerization, induced conformational changes, and interactome disruption have been underexplored, presenting an ongoing limitation in current drug discovery approaches. In this study, we generated a library of 32 cysteine-reactive warhead compounds using various combinations of scaffolds and warheads to represent diverse reactivities. A combinatory assay approach, including cysteine druggability mapping (CDM) to discover reactive residues and SDS-PAGE fractionation assays to identify disrupted protein interaction events, was employed. Characterization of the library revealed distinct reactive cysteines and dimerization profiles among the 32 unique compounds. Compound 1C9, identified as a lead compound, demonstrated significant dimerization of EML4, a common fusion gene partner in lung cancer. Using the EML4ALK fusion gene as a proof of concept, we explored potential mechanisms underlying the compound-induced dimerization of EML4. Subsequent structure-activity relationship (SAR) studies and screening of 70 additional compounds were conducted to optimize ALK dimerization and minimize off-target effects. The enhanced compound disrupted the ALK cellular signaling pathways AKT and ERK upon dimerization of the EML4ALK fusion gene. Additionally, we discovered that covalent dimerization induced EML4ALK degradation without requiring a ubiquitin ligase like a PROTAC. In conclusion, our work has uncovered a novel class of cysteine covalent binders, which we believe are valuable tools to modulate protein-protein interactions in previously undruggable proteins in cancer. This discovery holds significant therapeutic potential for future drug development.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Drug Resistance 1
Poster Session

#1985 Ablation of adenylosuccinate lyase retarded the cell proliferation and induces mitochondrial dysfunction in endocrine therapy resistant breast cancer cells.

A. Yadav, L. Jin, R. Clarke, S. Sengupta;
The Hormel Institute, University of Minnesota, Austin, MN

Approximately 75% of breast tumors express estrogen receptors (ER+); recurrent ER+ breast cancer is generally incurable. Endocrine therapy (ET) is the mainstay of treatment for ER+ breast cancer and works by targeting either ER activity (Tamoxifen or Fulvestrant) or availability of its ligand estrogen (Letrozole, Exemestane). Unfortunately, endocrine therapies are limited by the emergence of resistance; resistance to endocrine therapies (ET) remains a significant clinical challenge. We have explored the role of adenylosuccinate lyase (ADSL), an enzyme of the *de-novo* purine biosynthesis pathway, in ET-resistant breast cancer cells. Protein expression of ADSL was significantly higher in two different ET-resistant cells (LCC9 and T47D-4HT) when compared with their respective parental ET-sensitive cells (MCF-7 and T47D). siRNA mediated ablation of ADSL in LCC9 and T47D-4HT cells blocked cell proliferation and both colony and spheroid formation. Depletion of ADSL in LCC9 cells obstructed cell cycle progression from G1 to S phase and elevated the protein expression of cyclin D1/D3, CDK2/4, and cyclin E. In T47D-4HT cells, ADSL depletion led to an accumulation of cells in S-phase with reduced protein expression of cyclin D1. Notably, ADSL ablation in LCC9 cells lead to DNA replication stress, resulting in activation (phosphorylation) of ataxia-telangiectasia-mutated-and-Rad3-related kinase (ATR) and its key downstream effector checkpoint kinase 1 (Chk1), which further limited the phosphatase activity of cdc25A leading to deactivation (phosphorylation) of Cyclin-Dependent Kinase 2 (CDK2). ADSL knockdown reduced the mitochondrial membrane potential and impaired the oxygen consumption (OCR) and extracellular acidification (ECAR) rates in both LCC9 and T47D-4HT cells. Of
note, addition of AICAR to ADSL-depleted LCC9 cells significantly increased cell proliferation, colony formation, and restored mitochondrial membrane potential. RNA sequencing data revealed the effect of ADSL depletion on enrichment of different pathways in LCC9 and TH47D-4HT cells. Importantly, p53 signaling was significantly enriched in LCC9 cells but not in T47D-4HT cells after ADSL knockdown (T47D cells have a mutated p53 gene). ER+ breast cancer patients treated with ET showed high ADSL expression that is associated with poor recurrence-free survival. In summary, our findings indicate that ADSL-mediated *de novo* purine synthesis is crucial for cell proliferation. Therefore, targeting ADSL may be a novel therapeutic approach for ER, ET-resistant breast cancer.

#1986 Acquisition of carboplatin resistance corresponds with reduced sacituzumab govitecan efficacy in triple negative breast cancer patient derived xenografts.

C. J. Walker, J. E. Altman, E. K. Zboril, R. K. Myrick, N. S. Hairr, D. C. Boyd, B. Hu, M. G. Dozmorov, J. Harrell;
Virginia Commonwealth University, Richmond, VA

Sacituzumab Govitecan (SG) is an antibody drug conjugate that targets the epithelial glycoprotein Trop-2. SG has been approved for the treatment of patients with triple negative breast cancer (TNBC) or estrogen receptor positive (ER+) breast cancer after they have received at least two previous systemic treatments. The objectives of this study were to identify biomarkers of SG response using breast cancer patient-derived xenografts (PDXs) and determine if SG efficacy changes when cells become carboplatin resistant (CR). Analysis of transcriptomic and proteomic levels of Trop2 using bulk RNAseq, scRNA-seq, and tandem mass tag spectrometry found that overall ER+ PDXs had significantly lower RNA (p-value less than 0.001) and protein (p-value less than 0.001) expression of Trop-2 than TNBC PDXs. Immunohistochemical assessment of 42 TNBC and 27 ER+ patient tumor samples identified variation in Trop-2 expression; within each cohort, expression varied from highly positive to completely negative. To test the association of Trop-2 with drug responsiveness, cells from 19 different PDXs were cultured in vitro and administered increasing doses of SG. TNBC cells were more responsive to SG treatments compared to ER+ cells (p-value equaling 0.005). Correlation analysis identified a positive relationship of drug response with protein abundance which was stronger in TNBC samples. In vivo studies with 7 TNBC PDXs found that over 70% were highly susceptible to SG treatments, with some tumors being completely eradicated or exhibiting a total inhibition of tumor growth which resulted in a long-term durable response after 10 weeks of treatment. In vivo across all the PDXs, Trop-2 expression alone did not strongly correlate with SG treatment success. Interestingly, CR sublines derived from 2 carboplatin sensitive PDXs were significantly less responsive to SG than their parental PDXs (p-value less than 0.001). These two CR sublines were also significantly less sensitive to the majority of 555 other drugs identified by the NCI compared to their parental PDXs. Ongoing studies are defining mechanisms of reduced SG efficacy in CR models. Overall, these studies find that SG is highly effective in many TNBC PDX models and should be utilized earlier in treatment protocols, especially in metastatic patients.

#1987 PARP inhibitor (PARPi) rechallenge shows differential sensitivity in PARPi olaparib-resistant *BRCA1*-mutated (BRCA1m) high-grade serous ovarian cancer (HGSC).

Chi-Ting Shih, Tzu-Ting Huang, Jayakumar R. Nair, Jung-Min Lee

National Institutes of Health (NIH), Bethesda, MD

Background: PARPis have changed the treatment paradigm in HGSC, particularly for women with *BRCA* mutations. PARPi, olaparib (O), is a standard of care maintenance therapy following platinum-based chemotherapy in newly diagnosed *BRCA*-mutated (BRCAm) HGSC. But patients ultimately develop resistance to O. We investigated whether rechallenge with different PARPi monotherapy could cause cytotoxicity in BRCAm HGSC after becoming O-resistant. We also aimed to identify possible mechanisms of actions of PARPi's differential sensitivity.
Methods: We developed a PARPi-resistant line (UWB-OlaJR) from BRCA1m PARPi-sensitive cells (UWB1.289) by gradient exposure of O with initial lower doses to a final concentration of 20 μM over 10 months. Four PARPis including O, niraparib (N), talazoparib (T), and veliparib (V) were tested. Cell growth was assessed using 5-day XTT and 10-day clonogenic assays. DNA damage and homologous recombination (HR) repair activity were evaluated using immunofluorescence (IF) staining of γH2AX and RAD51 foci, respectively. Replication fork (RF) dynamics was measured by DNA fiber assay. All data were repeated in triplicate and analyzed using t-test or one-way ANOVA. Data were shown as mean ± SD and $P < 0.05$ was considered statistically significant.
Results: 5-day XTT assay shows a 53.7-fold increase in resistance to O in UWB-OlaJR relative to UWB1.289 (IC_{50} 2.2 μM vs. 118.1 μM). Cross-resistance was observed with other 3 PARPis, showing increased IC_{50} values compared to its parental line (V: 23.4-fold, N: 160.5-fold, T: 229.6-fold). However, 10-day clonogenic assay showed no resistance against N (1.09-fold) and T (0.51-fold) in UWB-OlaJR, indicating differential sensitivity to different PARPis by a long-term cytotoxicity measure. Surprisingly, γH2AX foci did not increase in response to PARPis in UWB-OlaJR compared to UWB1.289 (O: 2.58-fold, V: 2.33-fold; N: 2.89-fold, T: 2.58-fold; all $P < 0.05$), suggesting possible restored DNA repair function. All four PARPis induced replication stress in both O-sensitive and -resistant cell lines as evidenced by decreased RF speed compared to untreated group (O: 0.57- and 0.7-fold, V: 0.68- and 0.74-fold, N: 0.47- and 0.47-fold, T: 0.47- and 0.52-fold; all $P < 0.001$). Notably, N and T treatments reduced fork speed to a greater extent than O and V in UWB-OlaJR. However, RF protection was not affected when UWB-OlaJR treated with different PARPis compared to UWB1.289 (O: 0.89-fold, V: 0.87-fold, N: 0.71-fold, T: 0.83-fold; all $P < 0.05$), suggesting that differential sensitivity to different PARPis was unlikely due to modulation of RF stabilization.
Conclusions: Our findings demonstrate different PARPis may induce varied levels of cytotoxicity and replication stress in O-resistant BRCA1m HGSC, possibly via modulating alternative RF dynamics besides RF protection.

#1988 Mass spectrometry profiling identifies ENO2 as a driver of lenvatinib resistance in hepatocellular carcinoma.

Sukbum Kim[1], Jia-Jian Loh[1], Huajian Yu[1], Ki-Fong Man[1], Kai-Yu Ng[1], Terence Kin-Wah Lee[2], Clive Yik-Sham Chung[1], Stephanie Ma[1]

[1]School of Biomedical Sciences, The University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Hepatocellular carcinoma (HCC) is the predominant type of primary liver cancer, and lenvatinib is a multi-kinase inhibitor approved by the FDA as a first-line drug for advanced HCC since 2018. Lenvatinib demonstrated antitumor activity with a higher objective response rate, longer progression-free survival, and time to progression in a non-inferiority trial compared with sorafenib. However, the clinical benefits of lenvatinib remain limited as acquired resistance to lenvatinib during HCC treatment is inevitable. This highlights the need to understand the molecular mechanisms of lenvatinib resistance and to explore new therapeutic approaches to overcome this resistance. Tumor lineage plasticity, a recognized hallmark of cancer, is a phenomenon in which tumor cells dedifferentiate into a more stemness state to attain cellular plasticity, enabling them to evade targeted therapeutic interventions. However, the mechanism by which cellular plasticity contributes to lenvatinib resistance remains elusive. In this study, we employed proteomic mass spectrometry to investigate altered proteins in two pairs of parental lenvatinib-sensitive and their corresponding trained lenvatinib-resistant HCC cell lines. This analysis revealed that upregulation of enolase 2 (ENO2), a glycolytic enzyme that catalyzes the dehydration and conversion of 2-phosphoglycerate to phosphoenolpyruvate, is a critical contributor. ENO2 upregulation is frequently observed in HCC and is strongly correlated with aggressive clinical features, including poor survival, advanced tumor stage, and poor differentiation status. We further showed that ENO2 upregulation in HCC is positively correlated with stemness and hepatic progenitor marker signatures, as well as hypoxia, and subsequently demonstrated that ENO2 is regulated by hypoxia/HIF-1α, with hypoxia response element sequences located in the ENO2 promoter region. Research is underway to investigate the functional role and underlying molecular mechanisms associated with ENO2-driven lenvatinib resistance and cellular plasticity in HCC.

#1989 Intratumor heterogeneity in EGFR-mutant lung tumors mediates targeted therapy resistance and formation of drug tolerant microenvironment.

H. M. Haikala[1], B. Alsaed[1], J. Son[2], L. Lin[1], P. Gokhale[2], P. Janne[2];
[1]University of Helsinki, Helsinki, Finland, [2]Dana-Farber Cancer Institute & Harvard Medical School, Boston, MA

Introduction: Non-small cell lung cancers (NSCLC) harboring *EGFR* mutations are commonly treated with EGFR tyrosine kinase inhibitors (TKIs), but the emergence of drug resistance often leads to treatment failure. While various acquired resistance mechanisms have been identified, they are not always actionable. Furthermore, since drug resistance is typically studied after cancer relapse, little is known about the cellular or microenvironmental taking place during the formation of resistance at the stage of minimal residual disease (MRD). Therefore, it is necessary to understand the mechanisms leading to resistance during MRD and develop new ways to prevent drug resistance in *EGFR*-mutant cancers.
Methods: In this study, we discovered pre-existing intratumor heterogeneity in EGFR expression within *EGFR*-mutant NSCLCs and found that patient tumors contain clones with low mutant EGFR expression. To study the effect of this intratumor heterogeneity on drug response, we isolated low and high expressing cells and conducted longitudinal drug challenge assays in *ex vivo* and *in vivo* models. To dissect how the observed heterogeneity affects drug resistance and the tumor microenvironment during MRD, we employed patient-derived tumor cells and used novel tumor-on-a-chip co-culture approaches.
Results: Our findings reveal that EGFR-low cells are more tolerant to drug treatment and can survive the initial TKI insult, making them more likely to contribute to drug resistance in *EGFR*-mutant NSCLCs. Additionally, the surviving EGFR-low cells were able to modify the tumor microenvironment leading to fibroblast accumulation and immune suppression, contributing to the drug-tolerant tumor microenvironment. Importantly, we found that pharmacological induction of EGFR using epigenetic inhibitors was able to sensitize the drug tolerant cells to EGFR inhibition, suggesting a potential strategy to overcome TKI resistance in NSCLC patients.
Conclusions: In conclusion, our study sheds light on the critical role of intratumoral heterogeneity in treatment resistance and offers valuable insights into potential strategies to overcome this challenge. Our findings suggest that combination therapies that can alter the cellular phenotype during MRD have the potential to prevent intrinsic drug resistance. This underscores the importance of gaining a better understanding of the mechanisms underlying drug-tolerant microenvironment and developing more effective treatment strategies for patients with *EGFR*-mutant NSCLCs.

#1990 TIP60-mediated acetylation of ΔNp63α is associated with cisplatin resistance.

A. Hira, J. Zhang, M. Kemp, M. P. Kadakia;
Wright State University, Dayton, OH

The chemotherapeutic drug Cisplatin is often used to treat squamous cell carcinoma (SCC) patients, but low response rates and disease recurrence are common. About 5.4 million basal and squamous cell skin cancers are diagnosed each year in the US. ΔNp63α, a member of the p53 family of transcription factors, is overexpressed and considered oncogenic in non-melanoma skin cancer where it regulates cell survival, promotes proliferation, and inhibits cell apoptosis. ΔNp63α has also been shown to promote resistance to cisplatin by orchestrating the transcriptional regulation of several DNA damage response (DDR) genes. Our previous study showed that the histone acetyltransferase (HAT) TIP60 promotes SCC proliferation by positively regulating ΔNp63α protein levels in a manner reliant on the catalytic activity of TIP60. This observation suggested that TIP60 may contribute to the failure of platinum-based drugs in SCC and led us to hypothesize that TIP60-mediated acetylation of ΔNp63α regulates its stability and transcriptional activity to promote chemoresistance. We found that TIP60 levels positively correlated with ΔNp63α stability, protein levels, and cisplatin resistance. Further, silencing endogenous TIP60 led to a decrease in ΔNp63α transcript and protein levels in multiple cisplatin resistant SCC cell lines. Further, stable expression of TIP60 or ΔNp63α individually promoted resistance to cisplatin and reduced cell death, whereas loss of ΔNp63α or TIP60 induced G2/M arrest, increased cell death, and sensitized cells to cisplatin. Additionally, pharmacological inhibition of TIP60 reduced acetylation of ΔNp63α, decreased colony formation, and sensitized resistant cells to cisplatin. Finally, we demonstrated that ΔNp63α and TIP60 levels positively correlated with DNA repair capacity and negatively correlated with cisplatin-DNA adduct formation. Silencing of either TIP60 or ΔNp63α intensified cisplatin-DNA adduct formation and significantly reduced the expression of drug efflux transporters. Taken together, our data indicate that TIP60-mediated stabilization of ΔNp63α increases cisplatin resistance and provides critical insights into the mechanisms by which ΔNp63α confers cisplatin resistance in SCC. Our findings suggest that the inhibition of TIP60 may be therapeutically advantageous in overcoming cisplatin resistance in SCC and other epithelial cancers.

#1991 Leiomyosarcoma poly-aneuploid cancer cells form in response to chemotherapy, contribute to chemoresistance, and lead to higher rates of metastatic recurrence.

R. Kennington[1], G. Mitchell[1], E. Payne[1], N. Bhachech[1], J. A. Fletcher[2], T. Liu[3], M. van de Rijn[4], S. Amend[5], K. J. Pienta[5], J. D. Schiffman[1], L. M. Abegglen[1]; [1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Harvard University, Boston, MA, [3]University of Utah, Salt Lake City, UT, [4]Stanford University, Stanford, CA, [5]John Hopkins University, Baltimore, MD

Poly-aneuploid cancer cells (PACCs) or as also known as “giant cells”, are a treatment resistant stem cell-like cancer phenotype. PACCs have been identified in numerous cancer types, and their presence appears to play a significant role in chemoresistance and poor patient outcomes. PACCs employ a multitude of polyploidization programs to enter this transient state in response to stress. After removal of stress, PACCs give rise to non-PACC progeny through potential mechanisms of neosis or depolyploidization that maintain chemotherapeutic resistance. Leiomyosarcoma (LMS) is a difficult to treat sarcoma that grows in smooth muscle that often develops chemoresistance. Here we report the first description of PACCs in LMS cell culture, LMS xenografts, and LMS patient tumor microarrays. LMS cells treated (doxorubicin, docetaxel, and gemcitabine) in vitro and in vivo lead to the development of mononucleated and multinucleated polypoid cells as the predominant phenotype via polyploidization. Polyploidization mechanisms identified included endocycling, endomitosis, and cell-cell fusion. In vitro, LMS PACCs had a significant increase in size and DNA content as well as an increase in resistance to chemotherapy as compared to parents. LMS PACCs also repopulated the culture with non-PACC LMS progeny cells. The PACC progeny cells maintained a significantly decreased ($p<0.0001$) response to chemotherapy compared to parent cells. PACCs were also identified in clinical samples from patients with LMS. Twenty-nine percent of samples (N=289) contained abnormally large tumor cells and fifty-eight percent contained abnormal nuclei. A positive correlation was observed in patient tumor samples between PACCs in metastatic tumors and recurrence ($p=0.0277$) and survival ($p=0.0009$) than those patient tumors without PACCs. The high rate of functional loss of TP53 in LMS (>90%) may contribute to the ability of PACCs to form abnormal, multiple nuclei. We therefore transfected LMS PACCs to express TP53 and observed an increased apoptotic response. Additionally, combining functional TP53 expression with low doses of doxorubicin increases the apoptotic response of LMS cells, potentially by targeting PACCs. LMS PACCs may contribute to the lack of response in patients with LMS. Identifying therapeutic approaches that prevent or target LMS PACCs, including TP53 replacement, may improve response to chemotherapy and improve outcomes for patients.

#1992 A novel RB1 E3 ligase TRIM37 contributes to palbociclib resistance in breast cancer.

C. You, H. Tsoi, P. Man, L. Chow, W. Dai, U. Khoo;
The University of Hong Kong, Hong Kong, Hong Kong

The tripartite motif-containing 37 (TRIM37) is a RING finger E3 ubiquitin ligase and is a poor prognostic factor in breast cancer patients. The gene is located in chromosome 17q23, a region amplified in up to 40% of breast cancers. We observed that activation of androgen receptor (AR) could induce resistance to the CDK4/6 inhibitor Palbociclib, the mechanism yet to be clarified. ChIP-sequencing data suggested that AR binds to the TRIM37 promoter, with AR activation resulting in TRIM37 expression. We hypothesized that TRIM37 might be involved in Palbociclib resistance. Using an ER+ve cell line MCF7 and a TNBC cell line MDA-MB 453, we found that overexpression of TRIM37 could induce Palbociclib resistance. TRIM37 overexpression resulted in RB1 protein downregulation, which is the primary downstream target of CDK4/6, while TRIM37 knockdown enhanced RB1 protein expression. Ubiquitination assay demonstrated TRIM37 overexpression increased the level of RB1 protein ubiquitination. The co-immunoprecipitation (Co-IP) assay confirmed that TRIM37 protein could interact with the RB1 protein. These results suggest that TRIM37 could be the E3 ligase that regulates RB1 degradation. Various deletion mutants of TRIM37 were cloned for Co-IP experiments between these mutants and RB1. Results show that the MATH and c-terminal domains of TRIM37 was the essential region for the interaction. Overexpression of the mutant with the TRIM37 MATH and c-terminal domains (TRIM37-MATH/C) could enhance RB1 protein level. This might be due to competition of TRIM37-MATH/C with wild-type TRIM37 for RB1 binding. Our findings suggest TRIM37 is a novel RB1 E3 ligase, and it binds to the RB1 protein via the MATH and C-terminal domains to regulate protein degradation. Our study also suggests that high expression of TRIM37 mediated by AR activation could deplete RB1, which is the target of Palbociclib, eventually leading to resistance. These findings are supportive of the contribution of AR activation to Palbociclib resistance.

#1993 Cytosolic BAX dimerization as a mechanism of resistance to apoptosis and a novel target to potentiate BAX activation and apoptosis.

N. Gitego[1], B. Agianian[1], O. Mak[1], V. Kumar MV[1], E. Cheng[2], **E. Gavathiotis**[1];

[1]Albert Einstein College of Medicine, Bronx, NY, [2]Memorial Sloan-Ketetring Cancer Center, New York City, NY

BCL-2 family proteins are master regulators of cellular life and death and have become drug targets for the development of therapeutic agents to overcome the apoptotic blockade of cancer. BAX is a pro-apoptotic BCL-2 member that is a crucial mediator of apoptosis induced by diverse stimuli including various chemotherapeutic and targeted agents. BAX predominantly resides in the cytosol in a quiescent state and upon stress, it undergoes conformational activation and mitochondrial translocation leading to mitochondrial outer membrane permeabilization, a critical event in apoptosis execution. While cytosolic BAX is typically considered an inactive monomer, we previously reported structural and cell-based evidence of a cytosolic BAX dimer. However, it remains unclear how this regulates BAX. Moreover, we found that specific BAX mutants such as P168G and G67R formed inactive BAX dimers and mutations of P168A and G67R have been identified in AML patients and found to have impaired apoptotic activity and notably the BAX P168A mutant appeared in AML patients acquiring resistance to the BCL-2 inhibitor Venetoclax. Here, we investigated the role of the inactive BAX dimer in regulating apoptosis and pro-apoptotic drug treatments in various hematologic and solid tumor cancer cells. Surprisingly, cancer cell lines express cytosolic inactive BAX dimers and/or monomers. Expression of inactive dimers, results in reduced BAX activation, translocation and apoptosis upon pro-apoptotic drug treatments such as BH3 mimetics and chemotherapy drugs. Our findings support the notion that formation of the inactive BAX dimer is a mechanism adopted by cancer cells to further suppress BAX activation and gain survival advantage. Using the inactive BAX dimer crystal structure, we designed a pharmacophore-based drug screen, and identified a small-molecule modulator, BDM19 that binds and activates cytosolic BAX dimers and prompts cells to apoptosis alone or in combination with BCL-2/BCL-XL inhibitors. Moreover, we validated interactions of BDM19 and BAX, using structural, biochemical and cellular methods, critical for BAX activation. Our findings provide mechanistic insights into the regulation of BAX and resistance to apoptosis in cancer through inactive BAX dimerization. Further, we demonstrate a rational strategy to target BAX dimer for therapeutic modulation of BAX and overcoming resistance to apoptosis by pro-apoptotic agents.

#1994 Drug-induced cancer cell secretome promotes resistance in colon cancer.

S. R. Satapathy, S. Ghatak, A. Sjolander;
Lund University, Malmo, Sweden

Colorectal cancer (CRC) is the third most common cancer in the world, with a projection of increased lethality in the upcoming years. Adjuvant chemotherapy with biological agents is the most practiced standard of care today. However, patients with metastatic CRC (mCRC) do not benefit from the wide range of therapies available for CRC, which either owe to unresectability or co-morbidity or more importantly resistance to therapy. 5-fluorouracil (5-FU) combined with leucovorin, oxaliplatin, or irinotecan (FOLFOX or FOLFIRI) has been routinely employed as the first-line therapy in colon cancer, but patients often develop resistance to 5-FU. Additionally, tumor cell dormancy plays a major role in tumor relapse which leads to poor prognosis in the patients. Despite many advances, the understanding of therapy-induced resistance is still in its infancy. Here, we show that 5-FU-induced tumor cell secretome helps in the outgrowth and metastasis of 5-FU-resistant clones in colon cancer. We used parental and 5-FU-resistant colon cancer cell lines, and transgenic zebrafish embryos to test the hypothesis and perform the colon cancer cell-based functional assays. We observed that 5-FU resistant (5-FU-R) colon cancer cells showed an increase in proliferation and survival when cultured with the secretome of 5-FU exposed colon cancer cells compared to the DMSO-induced secretome. Interestingly, we also noted elevated migration and invasion in the 5-FU-R colon cancer cells exposed to 5-FU-induced secretome compared to the DMSO counterpart. Additionally, in zebrafish xenograft, we found that 5-FU-R colon cancer cells cultured with 5-FU-induced secretome showed higher tail-vein metastatic burden compared to the 5-FU-R cells cultured with DMSO-induced secretome. This provides a background to further study in detail the therapy-induced resistance as well as dormancy in colorectal cancer which will help to develop approaches to prevent or reverse chemoresistance in patients who receive systemic therapy for mCRC.

#1995 DUSP4 loss enhances resistance to encorafenib plus cetuximab in *BRAF* mutant colorectal cancer.

K. Needham, F. Chionh, S. Kaczmarczyk, C. Kearney, L. Jenkins, I. Luk, J. M. Mariadason;
Olivia Newton-John Cancer Research Institute, Melbourne, Australia

The 5-year survival rate for metastatic colorectal cancer (CRC) is less than 14%. Hyperactivation of the ERK/MAPK pathway occurs at a high frequency in CRC, due to mutations (RAS, BRAF) or overexpression/amplification (EGFR) of its signalling components. Aberrant activation of this pathway drives tumour growth and survival and several inhibitors of this pathway are now clinically utilized. The *BRAF* V600E activating mutation occurs in ~10% of CRC patients and is correlated with an extremely poor prognosis. Use of the small molecule BRAF inhibitor encorafenib in combination with the EGFR inhibitor cetuximab is now approved for *BRAF* V600E mutant patients, however, the objective response rate is only ~20% and the treatment is rarely curative. Therefore, there is an urgent need to identify predictive biomarkers of response to encorafenib+cetuximab treatment. Dual-specificity phosphatase 4 (DUSP4) is rapidly induced upon activation of ERK/MAPK signaling upon which it acts as a critical negative regulator of signaling output by directly de-phosphorylating ERK. We have observed that DUSP4 is highly expressed in *BRAF*-mutant CRC cell lines and primary tumours, although there is a range of expression. Whether DUSP4 expression status impacts on response to encorafenib+cetuximab therapy is unknown. The aim of this study therefore was to determine the role of DUSP4 on sensitivity of *BRAF*-mutant CRC cells to encorafenib+cetuximab treatment *in vitro*. To examine this, we determined the impact of DUSP4 knock-down, knock-out and re-expression on sensitivity of *BRAF*-mutant CRC cancer cell lines to encorafenib+cetuximab treatment. Screening a panel of BRAF mutant CRC cell lines for sensitivity to encorafenib+cetuximab revealed a subset of resistant cell lines had either low or undetectable DUSP4 protein expression, while all sensitive cell lines had high DUSP4 expression. siRNA-mediated knockdown of DUSP4 in DUSP4 expressing *BRAF*-mutant CRC cell lines increased pERK and pFRA1, suggesting activation of ERK/MAPK signalling. DUSP4 knockdown also reduced sensitivity of BRAF mutant CRC cell lines to encorafenib+cetuximab compared to control. These findings were further validated using DUSP4 knock-out with CRISPR-Cas9. Conversely, DUSP4 re-expression in *BRAF*-mutant CRC cell lines lacking DUSP4 expression, decreased pERK and increased sensitivity to encorafenib+cetuximab treatment. These results demonstrate that DUSP4 regulates ERK/MAPK signalling in BRAF mutant CRC cell lines and that loss of DUSP4 promotes resistance to encorafenib plus cetuximab treatment. These findings warrant investigation of DUSP4 expression status as a predictive biomarker of encorafenib+cetuximab response in patient samples.

#1996 Novel mechanism of temozolomide resistance in glioblastoma.

Y. Hung, M. Kiang, K. Leung;
The University of Hong Kong, Hong Kong, China

Intrinsic expression of PD-1 has been discovered in different types of tumurs, exhibiting either oncogenic or tumor-suppressing function. In glioblastoma (GBM), intrinsic PD-1 has been found to play a role in promoting the proliferation and self-renewal of brain tumor-initiating cells through nuclear factor κB without involving PD-L1 ligation, with unknown factors activating this signalling pathway. Meanwhile, TMZ resistance significantly contributes to treatment failure and an extremely poor prognosis for GBM. This study investigated whether intrinsic PD-1 is also expressed in differentiated human GBM cell lines and its role in GBM proliferation and temozolomide (TMZ) resistance. In vitro studies demonstrated the presence of PD-1 in both U87 and U251 TMZ-sensitive and -resistant cell lines, with a higher expression on TMZ-resistant cell lines. *PDCD1* knockdown led to decreased GBM progression, including cell proliferation, colony formation and cell migration, in TMZ-resistant U87 and U251 cell lines using cell viability assays. It also resensitizes these cell lines to TMZ. Overexpression of *PDCD1* in the *PDCD1*-knockdown cell lines increases their proliferation and restores their resistance to TMZ. Treatment of U87 and U251 TMZ-resistant cell lines with TMZ upregulated PD-1 expression. An orthotopic xenograft mouse model is further deployed by injecting previously cultured U87 and U251 cell lines into the mouse brains. A smaller tumour size is observed in the model with *PDCD1* knockdown model than the one without *PDCD1* knockdown when treated with TMZ. This study reveals that intrinsic PD-1 expression contributes to TMZ resistance in GBM and TMZ may be a factor activating the PD-L1-independent PD-1 signalling. PD-1 and its downstream signalling pathway, such as SHP-2 and IKK, may be potential therapeutic targets for GBM patients with TMZ resistance. Co-administration of TMZ and agents inhibiting the intrinsic PD-1 signalling pathway can potentially produce synergistic therapeutic effects. The higher expression of PD-1 on TMZ-resistant GBM than on TMZ-sensitive GBM also suggests that the intrinsic PD-1 level can be a predictor of TMZ outcome.

#1997 The small GTPase ARF6 augments BRAF and PI3K expression to promote melanoma survival.

J. Wang, C. Rich, A. Rogers, S. Holmen, R. Wolff, A. Grossmann;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

RAF and MEK inhibitors greatly benefit BRAF-mutant melanoma patients, but eventually, nearly 80% of patients relapse. Reactivation of MAPK signaling and activation of PI3K/AKT signaling play a major role in the development of targeted therapy resistance. Therefore, understanding how tumor cells regulate these signaling pathways may yield new insights into drug resistance. The small GTPase ARF6, a member of the RAS superfamily, influences oncogenic signaling by controlling cytoskeletal rearrangements and through endomembrane trafficking. We previously reported that ARF6 is aberrantly activated in metastatic melanoma and that activation of ARF6 is sufficient to promote invasion and accelerate spontaneous metastasis *in vivo* through WNT5A/beta-catenin and PI3K/AKT signaling. In contrast to ARF6 activation, herein we show that tumor-specific deletion of *Arf6* significantly limits development and progression of $BRAF^{V600E}$ melanoma *in vivo*. Mechanistically, we discovered these ARF6-dependent phenotypes may be attributed to a previously unknown role for ARF6 in augmenting $BRAF^{V600E}$ and PI3K protein levels. Specifically, pharmacologic or genetic activation ARF6 (ARF6-GTP) is sufficient to increase $BRAF^{V600E}$ and PI3K protein levels in both murine and human melanoma. As a result, ARF6-GTP is also sufficient to enhance activation of MEK, ERK and AKT. Importantly, murine tumors expressing constitutively active ARF6 ($ARF6^{Q67L}$) show increased expression of anti-apoptotic proteins compared to $ARF6^{WT}$ tumors. Together these data suggest that ARF6 promotes tumor survival through augmentation of the BRAF/MAPK and PI3K/AKT pathways. To test this, we pharmacologically activated ARF6 during serum withdrawal or vemurafenib treatment. In both conditions, ARF6 activation is sufficient to prevent apoptosis. Surprisingly, we found that vemurafenib treatment leads to ARF6 activation, suggesting that ARF6 may be an important component of the cellular machinery that reactivates MAPK signaling after RAF inhibition. Indeed, pharmacologic activation of ARF6 maintains MAPK signaling (pERK levels) in the presence of vemurafenib and enhances pERK and pAKT-mediated suppression of apoptotic signaling. In summary, our data suggest that in addition to well-established roles in tumor cell invasion, ARF6 is a crucial mediator of survival during tumor progression and in the context of BRAF targeted therapy. More work is needed to understand how ARF6 activation increases BRAF and PI3K expression and if ARF6 activation contributes to the development of persister cells in melanoma.

#1998 ABCB1 promotes uveal melanoma cell resistance to FR900359 and identifies a tumor cell subpopulation with a distinct gene expression signature.

S. D. Murray[1], J. D. Riordan[1], E. R. Anderson[1], M. D. Onken[2], K. J. Blumer[2], A. J. Dupuy[1], C. S. Stipp[1];
[1]University of Iowa Holden Comprehensive Cancer Center, Iowa City, IA, [2]Washington University School of Medicine, St. Louis, MO

Uveal melanoma (UM) is the leading form of intraocular cancer in adults and the second most common form of melanoma. Although rare, UM has a median survival rate of ~1 year after metastasis occurs. Metastatic UM is largely refractory to treatment and there are no effective pharmacological therapies, resulting in poor overall survival. In >90% UM cases, the oncogenic initiator proteins are constitutively active mutant GNAQ or GNA11 proteins (GNAQ/11). FR900359 (FR) is a natural compound that inhibits GNAQ/11 and has anti-proliferative effects on UM cells. To identify key oncogenic mechanisms downstream of mutant GNAQ/11, we performed a *Sleeping Beauty* (SB) transposon forward genetic screen to identify drivers of FR resistance. The SB screen identified ATP-binding cassette sub-family B member 1 (ABCB1) as one of the top genes upregulated by SB in FR-resistant UM cell populations. We determined that although ABCB1 does not provide immediate resistance to FR, the overexpression of ABCB1 leads to emergence of resistant colonies at a much higher rate than spontaneous resistance, validating ABCB1 as contributors to FR resistance. Unexpectedly, immunofluorescence revealed that a relatively small fraction of UM cells strongly expresses the transgenes after stable transfection. Immunoblotting confirmed that ABCB1 expression was initially modest in ABCB1-transfected populations but increased in the cells that developed resistance to FR. To examine the kinetics of FR resistance, population doubling versus time (PDVT) assays were performed in UM cells expressing ABCB1 or empty vector control treated with FR or vehicle. FR potently suppressed the proliferation of vector control cells. Drug-naïve ABCB1-transfected cells developed resistance to FR over time but accomplished fewer population doublings than vehicle-treated cells in the same time interval. Once transgenic populations emerged as resistant populations in FR, they grew similarly in drug or vehicle. Ongoing RNA-sequencing analysis from PDVT samples has identified distinct gene expression signatures associated with FR treatment and ABCB1 expression. These findings are expected to illuminate tumor cell heterogeneity amongst UM cell populations that may be related to drug resistance and metastasis.

#2000 Role of O-GlcNAc conjugation and TS translational repression in 5-FU/LV resistance in CRC and CF10 response.

C. C. Okechukwu, X. Ma, W. H. Gmeiner;
Wake Forest University School of Medicine, Winston-Salem, NC

Rationale: Fluoropyrimidine drugs (FPs; e.g., 5-FU) are widely used to treat colorectal cancer (CRC), the 3rd leading cause of cancer-related mortality. However, acquired resistance to 5-FU is a principal cause of treatment failure in the metastatic setting. Further, previous studies selected for cells resistant to single agent 5-FU however 5-FU is invariably used clinically in combination with the reduced folate leucovorin (LV). Our studies focus on resistance mechanisms upon treatment with 5-FU+LV in folate-restricted media and test if CF10, a novel polymeric FP being developed in our laboratory displays activity in CRC cells resistant to 5-FU+LV.

Experimental: We selected CRC cells (HCT-116, LS174T, HCT15, MC38) resistant to 5-FU+LV by selecting for survival upon culture in folate-restricted media with stepwise increased concentrations of 5-FU+LV over 5 months. Since elevated thymidylate synthase (TS) levels were observed in multiple studies selecting CRC cells for 5-FU resistance, we performed Western blot on cell lysates from parental and (5-FU+LV)-R cells. Since Myc and p53 expression are regulated in part via translational inhibition by TS binding to these mRNAs we also compared Myc and p53 levels in parental and (5-FU+LV)-R cells by Western blot. Further, since TS, Myc, and p53 protein stability are all regulated in part via O-GlcNAc conjugation we tested if OGT levels were changed in (5-FU+LV)-R cells. Resistance factors for CF10 were also determined in (5-FU+LV)-R cells.

Results: A surprising result was that basal TS levels were reduced in (5-FU+LV)-R cells relative to the parental cells. We also observed that TS levels were increased in both parental and (5-FU+LV)-R cells by 5-FU+LV treatment however the effect was much greater in (5-FU+LV)-R cells. We observed strongly decreased p53 and Myc levels in the (5-FU+LV)-R cells. CF10 treatment further decreased p53 and Myc levels in parental cells, but increased p53 and further decreased Myc in (5-FU+LV)-R cells. In contrast, 5-FU alone treatment in (5-FU+LV)-R cells increased Myc and decreased p53 levels and further decreased in combination with LV. CF10 retained strong activity in (5-FU+LV)-R cells.

Conclusions: Overall, we have validated that cancer cells can be cultured under conditions with human-like folate levels and selected for resistance to 5-FU+LV under folate-restricted conditions. The causes of 5-FU+LV resistance are multi-factorial and include TS overexpression induced by 5-FU+LV treatment that may be mediated by O-GlcNAc conjugation. We demonstrated that CF10 is more potent than 5-FU, and importantly its potency advantage is enhanced in cells selected for 5-FU+LV resistance. Our studies support CF10 translation for treatment of metastatic CRC in patients with progressive disease following treatment with combination therapy that includes 5-FU+LV.

#2001 Autocrine HGF maturation as a targetable regulatory step in cetuximab resistance in colorectal cancer.

V. Truong Jones[1], R. Graves-Deal[2], Z. Cao[2], G. Bogatcheva[2], M. A. Ramirez[2], S. J. Harmych[1], J. N. Higginbotham[2], C. C. Wahoski[1], N. Joshi[2], J. T. Roland[2], G. D. Ayers[2], Q. Liu[2], R. J. Coffey[2], J. W. Janetka[3], **B. Singh**[2];

[1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Washington University School of Medicine, Saint Louis, MO

Although amplifications and mutations in receptor tyrosine kinases (RTKs) act as bona fide oncogenes, in most cancers, RTKs maintain moderate expression and remain wild-type. Consequently, cognate ligands control many facets of tumorigenesis, including resistance to anti-RTK therapies. Herein, we show that the ligands for the RTKs MET and RON, HGF and HGFL, respectively, are synthesized as inactive precursors that are activated by cellular proteases. Our newly generated HGF/HGFL protease inhibitors could overcome both *de novo* and acquired cetuximab resistance in colorectal cancer (CRC). Conversely, HGF overexpression was necessary and sufficient to induce cetuximab resistance and loss of polarity. Moreover, HGF-induced cetuximab resistance could be overcome by the downstream MET inhibitor, crizotinib, and upstream protease inhibitors. Additionally, HAI-1, an endogenous inhibitor of HGF proteases, (i) was downregulated in CRC, (ii) exhibited increased genomic methylation that correlated with poor prognosis, (iii) HAI-1 expression correlated with cetuximab response in a panel of cancer cell lines, and (iv) exogenous addition of recombinant HAI-1 overcame cetuximab resistance in CC-HGF cells. Thus, we describe a targetable, autocrine HAI-1/Protease/HGF/MET axis in cetuximab resistance in CRC.

#2003 Chromatin based targeting of a master regulatory complex in estrogen receptor epithelial ovarian cancer.

S. K. Jaiswal[1], K. Fedkenheuer[1], R. Khamar[1], H. Tan[1], V. Gotea[1], A. Elkahloun[1], C. Annunziata[2], L. Elnitski[1];
[1]National Human Genome Research Institute, Bethesda, MD, [2]National Cancer Institute, Bethesda, MD

Ovarian cancer remains a significant contributor to cancer-related mortality in the United States, with low survival rates over the past decades. Hormonal therapies targeting estrogen receptors have shown limited efficacy. To explore mechanism of the inefficacy, our approach involved investigating ESR1 degradation within the higher order chromatin structure formed by Megacomplex. We identified a 1.3MDa Megacomplex containing ESR1, FOXA1 and PITX1, with colocalization at 2,440 genomic positions within the PEO4 cell line. Unlike cytoplasmic ESR1, the nuclear form was degraded minimally by ICI182780 (ICI), moreover, ESR1 incorporated into the Megacomplex macromolecule was least degraded. We hypothesized that this resistance might be due to sequestration within the Megacomplex, thereby preventing ICI from effectively targeting ESR1. Addition of a small molecule inhibitor of active chromatin, JQ1, in combination with ICI effectively enhanced the degradation of ESR1 within Megacomplex. The combination stopped nuclear occupancy of ESR1 and also degraded the cytoplasmic protein, thus breaking the ESR1 signaling circuit responsible for tumor cell proliferation. Pathway enrichment results consistently identified similar gene sets obtained independently for RNA-seq analysis after ESR1 modulation, and ChIP-seq analysis of Megacomplex bound genes. Likewise, proteins enriched within the Megacomplex macromolecule, as revealed from mass-spec analysis, returned similar pathway enrichments, directly implicating Megacomplex in ESR1 ovarian cancer gene regulation. We conclude, ESR1 in Megacomplex is resistant to ICI and sensitized by combining ICI with JQ1. This combined treatment strategy showed inhibition of cell proliferation and viability by uncovering ESR1 within the Megacomplex, thus elucidating a novel drug resistance mechanism.

#2004 CDC7 inhibition prevents neuroendocrine transformation in the lung and prostate through MYC degradation.

A. Quintanal-Villalonga[1], F. Uddin[1], K. Kawasaki[1], E. Redin[1], V. Durani[1], A. Sabet[1], W. Karthaus[1], Y. A. Zhan[1], S. Zaidi[1], M. Shaffer[1], H. Sridhar[1], J. Qiu[1], P. Manoj[1], E. De Stanchina[1], M. C. Haffner[2], C. L. Sawyers[1], C. M. Rudin[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Fred Hutchinson Cancer Research Center, Seattle, WA

Neuroendocrine (NE) transformation occurs as a mechanism of resistance to targeted therapy in up to 14% and 30% of *EGFR*-mutant lung and AR-dependent prostate adenocarcinomas, respectively, leading to poor prognosis. Even if we know the tumor population at high risk of transformation (*TP53/RB1*-mutated), no therapies to prevent NE relapse are currently available. To identify therapeutic vulnerabilities for tumors undergoing NE transformation, we performed an *in vitro* CRISPR screen in a NE-transformed lung tumor model. This screen identified CDC7, involved in DNA replication and DNA damage response, as a potential therapeutic target in this setting. Proteogenomic analyses revealed CDC7 upregulation in lung and prostate clinical samples undergoing NE transformation, detected already in pre-transformation adenocarcinomas. These results indicated that CDC7 expression is induced already at early steps of transformation. Consistently, TP53/RB1-mutated lung and prostate adenocarcinomas exhibited higher CDC7 expression than their double wild-type counterparts. Combined ChIP-seq and promoter reporter assays indicated that CDC7 expression was directly regulated by TP53 and RB1 inactivation. Importantly, TP53/RB1-inactivation induced sensitivity to the CDC7 inhibitor simurosertib, unraveling a therapeutic vulnerability in tumors at high risk of NE transformation. Thus, we tested the combination of simurosertib with targeted therapy *in vivo* in different lung and prostate patient-derived models of NE transformation, namely TP53/RB1-knock out adenocarcinomas known to undergo NE transformation on targeted therapy. In these, simurosertib was able to suppress NE transformation and dramatically delay tumor relapse. Trajectory analysis on single-cell transcriptomic data for such models revealed a NE transformation transcriptional program occurring already in the untreated tumors before transformation. Remarkably, simurosertib treatment reverted this transcriptomic state and induced a reversion to the original adenocarcinoma transcriptomic profile. CDC7 inhibition led to increased proteasomal activity and degradation of MYC, a stemness transcription factor involved in NE transformation. Ectopic overexpression of MYC^{T58A}, a proteasome degradation-resistant MYC isoform, rescued the NE phenotype in these transformation models, suggesting that CDC7 inhibition-induced MYC degradation is the mechanism by which NE transformation is prevented. In sum, CDC7 inhibition may suppress, or at least dramatically delay NE transformation in patients with lung and prostate adenocarcinomas at high risk of transformation, by inducing MYC proteasomal degradation. The clinical availability of CDC7 inhibitors, currently in phase II clinical trials after demonstrating tolerability and preliminary efficacy, will allow rapid translation of these results into the clinics.

#2006 Deciphering the interplay of β-catenin/YAP signaling and alveolar lineage plasticity during targeted therapy in non-small cell lung cancer.

Yu-Ting Chou[1], Wei Wu[2], Daniel Kerr[2], Macey Slota[3], Trever Bivona[1]

[1]Medicine/Cellular and Molecular Pharmacology/Helen Diller Family Comprehensive Cancer Center, University of California San Francisco; Chan-Zuckerberg Biohub, San Francisco, CA,[2]Medicine, University of California San Francisco, San Francisco, CA,[3]Urology, University of California San Francisco, San Francisco, CA

Molecularly targeted therapies have significantly enhanced clinical outcomes by directly addressing oncogenic driver mutations in genes such as EGFR. However, despite the success of treatments targeting these mutations, long-term patient survival remains limited. This study investigates the molecular mechanisms underlying drug-tolerance in response to targeted therapies in non-small cell lung cancer (NSCLC). Using single-cell RNA sequencing of oncogene-driven human NSCLCs at the residual disease (RD) state during active targeted therapy, our investigation reveals an increase of an alveolar type I/II (AT1/2) mixed lineage program in surviving cancer cells, resembling an alveolar cell-like state. We observed increased WNT3A/4 ligands, FZD2 receptors, β-catenin signaling, and AT1/2 signatures at the RD stage. Consistent with clinical results, AT1/2 signatures and target genes of β-catenin and YAP are increased in drug-tolerant persister (DTP) cells in preclinical models. Additionally, we discovered that β-catenin and YAP form a stable nuclear protein complex in DTP cells. Disrupting β-catenin/YAP protein expression and stability in DTP cells by knocking down FZD2 or interrupting the destruction complex of β-catenin/YAP leads to re-sensitization to the EGFR inhibitor Osimertinib, suggesting a potential therapeutic approach. Furthermore, this therapeutic strategy decreased AT1/2 gene signatures. Our results highlight an interdependence between β-catenin and YAP, with both proteins playing crucial roles in sustaining DTP cells and promoting the alveolar cell like lineage plasticity. These findings shed light on the complex interplay between β-catenin/YAP signaling and alveolar signatures in the residual cancer state, offering mechanistic insights and potential therapeutic strategies to address drug tolerance and improve clinical outcomes.

#2007 Neurolysin: A novel architect of the prostate cancer microenvironment and therapeutic resistance.

C. Wang, P. Mu;
UT Southwestern Medical Center, Dallas, TX

Introduction: Prostate cancer is the second leading cause of cancer-related death in American men, primarily driven by its ability to evade therapeutic interventions. This study uncovers a novel paradigm where neurolysin, a peptidase previously ascribed to neuronal function, orchestrates the tumor microenvironment (TME) by interfacing with cellular motor proteins. This interaction precipitates a series of events that not only fortify the cancer cells' survival but also underpin the resistance to antiandrogen therapies.

Experimental Procedures: We deployed advanced prostate cancer models to delve into the extra-neuronal influence of neurolysin, probing its role in the orchestration of the TME. An exhaustive suite of transcriptomic and proteomic analyses, complemented by comprehensive patient cohort studies, laid the foundation for unraveling the complex interplay between neurolysin, motor proteins, and the TME dynamics.

Results: Our data elucidates that neurolysin's depletion correlates with an altered TME, conducive to cancer proliferation and resilience against targeted therapies. This shift is mediated through neurolysin's interaction with cellular motor proteins, a liaison that appears to be a cornerstone in TME modulation. A significant subset of prostate cancer cases exhibits a neurolysin deficiency, paralleling more aggressive disease and therapeutic defiance, highlighting its role as a critical biomarker and a novel target for intervention.

Conclusions: Neurolysin steps into the limelight as a pivotal modulator of the TME, operating through mechanisms distinct from its known neuronal functions. Its interplay with motor proteins opens a novel avenue in prostate cancer biology, providing a unique perspective on the regulation of the TME and subsequent therapeutic resistance. Targeting this newly discovered regulatory axis presents a promising therapeutic strategy that could potentially redefine the clinical approach to managing prostate cancer and may have implications for other malignancies driven by similar TME alterations.

#2008 The N6-methyladenine-long noncoding RNA axis promotes drug resistance through PI3k signaling in leukemia.

Y. Tan[1], C. Zhou[1], S. Bian[1], W. Walter[2], J. Pang[1], T. Cheng[1], G. Huang[3], G. Hoermann[2], W. Tse[1], S. Liu[1];

[1]Case Western Reserve University, Cleveland, OH, [2]MLL Munich Leukemia Laboratory, Munich, Germany, [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX

Disease recurrence characterized by drug resistance remains a major hurdle to the successful cancer treatment. Long noncoding RNAs (lncRNAs) and RNA N^6-methyladenosine (m6A) have been linked to cancer recurrence. However, if and how lncRNAs and m6A coordinately determine drug resistance in tyrosine kinase (TK)-driven cancers are still unclear. We hypothesize that upon exposure to TK inhibitors (TKI), the dynamic m6A methylation epitransciptomically allows a set of proliferation/anti-apoptosis-relevant lncRNAs bearing m6A motifs to be rapidly upregulated, thus facilitating a subpopulation of cancer cells to evade TKI killing. By performing transcriptomic and epitransciptomic profiling in long-term TKI (nilotinib)-deprived leukemia resistant cells, we show that many differentially expressed lncRNAs enrich m6A, and more lncRNAs tend to have higher m6A content in resistant cells. We further demonstrate a broad clinical relevance of our findings, showing that upregulation of specific top-ranked lncRNAs (e.g., SENCR, PROX1-AS1, LN892) in TKI-resistant cell lines also occurs in leukemia patients at the diagnostic stage, blast crisis phase or in those not-responding to TKI treatment compared to chronic phase or TKI responders, respectively. Some of the upregulated lncRNAs in leukemia patients pre- and post-TKI treatment predict unfavorable outcomes and are associated with shorter survival duration. Through proliferative and clonogenic assays, we demonstrate that knockdown of SENCR, PROX1-AS1 or LN892 impairs resistant cell growth and renders resistant cells sensitive to nilotinib-induced cell death. We further found that this lncRNA upregulation is attributed to FTO-dependent m6A hypomethylation that stabilizes lncRNA transcripts. Using ectopic expression or genetic/pharmacological inhibition, we demonstrate that lncRNA upregulation empowers resistant cell growth through an activated PI3K signaling as supported by overexpression of PI3K signaling mediators (e.g., ITGA2, F2R, COL6A1). Treatment with PI3K inhibitor alpelisib sensitizes TKI-resistant cells to TKI-induced cell death and reduces leukemia burden in mice via downregulation of F2R, ITGA2, and COL6A1. In conclusion, our findings add a new layer to the complexity of mechanisms regulating leukemia cell fate under TKI selection and raise the possibility that the m6A-regulated lncRNAs represents a new non-genetic factor to affect the development and maintenance of TKI resistance; our discoveries identify a promising therapeutic target, the m6A-lncRNAs axis, for specifically the most challenging patient subpopulations who are TKI non-responders/relapsed but do not carry the acquired mutations on top of BCR/ABL; our results also uncover a strong predictor, m6A-regulated lncRNA-PI3K axis, for poorer prognosis and failure in drug response which might be a pan-cancer mechanism.

#2009 Novel clinically relevant CLIP-170 variants display an extended conformation microtubule-lattice bound conformation associated with taxane resistance.

U. del Castillo, K. Sahu, W. G. Stone IV, M. A. Shah, P. Giannakakou;
Weill Cornell Medicine, New York, NY

Taxanes are microtubule (MT)-stabilizing drugs widely used for the treatment of solid tumors, including the highly prevalent cancers of the breast, the prostate and gastric cancer. However, despite their initial activity, taxane resistance invariably occurs, leaving patients with limited therapeutic options. Currently, the molecular determinants of clinical taxane resistance remain poorly understood. We recently identified CLIP-170S, a novel truncated variant of the MT plus-end binding protein CLIP-170, that confers taxane resistance *in vitro* and is associated with clinical taxane resistance in patients with gastric cancer. We further showed that CLIP-170S is aberrantly localized along the MT lattice, thus impairing taxane access to its binding site in the MT lumen. However, the mechanism underlying the resistance-inducing extensive lattice localization of CLIP-170S is unknown. The activity and MT binding properties of canonical CLIP-170 are regulated by conformational changes mediated by the interaction of its N- and C-terminal domains. In its inactive, “closed” conformation, CLIP-170 is soluble as the N- and C-terminal domains interact with each other. In the active “open” conformation, CLIP-170’s N- and C-terminal domains are apart, thus exposing its MT-binding domain and allowing MT plus-end binding. As CLIP-170S is missing part of its N-terminal domain, we hypothesized that CLIP-170S is constitutively displayed in an open conformation that promotes its extensive and aberrant localization to the MT lattice. To prove this hypothesis, we used the FKBP-rapalog-FRB system to “force” CLIP-170S to assume a “closed” conformation. We generated a fusion CLIP-170S protein tagged with FKBP and FRB domains in its N- and C-terminal, respectively. The addition of rapalog induced FKBP (N-ter) and FRB (C-ter) domains to interact, promoting CLIP-170S to adopt a “closed” conformation. CLIP-170S in this “closed” conformation resulted in its release from the MT-lattice and restored taxane binding to MTs. We next extended our search to other CLIP-170 clinically prevalent variants with sequence alteration predicted to bind to the MT-lattice and potentially interfere with taxane sensitivity. This search identified CLIP-170IR (an intron retention variant) and several other truncation mutants prevalent in gastric, breast and lung cancer cell lines. Experimentally, we showed that these variants not only phenocopy CLIP-170S binding to the MT- lattice but also confer taxane-resistance. Together, these data demonstrate a novel mechanism of taxane resistance mediated by CLIP-170 mutations that induce CLIP-170 to adopt a constitutively “open” MT-lattice binding conformation, which renders them susceptible to causing taxane resistance.

#2010 TRIM27 Interacts with KLF12 to regulate L1CAM expression, influencing cisplatin resistance and cancer metastasis in esophageal squamous cell carcinoma.

H. Zhang, **C. Li**, J. He;
Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Esophageal squamous cell carcinoma (ESCC) accounts for 85% of cases of esophageal cancer worldwide and is the predominant form of esophageal cancer in Asia. A significant number of patients with ESCC are diagnosed at an advanced stage, resulting in poor prognosis. Cisplatin resistance and cancer metastasis are the main clinical challenges in the treatment of advanced ESCC. KLF12 has been extensively characterized as a transcriptional repressor, and previous studies have unveiled its roles in angiogenesis, neural tube defect, and NK cell proliferation. However, the precise contribution of KLF12 to cancer treatment remains undefined. Here, we show that KLF12 is downregulated in various cancer types, and KLF12 downregulation promotes cisplatin resistance, cancer metastasis and recruitment of regulatory T cells (Tregs) in ESCC cell lines. Mechanistically, KLF12 binds to the promoters of L1CAM and represses its expression. Depletion of L1CAM abrogates cisplatin resistance, cancer metastasis, and Treg recruitment caused by KLF12 loss. Moreover, the E3 ubiquitin ligase TRIM27 binds to the N-terminal region of KLF12 and ubiquitinates KLF12 at K326 via K33-linked polyubiquitination. Notably, TRIM27 depletion enhances the transcriptional activity of KLF12 and consequently inhibits L1CAM expression. Overall, our study has firstly elucidated a novel regulatory mechanism involving TRIM27, KLF12 and L1CAM, which plays a substantial role in cisplatin resistance and cancer metastasis in ESCC, and targeting KLF12/L1CAM axis may be a promising approach for ESCC treatment.

#2011 MAOA Drives Anti Androgen Therapy Resistance in Advanced Prostate Cancer by Conferring Neuroendocrine Plasticity via a Twist1 BRN2 Signaling Pathway.

J. Wei, J. Wang, C.-h. Chen, W. Guan, B. Wu;
Washington State University, SPOKANE, WA

Background: Therapy resistance in cancer is often linked to cancer cell state or lineage changes. In prostate cancer (PCa), a subset of castration-resistant prostate cancer (CRPC) loses reliance on the androgen receptor (AR) signaling and gains neuroendocrine (NE) traits through a lineage switch along disease progression. However, the molecular mechanisms driving such cellular lineage plasticity remain unclear. This study investigated the functional and mechanistic role of monoamine oxidase A (MAOA) in driving adenocarcinoma (adeno)-to-NE lineage conversion in CRPC cells upon enzalutamide (ENZ), a FDA-approved newer-generation antiandrogen drug, and evaluated the efficacy of MAOA inhibitors for treating CRPC and overcoming ENZ resistance.**Methods:** ENZ-resistant C4-2B and CWR-R1 cells (C4-2B^{ENZR} and CWR-R1^{ENZR}) CRPC cells were transfected with a PSA promoter-driven GFP expression construct for isolating a PSA$^{lo/-}$ cell population distinct from PSA^{hi} cells, which was used for manipulation of MAOA expression levels and subsequent functional assays in vitro and in vivo. The MAOA expression levels were determined and correlated with NE parameters in PCa clinical samples by immunohistochemistry and data mining of multiple publicly available clinical datasets. **Results:** MAOA protein expression was significantly upregulated in the PSA$^{lo/-}$ ENZ-resistant cell population, accompanied by concomitant activation of NE markers and downregulation of luminal markers including AR and AR targets, compared to the PSA^{hi} counterpart. Elevated MAOA expression was also found in PCa patient samples associated with NE features from multiple independent cohorts. Silencing MAOA suppressed the proliferation, migration, invasion, stem-like properties and NE plasticity of both PSA$^{lo/-}$ C4-2B^{ENZR} and CWR-R1^{ENZR} cells. Moreover, co-culturing adeno LNCaP or C4-2B cells with MAOA-silenced PSA$^{lo/-}$ cells exhibiting a repressed secretory phenotype attenuated acquired induction of NE markers and proliferation of adeno cells as compared to controls. Mechanistically, MAOA induces Twist1, which directly activates the transcription and expression of BRN2, a master neural transcription factor known to confer NE differentiation and anti-AR therapy resistance in CRPC. Further, pharmacological inhibition of MAOA greatly enhanced the growth-inhibitory efficacy of ENZ with ENZ sensitivity restored in ENZ-resistant LuCaP PC PDX-derived organoids as well as a PSA$^{lo/-}$ CWR-R1^{ENZR} xenograft mouse model.**Conclusion:** Our results suggest MAOA as a potential therapeutic target for reversing ENZ resistance in CRPC treatment by blockade of NE transdifferentiation.**Funding Acknowledgements:** This work was supported by the NIH/NCI grants R37CA233658 and R01CA258634 (to B. Wu) and the DOD Department of Defense EIRA award W81XWH-21-1-0218 (to J. Wei)

#2012 Extrachromosomal DNA promotes drug resistance in pancreatic ductal adenocarcinoma cells.

T. Vorberg[1], M. Reitberger[1], B. Rodriguez-Martin[2], M. Starostecka[2], O. Kossi[1], V. Vogel[1], J. Korbel[2], A. Trumpp[1], M. Sprick[1];
[1]German Cancer Research Center, Heidelberg, Germany, [2]European Molecular Biology Laboratory, Heidelberg, Germany

Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer-related deaths in Western Countries and has been predicted to become the second leading cause of cancer-related deaths by 2030. Difficulties in early detection as well as strong chemoresistance of the disease prevent the successful treatment of PDAC patients. Although we have previously identified CYP3A5 as a mediator of paclitaxel resistance, further targets remain elusive. Thus, we set out to identify these CYP3A5-independent mechanisms which could lead to the identification of novel biomarkers and drug targets to improve PDAC treatment. For this project, pancreatic cancer cell lines were derived from treatment-naive PDAC samples and exposed to increasing paclitaxel concentrations to induce resistance. The cells were characterized on a genomic and transcriptomic level using short-read sequencing as well as optical mapping to characterize potential candidate genes *in vitro*. In our results, multi-drug resistance protein 1 (ABCB1) was highly upregulated in our differential gene expression analysis and confirmed as a CYP3A5-independent mediator of acquired paclitaxel resistance. Its overexpression was mediated by extrachromosomal DNA (ecDNA) amplifications upon drug treatment. These circular DNAs were characterized by short-read sequencing as well as long-read optical mapping, which revealed the structures of the most abundant molecules. Furthermore, we investigated the biogenesis of the ecDNA. Current models propose different events such as chromothripsis or breakage-fusion-bridge cycles to initiate ecDNA formation, however, knowledge about the underlying mechanisms remains limited. To study the ecDNA dynamics, we generated ecDNA-negative cell clones from a paclitaxel resistant PDAC cell line. Interestingly, our clonal cell population appears to show the capacity for ecDNA *de novo* generation and quickly adapts to changing selective pressure such as therapy. This finding might unveil new insights into the triggers of ecDNA formation and its dynamic regulation. In conclusion, our results suggest the clinical relevance of ABCB1 as a mediator of paclitaxel resistance in PDAC and we currently validate our findings in patient samples. However, ABCB1 inhibition is associated with severe side effects. Instead, the regulatory pathways associated with enhanced ABCB1 expression and the formation of ecDNAs might provide therapeutic potential. Additionally, the characterization of ecDNA *de novo* generation might unveil new insights into how cancer cells adapt to changing selective pressures.

#2013 Extracellular vesicles transfer miR-181a to confer PARP inhibitor resistance and induce *STING* degradation in *BRCA*-mutated triple-negative breast and ovarian cancers cells.

M. A. Bustos[1], T. Yokoe[1], Y. Shoji[1], Y. Kobayashi[1], S. Mizuno[1], T. Murakami[1], S. C. Sekhar[2], M. Knarr[3], S. A. Vasilev[1], A. DiFeo[2], R. Drapkin[3], D. S. B. Hoon[1];

[1]Providence Saint John's Health Center, Santa Monica, CA, [2]University Michigan, Ann Arbor, MI, [3]University of Pennsylvania, Pensylvania, PA

Background: Patients with *BRCA*-mutated breast cancer (BC), including triple-negative BC (TNBC), and ovarian cancer (OvCa) are treated with poly (ADP-ribose) polymerase inhibitors (PARPi). BC and OvCa tumors develop similar mechanisms of resistance to platinum-based agents and PARPi. This study aimed to identify microRNAs (miRs) inducing PARPi resistance in cancer cells that can be transferred by extracellular vesicles (EV).

Methods: Olaparib-resistant (OlaR) cell lines were analyzed for 2,083 miRs using HTG miRNA Whole Transcriptomic Analysis (WTA) and NGS. Functional assays were performed in *BRCA1*-mutated TNBC and OvCa cell lines. *In-silico* analysis were performed using TCGA, GTEx, CCLE, GDSC, and GEO databases.

Results: The miR-181 family (including miR-181a, p=0.001) was significantly upregulated in OlaR TNBC cell lines. High miR-181a levels occurred in tumor tissues of TNBC patients (p=0.001). miR-181a binds to the stimulator of interferon genes (STING) mRNA to promote STING mRNA degradation in OvCa. We *hypothesized* that miR-181a downregulates STING and downstream proinflammatory cytokines, to mediate PARPi resistance. miR-181a-overexpression induced olaparib resistance and STING downregulation in *BRCA1*-mutated TNBC cell lines. EV isolated from OlaR TNBC cell lines horizontally transferred miR-181a to non-resistant parental cell lines, which conferred PARPi-resistance and decreased STING. In clinical settings, *STING* levels were positively correlated with interferon gamma (IFNG) response scores (p=0.01). Low-IFNG response scores in HER2-negative BC patients showed a worse response to neoadjuvant treatment (p=0.001). Consistently, OlaR TNBC cell lines showed resistance to platinum-based drugs. OvCa cell lines resistant to cisplatin showed resistance to olaparib; but miR-181a knockout significantly improved olaparib sensitivity (p=0.001).

Conclusions: High levels of miR-181a decrease STING pathway, correlate with IFNG scores, drive PARPi and platinum-based drug resistance. Horizontal miR-181a EVs transfer can facilitate drug resistance in cells. The miR-181a-STING axis can be used for predicting PARPi responses in TNBC and OvCa tumors.

#2014 Tumor glycosylation impacts the efficacy of HER2 targeting therapies.

Ana Ruiz-Saenz[1], Roos Vincken[1], Denise Wolf[2], Veronica Steri[2], Laura van't Veer[2], John Martens[3], Danny Huylebroeck[3], Mark M. Moasser[2]

[1]CIC bioGUNE, Bilbao, Spain,[2]UCSF, San Francisco, CA,[3]Erasmus University Medical Center, Rotterdam, Netherlands

Cancer progression remains a major obstacle to the successful treatment of cancer. In HER2+ breast cancer, targeting therapies against HER2 have revolutionized the treatment landscape. However, predictive factors for response are largely unknown and a significant number of patients develop resistance. An extensive body of work has revealed a plethora of mechanisms of resistance. However, a key aspect of cancer cells has been largely overlooked: their aberrant glycosylation profile. Aberrant glycosylation of proteins is a hallmark in cancer and has been linked to multiple processes such as invasion, angiogenesis and modulation of the immune response. Yet the influence of altered glycosylation on the efficacy of HER2-targeted therapies remains unknown. Therefore, here, we address this question using clinical data, 3D co-culture systems and advanced live microscopy. Bioinformatics analysis of SPY-2 clinical trial data reveals an association of specific glycogenes with response to HER2-targeting therapies in breast cancer patients. We validated these findings in resistance cell models generated in-vitro and in-vivo using gain and loss of function assays. Furthermore, to provide a more relevant cell model system, we implement the use of 3D co-cultures of cancer spheroids and immune cells. Thus, our research addresses a largely unexplored area in cancer biology combining clinical data from tumor biopsies, trastuzumab-resistant cancer cell models and, live imaging of 3D heterotypic cultures. This work holds the potential to identify new markers of response to therapies and highlights the importance of the interplay of cancer cells and their microenvironment on the efficacy of current treatments.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Microenvironment, Immunity, and DNA Repair in Therapeutic Response
Poster Session

#2018 Tumor treating fields (TTFields) disrupt cancer cell invasion by impacting cell-ECM traction forces.
S. M. Short, H. J. Bowers, J. A. Weis;
Wake Forest University School of Medicine, Winston-Salem, NC

Introduction: Tumor Treating Fields (TTFields) are an anti-cancer treatment that use low intensity, alternating electric fields. Anti-mitotic treatment effects of TTFields have been, to date, considered the primary anti-cancer effect. Recent studies have shown additional impacts on cancer cell invasion and migration, among other effects, resulting in a complex anti-tumor response derived from a combination of factors. By deploying computational imaging tools to assess experimental conditions that apply TTFields treatment to 3D cancer multicellular spheroid cultures, the goal of our study is to elucidate important mechanisms and effect sizes on anti-tumor effects relating to the modulation of cancer cell-extracellular matrix (ECM) biophysical interactions.
Methods: 3D multicellular tumor spheroids (MTS) are cultured using GFP-tagged U-87 MG glioma cells. A single 3D MTS is placed in a cell culture insert and embedded in collagen I ECM at 2.25 mg/mL. Fluorescent polystyrene microspheres are dispersed in the ECM to facilitate subsequent tracking of displacement fields induced by the MTS-ECM construct. Fluorescence microscopy imaging is acquired for all spheroids prior to treatment initiation. Then, with 3 replicates in each treatment condition, TTFields are applied for a duration of 48 hours at 200 kHz frequency with a no treatment condition as a control. At 48 hours, we acquire fluorescence microscopy images to track spheroid growth and bead-field displacement. To determine deformation fields induced by the cancer spheroid, we compare each image at 48 hours to their respective baseline image. Deformation fields are analyzed using a custom-developed analysis code that performs an initial alignment of the baseline and specific time point images using a global rigid registration. Next, we perform a B-spline based nonrigid image registration to generate an estimate of the deformation field vector at each pixel location within the image. Deformation intensity is measured within a circular region of interest ($r = 900$ μm) centered at the spheroid core.
Results: The average magnitude of displacement for treatment and control groups is 0.52±0.2 μm and 1.07±0.1 μm, respectively. Analysis of deformation fields reveals a significant difference ($p < 0.1$) in the magnitude of deformation present between treatment and control groups.
Conclusions: Implementation of our computational imaging analysis methods using rigid and nonrigid registration, we observe a 69.6% decrease in the magnitude of deformation in TTFields treated spheroids compared to control spheroids. Due to the decrease in deformation induced by cancer spheroids treated with TTFields, we conclude that TTFields impact cancer cell traction forces applied to the ECM to disrupt cancer cell invasion.

#2019 Primary cancer associated fibroblasts increase the chemoresistance of triple negative breast cancer cells by mitochondria metabolic upregulation.

I. Hofer[1], A. Mencattini[2], Y. Kieffer[1], E. Martinelli[2], M. Parrini[1], F. Mechta-Grigoriou[1];
[1]Institut Curie, Paris, France, [2]University of Rome Tor Vergata, Rome, Italy

Breast cancers (BCs) are the most prevalent cancers occurring in women. Tumor reoccurrence attributed to chemotherapy resistance remains a main challenge in fighting disease relapse. Cancer associated fibroblasts (CAFs) are the most prominent component of the tumor microenvironment (TME) and have already been implicated in therapy resistances. Although the exact molecular mechanisms behind this resistance remain unclear. In this regard, we recently identified 4 CAF populations (S1-S4) in ovarian and BCs, and showed that only CAF-S1 promote immunotherapy resistance as well as metastasis. Based on these observations, we are now investigating the impact of CAF-S1 on the chemotherapy response of BCs. To study the interactions between CAF-S1 and BC cells, we developed a tumor on chip (ToC) device, mimicking the TME in 3D. Using ToC live imaging, we show that primary CAF-S1 mediate a chemoprotective effect over luminal and triple negative BC (TNBC) cells by significantly decreasing their apoptosis rate as early as 10h after Doxorubicin and 40h after Paclitaxel treatment. Interestingly, CAF-S1 display a highly heterogenous response to Doxorubicin, allowing the classification into chemo-sensitive and -resistant CAF-S1. Regardless of premature CAF-S1 cell death, the chemoprotective effect over BC cells is maintained for at least 3 days. This indicates a crucial CAF-S1 - cancer cell cross talk at early timepoints. Additionally, by applying machine learning algorithms on live imaging videos, we demonstrate that physical proximity of CAF-S1 to BC cells immediately after treatment initiation correlates with BC cell survival, even after several days of treatment. This again implies cancer cell priming by CAF-S1 as a possible mechanism of chemotherapy resistance. To investigate this molecular interplay further, we performed scRNA-seq of ToC extracted and treatment naïve CAF-S1 and TNBC cells as well as bulk RNA-seq of patient derived TNBC tumors before/after chemotherapy treatment. We identify mitochondrial metabolic pathways to be upregulated in TNBC cells after CAF-S1 co-culture inside ToC devices and in TNBC cells of chemo-resistant patients enriched in CAF-S1 at baseline. We are now validating the impact of target gene knock downs on the survival of TNBC cells in CAF-S1 co-cultures after chemotherapy treatment on chip. Overall, these results provide insights into molecular mechanisms by which CAF-S1 promote chemotherapy resistance of breast cancers.

#2020 Determination of parameters to understand the metabolism in the tumor microenvironment by *in vivo* microdialysis.

Mariette Suzan Heins, Gunnar Flik

Charles River Laboratories, Inc., Groningen, Netherlands

The tumor microenvironment presents a unique surrounding with more favorable conditions for the cancer cells to growth thrive and interact than for the host cells. To obtain a better understanding of cancer biology and pathophysiology, information about the physiological state of the tumor microenvironment is crucial. By using the *in situ* microdialysis technique we can quantitate relevant modulators in the interstitial space of the tumor.

The current set of experiments demonstrates the benefits of the use of microdialysis in freely-moving awake tumor-bearing animals. Following inoculation, growth was monitored continuously and upon an average tumor volume of 400 mm^3, the animals underwent surgical implantation of microdialysis probes. The next day, the sample collection was initiated by perfusion of the implanted probes with dialysate fluid. Samples were continuously collected over several hours and stored at -80C. Levels of analytes indicative of metabolic and physiological conditions of the tumor microdialysis were quantified by EIA and/or LC-MS/MS analysis.

The microdialysis technology combined with sensitive analytical methods allows us to quantify several analytes from the tumor microenvironment simultaneously and monitor changes over time. Metabolic activity is an important indicator of tumor growth speed. Depletion of energy can lead to increases in lactate levels and acidification of the tumor microenvironment. Resulting in a reduction of host immunological efficacy. Elucidation of the status of the tumor environment during tumor growth and treatment allows for better translational models.

#2021 The RXR agonist MSU-42011 and the MEK inhibitor selumetinib reduce pERK levels in NF1-deficient cells and inhibit cytokine production in macrophages.

P.-Y. Hung[1], J. A. Moerland[1], K. T. Liby[2];

[1]Michigan State University, East Lansing, MI, [2]IU School of Medicine, Indianapolis, IN

Neurofibromatosis type 1 (NF1) is a common genetic disease that predisposes approximately 50% of affected individuals to develop plexiform neurofibromas (PNFs), which can progress to highly aggressive malignant peripheral nerve sheath tumors (MPNSTs) in approximately 10% of patients. NF1 is caused by mutations in the tumor suppressor gene *NF1*, which encodes for neurofibromin, a negative regulator of RAS activity. Selumetinib, a specific inhibitor of MEK1/2, is the only FDA-approved drug for NF1-associated PNFs. However, the anti-tumor effects of selumetinib are limited in MPNSTs and have dose-limiting side effects. Deficiency of the *NF1* gene not only promotes tumorigenesis but also has broad effects on the immune cells and cytokine signaling driven by hyperactive RAS signaling. Because macrophages account for almost half of cells in NF1 lesions and their infiltration correlates with disease progression, we hypothesized that targeting tumor-promoting immune cells could be an alternative approach for treating NF1. The novel retinoid X receptor (RXR) agonist MSU-42011 reduces tumor growth in experimental Kras-driven cancers by decreasing pERK expression, reducing tumor-promoting immune cells like CD206+ macrophages and regulatory T cells, and increasing activated cytotoxic T cells. Here, we treated NF1-deficient cells and macrophages with MSU-42011 and selumetinib, either alone or in combination, using monoculture and conditioned media (CM) conditions. In human PNF cells and mouse MPNSTs, treatment with 200 nM MSU-40211 or 50 nM selumetinib for 3 hours reduced pERK protein levels compared with untreated controls, and the combination treatment enhanced this reduction in pERK protein levels. Additionally, there was a trend toward reduction in cell viability with increasing drug concentrations after 72 hours of the combination treatment. Moreover, CM from human and mouse PNF cells increased the mRNA expression of monocyte chemoattractant *CCL2* (C-C motif chemokine ligand 2) and the secretion of IL-6 and TNFα in human THP1 monocytes/macrophages and bone marrow derived macrophages (BMDM). Notably, MSU-42011 and selumetinib alone inhibited *CCL2* mRNA expression in THP1 macrophages and BMDM stimulated with CM from human and mouse PNF cells, respectively, and the inhibition of *CCL2* mRNA expression was greatest with combination treatment. The combination of MSU42011 and selumetinib also significantly reduced tumor burden in a LL2 model of lung cancer driven by an activating *Kras* mutation. Based on the similarities in RAS activation and immune cell infiltration in NF1 and lung cancer, our next step is to confirm the immunomodulatory and anti-tumor effects of MSU-42011 and selumetinib in a syngeneic model of PNF and MPNST.

#2022 E7386, a Wnt/β-catenin signaling modulator, suppresses the differentiation of regulatory T cells in combination with lenvatinib plus anti-PD-1 antibody.

J. Shen, R. Ishida, M. Kume, T. Kimura, Y. Adachi, Y. Kato;
Eisai Co., Ltd., Tsukuba, Japan

Background: E7386, a selective inhibitor of the interaction between β-catenin and CREB binding protein (CBP), showed antitumor activity in preclinical tumor models with aberrant activation of the Wnt/β-catenin signaling pathway. Previously, we reported the enhanced antitumor activity of a triple combination (E7386 in combination with Lenvatinib [LEN, a multiple receptor tyrosine kinase inhibitor mainly targeting VEGFRs and FGFRs] plus anti-PD-1 antibody) versus a 2-drug combination (LEN plus anti-PD-1 antibody). In this study, we further investigated the immunomodulatory functions of E7386 as a triple combination by single-cell RNA-sequencing (scRNA-Seq) analysis and subsequent functional assays.

Methods: Mice bearing subcutaneous RAG (mouse renal cell carcinoma) tumors were randomized into 4 groups (n=6 in each group), including ⑴ Nontreatment, ⑵ E7386 at 25 mg/kg (PO, QD), ⑶ LEN at 10 mg/kg (PO, QD) plus anti-PD-1 antibody at 10 mg/kg (IP, BIW), and ⑷ triple combination. Tumor tissues were collected after a 2-week treatment period. $CD45^{\pm}$ immune cells were isolated from the tumors by magnetic cell separation (MACS) and subjected to scRNA-Seq using 10x Genomics pipelines. Bioinformatics data analysis was conducted with Clarivate Analytics. To evaluate the effects of E7386 on Treg differentiation, an in vitro-induced regulatory T cells (Tregs) differentiation assay was conducted. Naïve $CD4^{\pm}$ T cells were isolated by MACS and plated under iTreg differentiation conditions (stimulation of TGF-β and IL-2) with or without treatment of E7386. Induced Tregs and conditional culture medium were collected for evaluation of Treg differentiation, including gene expression and protein analysis.

Results: $CD45^{\pm}$ immune cells were clustered into 14 cell-type groups. Increased proportion of monocytes, NK cells, Tregs, $CD4^{\pm}$ T cells, $CD8^{\pm}$ T cells, eosinophils, and neutrophils were observed after LEN plus anti-PD-1 treatment. Among these subpopulations, Treg were most significantly suppressed by E7386 plus LEN plus anti-PD-1. Gene expression analysis revealed that the triple combination suppressed the activated gene expression of the Stat5/Foxp3 axis in $CD4^{\pm}$ T cells, particularly Tregs, induced by LEN plus anti-PD-1 treatment. Consistently, the iTreg differentiation assay confirmed the suppressive function of E7386 on the Treg differentiation rate. Multiple subsequent in vitro assays also demonstrated the inhibitory effects of E7386 on TGF-β secretion and the expression levels of TGF-β downstream target genes.

Conclusion: In summary, these data suggest a suppressive role of E7386 on Treg differentiation, which leads to antitumor activity of E7386 in combination with lenvatinib and anti-PD-1 antibody in a preclinical tumor model.

#2023 Multiplex immunofluorescence profiling of the tumor microenvironment and CD73: Activity of neoadjuvant oleclumab in patients with non-small-cell lung cancer in NeoCOAST.

I. Bisha[1], T. Tan[1], M. Weitkunat[1], A. Andoni[1], I. Dino[1], P. Martin[2], M. Saraiya[1], K. DaCosta[1], P. Sontakke[1], M. Schick[1], M. Surace[2], J. Blando[2], I. Grenga[3], R. Kumar[2], L. McGrath[3];

[1]AstraZeneca, Munich, Germany, [2]AstraZeneca, Gaithersburg, MD, [3]AstraZeneca, Waltham, MA

Background: The NeoCOAST study (NCT03794544) investigated the efficacy of neoadjuvant immuno-oncology combinations in patients with resectable non-small-cell lung cancer (NSCLC), using major pathological response (MPR) as the primary endpoint (Cascone T, et al. *Cancer Discov* 2023;13:2394-411). Patients received a single cycle of the following treatments: durvalumab monotherapy (durva; anti-PD-L1), durva + oleclumab (ole; anti-CD73), or durva + monalizumab (mona; anti-NKG2A). Here we analyze the tumor microenvironment to investigate the mechanism of action of ole.

Methods: A cohort of 47 patients (17 durva, 13 durva + mona, 17 durva + ole) with tumor tissue samples from pre-treatment (baseline, n=31) and surgery (post-treatment, n=24; n=8 paired pre- and post-treatment samples) were evaluated. Tumor sections were stained with (1) multiplex immunofluorescence (Panel 1: CD8-PD-L1-PD1-CD68-Ki67-panCK, Panel 2: NKp46-CD20), (2) CD73 immunohistochemistry (IHC), and (3) NKG2A IHC. Stains were analyzed using deep learning algorithms, manual pathology, and digital pathology scoring, respectively.

Results: All arms showed similar infiltration of tumors by T cells (CD8), B cells (CD20), NK cells (NKp46), and macrophages (CD68) at the pre-treatment time point (Kruskal-Wallis, p=0.5-0.9 *n.s.*). Percent CD73+ tumor cells (TCs) at baseline was correlated with increased B cell, T cell, NK cell, and macrophage abundance (Spearman's Rho=0.4-0.6, p<0.05). Percent CD73+ TC and B cell abundance was higher in patients with MPR vs those without MPR in the durva + ole arm, but not in the durva monotherapy or durva + mona arms. Increased CD8 T cell and NK cell abundance was not associated with MPR in any arm. Moreover, comparison of baseline to post-treatment tumor samples revealed a greater increase in CD8 T cells in the durva + ole arm (FC=2.1, p=0.02), particularly in proliferating activated T cells (CD8+Ki67+PD-1+; FC=8.0, p=0.003), compared to durva alone (FC=1.8, p=0.4 and FC=2.9, p=0.04, respectively).

Conclusion: Increased abundance of CD73+ TCs is correlated with high B cells in the tumor microenvironment and associated with patients who experienced MPR in the durva + ole arm. Treatment with neoadjuvant durva + ole results in a greater increase in proliferating CD8 T cells than durva alone.

#2024 Deep and durable responses to ALK-targeted therapy require CD8+ T cells.

Greg Reis, Stevie Phelabaum, Andre Navarro, Emily Kleczko, Lynn Heasley, Raphael Nemenoff, **Erin L. Schenk**

University of Colorado Anschutz Medical Campus, Aurora, CO

Despite major advances in therapies for lung cancer, it remains the leading cause of cancer related deaths in the United States. Tyrosine kinase inhibitors (TKI) designed to inhibit oncogenic anaplastic lymphoma kinase (ALK) fusions have transformed the treatment of patients with ALK+ NSCLC and many survive for several years on TKIs. While most patients experience a decrease in tumor burden on initial alectinib therapy, for many, tumor shrinkage is incomplete and persistent, residual disease remains. Critically, the degree of tumor shrinkage and amount of residual disease that persists despite TKI associates with overall survival. Multiple cancer-cell intrinsic mechanisms of persistence despite TKI therapy have been reported, but they do not fully account for the heterogeneity of this initial tumor response, suggesting other determinants are present beyond inhibiting the primary oncogene. However, extrinsic mediators of persistent disease, such as immune cells within the tumor microenvironment (TME), have not been rigorously studied in ALK+ NSCLC as they are considered immunologically “cold” tumors. Using EA-1 and EA-2, two distinct murine ALK+ adenocarcinoma cells lines derived from immunocompetent C57BL/6J mice, we have demonstrated that ALK+ NSCLC response to alectinib requires the adaptive immune system. C57BL/6J mice bearing orthotopic EA-1 tumors experience tumor shrinkage but have persistent, residual disease on CT imaging; those bearing EA-2 tumors have no residual disease. In this model system, when alectinib treatment stops, no EA-2 tumors recur but all animals bearing EA-1 tumors experience tumor outgrowth. TME interrogations by multispectral tissue imaging demonstrated more CD8+ T cells in the EA-2 TME compared to EA-1 and no difference in CD4+ T cells. Flow cytometry revealed a significant increase in activated CD8+ T cells and CD86+ CD103+ dendritic cells within the TME of EA-2 tumors compared to EA-1. When implanted into nude mice, EA-1 and EA-2 both experience initial disease shrinkage on alectinib, but EA-2 tumors now exhibit residual disease on imaging. Notably for both cell lines, tumor outgrowth occurs in the nude mice despite continued TKI therapy. Using knock out animal models, we established that CD8+ T cells, but not CD4+ T cells, were required for response to alectinib. In animals lacking CD8+ T cells, EA-2 tumors shrink with alectinib therapy but are not eliminated as in the wild type controls. Notably, despite continued alectinib therapy, tumors grew out in the CD8+ knock out animals. In the EA-2 model, CD4+ T cells we not required for response to alectinib, and CD4+ knock out animals did not experience tumor outgrowth when alectinib was held. Taken together, these data suggest that the adaptive immune system, specifically CD8+ T cells, are required for a deep and durable response to molecularly targeted therapy for ALK+ NSCLC.

#2025 Zeb1 downregulation sensitizes pancreatic cancer-associated fibroblasts to killing by oncolytic reovirus through upregulation of the reovirus receptor junction adhesion molecule A.

N. Dam[1], T. J. Harryvan[1], B. Schmierer[2], L. J. Hawinkels[1], V. Kemp[1];
[1]LUMC, Leiden, Netherlands, [2]Karolinska Institutet, Stockholm, Sweden

Pancreatic tumors display an abundance of cancer-associated fibroblasts (CAFs), which negatively affect prognosis and therapy response. Oncolytic virotherapy exploits viruses that preferentially lyse epithelial cancer cells as opposed to normal cells. Interestingly, we have observed that oncolytic reoviruses are able to infect and lyse CAFs, in addition to epithelial cancer cells. Targeting CAFs, in addition to cancer cells, could be advantageous to increase therapy effectiveness. It could serve as a conduit for viral spread and simultaneously disrupt the desmoplastic barrier around tumors, thereby also accelerating the influx of other therapeutics and immune cells. We previously found that the proneness of CAFs to lysis by oncolytic reovirus correlates with the cell surface expression levels of the reovirus entry receptor junction adhesion molecule A (JAM-A). However, most pancreatic CAFs do not express JAM-A. Therefore, a genome-wide CRISPR/Cas9 screen was employed to identify the genes regulating JAM-A expression on fibroblasts, which can subsequently be targeted to sensitize CAFs to reovirus. Pancreatic stellate cells with a moderate JAM-A expression level were transduced with a gRNA library making a knockout of one gene per cell. The highest and lowest JAM-A expressing cells were sorted and sequenced to identify the gRNAs that regulate JAM-A expression. Clonal CRISPR/Cas9-generated knockouts of a top negative regulator were generated and infected with reovirus, followed by cell viability assays to quantify their susceptibilities to reovirus-induced cell death. F11R, the gene encoding JAM-A, was identified as the top positive regulator of JAM-A expression in the CRISPR/Cas9 screen, verifying the validity of the screen. The top negative regulators identified were Fibroblast Growth Factor Receptor 1 (FGFR1) and Zinc finger E-box Binding homeobox 1 (Zeb1), thereby serving as potential therapeutic targets to sensitize CAFs to reovirus treatment. Using clonal Zeb1 knock-outs, Zeb1 was confirmed as a strong regulator of JAM-A expression. Zeb1 knockout in JAM-A negative pancreatic fibroblasts caused a robust upregulation of JAM-A and sensitized these inherently resistant fibroblasts to reovirus-directed cytolysis. Additionally, the clinically approved drug Mocetinostat, previously described to inhibit Zeb1, upregulated JAM-A expression on CAFs and increased cell lysis by reovirus. Altogether, our data show that Zeb1 is a strong negative regulator of JAM-A expression on fibroblasts and that Zeb1 inhibition can sensitize CAFs to reovirus-induced cell death. This research provides a rationale for combining Zeb1 inhibitory drugs with oncolytic reovirus treatment to improve killing of CAFs, which in turn could boost overall tumor eradication.

#2026 Single-cell RNA-sequencing analysis of tumor endothelial cells reveals suppression of specific endothelial subtypes by the combination treatment of Wnt/β-catenin signaling modulator E7386 plus lenvatinib.

M. Kume, R. Ishida, Y. Ozawa, J. Shen, H. Konishi, M. Kuronishi, T. Kimura, Y. Adachi, Y. Kato;
Eisai Co., Ltd., Tsukuba, Japan

Background: Aberrant activation of Wnt/β-catenin signaling plays an important role in both carcinogenesis and modulation of the tumor microenvironment. E7386, a novel orally active antitumor agent, inhibits the interaction between β-catenin and CREB-binding protein (CBP) and thereby modulates Wnt/β-catenin signaling. We previously reported that E7386 in combination with lenvatinib (LEN), a multiple receptor tyrosine kinase inhibitor mainly targeting VEGFRs and FGFRs, showed a greater antitumor activity and reduction of tumor microvessels than each treatment alone in preclinical tumor models. Multiple clinical studies are in progress including the combination of E7386 plus LEN (NCT04008797). Here, we further tried to elucidate the mechanism underlying the antitumor and antiangiogenic effect of the combination of E7386 plus LEN by using single-cell RNA sequencing (scRNA-seq) of tumor endothelial cells (ECs).
Methods: Mice bearing subcutaneous RAG (mouse renal cell carcinoma cell line) tumors were treated with E7386 at 25 mg/kg and/or with LEN at 10 mg/kg by daily oral gavage for 8 days. Tumor ECs ($CD31^{+}/CD45^{-}$) were isolated by magnetic cell separation and flow cytometry and were subjected to scRNA-seq using 10x Genomics pipeline. Bioinformatics data analysis was conducted by Clarivate Analytics. After quality control and filtering, ECs were gated by their expression of pan-EC markers and were further classified into 9 subtypes (tip, capillary, arterial, venous, proliferating, immature, interferon, activated artery, and lymphatic) according to previously reported markers for each subtype.
Results: Among classified subtypes, proliferating and immature subtypes showed clear reduction in the percentage of total ECs with combination of E7386 plus LEN versus LEN monotherapy. In both proliferating and immature subtypes, a subset of Wnt/β-catenin downstream genes showed increased expression with LEN monotreatment. Conversely, these Wnt/β-catenin downstream genes were downregulated with the combination of E7386 plus LEN, suggesting that Wnt/β-catenin signaling may be associated with a drug resistance mechanism against LEN in these subtypes. Pathway analysis indicated that genes involved in cell proliferation and survival were downregulated by the E7386 plus LEN combination versus LEN monotreatment in both proliferating and immature subtypes.
Conclusion: Taken together, these results suggest a role for E7386 in suppressing the activation of Wnt/β-catenin signaling induced by LEN monotreatment in specific EC subtypes; this activity leads to enhanced antiangiogenic and antitumor activity with E7386 plus LEN combination therapy in a preclinical tumor model.

#2027 Serological assessment of cancer associated myo-fibroblast (myCAF) activity by collagen pro-peptide biomarkers provides high prognostic power.

N. Willumsen, N. I. Nissen, M. A. Karsdal;
Nordic Bioscience, Herlev, Denmark

Background: Myofibroblast Cancer Associated Fibroblasts (myCAFs) are the main tumor fibrosis drivers and hence different from inflammatory CAFs (iCAFs). MyCAFs are emerging as an important tool for understanding tumor biology. CAFs produce type III, V, VI and XI collagen that are the essential components of tumor fibrosis. Pro-peptides of these collagens can be quantified both in serum with the PRO-C3, PRO-C5, PRO-C6 and PRO-C11 biomarkers where they are prognostic for poor overall survival in patients with various solid tumor types and may be applied in vitro. Here we investigated the association and difference between myCAFs and iCAFs and their collagen expression profile and related that to data available data on serological assessments of PRO-C3, PRO-C5, PRO-C6 and PRO-C11, and cultured CAFs.
Methods: The collagen expression in CAF subtypes were established from publicly available single-cell RNA-Seq dataset from pancreas cancer (PMID: 31273297) and non-small cell lung cancer (PMID: 36973297). In addition, we generated a biomarker profile using PRO-C3, PRO-C5, PRO-C6 and PRO-C11 ELISA to measure in serum of 220 patients with various solid tumor types and 33 healthy controls. We cultured CAFs in vitro and measured the same biomarkers in conditioned medium. We compared the result to historical PRO-C3, PRO-C6 and PRO-C11 prognostic data for pancreas cancer patient data.
Results: Based on the single-cell RNA-Seq dataset, while type III and type VI collagen were found expressed in fibroblasts both from normal tissues and tumor tissues whereas type V collagen and XI collagen were found almost exclusively expressed in CAFs (tumor tissue). When further examining the CAF subtypes, type III collagen and VI collagen were found expressed in both myCAFs and iCAFs whereas type V collagen and XI collagen were found almost exclusively expressed in myCAFs and not iCAFs. Moreover, in the 220 patients, PRO-C3 and PRO-C6 was elevated in elevated in a few cancer types ($p<0.05$-0.01) with an inter-patient variation ~2-fold whereas PRO-C5 and PRO-C11 were elevated in all cancer types ($p<0.0001$) with a ~5-fold inter-patient variation. These four biomarkers identified different pancreas cancer patients endotypes all with poor overall survival, $P<0.001$. In direct alignment, collagen pro-peptides we highly upregulated in cultures of CAFs.
Conclusions: Profiling collagen expression in fibroblast from PDAC and NSCLC reveals that type V collagen and type XI collagen are exclusively found in myCAF not iCAF. Biomarkers of these collagens can be measured in serum from cancer patients and are prognostic for poor overall survival. Thus, these data suggest that cancer associated myo-fibroblast (myCAF) activity can be assessed non-invasively by specific collagen pro-peptide biomarkers.

#2028 The triterpenoid CDDO-Methyl ester requires Nrf2 to decrease lung tumor burden and to protect against the toxicity of chemotherapy in experimental lung cancer.

J. A. Moerland[1], K. T. Liby[2];

[1]Michigan State University, Lansing, MI, [2]Indiana University School of Medicine, Indianapolis, IN

The NRF2 cytoprotective pathway, a drug target for many inflammation-related diseases, regulates immune cell function. While the anti-inflammatory nature of NRF2 activation protects healthy cells from malignant transformation, cancer cells can utilize the pathway to promote resistance to anti-cancer drugs. Up to 30% of human lung adenocarcinomas acquire mutations in either *NFE2L2* or its negative regulator *KEAP1* which result in constitutive activation of the NRF2 pathway. However, despite our knowledge of the important immunomodulatory effects of NRF2, these effects are not well characterized in the context of cancer. With NRF2 activators now approved for clinical use, it is critical to understand the impact of these drugs in cancer. Triterpenoids including CDDO-methyl ester (CDDO-Me, also known as bardoxolone methyl) are potent pharmacological NRF2 activators with demonstrated anti-cancer activity in preclinical models. In an early-stage preclinical model of lung cancer, CDDO-Me significantly decreased tumor burden in a dose- and Nrf2-dependent manner and improved immune signatures within the tumor microenvironment. However, most human lung cancers are not diagnosed until more advanced stages. To test CDDO-Me in an established tumor intervention model, lung tumors were initiated with vinyl carbamate in A/J WT and Nrf2 knockout (KO) mice. Tumors were allowed to develop for 8 weeks post initiation, after which mice were fed either a vehicle control diet or CDDO-Me (50-100 mg/kg of diet) for an additional 8-12 weeks, alone or in combination with carboplatin and paclitaxel (C/P) at 50 mg/kg and 15 mg/kg, respectively, by IP injection every other week. CDDO-Me significantly ($p < 0.05$) decreased surface lung tumor counts 35-71% in a Nrf2-dependent manner, and C/P significantly ($p < 0.001$) reduced tumor burden 53-59% regardless of Nrf2 status. The combination of CDDO-Me + C/P reduced tumor burden in WT lungs by 84% ($p < 0.05$), more than either agent alone. Nrf2 KO mice had an approximately two-fold increase ($p < 0.001$) of surface tumors compared to WT mice in both studies, regardless of treatment. C/P reduced tumor burden similarly in Nrf2 WT and Nrf2 KO mice. Interestingly, the combination of CDDO-Me + C/P increased T cell infiltration into the lungs of WT mice, but this change was not observed in groups treated with either agent alone. Importantly, CDDO-Me did not decrease the efficacy of C/P but protected WT mice from mortality and weight loss and lowered white and red blood cell counts. These studies suggest that NRF2 activation in advanced lung cancers can still decrease tumor burden by favorably modulating the immune microenvironment and, importantly, complements the anti-tumor efficacy of conventional chemotherapy while decreasing drug toxicity.

#2029 Investigation of anti-tumor activity of porcine myeloperoxidase for urothelial carcinoma of the bladder.

J. Liu[1], R. C. Allen[2], J. T. Stephens, Jr.[3], P. Shah[1], H. Huang[1];
[1]Mayo Clinic, Rochester, MN, [2]Creighton University, Omaha, NE, [3]Exoxemis, Inc, Little Rock, AR

Introduction: Porcine myeloperoxidase (pMPO) is a cationic enzyme secreted by granulocytic leukocytes capable of selectively binding cancer cells due to their negative surface charge. In the presence of hydrogen peroxide (H_2O_2) and sodium chloride (NaCl), MPO catalyzes the production of electronically excited singlet molecular oxygen, which exerts focused cytotoxic activity against cancer cells.
Methods: Human bladder non-cancer (SV-HUC1) and cancer cells (T24 and 5637) were used to assess differential cytotoxic activity of pMPO. pMPO was combined with associated reagents, including H_2O_2, NaCl, and L-proline and glycine for 45 minutes to support the generation of singlet oxygen. MTS assay was used to assessed cell viability at day 3 post-treatment. Non-cancer and cancer cells were labeled with GFP and mCherry, respectively, via infection with lentivirus and cultured in tandem to allow for simultaneous treatment of both cell types. After the treatment, flow cytometry and microscopy were used to monitor the growth of the cells.
Results: No cytotoxicity was noted when SV-HUC1 cells were cultured with individual reagents pMPO, NaCl, L-Proline, or Glycine, and limited cytotoxicity was observed with H_2O_2. Notably, cell viability was nearly maximally preserved for SV-HUC1 cells. The combination of pMPO with associated reagents resulted in killing of 5637 and T24 cells, with tumoricidal activity maintained across increasing tumor cell density, with cell viability preserved for SV-HUC1 cells. Within the cell co-culture system, simultaneous treatment of both cell types with the pMPO treatment resulted in selective killing of tumor cells and preservation of SV-HUC1 cells. Mechanistic studies confirm specificity of pMPO binding to tumor cells, and further, high levels of expression of gammaH2AX and phospho-ATM in 5637 and T24 cells following treatment.
Conclusion: pMPO demonstrates selective and efficient killing of bladder cancer cells with minimal cytotoxicity against non-cancer urothelial cells. Given its reliance on direct surface contact with tumor cells for activity, pMPO may be developed as an intravesical therapy for treatment of non-muscle invasive bladder cancers.

#2030 N-cadherin-mediated activation of PI3K/Akt pathway following application of tumor treating fields (TTFields).

A. Klein-Goldberg, **T. Voloshin**, E. Zemer-Tov, R. Paz, L. Koren, K. Wainer-Katsir, A. Volodin, B. Koltun, B. Brant, Y. Barsheshet, T. Kan, C. David, T. Haj Khalil, A. Haber, M. Giladi, U. Weinberg, Y. Palti;
Novocure Ltd, Haifa, Israel

Introduction: Tumor Treating Fields (TTFields) therapy is FDA-approved for the treatment of glioblastoma and unresectable pleural mesothelioma, and has recently demonstrated benefit (together with an immune checkpoint inhibitor) for the treatment of metastatic non-small cell lung carcinoma (NSCLC) progressing on or after platinum-based therapy. The current study aimed to uncover cellular response mechanisms to TTFields.
Methods: A2780 ovarian cancer cells and H1299 NSCLC cells were treated with TTFields for 72 h (200 and 150 kHz, respectively; 1.7 V/cm RMS). Changes in signaling pathways were analyzed using the Luminex multiplex assay and validated by protein expression. Fluorescence microscopy, calcium switch assay, antibody neutralization assay, and immunoprecipitation were employed to investigate the mechanism of action. The efficacy of concomitant treatment with TTFields and a potential inhibitor was tested in cell lines (cytotoxic and clonogenic effects) and two orthotopic mouse models: MOSE-L-FFL ovarian cancer and LL/2 lung cancer. Immunohistochemistry was performed on tumor sections from both models.
Results: Increased AKT phosphorylation was observed in the cancer cells treated with TTFields. N-cadherin, known to be involved in the activation of the PI3K/AKT pathway, was elevated in the membranes of cells treated with TTFields. Elimination of calcium ions required for N-cadherin homophilic ligation abrogated TTFields-induced AKT phosphorylation, whereas calcium supplementation restored AKT phosphorylation. Inhibition of N-cadherin-mediated cell-cell contacts by neutralizing antibody resulted in a significant reduction in TTFields-induced AKT phosphorylation. Pull-down assays with an anti-N-cadherin antibody demonstrated increased recruitment of the p85 regulatory subunit of PI3K to N-cadherin complexes following TTFields application. TTFields-induced activation of AKT could be mitigated in cell cultures as well as in animal models by application of the PI3K inhibitor alpelisib. Co-treatment with alpelisib also enhanced the effectiveness of TTFields *in vitro* and *in vivo*.
Conclusions: The PI3K/AKT signaling pathway, activated via cell-cell N-cadherin interactions, plays a role in the cancer cell response to TTFields treatment. Inhibiting the PI3K/AKT pathway may potentially sensitize tumors to TTFields.

#2031 A phase 1b/2 clinical study of onvansertib in combination with FOLFIRI/bevacizumab revealed a new role of PLK1 in regulating the hypoxia pathway in KRAS-mutant colorectal cancer.

M. Ridinger[1], A. Karki[1], R. A. Subramanian[1], E. Samuelsz[1], D. Yemane[1], R. Kim[1], C.-C. Wu[1], F. F. Kabbinavar[1], T. Smeal[1], H.-J. Lenz[2];
[1]Cardiff Oncology, Inc., San Diego, CA, [2]University of Southern California, Los Angeles, CA

Background: Onvansertib (Onv) is an oral, small molecule, selective PLK1 kinase inhibitor that demonstrated clinical activity at tolerated drug exposures in combination with FOLFIRI/Bevacizumab (Bev) in the 2nd-line treatment of mutated KRAS (mKRAS) metastatic colorectal cancer (mCRC) (Lenz, JCO, 2022). Here we explored biomarkers of response to the combination therapy and their associated biology.
Methods: In a Phase 1b/2 study, mKRAS mCRC patients with prior exposure to oxaliplatin (with or without Bev) were treated with Onv (Days 1-5 and 15-19) in combination with FOLFIRI/Bev (Days 1 and 15) of each 28-day cycle (NCT03829410). Efficacy endpoints included objective response rate (ORR, RECIST v1.1), progression-free survival (PFS) and duration of response (DoR). Preclinically, the combination of Onv and Bev was tested in 3 mKRAS CRC xenograft models. The role of PLK1 in hypoxia was assessed through protein and RNA analyses of mKRAS CRC cell lines exposed to low oxygen levels and treated with Onv.
Results: As of 25-AUG-2023, 66 patients were evaluable for efficacy in the Phase 1b/2 and ORR of Onv + FOLFIRI/Bev was 28.8%. Patients had a median PFS of 9.8 months [95%CI: 7.6, 12.6] and median DoR of 11.7 months [95%CI: 9.0, NR]. An analysis of baseline characteristics revealed that patients not exposed to Bev in the 1st-line setting (Bev-naïve patients, n=15) achieved superior clinical benefit compared to Bev-exposed patients (n=51). Bev-naïve patients had significantly higher ORR (73.3% versus 15.7%, p<0.0001) and longer median PFS (14.9 months [95%CI: 10.5, NR] versus 7.8 months [95%CI: 5.6, 9.8], p=0.0013) than Bev-exposed patients. This data prompted us to assess the effect of Onv+Bev in mKRAS CRC xenograft models. Onv+Bev significantly reduced tumor growth in the 3 xenograft models tested. The combination resulted in a greater decrease in tumor vascularization and tumor cell proliferation, and a corresponding increase in apoptosis, compared to either monotherapy. Further, the effect of Onv on the hypoxia pathway was assessed in mKRAS CRC cell lines. Our findings indicated that under low oxygen levels, Onv inhibited the hypoxia pathway by reducing the expression of the hypoxia-inducible factor 1-alpha (HIF1α) protein, and the mRNA expression of its downstream targets.
Conclusions: Onv + FOLFIRI/Bev resulted in greater clinical benefit in Bev- naïve than Bev-exposed mKRAS CRC patients. Preclinical studies revealed synergistic effect of Onv and Bev in mKRAS CRC xenografts, and a new function of PLK1 in modulating the hypoxia pathway through the regulation of HIF1α. Collectively, this data supports a crosstalk between PLK1 and angiogenesis, and further exploration of Onv + FOLFIRI/Bev therapy in Bev-naïve mCRC patients with KRAS mutation.

#2032 Osteoblasts alter their protein expression profile in the presence of prostate cancer cells to facilitate their invasion.

A. J. Todman, W. S. Ratnayake, L. Lajmi, S. Breedy, A. H. Shourav, K. Bisht, M. Acevedo-Duncan;
University of South Florida, Tampa, FL

Bone metastasis is the leading cause of death in prostate cancer patients, for which there is currently no effective treatment. Since the bone microenvironment plays an important role in this process, attention has been directed to the interactions between cancer cells and the bone microenvironment, including osteoblasts. Here, we investigated the mechanism of interactions between prostate cancer cells (DU-145 and PC-3) and osteoblast cell line hFOB.1.19. We are investigating the broader effects of four different nucleoside reverse transcriptase inhibitor (NRTI) analogs 5-fluoro-1-((1R,4R)-4-hydroxycyclopent-2-en-1-yl)pyrimidine-2,4(1H,3H)-dione (KBMD-E), 3-benzoyl-5-fluoro-1-((1S,4S)-4-((tetrahydro-2H-pyran-2-yl)oxy)cyclopent-2-en-1-yl)pyrimidine-2,4(1H,3H)-dione (KBMD-G), 1-((1R,4R)-4-hydroxycyclopent-2-en-1-yl)-5-methylpyrimidine-2,4(1H,3H)-dione (KBMD-H) and 1-(5-hydroxymethyl)-2,5-dihydrofuran-2-yl)-5-methylpyrimidine-2,4(*1H,3H*)-dione (KBMD-S) along with aPKC specific inhibitors ICA-1S and ζ-Stat to develop as potential anti-cancer drugs. Our previous publications suggested that aPKC-ι and ζ are involved in prostate cancer progression and metastasis. Current data suggested that aPKC specific inhibitors along with KBMD compounds induced apoptosis and pyroptosis of DU-145 and PC-3 while having lesser effects on hFOB.1.19 cell line. Our data demonstrate that osteoblasts assist prostate cells to establish in the bone microenvironment by producing metastatic stimulating chemokines while upregulating responsible transcription factors such as c-Jun. In addition, our preliminary data suggested that PKC-ι and ζ are crucial for driving critical steps of the metastatic cascades of prostate cancer cells. Preliminary data suggested that all 6 compounds upregulated interleukin (IL)-18 and IL-1β while downregulating IL-8, IL-6 and CXCL-1. Upregulation of Caspase 8 with cleaved gasdermin D in prostate cells indicates an increase in pyroptosis. Our preliminary results suggest that all 6 compounds can be used to disrupt the main steps of prostate cancer bone metastasis which can be targeted to develop customized, tailored therapies for bone metastatic prostate cancer which merit further research.

#2033 Rigosertib promotes anti-tumor activity of cancer cells via CETSA revealed novel targets and activates NLRP3-dependent inflammatory responses.

P. Kechagioglou[1], C. Dupont[1], H. Yurugi[1], A. Chernobrovkin[2], R. Romero[1], R. Tweedell[3], T.-D. Kanneganti[3], S. Cosenza[4], S. M. Fruchtman[4], K. Rajalingam[1]; [1]University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany, [2]Pelagobio Bioscience, Solna, Sweden, [3]St. Jude Children's Research Hospital, Memphis, TN, [4]Onconova Therapeutics Inc, Newtown, PA

Background: Rigosertib (ON 01910.Na) is considered a promising anticancer agent due to its ability to inhibit multiple disease signaling pathways, including RAS-MAPK signaling. Rigosertib is in a Phase 2 program in advanced squamous cell carcinoma complicating recessive dystrophic epidermolysis bullosa (RDEB-associated SCC) (NCT03786237, NCT04177498), and a Phase 2 trial in combination with pembrolizumab in patients with metastatic melanoma (NCT05764395). The aim of our study was to further elucidate the mechanism of action and to identify potential novel targets engaged by rigosertib.
Methods: A variety of biochemical, molecular and cell biological assays were performed to characterize the binding of rigosertib to previously proposed targets and its effect on RAS-MAPK signaling and tumor cell survival. A mass spectrometry-based Cellular Thermal Shift Assay (CETSA-MS) was conducted to identify potential new protein targets of rigosertib. Time-lapse microscopy was used for detection of ROS levels and tubulin polymerization in rigosertib treated lung cancer cells. Bone Marrow Derived Macrophages (BMDM) collected from C57/BL6 mice and human lung cancer organoids were treated with rigosertib and the cell death was determined by flow cytometry.
Results: Comparative CETSA profiling of rigosertib and colchicine, a classical tubulin depolymerizing agent, reveals unique targets of rigosertib in multiple tumor cell types. We identify two ROS-related proteins, ERO1A and NQO2 that potentially contribute to the induction of ROS-dependent JNK activation. Fluorescence live-cell imaging confirms the effect of ERO1A and NQO2 on rigosertib induced ROS generation. NEK7, a relevant protein for microtubule organization, is another potential target for rigosertib. NEK7 knock-down reveals reduced microtubule depolymerization in rigosertib treated lung cancer cells. While we confirm that rigosertib might affect microtubules at higher concentrations, the main cellular target(s) responsible for the induction of stress and JNK-mediated inhibition of RAS-RAF-MEK signaling needs to be further characterized. Rigosertib affects the tumor immune environment by activating NLRP3-dependent inflammatory responses and Caspase-1 to trigger IL-1β and IL-18 secretion in THP1 cells, as well as in human cancer organoids, and in wild-type, Casp1/11$^{-/-}$, Asc$^{-/-}$ and Nlrp3$^{-/-}$ BMDMs.
Conclusion: These findings indicate that rigosertib may represent an effective compound for inhibition of RAS-MAPK signaling through ROS-mediated JNK activation. The rigosertib-dependent mechanism for NLRP3 activation suggests a reprogramming of the tumor immune environment which may contribute to the synergistic effect seen with immune checkpoint inhibitors pre-clinically and clinically. Clinical trials in several difficult-to-treat cancers continue.

#2034 The NAE1 inhibitor MLN4924 sensitizes both BRCA1 wild type and mutant triple negative breast cancers to cisplatin by reducing the nucleotide excision repair protein XPC level..

S. Misra[1], M. Opyrchal[2], **A. Ray**[2];

[1]Ohio State University Medical Center, Columbus, OH, [2]Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN

Background: Triple-negative breast cancer (TNBC) shows poor survival and prognosis, high recurrence, and poor response to conventional therapeutics. To develop novel therapeutics for TNBC, we explored the efficacy of the neddylation inhibitor, MLN4924. We showed that MLN4924 displayed increased sensitivity against TNBC compared to non-TNBC subtypes. Mechanistically, MLN4924 induced extensive re-replication and DNA damage leading to cell death. Furthermore, MLN4924 improved cisplatin efficacy by elevating the DNA damage levels. To demonstrate the mechanisms of MLN4924+cisplatin-mediated enhanced cell death, we examined the XPC level, a key factor in the nucleotide excision repair (NER) pathway, playing a central role in cisplatin damage repair. Neddylation of CUL4A promotes XPC ubiquitination which influences XPC binding to the DNA damage sites for NER.

Methods: We examined the XPC protein level by Western blot assay and RNA level by Real Time PCR using both BRCA1-wild type (MDA-MB-231) and BRCA1-mutated (MDA-MB-436) cell lines and mouse xenograft tumor samples. We evaluated if the proteosome inhibitor MG132 stabilizes XPC ubiquitination and protein levels by treating these cells with MG132 for various times. We also overexpressed XPC in these cell lines and examined the effect on survival upon MLN4924 and MLN4924+cisplatin treatments.

Results: Our results demonstrate that MLN4924 reduces XPC ubiquitination upon shorter drug treatment but reduces the protein level upon longer drug treatment in both BRCA1-wild type and BRCA1-mutated cell lines. MG132 treatment did not stabilize the XPC ubiquitination level upon shorter drug treatment but stabilized the protein level upon longer drug treatment. We also observed a reduction in the XPC protein level in tumor samples which correlated with the increase in the DNA damage level. Surprisingly, XPC overexpression improved the cell survival in both MLN4924- and MLN4924+cisplatin-treated BRCA1-wild type and mutated TNBC cells.

Conclusion: We hypothesize that a reduction in the XPC ubiquitination and protein levels plays a role in cisplatin-induced DNA damage repair reducing NER efficiency and consequently increasing the DNA damage upon MLN4924+cisplatin treatment. Since overexpression of XPC results in improved survival of both MLN4924-and MLN4924+cisplatin-treated cells, we anticipate that XPC not only regulates cisplatin damage repair through NER but may have a broader role in MLN4924 sensitization beyond the NER pathway. Importantly, MLN4924 treatment does not affect the XPC mRNA level emphasizing that neddylation influences the XPC protein level. In summary, our research uncovers novel insights into the role of XPC in both MLN4924 and MLN4924+cisplatin sensitization, shedding light on potential avenues for innovative therapeutic strategies for TNBC patients.

#2035 A Benzenesulfornamide with potential to improve chemoresponse of ovarian cancer through activation of AMPK and immunogenic cell death.

J. Kim, N. Montero, S. Sharma, M. Mansolf, K. Yang, T. Hartwich, Y. Yang-Hartwich;
Yale School of Medicine, New Haven, CT

Introduction: Ovarian cancer is a leading cause of death among women globally often characterized by poor prognosis and aggressive tumor growth. The therapeutic outcomes of ovarian cancer patients are limited by the development of acquired chemoresistance and the lack of targeted therapies. This study aimed to understand the mechanism in which a benzenesulfornamide named Y3 enhances the efficacy of chemotherapeutic agents. Y3 was previously identified by our team as an activator of AMPK with the activity to induce immunogenic cell death of ovarian cancer cells.
Material and Methods: Patient-derived ovarian cancer cell lines were pretreated with Y3 for 3 h before treatment of carboplatin or paclitaxel. Celltiter Glo assay was performed to determine the impact of Y3 pretreatment on the IC50 values of carboplatin or paclitaxel after 48 h. Apoptosis was evaluated using Annexin VI/PI staining and Caspase 3 activity assays. The role of AMPK pathway was assessed using AMPK siRNAs and western blot. The potential of Y3 to enhance immunogenic cell death induced by carboplatin or paclitaxel was evaluated in a syngeneic mouse model of ovarian cancer using a vaccination assay. The control group mice were vaccinated by subcutaneously injecting mouse ovarian cancer cells treated by carboplatin in vitro for 24 h into the left flank. The test group mice were vaccinated by injecting Y3-carboplatin co-treated cells. One week after vaccination, untreated live cancer cells were injected into the right flank of both groups. Tumor growth was monitored.
Results: Ovarian cancer cell lines pretreated with Y3 showed decreased IC50 values for carboplatin and paclitaxel treatments. The apoptotic cell populations stained by Annexin VI were increased in the Y3 pretreated in comparisons with the single treatment groups. Caspase-3 activity validated the results of Annexin VI/PI staining assay. AMPK knockdown by siRNAs effectively reduced the levels of phospho-AMPK that was induced by Y3, which also dampened the Y3-promoted chemotherapeutic effects on ovarian cancer cells. In the in vivo vaccination assay, tumor growth in the right flank was suppressed in the mice vaccinated with Y3-carboplatin co-treated cells to an extend that is more significant than the control group.
Conclusion: Y3 pretreatment increased the sensitivity of ovarian cancer cell lines to carboplatin and paclitaxel. The effects of Y3 on ovarian cancer cells depend on the activation of AMPK. Y3 enhances the immunogenicity of carboplatin-treated ovarian cancer cells.

#2036 Characterizing PARP inhibitor and next-generation anti-androgen therapy responses in advanced prostate cancer.

L. A. Moore, B. Correa Gonzalez, A. C. Gao, **A. P. Lombard**;
University of California, Davis Health, Sacramento, CA

PARP inhibitors (PARPi) have been shown to be effective in prostate cancer patients with certain DNA repair defects, thus ushering in the era of precision medicine for this disease. Despite this advance, barriers remain which impede further progress including an incomplete understanding of therapeutic response. Our previous and on-going work shows that PARP inhibition leads to both cell death and a more cytostatic, senescence-like arrest. We hypothesize that persistent cells may later promote progression and treatment resistance. Recent clinical trials such as PROpel and TALAPRO-2 have demonstrated success in combining PARPi's with next-generation anti-androgen therapies (NGAT) including abiraterone and enzalutamide. Whether NGAT's are synthetic lethal and cell death promoting with PARP inhibition is poorly understood. Additionally, given the evolving clinical landscape for prostate cancer, it is important to test whether prior NGAT exposure may preclude response to combination therapy. In this study, we sought to characterize these combinations to better understand tumor cell response to treatment and the placement of treatment within the overall therapeutic paradigm. We've previously used the C4-2B metastatic castration-resistant prostate cancer cell line as a model which responds well to PARP inhibition. Here, we additionally utilize the C4-2B-derived enzalutamide and abiraterone resistant lines MDVR and AbiR, respectively. The combination of olaparib with abiraterone (recently approved from results of PROpel) was significantly more efficacious than either monotherapy in all three models. Additionally, combination of talazoparib and enzalutamide (approved from results of TALAPRO-2) was also more effective than monotherapy. These data suggest that prior development of NGAT resistance does not prevent benefit from NGAT and PARPi combinations. Although both combinations were found to cause significantly less cell growth, cells appeared more cytostatic rather than apoptotic, suggesting NGAT's do not induce significant synthetic lethality with PARPi's. Our work suggests that combining a PARPi with an NGAT promotes a persistent cytostasis which may give rise to eventual tumor progression and the development of resistance. Future studies are directed at further characterizing combinations with PARPi's and the development of novel strategies to enhance their efficacy.

#2037 Enhanced chemosensitivity to DNA-damaging agents in human high-grade glioma through 2-DG treatment.

T. Miller[1], E. Jane[2], M. Halbert[2], T. Gatesman[2], S. Wendell[2], D. Mohanakrishnan[2], S. Agnihotri[2], D. Premkumar[2], I. Pollack[2];
[1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Human high-grade gliomas are aggressive brain cancers known for their resistance to treatment. Targeted therapies with single agents have shown limited success, and the presence of tumor heterogeneity complicates treatment. Combining multiple chemotherapeutic agents has emerged as a potential strategy to overcome these challenges. 2-deoxy-D-glucose (2-DG) is a glucose analog known for its ability to disrupt glycolysis, protein folding, and the pentose phosphate pathway. This disruption renders cancer cells more susceptible to further damage from reactive oxygen species and DNA damage. Previous studies have demonstrated synergistic effects when combining 2-DG with chemotherapeutic drugs in various cancers. Our study examines combining 2-DG with DNA-damaging agents for high-grade gliomas to uncover potential synergies, theorizing that this combination enhances cell death and metabolic stress, offering insights for better treatments against these tumors.
Methods: The cell proliferation, clonogenic growth, and cell migration assays assessed viability, clonogenic formation, and migration. Additionally, the cell cycle and reactive oxygen species analysis were employed to evaluate cell division, oxidative stress, and antioxidant capacity. The Illumina NovaSeq 6000 platform measured transcript levels, and Liquid Chromatography-High-Resolution Mass Spectrometry analyzed metabolite changes in high-grade glioma cell lines following 2-DG treatment. The Agilent Seahorse Mito Stress Test evaluated alterations in cellular bioenergetics. SYNERGYFINDER 3 quantified synergistic effects of 2-DG with DNA-damaging agents, while the Annexin V-FITC Conjugates and a ROS multiplex assay assessed cell death and metabolic stress.
Results: Our findings demonstrate that when used as a single agent, 2-DG induces cell senescence and limits cell migration but is insufficient to trigger cell death. Moreover, 2-DG treatment shifts glioma cells towards oxidative phosphorylation for energy production, elevates ROS levels, and hampers DNA synthesis and repair mechanisms. Our synergy study reveals promising synergistic effects when combining 2-DG with DNA-damaging agents, including 5-FU, Methotrexate, Gemcitabine, and Lomustine. This combined therapy leads to significant ROS generation and increased cell death compared to single-agent treatments. Furthermore, prolonged exposure to 2-DG leads to increased levels of both glucogenic and ketogenic amino acids within glioma cells, potentially serving as an alternative energy source. This finding hints at a prospective therapeutic approach for targeting drug-resistant cells.
Conclusions: Our results suggest that the anticancer therapeutic effect of 2-DG is enhanced when used in combination with DNA-damaging agents, indicating this strategy as a potential approach for treating human high-grade glioma.

#2038 Combination therapy leads to decreased viability in cardiomyblasts cells.

A. N. Greenlee, E. J. Schwendeman, S. A. Smith;
The Ohio State University, Columbus, OH

Anti-cancer therapies (ACT) have been extremely effective in improving survival in cancer patients; however, they have also been known to cause cardiovascular diseases (CVD) in the same patients. Published research shows that ACTs are toxic to cardiomyocytes through decreased viability. However, they have mainly focused on drugs that are phasing out of clinical practice while newly generated tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICIs) have rarely been studied, despite their increase in popularity for treating multiple cancers as monotherapies and combination therapies. Additionally, most of the concentrations tested tend to be higher than the concentration that directly interacts with cardiomyocytes, therefore overestimating its effects. The goal of this project is to elucidate whether newly generated TKIs and ICIs, both by itself and in combination, lead to decreased viability in cells. We tested three TKIs (Axitinib, Cabozantinib, and Lenvatinib) and two ICIs (Nivolumab and Pembrolizumab), both solely and together, on rat ventricular myoblasts (H9c2) cells using clinically relevant concentrations by calculating the unbound serum drug concentrations found in cancer patients. After 24 hours, we tested cell viability using the cell counting kit-8 (CCK-8) assay. After 24 hours, neither TKIs nor ICIs by themselves caused decreased viability compared to the control group. However, there were significant decreases in viability when treated with combination of the two, with more than 50% depletion in the Lenvatinib/Pembrolizumab group. Our study indicates although TKIs and ICIs by themselves do not effect viability, they have significant effects after 24 hours when the drugs are combined, even at clinically relevant concentrations. We plan to further characterize whether these drug combinations lead to cardiomyocyte death and through which pathway. Additionally, our lab has successfully differentiated and validated human-induced pluripotent ventricular myocytes (hiPSC-CMs) and testing whether these monotherapies and combination therapies effect viability and functionality on human-induced pluripotent ventricular myocytes (hiPSC-CMs) is currently in progress.

#2039 Cellular characterization of small molecule PD-L1 inhibitors reveal their novel mechanisms of action.

W. Pan, Y. Zhang, F. Qi, W. Xin, Z. Feng, Z. Chen, **H. Ying**;
Abbisko Therapeutics, Shanghai, China

Introductions: Immune checkpoint inhibitors, including PD-1/L1, are key regulators of immune response and promising targets in cancer immunotherapy. Like anti-PD-1/L1 antibodies, small molecule PD-L1 inhibitors that have been discovered by us and others could also efficiently block PD-1 and PD-L1 interaction and exhibit anti-tumor efficacy in preclinical and clinically settings. In this study, we explore the cellular mechanism of small molecule PD-L1 inhibitors, unveiling their novel mechanisms of action in the regulation of PD-L1 and its functions.

Materials and Methods: The cellular effects of the small molecule PD-L1 inhibitor on PD-L1 protein and RNA levels were assessed through Western blot and real-time qPCR experiments. HTRF assay and cellular luciferase reporter assay were used to evaluate the blockade of PD-1 and PD-L1 interaction *in vitro* and in cells. Flow cytometry and confocal microscopy were used to investigate the internalization of PD-L1 upon treatment with inhibitors. MSD assay was used to evaluate the alteration of soluble PD-L1 proteins.

Results: Small molecule PD-L1 inhibitors discovered by Abbisko Therapeutics potently blocked PD-1/PD-L1 interaction *in vitro* and in cellular system. It could also rapidly and strongly induce PD-L1 internalization in cells. Further profiling suggested that small molecule PD-L1 inhibitors specifically disrupt PD-L1 N-glycosylation, resulting in aberrant PD-L1 glycosylation. This, in turn, may hinder the proper translocation of newly synthesized PD-L1 to the cell surface, thereby abolishing its interaction with PD-1 and functions in immune regulation.

Conclusion: Taken together, these results for the first time revealed the distinctive mechanisms of our small molecule PD-L1 inhibitors. With their multi-layer inhibitory effects stemming from various mechanisms, small molecule PD-L1 inhibitors may offer potentially improved activities and an alternative therapeutic treatment for the cancer patients.

#2040 Targeting MUS81 endonuclease to enhance chemo-immunotherapy response in head and neck squamous cell carcinoma.

A. A. Suwaidan[1], A. Pasto[1], C. McCarthy[1], T. Pan[1], J. Deng[1], L. Dolcetti[1], G. Alfano[1], R. Mustapha[1], J. Monypenny[1], M. Forster[2], T. Ng[1];
[1]King's College London, London, United Kingdom, [2]University College London, London, United Kingdom

Background: In advanced head and neck squamous cell carcinoma (HNSCC), immune checkpoint inhibitors are only effective in 15-20% of cases. Defects in replication stress response represent a promising avenue for enhancing the therapeutic efficacy of immunotherapy through DNA damage and the release of immunostimulatory DNA. MUS81, a DNA structure-specific endonuclease involved in resolving replication stress, is upregulated in many cancer types including HNSCC, and MUS81-associated cytosolic DNA is implicated in triggering cGAS-STING mediated innate immunity. The objectives of this study were to assess the impact of targeting MUS81 on HNSCC cell sensitivity to cisplatin, and investigate its role in enhancing immunotherapy response in HNSCC, through the cell viability and cell cycle analysis, differential gene expression, and DNA release within small extracellular vesicles (exosomes).
Methods and Results: We used HNSCC cell lines and patient-derived organoids (PDOs) to investigate the consequences of CRISPR/Cas9-mediated MUS81 knockout (KO). We demonstrated that MUS81 KO increased HNSCC cell sensitivity to cisplatin, inducing a G2/M cell cycle arrest. Transcriptomic analysis of differentially expressed genes (DEG) in MUS81 KO vs control cells highlighted upregulation of *ANXA6* (tumor suppressor gene encoding for Annexin A6), *MACROH2A2* (involved in the quiescent phenotype acquisition of malignant HNSCC cells) and *CDA* (encoding for cytidine deaminase, implicated in replication stress). MUS81 KO was also associated with downregulation of LCP1 (encoding for lymphocyte cytosolic protein 1, upregulated in oral cancer and controlling cellular proliferation, invasiveness, and migratory activities). Gene Set Enrichment Analysis (GSEA) of RNA-seq data, revealed positive enrichment in MUS81 KO cells treated with cisplatin in genes involved in the hallmark interferon alpha (Normalized Enrichment Score (NES) 3.03, p-value < 0.001) and interferon gamma (NES 2.83, p- value < 0.001) pathways, indicative of innate and adaptive immune responses. Additionally, the pathway of hallmark inflammatory response was positively enriched (NES 2.22, p < 0.001). In addition, cisplatin treatment in MUS81 KO was associated with notable alterations in the concentration and length of exosomal DNA, with implications for immune response modulation within the tumor microenvironment.
Conclusions: Our study underscores the potential significance of MUS81 as a novel therapeutic target in HNSCC. In addition to sensitizing HNSCC cells to chemotherapeutic agents, targeting MUS81 may influence the dynamics of the tumor microenvironment, thereby enhancing the prospects of immunotherapy in this context. Further in-depth investigations are imperative to validate these observations and facilitate the development of innovative therapeutic strategies tailored to targeting MUS81 in HNSCC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Technologies
Poster Session

#2044 A live cell PRMT5 NanoBRET Target Engagement Assay querying competitive and uncompetitive modes of inhibition.

A. Michaud[1], E. Rothweiler[2], **C. Corona**[3], M. Beck[1], J. Wilkinson[1], J. Vasta[1], K. Huber[2], M. Robers[1];

PRMT5 is an essential arginine methyltransferase that regulates a wide spectrum of cellular processes through the methylation of histone and non-histone substrates. In PRMT5 catalysis, SAM serves as the cofactor and methyl group donor, generating a methylated guanidinium moiety on the target substrate. In normal cells, the SAM pools are maintained through the methionine salvage pathway. In 15% of cancers, a key enzyme in this pathway (MTAP) is deleted, leading to an accumulation of the intermediate MTA, which inhibits PRMT5 activity. This genetic loss of function has therefore been pursued as a collateral vulnerability in MTAP deleted cancers. To exploit this synthetic lethality, a number of novel inhibitors have been developed that bind cooperatively at the PRMT5/MTA complex, offering a compelling pathway to precision medicine. Here we describe a novel, live cell NanoBRET Target Engagement assay that enables mechanistic studies on a variety of PRMT5 inhibitors. Using a cell-permeable NanoBRET probe directed to the substrate pocket of PRMT5, both substrate- and cofactor-competitive engagement can be quantified in cells. Moreover, this method can be used to quantify MTA-uncompetitive target engagement in cells, providing a platform to measure the potency of PRMT5-MTA-drug ternary complex formation. This method serves as a first-in-class method to quantify uncompetitive target engagement in live cells, which can be applied to other model systems.

#2045 Novel TFRC humanized mouse model for drug delivery to the brain.

F. Sonego[1], A. Pappalardo[1], G. Martin[1], B. Ozgur[2], P. Ravn[2], Y. Cherifi[1], F. Sotty[2], P. Isnard-Petit[1], **K. Thiam**[1];
[1]genOway, Lyon, France, [2]Lundbeck, Copenhagen, Denmark

Gliomas are the most common neoplasm in the central nervous system (CNS). Although immunotherapy has shown efficacy in several tumor types, no immunotherapies are approved by the US Food and Drug Administration for treatment of gliomas. One of the biggest challenges in using immunotherapies in the CNS is the existence of the blood-brain barrier (BBB), which limits drug delivery and the subsequent therapeutic drug efficacy. In addition to biodistribution, assessment of PK in preclinical models do not reflect the clinical findings. Conjugation of therapeutic agents with molecules binding to TRFC expressed along the BBB are being used as one of the alternative approaches to deliver drugs into the CNS. Herein, we describe a novel TFRC humanized mouse model (hTFRC), developed to enable assessment of compounds targeting human TFRC and aiming to deliver drug through the BBB. hTFRC model was developed by knock-in at the mouse endogenous locus to enable a physiological expression of TFRC. Splenocytes from hTFRC mice stimulated with labelled pHrodo Red human transferrin show internalization of human transferrin, suggesting that humanization of the transferrin receptor does not change the endocytosis process. *In vivo*, treatment of hTFRC mice with anti-BACE1/anti-TFRC antibodies enables the transfer of anti-BACE1 to the brain, while anti-BACE1 antibody is not. As a consequence of the drug delivery, mice treated with anti-BACE1/anti-TFRC show a marked reduction in Amyloid-β 1-40 levels in the brain. Altogether, the data suggest that hTFRC is expressed in the BBB and enables the efficient shuttling of therapeutic antibodies to the brain. While assessment of TFRC-targeting antibodies in a glioma model remains to be performed, the hTFRC model is a promising tool to assess delivery and efficacy of immunotherapies in gliomas. Moreover, the hTFRC model is also being intercrossed with the well-established hSA/FcRn humanized mouse model (Viuff *et al*., 2016), to enable a more translatable PK and biodistribution of compounds targeting TFRC.

#2046 Targeting cellular models of glioblastoma versus non-target and off-target cell populations using U87-MG membrane lipid-modified nanoliposomes.

K. Janton, D. Baamir, A. Patel, S. Boco, R. Campbell;
Massachusetts Col. of Pharmacy & Health Sci., Worcester, MA

Background: Glioblastoma Multiform (GBM) is an aggressive and malignant form of brain cancer known for its invasiveness and significant heterogenicity. The majority of GBM cases are linked to genetic mutations (ie. TP53, EGFR, and PTEN), which disrupt the normal regulation of cell growth and division, resulting in uncontrolled cell proliferation. The utilization of nanoparticles presents a promising approach for addressing the complexities associated with selective drug delivery to GMB and treatment. The purpose of this study was to investigate the effect of including U87-MG membrane lipid extracts in nanoliposomes using target, non-target, and normal healthy cellular populations in vitro.
Methods: The nanoliposomes employed for the experiments included various ratios of U87-MG lipid extracts (lipids derived from U87-MG cells), DOPC, Cholesterol, and DPPE-Rhodamine for fluorescence studies. The particle size and zeta potential values were measured and monitored throughout for consistency. Fluorescence intensity values (arbitrary units) were used to assess extent of cell binding, and uptake at the various time points. In vitro studies were employed to evaluate the cellular uptake activity of U87-MG-modified nanoliposome preparations using mixed ratios and compositions of lipid materials. Cell lines employed were, LN-18 (human glioma), T98G (human glioma), U87-MG (human glioma), 4TI (murine breast), and HBEC-5i (normal healthy) cells.
Results: The average size for the nanoliposomes (with and without lipid extract) fell within the range of 110 to 220 nm, while the zeta potential for the CLENs was negatively-charged. In vitro studies revealed that the inclusion of U87MG lipid extract in nanoliposomes increased cellular uptake in glioma cells when compared to control. Current investigations focus on different microenvironments, including non-target and off target cell populations. The findings from the cellular uptake analyses to date suggest that the *in vitro* cellular uptake of the CLENs varied in accordance with the total lipid extract content for all cell lines.

#2047 Scale up and scale down approaches for screening of 3D patient-derived cell models.

C. Paul[1], A. Chatman[1], A. Bullock[1], X. Yang[2], G. Wong[2], B. Balhouse[1], C. Yankaskas[1], E. Willems[2], M. Dallas[1], D. Kuninger[1];
[1]Thermo Fisher Scientific, Frederick, MD, [2]Thermo Fisher Scientific, Carlsbad, CA

3D cell culture is becoming more prevalent as scientists work to better model human physiology using in vitro systems. However, differences in handling 3D cell cultures compared to traditional 2D cell lines have limited adoption of 3D techniques in compound and cell therapy screening experiments. To facilitate use of patient-derived 3D tumoroid models, we developed protocols for both scale up and scale down of these models in Gibco™ OncoPro™ Tumoroid Culture Medium. OncoPro Tumoroid Culture Medium is a serum-free, conditioned medium-free culture medium designed to promote the growth of patient-derived 3D cancer models (tumoroids, cancer organoids). OncoPro medium is compatible with a suspension culture approach for easier handling compared to traditional embedded culture formats. We studied the growth of tumoroids in different flask sizes during suspension culture to optimize scale up for downstream assays. Tumoroid growth rates and morphologies were consistent across non-tissue culture treated flask sizes, and viable cell yield increased with surface area during scale up. In some cases, as many as $100x10^6$ dissociated tumoroid cells can be recovered from a single Nunc™ TripleFlask™ after a week of growth. After scaling up, tumoroids were dissociated and seeded in multiwell plates to test multiple screening conditions (compound identity, compound concentration) in parallel. Dissociated cells were seeded in 96-well plates using both manual and automated liquid handling (Tecan Fluent 780). Due to the tendency of 3D cell models to aggregate and fall out of solution, initial seeding in a 96-well flat bottom plate resulted in high well-to-well variability. Optimization of cell seeding protocols led to standard deviations in tumoroid metabolic activity, number, and size that were comparable to manual seeding, with a coefficient of variation of less than 3% between wells for multiple tumoroid lines when automation was implemented. Generally, variability in cell seeding was lower when using the optimized, automated cell seeding protocol compared to manual methods. After seeding, cells were grown for three days to form tumoroids prior to the addition of compounds. At this time point, there was low well-to-well variability in tumoroid metabolic activity (CV<2%). Compounds and reagents to analyze cell health could also be added using automated liquid handling prior to analysis on plate readers or high-content imaging platforms.

#2048 Integrated tumor models for immune oncology: Using live cell imaging for prediction of treatment efficacy *in vitro* and *in vivo*.

D. Kobelt, M. Stecklum, S. Rhein, W. Walther, J. Hoffmann;
Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin-Buch, Germany, Germany

Background: The preclinical evaluation of novel cancer treatments demands comprehensive model systems in vitro that provide meaningful data before entering in vivo studies. Here we evaluate the capabilities of live cell imaging systems to evaluate novel immune therapies. Using integrated immune and tumor cell models in vitro we demonstrate, that these model systems can generate reliable data of pharmacodynamic activity of biologicals, small molecules or combinatorial approaches for further preclinical in vivo characterization.

Methods: Target tumor cell killing was assessed in vitro with immune cells (T- and NK-cells) and engagers. Tumor cells were transduced with a fluorescent marker to discriminate tumor cells from immune cells. The technology was used to determine inhibition of cell motility (re-invasion) after scratching of tumor cell monolayers. Cells were monitored using the IncuCyte. Dose-response-curves of single treatments and all combinations were generated in parallel. Active therapies were selected for further in vivo validation of immune cell killing. Humanized mice were generated by injection of CD34+ HSC or human immune cell subsets. Immune cell engraftment was monitored by FACS. To analyze the effect biologicals or small molecules, tumor cells were transplanted into these humanized mice. Tumor development and therapeutic effects were monitored by BLI measurements.

Results and conclusion: Tumor cell killing by immune cells and monolayer scratch assay in 96 well format were successfully monitored in the IncuCyte. Here, data can be generated over time without the need of new samples at every time point compared with conventional end point measurements. Using antibodies directing immune cells to attack target cells extensive cell killing was observed over time. These data predicted in vivo treatment outcome in mice co-engrafted with human immune cells. After successful humanization of mice, immune cells can be directed to kill target tumor cells. Small molecule combinations were tested in vitro utilizing the metastasis/2D scratch assay. After setup of dose-response curves for two molecules combinatorial treatments were tested. Here we found a synergistic increase in efficacy. These combinations were tested in vivo to evaluate their abilities to inhibit cell motility and distant metastasis. Here we show that the in vitro assays predicted correctly the highest efficacy of combined treatments compared to mono treatments.The IncuCyte System provides data that translate our integrated model systems into in vivo studies. We have shown that activated immune cells can kill target tumor cells in vitro. These data have been validated in vivo using immune cell humanized mice. Further, immune cells, biologicals and small molecule based treatments can be tested either alone or in combination, allowing the preselection of active combinations for further development.

#2049 Novel preclinical models for PROTAC evaluation: And beyond.

y. xu, J. Zhang, Y. Tian, Z. Chen, A. Wang, T. Ma, Q. Chen, Y. Yin;
Shanghai ChemPartner Co., Ltd., Shanghai, China

Proteolysis-targeting chimeras (PROTACs) are a novel class of small molecules that induce the degradation of target proteins. Unlike conventional inhibitors that disable target proteins by direct binding, PROTACs are event-driven, meaning that a single PROTAC molecule can induce the degradation of multiple target protein molecules. This catalytic mechanism allows PROTACs to achieve complete inhibition of target proteins at lower concentrations compared to conventional inhibitors, making them a promising therapeutic approach for previously considered "undruggable" targets.Despite their promise, the development of PROTACs faces several challenges. The large molecular weight of PROTACs can lead to poor cell permeability and bioavailability. Additionally, the lack of high-throughput, quantitative assays for evaluating PROTAC efficacy hinders structure-activity relationship (SAR) studies. The formation of the Protein-PROTAC-E3 ternary complex is crucial for PROTAC function, and reliable methods for assessing this interaction are essential for PROTAC development.In this poster, ChemPartner showcases a comprehensive suite of preclinical models for PROTAC evaluation, encompassing both in vitro and in vivo approaches. Using low-cost, high-throughput biochemical assays, we can provide valuable insights into PROTAC efficacy, facilitating SAR studies and elucidating the relationship between molecular structure and activity. Followed by in cell and in vivo function assays, we can test PROTAC PK/PD, toxicity, and efficacy. This suite of assays provides a powerful tool to speed up PROTAC development and reduce the fail rate.

#2050 Preclinical characterization of PRO1106, a novel and promising SLITRK6-directed sesutecan ADC.

W. Shen[1], H. Lu[1], Y. Xiao[1], X. Qiu[1], H. Liu[1], L. Wang[1], **Z. Chen**[2];
[1]ProfoundBio (Suzhou) Co., Ltd., Suzhou, China, [2]ProfoundBio US Co., Seattle, WA

SLITRK6 is a type I transmembrane member of the SLITRK family of proteins and is highly expressed in certain epithelial tumors including urothelial, lung, breast cancer and glioblastoma, with minimal-to-low expression in normal tissues. Recent studies with a vedotin-based SLITRK6-directed ADC, AGS15E, have offered clinical proof-of-concept of harnessing this target with the ADC modality for addressing high unmet need at least in bladder cancer. PRO1106 is comprised of a proprietary humanized SLITRK6-targeting IgG1 (dubbed as “mAb”) and the proprietary topoisomerase 1 inhibitor-based linker-drug, sesutecan. Sesutecan previously demonstrated promising characteristics in preclinical studies with multiple targets and conferred an encouraging benefit:risk profile in the clinic with a FRα-directed ADC (rinatabart sesutecan). PRO1106 and the parent mAb exhibited strong binding (with low nanomolar affinity) to recombinant human or cynomolgus monkey SLITRK6 on bio-layer interferometry. No binding was observed with human SLITRK1 or SLITRK4 or in additional negative-binding assays. Potent cellular binding (with sub-nanomolar EC_{50}) was also observed for the parent mAb and ADC with bladder, head and neck, and brain cancer cell lines as well as SLITRK6-overexpressing 293F cells. Target-binding was superior to sirtratumab (the parent antibody in AGS15E) and the binding epitope appeared to be distinct from that of sirtratumab in cross-block studies. PRO1106 displayed rapid internalization and elicited robust cytotoxicity (IC_{50} in the sub-nanomolar to low nanomolar range) in SLITRK6-expressing tumor cells but not target-negative cells. PRO1106 produced strong tumor growth inhibition in multiple cell-derived xenograft (CDX) models in mice representing bladder cancer and esophageal squamous cell carcinoma. PRO1106 showed a stable PK with much higher exposure compared to an in-house synthesized analog of AGS15E in rats. In an exploratory PK study in cynomolgus monkeys, PRO1106 at 5 mg/kg exhibited extended PK with minimal release of exatecan in circulation and with no apparent toxicity observed. In summary, PRO1106 is an ADC built on a clinically validated linker-drug directed at a clinically validated target, with promising data in preclinical pharmacology studies. As SLITRK6 expression in skin is negligible, PRO1106 may offer an exciting new option for patients with bladder cancer where the current standard-of-care ADC therapy (enfortumab vedotin) confers significant skin-related toxicity burden as well as for patients with additional cancer types.

#2051 Innovations in ADC technology platform with legumain-cleavable KSP-inhibitor payloads adaptable to various aspects of cancer biology.

H.-G. Lerchen[1], A.-S. Rebstock[1], M. Wiedmann[1], B. Stelte-Ludwig[1], A. J. Johnson[2], R. Izumi[2], A. Hamdy[2];
[1]Vincerx Pharma, Monheim, Germany, [2]Vincerx Pharma, Palo Alto, CA

Despite recent advances in the antibody-drug conjugate (ADC) field it remains challenging to achieve a sufficient therapeutic window. To address key issues of current ADCs such as aggregate formation and payload-related toxicities, we have developed a platform technology with tailored solutions for ADCs and small molecule-drug conjugates (SMDCs). Key features of the ADC technology comprise of kinesin spindle protein inhibitors (KSPi) as a novel payload class, a unique linker selectively cleaved by the tumor-associated protease legumain, and a CellTrapper® modification of the KSPi payload to reduce membrane permeability and provide accumulation in tumor cells beneficial for efficacy and safety[1,2]. Our advanced ADC VIP943 is targeting CD123 for the treatment of AML and MDS and is currently in Phase 1 clinical trial (NCT06034275). Here we show the extension and applicability of the platform in combination with various antibodies. Two case studies demonstrate how the payload-linker optimization increases the selectivity for tumor over healthy cells and potentially overcomes transporter-mediated drug resistance. Tuning the cleavable linker of cetuximab-ADCs for a higher challenge of legumain-mediated payload release resulted in a 52-fold improved selectivity of cytotoxicity against tumor cells versus HaCaT skin cells. A trastuzumab-ADC using a KSPi payload modified with the CellTrapper, shows low nanomolar potency against JIMT-1 cells resistant to trastuzumab-deruxtecan and thus may overcome resistance. An increased potency was not observed with an ADC releasing a permeable KSPi without CellTrapper. To address heterogenous target expression in solid tumors, novel antibody-2-drug conjugates (A2DCs) were synthesized to combine the advantages of intracellular accumulation of non-permeable payloads with the release of a second, membrane permeable KSPi payload. In vitro studies comparing the A2DCs with their respective mono-drug ADCs on 4 different targets shows the highest cytotoxicity achieved with A2DCs independent of the efficacy driver in mono ADCs. Lastly, synthesis of homogenous KSPi ADCs with a drug to antibody ratio of ~8 is compatible with different antibodies without significant aggregate formation. Furthermore, an easy and efficient process for ring-opening of the thiosuccinimide ring after conjugation was developed and shown to successfully avoid ADC de-conjugation via retro-Michael reaction. Selected examples of each of these subclasses were coupled to trastuzumab; all conjugates were highly efficacious and resulted in tumor regressions in the SKOV-3 model similar to trastuzumab-deruxtecan.

Conclusion: Our technology platform offers options for efficient and safe cancer treatments and allows for versatile adaptations to the various aspects of cancer biology. 1. Kirchhoff et al, *Cancers* (2020). 2. Lerchen et al, *Bioconj Chem*. (2020).

#2052 Screening novel format antibodies to design bispecific ADCs that address target heterogeneity.

S. D. Barnscher, D. Urosev, K. Yin, A. Hernandez Rojas, S. Lawn, V. Fung, J. Wong, A. Sagoe-Wagner, L. Degefie, A. Livernois, C. Kim, P. A. Moore, J. R. Rich;

Zymeworks Inc., Vancouver, BC, Canada

Addressing inter-patient and intra-tumoral target heterogeneity is a challenge for antibody drug conjugates (ADCs). The most common approach to mitigate intra-tumoral ADC target heterogeneity is to employ a bystander active payload. Once the ADC is internalized and metabolized, the payload can diffuse into tumor cells, independent of target expression. This strategy has proven effective, as evidenced by all but one of the eleven FDA-approved ADCs incorporating a bystander active payload. Nevertheless, it is important to note that in most cases there is clear evidence of an expression-response relationship, and the bystander approach does not specifically address inter-patient heterogeneity in target expression. Bispecific ADCs that can target two different tumor associated antigens (TAAs) are a promising approach to overcoming challenges associated with spatial and temporal target heterogeneity. A traditional bispecific ADC design employs a bivalent IgG where one paratope interacts with target A, and the other paratope interacts with target B. This design ensures that the molecule is maximally active when both targets A and B are present. However, this enhanced specificity approach has limitations, as it requires cellular co-expression of both targets to be effective. In contrast, a novel-format bispecific ADC targeting two different TAAs independently could increase the addressable patient population relative to a monospecific ADC. For example, a bispecific ADC with the potential for both independent and dual targeting of folate receptor alpha (FRα) and NaPi2b, established targets in ovarian cancers, could significantly expand the number of patients who could benefit relative to an ADC against either target alone. Here we describe a novel approach to the design and screening of a FRα x NaPi2b bispecific ADC library with the aim of targeting tumors that express either FRα, NaPi2b, or both targets. A library of 48 bispecific molecules was designed, employing multiple paratopes and variable antibody formats. The library comprised three valency bins, 1+1, 2+1, and 2+2, corresponding to the number of binding arms to each target. Bispecific antibodies were generated from 31 half antibodies containing Azymetric™ Het_Fc mutations. Complementary half-antibodies were combined and oxidized to generate interchain disulfide bonds, with bispecific antibody purity in the range of 90%. Antibodies and their corresponding ADCs, prepared through direct conjugation to a cytotoxic payload, were evaluated on a panel of FRα-expressing and Napi2b-expressing cancer cell lines. Key ADC parameters, including binding, internalization, and in vitro cytotoxicity, highlighted paratope combinations, valencies, and geometric formats that offer the unique potential to overcome target heterogeneity in ovarian cancer.

#2053 Spatiotemporal tumor immune modulation by localized delivery of cancer therapeutics using an implantable microdevice.

X. Li[1], J. Tessier[1], J. Lee[1], S. Garren[1], V. Cortez-Retamozo[1], M. Sharma[1], A. Jankowski[2], E. Zarazinski[2], A. Fiore[2], O. Jonas[3], C. Brenan[3], D. Shaffer[1], **A. Hadjipanayis**[1];

[1]Sanofi Oncology, Cambridge, MA, [2]Charles River Labs, Worcester, MA, [3]KiburMed, Inc., Cambridge, MA

Mechanism of action studies are imperative to translating oncology therapeutics into the clinic informing testable hypotheses and potential combination partners. This often involves large and time-consuming mouse studies to test a small number of compounds in an attempt to show statistically significant benefit. Likewise, testing multiple compounds and combination partners in these systems is limited by time, cost, and a desire to reduce the number of animals used in biological research. To overcome these limitations, we utilized an implantable microdevice (IMD) developed by KiburMed to measure intra-tumoral drug responses and to differentiate the mechanism of action of multiple cytokine agents in parallel in the MC38 mouse model. After sizable tumor growth in mice and implantation of the IMD device with 9 different therapeutic candidates, MC38 mice were taken down at different time points (24 hour, 4 days,7 days) to assess response. Local tumor response in the study was measured by cyclical immunofluorescence for deep cellular response phenotyping with a panel of 32 markers for comprehensive immune cell phenotyping. Among the candidate murine surrogate compounds in the device, SAR445877 (anti-PD-1-IL-15 mutein) was tested as a monotherapy, as a combination partner with anti-PDL1 and compared against anti-PD1 monotherapy. With further validation of this novel platform, results from this work are aligned with previous studies (1) showing a murine surrogate for SAR445877 in combination with anti-PDL1 increases immune cell populations more than either single agent alone. These analyses show CD3, CD4, and CD8 were significantly increased in SAR'877 murine surrogate + anti-PDL1 compared to SAR'877 alone or anti-PD1 alone. In addition, T cells could infiltrate at a distance away from treatment release region, well into tumor core. Other significant changes in immune cell markers include increases in CD45+, CD11b, CD11c, CD20 and CD27. In conclusion, we have shown that multiple oncology therapeutics can be screened simultaneously in a small number of mice using an implantable microdevice and data obtained with this technology is consistent with that obtained from traditional mouse tumor experiments.

(1) Preclinical characterization of SAR445877, an anti-PD-1 antibody-IL-15 mutein fusion protein with robust anti-tumor efficacy as monotherapy and in combination with PD-L1 blockade. #2054 A sensitive and specific human primary stem cell-based *in vitro* assay for predicting the gastrointestinal toxicity risk of therapeutic agents.

J. Levi, R. Lorichon, L. Boone, M. Bunger, E. Boazak, **W. R. Thelin**;
Altis Biosystems, Durham, NC

Gastrointestinal (GI) toxicities are the most common drug-induced adverse events in human clinical trials. Drugs that cause GI toxicities often affect the proliferative stem and progenitor cell populations responsible for maintaining the cellular composition, self-renewing capacity, and barrier function of the intestinal epithelium. This disruption leads to impaired GI barrier integrity, culminating in a broad range of clinical symptoms, including diarrhea, inflammation, and increased risk of infection. The impact of GI toxicity is substantial and can cause dose-limiting clinical side-effects that may affect patient compliance and dosing adherence. Common nonclinical animal models, including rats, mice and dogs are often poor predictors of human GI toxicity and safety outcomes. Furthermore, in vivo animal testing poses limited screening throughput, which is particularly important in fields such as oncology, where matrices of double or triple drug combinations represent the standard of care. Additionally, existing cell-based model systems, such as Caco-2 cells, are of limited predictive value as they are tumor-derived and do not reprise native epithelium. Thus, there is a need for the development of assay systems that more accurately recapitulate human biology, have higher throughput testing capabilities, and ultimately improve clinical predictability. To this end, we have developed an assay to assess GI toxicity potential using the RepliGut Planar platform, which consists of a primary human stem cell-derived epithelium in a 96-well Transwell format. Quantitative dose-response curves were generated on proliferative and/or differentiated GI cultures for various test articles utilizing endpoints that assess GI proliferative capacity, cell viability, and epithelial barrier formation and maintenance. An initial set of marketed drugs (including diverse anti-proliferative, cytotoxic, or anti-inflammatory mechanisms) with known clinical incidence of diarrhea were over a 5-log dose range to enable modeling of the Toxic Concentration 50% (TC50). When benchmarked against the known human plasma concentrations (Cmax), this model was able to accurately predict clinical outcomes for diarrheagenic-drugs, as well as non-toxic negative controls, within 30-fold of the clinical Cmax. Overall, this model system provides straightforward and informative screening for GI toxicity that integrates sensitive and robust endpoints, enables screening to support early nonclinical development, and uniquely allows for mechanistic insights.

#2055 Delivery of oligonucleotide therapeutic drugs: Universal detection reagents specific for nucleic acid modifications.

T. Giardiello, **A. Anderson**, R. Salvo, C. Ascoli;
Rockland Immunochemicals Inc, Limerick, PA

Nucleic acid therapies, including oligonucleotide therapeutics (ONTs) and vaccines, have increased in development, respectively, since their inception as an emerging drug modality and after the first mRNA COVID-19 vaccine was granted EUA approval in 2020. RNA-based therapies, such as antisense oligonucleotides (ASO), RNAi, aptamers, and mRNA, are designed to modulate protein synthesis in patients and have applications in oncology, gene therapy, and infectious disease prevention. Strategies for ONT drug delivery have advanced over recent years with the goal of overcoming limitations when targeting extrahepatic tissues. Improving the “drug-likeness” of ONTs is facilitated by chemical modifications to the sugar-phosphate backbone and/or nitrogenous bases. Modifications are designed to increase ONT drug stability, uptake, and efficacy, but may increase the likelihood of toxicity. First generation chemical modifications include phosphorothioate (PS) modification of the phosphate portion of the backbone, whereas second generation modifications include adding substituent groups to the 2’ position of the ribose portion of the backbone, specifically 2’-O-methyl (OME), 2’-O-methoxy-ethyl (MOE), and 2’-fluoro modifications of RNA. Third generation modifications include peptide nucleic acids (PNA), locked nucleic acids (LNA), morpholino phosphoroamidate (PMO) modifications, and others. We have developed, optimized, and validated a library of monoclonal antibody reagents that detect these chemical modifications independent of nucleic acid composition, structure, strandedness, configuration, or platform. These “universal detection reagents” can be used in (1) immunohistochemistry (IHC) to determine biodistribution, (2) immunofluorescence (IF) to determine intracellular localization, (3) ELISA to determine anti-drug antibody binding, immunogenicity, and drug ranking, (4) immunoprecipitation to determine protein binding in serum and/or tissue lysates, (5) *in vivo* cell culture studies to determine potency, and (6) other immunoassays. While *in situ* hybridization (ISH) is an established method for the detection and localization of ONTs in cells and tissues, this method has limitations that include lack of utility (as unique probes must be designed individually for each ONT), high costs in time and materials to produce probes, the inability of ISH to bind and detect short ONT drug sequences, and difficulties encountered when repeated sequences are present within the ONT sequence. Here we report differential sensitivity and specificity of panels of antibodies specific for PS and MOE modifications. We demonstrate the performance of these antibodies by various *in vitro* assays that show the utility of these specialty reagents to facilitate the collection of analytical data to support ADMET studies useful to ensure ONT approval by regulatory agencies.

#2056 Click chemistry enabled selective activation of highly cytotoxic MMAE payload at tumors using TROP2 targeting agent.

G. Coricor, J. M. McFarland, S. Srinivasan, S. Wagner, T.-H. Nguyen, J. M. Mejia Oneto;
Shasqi Inc., San Francisco, CA

Shasqi is advancing the Click Activated Protodrugs Against Cancer (CAPAC®) platform based on click chemistry, a Nobel Prize winning technology. The platform is modular and comprises 1) an activator that target specific antigens, and 2) inert cancer drugs, protodrugs, which are selectively activated at tumors via click chemistry. The CAPAC technology separates the tumor targeting function from the payload and reunite them at the tumor creating the flexibility to optimize activity while limiting toxicity during preclinical and clinical development. The modularity of the platform enables the rapid development of new therapies as well as unlocking unique treatment benefits such as tunable combinations and payload cycling. We envision that CAPAC will expand the scope of potential targets, widen the therapeutic index of antibody drug conjugates (ADCs). Here we present a TROP2-targeting activator with a monomethyl auristatin E (MMAE) payload.

TROP2 expression has been observed in many cancers that express low-HER2. The clinical efficacy of anti-TROP2 ADCs is hindered by undesirable side effects, limiting their potential therapeutic window. We have developed the targeting activator SQT02, a TROP2 Fab binder conjugated with ~2.2 tetrazines per protein, and SQP22, an attenuated protodrug of MMAE coupled with *trans*-cyclooctene (TCO). The reaction between tetrazine and TCO moieties releases MMAE at the tumor site. Previously we have demonstrated that SQP22 is attenuated compared to free MMAE and in combination with a HER2 targeting activator led to significant tumor inhibition with no observable toxicity. The CAPAC platform's modular nature allows seamless exchange of targeting agents or payloads, thus enabling different therapeutic combinations to be generated quickly and efficiently, like SQT02 in combination with SQP22. Dosing of SQT02 occurs prior to dosing with SQP22 to reduce non-specific activation while enabling higher payload activation at the tumor site to induce tumor cell death. *In vitro*, SQT02 bound NCI-N87 human gastric cancer cells with similar EC_{50} (~0.07 µg/mL) to an antibody that binds to TROP2. *In vivo*, treatment of SQT02 followed by SQP22 led to 60% tumor growth inhibition compared to Sacituzumab govitecan's 35% inhibition in the NCI-N87 xenograft model. No body weight loss was observed in the animals treated with SQT02 in combination with SQP22.

We have demonstrated the use of click chemistry to deliver a highly potent cytotoxic agent to tumors, causing significant growth inhibition. The flexibility and adaptability of the CAPAC platform allowed us to quickly develop therapeutic combinations that can be deployed to accelerate the path to the clinic. Our findings provide evidence for developing SQT02 in combination with SQP22 for the treatment of TROP2 expressing cancers.

#2057 Monitoring cGAMP Biochemically and in cell using homogenous HTS formatted bioluminescent assay.

S. A. Goueli, k. Hsiao, N. Murray, d. Mikheil, M. Larsen, H. Wang;
Promega, Madison, WI

The STimulator of INterferon Genes (STING) is a transmembrane protein located at the endoplasmic reticulum, which serves as a molecular hub in response to cytoplasmic cyclic dinucleotide (CDN) second messengers such as cyclic GMP-AMP (cGAMP). Upon its generation via cyclic GMP-AMP synthase (cGAS) by a wide array of pathogens that provide extracellular microbial DNA and by intracellular (nuclear and mitochondrial) DNA, it binds directly to the STING protein resulting in the activation of the STING pathway. This activation by cytosolic DNA initiates a cascade of events, cGAS-STING-TBK1-IRF3 signaling, that induces type 1 IFN response, and eventually the signaling is terminated by degradation of pathway components and clearance of stimulatory DNA. Given its significant role as an adaptor for DNA sensors to pathogens and its involvement in immune sensing, tumor growth control, and control of autoinflammatory and autoimmune disorders, the STING pathway has become a very important drug target. Credible evidence suggests that the cGAS–cGAMP–STING pathway makes fundamental contributions to at least three major cancer therapies: radiation therapy, chemotherapy, and immunotherapy, and it thus represents a promising drug target. Therefore, there is a need to identify lead compounds that effectively modulate human STING for further drug development. Towards this goal, we have developed a bioluminescent assay to monitor the concentration of cGAMP in intracellular as well as extracellular compartments. The assay relies on the new concept of Protein Complementation Assay (PCA) using nanoluciferase (nanoluc) complementation technology where a small peptide (SmBiT) derived from nanoluc linked to cGAMP through a linker (cGAMP tracer) can be recognized by an anti cGAMP antibody that is linked to a nanoluc complementary fragment (LgBiT) resulting in bioluminescence upon the addition of nanoluc substrate. The presence of free cGAMP that is generated in the reaction competes with cGAMP tracer and decreases bioluminescence. We have optimized the assay for higher sensitivity down to less than 10 nM cGAMP and less than one ng of cGAS and thus, and it is suitable for testing compounds that modulate cGAS activity. We also improved cell lysis condition to increase recovery of cGAMP that is generated intracellularly using several cGAS activators and correlating its concentration with cytokine release. We envision using this assay to monitor cGAMP presence in sera and spinal fluids of patients who have ALS and Alzheimer diseases. The assay is homogenous, with minimal or no false hits using LOPAC screening and HTS formatted and can be completed in less than one hour. Thus, this assay provides valuable contribution for investigating modulators of the STING pathway and facilitates the search for novel therapeutics.

#2058 Compound library screening to identify modulators of alternative splicing in non-small cell lung cancer (NSCLC).

R. Cooley[1], M. V. Powers[1], A. G. Bond[1], P. Jensen[2], G. Newton[1], A. Scarpino[1], J. Braun[2], C. Esdar[2], P. A. Clarke[1];
[1]The Institute of Cancer Research, London, United Kingdom, [2]The Healthcare Business of Merck KGaA, Darmstadt, Germany

Alternative splicing is a molecular mechanism that allows a single gene to encode multiple proteins. It is a complex and highly controlled process used to regulate normal gene expression but is often dysregulated in cancer. Compounds that can modulate alternative splicing are currently being explored as a potential new class of therapeutic agent in cancer. This highlights the need for a deeper understanding of the splicing process, its regulation, and its impact. The discovery of novel and specific tool compounds that modulate splicing would therefore not only be beneficial in investigating the regulation and dysregulation of splicing in cancer but could also be exploited therapeutically.

To identify novel regulators of splicing, we generated a cell-based split luciferase screening assay based on alternative splicing of MCL-1 (myeloid cell leukemia-1 protein) pre-mRNA. The *MCL1* gene usually produces an mRNA encoding a 'long' variant (MCL1L) that is an anti-apoptotic protein often highly expressed in cancers. However, in some circumstances, for example following genetic knockdown of splicing factors, a pro-apoptotic 'short' variant (MCL1S) is expressed as a result of exon-skipping.

Here we engineered the human NSCLC cell line NCI-H1299 to express a luminescent-tagged version of the MCL1S splice variant to monitor its induction upon spliceosome modulation. Using this engineered cell line, we screened an unannotated library of 12,000 compounds selected to have low molecular weights and favorable properties for cellular uptake. The screen had an average Z' value of 0.89 over 45 microplates, indicating high assay robustness. Hits were identified as any compound with a luminescence of greater than the average + two standard deviations of the screening dataset. The compounds were validated by repetition in the screening assay, giving 34 candidate hits that were then triaged by qPCR assay to confirm splicing modulation of *MCL1*. One interesting hit was found to increase mRNA and cellular protein levels of MCL1S and induced altered splicing across the transcriptome that was distinct from the splicing profiles of a diverse panel of splicing modulators, including compounds targeting SF3B1, CLK, and RBM39. In addition, treatment with this hit compound resulted in accumulation of the splicing factor SC35 in cytoplasmic granules, an unusual phenotype not seen with known splicing modulators, that could explain the distinct splicing modulation we have observed.

Deconvolution and further characterization of screening hits and potentially unique new mechanisms of action could improve current understanding of alternative splicing and its regulation in NSCLC. The discovery of novel compounds to expand our current toolset of splicing modulators will be key in building the foundation for future splicing targeted drug discovery.

#2059 An image-based real time method to measure antibody-dependent cellular phagocytosis.

J. Wang, Y. Shi, Y. Sun, J. T. Koerber, A. Seki, S. Rutz;
Genentech, Inc., South San Francisco, CA

Antibody-dependent cellular phagocytosis (ADCP) is an important mechanism of action of therapeutic antibodies. *In vitro* quantification of macrophage phagocytosis has been technically challenging. Flow cytometry assays were traditionally used for ADCP activity measurements, these methods were static measurements at certain time point, thus provide no information about engulfment kinetics. Moreover, the flow cytometry assays require lifting the macrophage cells from the labware which may affect macrophage activities. We have developed a real time ADCP assay using a live cell analysis system. The target cells labeled with a pH sensitive dye only fluoresce when they are engulfed in acidic phagosomes in the presence of specific antibodies. Our assay is a plate-based with a simple mix and read protocol without disturbing the macrophages. The new method is quantitative and robust, can be readily used for high-throughput screening for functional antibodies. By studying the ADCP activities of different subtypes of macrophages, we found M2 microphages showed the strongest ADCP activity compare to M0 and M1 macrophages, due to their different expression levels of FcgRs. The assay is highly sensitive to differentiate the antibody variants with enhanced Fc function. It can also be used to study the kinetics and mechanisms of ADCP.

#2060 Automation of 3D cancer spheroid assay for compound screening.

O. Sirenko, A. Lim, A. Michlmayr, Z. Tong, E. Keidel, F. Spira;
Molecular Devices, LLC (Moldev), San Jose, CA

Finding efficient drug combinations to treat cancer patients is critical for therapy success. Accordingly, there is a critical need to develop methods for efficient testing drug efficacy to discover new therapeutic targets. 3D cancer models are highly valuable tools for cancer research and drug development. However, the complexity of performing 3D assays remains a hurdle for adopting these methods for compound screening. To alleviate the bottlenecks that come with labor-intensive manual protocols we developed cell culture automation methods using CellXpress.ai instrument. The instrument enables automation of 2D or 3D culture for prolonged complex workflows. The CellXpress.ai provides automated plating, passaging, media exchanges, monitoring organoids, alone with compound treatment and the end point assays with high content image analysis. In the present study we describe full automation of imaging, analysis, and cell culture process which enables scaling up complex 3D cell-based assays and compound screening. As an example of 3D protocol, we automated culture and imaging of colorectal cancer 3D spheroids formed from HCT116 cell line in U-shape low attachment plates. HCT116 cells were expanded in 2D, then spheroids were formed after automated dispensing of cell suspension into U-shape 96 or 384 plates. After 48h spheroids were treated with 12 anti-cancer compounds, at multiple concentrations for 3-5 days, then stained and imaged. Cell plating, compound additions, media exchange, and staining were performed automatically by CellXpressAI instrument. During the culture spheroids were monitored using transmitted light, with immediate analysis of phenotypic changes, including inhibition of growth or spheroid disintegration. For endpoint assay spheroids were stained with combination of Hoechst nuclear stain and viability dyes Calcein AM and EtHD, then imaged, and analyzed for multiple read-outs including spheroid size, marker intensities, and live-dead cell scoring. We observed concentration-dependent inhibition of spheroid growth and cell death in response to anti-cancer compounds and evaluated effective compound concentrations for cytotoxic or cytostatic effects. Cell culture process automation for 3D assays, powered by imaging and image analysis has a potential to bring 3D biology into another level, allowing to increase throughput and reproducibility, and enabling variety of high throughput drug discovery and precision medicine applications.

#2061 A proven activity-based workflow for the identification and characterization of time-dependent kinase inhibitors using a continuous assay format.

E. May[1], D. Urul[1], K. Huynh[1], S. Cornell-Kennon[1], V. Nemmara[1], Z. Lu[1], S. Hoare[2], M. Lyles[3], E. Schaefer[1];
[1]Assayquant Technologies, Inc., Marlborough, MA, [2]Pharmechanics LLC, Owego, NY, [3]Assayquant Technologies, Inc., Marlboro, MA

Time-dependent inhibitors (TDIs) of enzyme targets offer distinct advantages for the development of potent and selective compounds with favorable pharmacokinetic and pharmacodynamic properties. Such inhibitors are characterized by non-linear progress curves: after an initial inhibited velocity, a rate constant governs the transition to a final steady-state reaction rate of the inhibited enzyme. A final rate of zero indicates irreversible inhibition, whereas a non-zero final rate indicates slow-binding inhibition. Characterizing these inhibitory modes of action is enabled with a continuous assay format that avoids the common pitfalls and misleading results seen with end-point assays. A continuous assay format enables efficient and robust determination of the kinetic parameters required to drive structure-activity relationship optimization to streamline the development of more effective drugs. It is important to note that simple IC_{50}s for TDIs will not suffice, and can, indeed, also be misleading. We have developed a robust three-step workflow based on kinetic catalytic activity measurements to quickly identify and characterize TDIs. First, dose-response experiments are conducted with and without an enzyme-inhibitor preincubation step. The curvature of the reaction progress curve in the non-preincubated experiment and a shift in IC_{50} from the preincubated experiment are indicative of TDI. In the absence of TDI, simple IC_{50}s are reported with, if possible, K_i values. If TDI is present, a second experiment is conducted to assess compound reversibility using either a jump-dilution protocol or a novel free-compound clearance method that uses gel filtration spin columns or spin plates. In either protocol, forward progress curve analysis is used to monitor the recovery of enzymatic activity after dilution of inhibitor in solution. Lastly, the potency of the inhibitor is evaluated using kinetic experiments tailored to the nature of the inhibition – either reversible or irreversible. If reversible, then the rate constant from the reversibility experiment is used to determine the residence time of the molecule. If irreversible, then a 24-point dose-response experiment with serial 1.5-fold dilutions is performed, and all the progress curves are globally fit to determine k_{inact}/K_I, and, if possible, k_{inact} and K_I separately. The method will be fully described through the characterization of known EGFR inhibitors of three inhibition types: fast-off (Gefitinib), slow binding (Lapatinib), and irreversible (Osimertinib).

#2062 Identification of functional MAIT-specific TCRs using MR1 dCODE Dextramer® reagents and evaluating antigen presentation.

K. Lenogue, B. Hansen, K. Jacobsen, L. Brix, T. Holberg Blicher;
Immudex, Virum, Denmark

Objectives:

To support TCR discovery and enable evaluation of TCR target expression on the surface of cells, we have established a streamlined workflow allowing TCR Discovery, validation and evaluation of MHC-antigen expression on target cells. As proof of concept, MR1 dCODE Dextramer® reagents were used to identify antigen-specific MAIT cells using single-cell sequencing, TCR sequences were extracted from the resulting data and then cloned and expressed as TCR monomers. The specificity of the TCRs was subsequently validated as TCR Dextramer® reagents and used to evaluate target MHC-peptide presentation on cell surface.

Methods:

Mixed PBMC samples from three healthy donors were stained with antibodies targeting relevant phenotypic markers as well as MR1 dCODE Dextramer® reagents carrying the MAIT cell-specific ligand 5-OP-RU. Following staining, sorting, and partitioning on a BD Rhapsody™ Single-Cell Analysis System, the cells underwent sequencing for a characterization of gene and surface marker expression as well as paired alpha-beta TCR sequences. Single alpha and beta chains were individually expressed, refolded together and purified. Refolded TCR monomer functionality was validated using an artificial cell assay. The functional TCRs can be multimerized on a Dextramer® backbone and used to evaluate expression of target on cell surface.

Results:

The majority of the identified CD161+ MAIT cells (~70%) expressed typical TCRs consisting of TRAV1-2 and TRAJ33 as well as TRBV6/20, TRBD1/2, and TRBJ2 gene segments. Three alpha-beta TCR sequences were selected: Two TCRs having common TRAV+TRAJ, TRBV+TRBJ combinations and one having a rare TRAV+TRAJ one. TCR alpha and beta chains were successfully expressed for all selected TCRs but only 2 TCRs showed a correctly refolded TCR as demonstrated by proper recognition of MR1/5-OP-RU. Based on these two functional TCRs, TCR Dextramer® reagents were generated and used to evaluate expression of target antigen on cell surface.

Conclusion:

We demonstrate a workflow allowing: (i) Identification of MAIT cells and their corresponding TCR sequences. (ii) Generation of soluble TCR molecules based on the identified sequences and validation of their specificity. (iii) Generation of TCR Dextramer® reagents allowing identification of target expression on surface of cells.

This workflow is also useful for identification of other antigen-specific T cells and creates a new tool for evaluation of antigen-expression by MHC on surface of cells. By combining the high sensitivity of dCODE Dextramer® technology with TCR sequencing and creation of TCR Dextramer® reagents, both low-affinity interactions and rare cell types can be detected and studied in unique detail.

#2063 Using the edge wells in 96-well plates without increasing variability in cytotoxicity assays through thermal controls.

A. D. Henn, S. Darou, R. Yerden;
BioSpherix, Ltd., Parish, NY

There are very few things as fundamental to cancer research as the 96-well-plate, yet edge effect has continued to cause problems since its introduction. The most common remedy for edge effect is to avoid using edge wells altogether, which eliminates 37% of the plate from the assay. If all of those wells could be used, an estimated USD $119M could be saved in research costs annually across the globe. We have shown previously that maintaining constant thermal control of plating conditions reduces variability in stem cell toxicity assays. Here, we ask the question: can we use the edge wells in cancer screening assays if we control thermal changes that happen in the traditional lab as cells are plated at room temperature and incubated at 37 degrees C? We had the null hypothesis that including the edge wells would add variability to an A549 cytotoxicity assay, even if the cell handling and incubation temperatures were matched and held constant. We plated A549 cells at either room temperature (like a BSC) or at 37 degrees C using the Xvivo System, which maintains constant temperature, oxygen, CO2, and relative humidity levels around cell handling operations. The cells were treated with serial dilutions of peracetic acid/hydrogen peroxide solution. After incubation for 3 days, the plates were stained with Crystal Violet and assessed for cell density (n=3 separate experiments). The null hypothesis was disproven. We found that if the plates were maintained at 37 degrees C during cell handling as well as incubation, that cell distribution was random and even across all wells, even edge wells. We found that there was no statistical difference between edge well and center well results in cytotoxicity assays. Edge wells were usable without increasing variability in the assays. This is consistent with earlier findings showing that when temperature changes between cell plating and incubation were averted, stem cell distribution across the plate was random and the edge effect was eliminated.

#2064 Unveiling the correlation between gemtuzumab-ozogamicin efficacy and CD33+ expression in AML primary samples using the novel AML vitroscreen.

Mara Gilardi, Garima Kaushik, Brandon Walling, Paolo Schiavini, **Stefano Cairo**, Marianna Zipeto

Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Acute myeloid leukemia (AML) poses a significant therapeutic challenge, with a rising incidence in recent times. This clonal hematopoietic disorder of progenitor and stem cells exhibits aggressive behavior, and despite initial remission, recurrence is common[1]. The conventional shift from chemotherapy to monoclonal antibodies and antibody-drug conjugates (ADCs) has been hindered by the absence of AML-specific antigens. Notably, CD33, expressed strongly in 80-90% of AML cells, has become a target for gemtuzumab-ozogamicin (Mylotarg), the sole FDA approved ADC for AML treatment[2]. While advancements in understanding AML molecular mechanisms have influenced clinical approaches, the lack of clinically representative models hinders therapeutic progress. Existing models, both in vivo and ex vivo, struggle to capture the heterogeneity and complexity of AML[3]. Addressing this, we present our proprietary assay, Champions AML VitroScreen®[4], designed for testing therapeutic candidates in primary AML samples. Our diverse bank of deeply characterized AML samples encompasses multiple subtypes, allowing evaluation of therapeutic responses through cell viability, proliferation, and clonal composition analyses. To validate our novel assay, we employed the VitroScreen platform to test Mylotarg across various AML subtypes, considering CD33 expression levels. By assessing more than 20 AML models, we determined the IC50 for Mylotarg and observed dose-dependent responses, where sensitivity to the drugh correlated with CD33 expression. Through multiple endpoints, including viability, proliferation, apoptosis, and phenotyping, we categorized primary AML models as responders, low responders, or resistant, establishing a strong positive correlation between Mylotarg sensitivity and CD33 expression. Our innovative approach, utilizing deeply characterized AML patient samples in the AML VitroScreen® platform, facilitates high-throughput drug testing. This system, serving as an ideal clinical translational setting in preclinical research, holds promise for developing tailored therapeutic strategies. Ultimately, this approach could significantly impact patient outcomes by offering improved strategies for both primary and recurrent AML cases.

#2065 Development of a genetically validated, cell-based reporter assay for ADAR1 editing activity.

V. Sapp, J. Bilakovics, A. Burr, F. Martins, P. Shashkin, V. Baron, H. Zhu, J. Park;
BPS Bioscience, San Diego, CA

Adenosine Deaminase Acting on RNA (ADAR) enzymes perform adenosine to inosine base editing in RNA, particularly targeting adenosines located within a specific double-stranded stem-loop motif. The ADAR1 gene encodes both a universally expressed isoform (p110) and an interferon-inducible isoform (p150), which plays a role in innate immunity by mediating interferon signaling. In the context of healthy, uninfected cells, ADAR1 performs A-to-I editing on endogenous double-stranded RNA to prevent it from activating downstream dsRNA sensors RIG-I and MDA5, which in-turn activate a pro-inflammatory response. Loss of function mutations in ADAR1 result in aberrant activation of the dsRNA sensors and are involved in autoimmune disorders. ADAR1 dysfunction also impacts cancer cell growth, proliferation, and response to immunotherapy. ADAR1 expression is increased in several types of cancer and ADAR1 knock-out has been demonstrated to improve the response to certain immunotherapies such PD-1/PD-L1 blockade and to circumvent tumor immunotherapy resistance mechanisms, making ADAR1 an attractive target for therapeutic development. We have developed and validated a high-throughput, cell-based assay for measuring ADAR1 editing activity. Several ADAR editing reporter constructs were designed and evaluated for their relative response to ADAR1 over-expression. They all feature an ADAR1 hairpin target with a stop codon (UAG) which is susceptible to ADAR1-mediated editing to a tryptophan (UUG), located upstream of a firefly luciferase gene. We show that increasing transient expression of ADAR1 led to proportional increased activity of the downstream firefly luciferase, indicating dose-dependent transcript editing by ADAR1. Selected reporters were used in conjunction with ADAR2 overexpression to identify an ADAR1-biased reporter. Thus, a reporter with low luciferase activity in response to ADAR2 expression was chosen to establish stable HEK293 cell lines (which express low levels of ADAR1) with and without constitutively expressed ADAR1 protein. ADAR1-overexpressing HEK293 cells displayed high luciferase activity, in accordance with high ADAR1-mediated editing of the reporter transcript, which was decreased in response to siRNA-mediated knockdown of ADAR1 expression or pharmacological inhibition of ADAR1 activity. Sequencing of the reporter RNA confirmed that changes in reporter activity were correlated with editing of the RNA transcript. Finally, these validated ADAR1 editing reporter cell lines were further engineered to constitutively express Renilla luciferase under the control of a CMV promoter, serving as an internal control for the toxicity of ADAR1 inhibitors. In conclusion, our robust cell-based assay provides a well-validated resource to identify modulators of ADAR1 editing activity in a cellular context.

#2066 Measuring the activity of SMUG1 DNA glycosylase with a novel sSTRIDE-SMUG1 assay.

K. Stepien, F. Sierpowski, Z. Prucsi, S. Koman, M. Jarosz, A. Waligorska, M. Kordon-Kiszala, K. Solarczyk;
intoDNA, Krakow, Poland

On average, spontaneous deamination of cytosine to aberrant base uracil happens 70-200 times per human genome per day. These mutagenic U/G mispairs are, however, corrected by error-free base repair (BER) initiated by uracil-DNA glycosylases. SMUG1 (single-strand selective monofunctional uracil DNA glycosylase), as one of the major glycosylases, removes uracil and oxidized pyrimidines from DNA. In spite of the name, SMUG1 removes uracil also from double-stranded DNA. Unrepaired by SMUG1 U/G mispairs are mutagenic, and alterations in SMUG1 expression levels have been linked to cancer development. Low SMUG1 transcripts are associated with poor prognosis in breast cancer and SMUG1 loss has been shown to cause PARPi resistance in HR-deficient background. Hence, tools describing SMUG1 activities in DNA damage response may provide new approaches for cancer cell treatment. We report here the development, optimization and validation of an assay measuring the activity of SMUG1. The new assay is based on the STRIDE platform technology, which enables direct and sensitive detection of single- or double-strand DNA breaks in situ, in fixed cells. sSTRIDE-SMUG1 assay detects DNA nicks localized in close proximity to the SMUG1 protein and can thus be utilized as a direct reporter of its activity. The experiments were performed in HAP1 cells. First, in untreated cells we have shown that the sSTRIDE-SMUG1 signals constitute ca. 1-2% of total single-strand DNA breaks foci detected by the classic sSTRIDE assay variant, while the negative controls have shown that the number of false-positive foci does not exceed 15% of the total number of signals. As expected, treatment of cells with a cytotoxic nucleotide hydroxymethyl-deoxyuridine (hmdU) resulted in an increase in the number of detected sSTRIDE-SMUG1 signals. To verify the specificity of the assay, SMUG1 was knocked-down in HAP1 wild-type cells using siRNA and then the level of sSTRIDE-SMUG1 signals was measured in both untreated and hmdU-treated cells. In all tested conditions, SMUG1 expression silencing has resulted in a decrease in sSTRIDE-SMUG1 foci. We believe that the sSTRIDE-SMUG1 assay can prove to be a very useful solution to study DNA repair mechanisms involving aberrant base excision. Additionally, sSTRIDE-SMUG1 measurements may be of the utmost importance in characterization of agents inducing synthetic lethality or trapping BER intermediates.

#2067 QUANTROseq, a transcriptomic based drug discovery platform using time-resolved gene expression profiling: Identification of inhibitors and degraders of transcription factors and cell signaling regulators.

Arianna Sabo[1], Nina Fasching Griesmayr[1], Tobias Neumann[1], Raphael Manzenreither[1], Maja Ivankovic[1], Rodrigo Pacheco Valamatos Costa[1], Sarah Rieser[1], Sara Scinicariello[1], Petr Triska[1], Anna Stingeder[1], Astrid Gruss[1], Ryan Cubero[1], Olga Frank[1], Ivica Sowemimo[1], Paul Kirchgatterer[2], Adriana Cantoran[3], Stefan Ameres[4], Johannes Zuber[2], Michael Bauer[1]

[1]QUANTRO Therapeutics GmbH, Vienna, Austria,[2]Research Institue of Molecular Biology, Vienna, Austria,[3]St. Anna Children's Cancer Research Institute, Vienna, Austria,[4]Max Perutz Labs, Vienna, Austria

Integrative analyses of CRISPR/Cas9 screening datasets from different sources revealed - besides known oncogenes - a series of transcriptional master regulators as most prominent context-specific dependencies in cancer that remained largely inaccessible to conventional drug discovery approaches. New chemical entities (NCEs) that specifically interfere with a transcription factor (TF) at any level should induce and be detectable based on selective effects on their primary biochemical activity - i.e., the transcriptional activation of specific target genes. However, the definition of direct targets of a TF and, more generally, the unbiased detection of direct transcriptional effects has remained challenging due to the limited time resolution of conventional techniques for gene perturbation and transcriptional profiling. To overcome this limitation, QUANTRO Therapeutics relies on SLAMseq technology that, by metabolic labeling de novo-synthesized RNA immediately after intervention and conserving the information for later readout, provides unprecedent time-resolution in transcriptomic analysis.

Aiming to target previously undruggable targets, we set out to first build definitive knowledge around their direct effect on transcription, inducing their quick protein degradation through the auxin-inducible degron (AID) technology followed by immediate transcriptional readout though SLAMseq -before any secondary, confounding effect could appear in the cell.

The targets´ mRNA fingerprints produced are then used as a reference and cross-compared with existing and new chemical entities to:

(i) benchmark the real mode of action of existing drugs; (ii) identify new drug candidates that specifically interfere with disease-causing transcriptional programs in cancer; (iii) interrogate the efficiency, selectivity, and potency of drug candidates during Hit-validation and Hit-to-Lead activities.

Proof of concept data demonstrated that time-resolved transcriptional profiling can reveal drugs´ mode of action with unprecedent precision and sensitivity, when drugs act on Targets that have a direct effect on transcriptional regulation - such as TFs and signaling pathways. Building on this knowledge, QUANTRO Therapeutics unleashed the unique potential of mRNA fingerprinting technology for HTS-compatible drug discovery by (1) establishing scalable and automated workflows for metabolic RNA labeling, treatment of cells, and RNA extraction; (2) developing algorithms for combinatorial mRNA fingerprint-readout that allow for the simultaneous assessment of TF signatures by multiplexed targeted RNA sequencing (QUANTROseq), thus transforming the precision and scope of cell-based compound screens.

#2068 Multi-pass flow cytometry for high-marker panels with minimal spillover spread.

T. Brown, S. Forward, E. Assita, G. Abbott, M. Fahlberg, S. J. J. Kwok;
LASE Innovation, Woburn, MA

Multiparametric flow cytometry on immune cells is essential in cancer research, disease diagnosis, and treatment monitoring. Collecting data on >10 markers at a time is ideal due to deeper cell characterization and assay sensitivity, however, high-marker panels are subject to significant spillover spread from spectrally overlapping fluorophores that compromise data quality, standardization, and interpretation. Clinical flow cytometry still relies on the use of multi-tube low-marker (<10) panels that minimize spillover spread and ease analysis and interpretation of results. To improve and expand the clinical utility of flow cytometry, there is a need for higher marker measurements without use of highly overlapping fluorophores, which would also serve to streamline the use of samples and reagents. Here, we present the development of a novel barcoding method using micron-sized laser particles (LPs) that confer an optical signature to individual cells at high-throughput, enabling tracking of cells through multiple passes in a flow cytometer. This process is possible using a custom cytometer equipped to detect LPs and capture samples. Sequential staining of samples with releasing or photobleaching antibodies/fluors between cycles enables merging of multiple smaller panels that each have minimal spillover, resulting in a high-marker dataset with drastic reduction in spillover compared to conventional single-acquisition flow cytometry.

We demonstrate the utility of this technology through three different assays. Human PBMCs were barcoded with LPs and stained with 1) a panel of releasable antibodies (Miltenyi Biotec, 10 markers, 2 passes), 2) a laboratory-designed panel that utilized photobleaching (32 markers, 3 passes), and 3) a panel of dried and validated DuraClone antibodies that utilized photobleaching (Beckman Coulter, 18 markers, 2 passes). For each assay, cells were stained, acquired, photobleached/released, captured, re-stained, re-acquired and steps were repeated either once (for 2 passes) or twice (for 3 passes). In all cases, we found drastically reduced spillover, better data quality, and identified the same cell subtypes detected by conventional flow cytometry. Reproducibility was high across multiple (3+) replicates with CVs <30% among all populations with >1% frequency of total. New cell populations were identified that would not be possible with separate acquisitions of each pass.

Recent advances in flow cytometry now allow more markers to be analyzed together, but at the cost of increasing spectral overlap and spillover spread. Multi-pass flow cytometry confines spillover to individual panels, reducing overall interference and simplifying analysis. This enhances data quality and usability while streamlining resources, facilitating the clinical uptake of complex flow cytometry in cancer research, diagnosis, and treatment.

#2069 High content imaging without sacrificing coverage, resolution or speed: Functional validation through multiple assays.

M. Boisvert, J. Kieler, D. DiSepio, D. Weldon;
Araceli Biosciences Inc., Portland, OR

Traditionally, high content screening (HCS) required compromise: sacrificing resolution, sample coverage or speed. This has limited high content screening's utility as a high throughput tool, as speed is essential to cancer research at scale. Using a new approach, Araceli Endeavor® offers a solution to this compromise. This system images 96, 384 or 1536 -well high content microplates in under 10 minutes with full well coverage and sub-micron resolution, enabling high content screening at high throughput speeds without compromising resolution or coverage. Paired with the Clairvoyance™ analysis software, plates are analyzed at similar speeds, going from images to object-level data in 5-25 minutes. As with any new technology, validation is needed. Here we validate Endeavor and Clairvoyance at the level of the bioassay, using a range of common high content assays across different modalities. Assays are chosen to quantifiably demonstrate sensitivity, breadth, and broad applicability. Performance was benchmarked by using well-characterized compounds, matching published EC50/IC50 values when possible. We examined submicron-level nuclear spot counting, measuring histone γH2Ax and micronuclei formation after genotoxic insult. Intensity-based assays include cellular positivity, here live/dead, and subcellular translocation with transcription factor NFKB after induction with cytokines Il1b and TNFα. Looking at cytosolic vesicle aggregation, we measured autophagic flux with two distinct modalities, comparative imaging and analysis of live cell dye and immunohistochemistry-based detection yielded consistent EC50 values between methods. Overall, these assays yield consistent, robust results corresponding to literature values, showing the importance of full well coverage and resolution. We demonstrate how assays that formerly took hours can be effectively imaged and analyzed without sacrificing quality in 10-30 minutes.

#2070 Engineered Inhalation nanoparticle formulation for lung cancer.

R. Tiwari, E. N. H. Ghali, N. Chauhan, V. Kashyap, S. C. Chauhan, **M. M. Yallapu**;
University of Texas Rio Grande Valley, McAllen, TX

Background: Lung cancer is a predominant cause of cancer-related morbidity and mortality across the world including in the United States. Treatment modalities for lung cancer include surgery, chemotherapy, radiotherapy, and/or targeted therapies depending on the cancer stage. Despite the survival benefits of chemotherapy, its value is offset by severe systemic side effects such as renal and/or hepatic toxicity or insufficient amounts of drug reaching to the target site. Such pitfalls can be handled by inhalable therapy which avoids first-pass metabolism and increases patients' compliance. In this study, we have investigated the inhalable therapy of cross-linked tannic acid-based nanoparticles (CTA NPs) into cancer cells and determined the synergistic effect of gambogic acid (GA) and gemcitabine (Gem).

Methods: The CTA NPs formulations were characterized for particle size, chemical composition, and drug loading efficiency using various physicochemical methods (FT-IR, DSC, SEM, and TGA). Cellular uptake of CTA NPs was evaluated in lung cancer cell lines (A549 and NCI-H1299) using fluorescence microscopy and flow cytometry analysis. Further, the therapeutic efficacy of GA-Gem encapsulated CTA NPs (G-G CTA NPs) formulation was determined by various *in vitro* assays (CCK-8, mucoadhesion Boyden chamber, and apoptosis assays). The molecular effects of G-G CTA NPs formulation were also observed in lung cancer cell lines.

Results: Our novel CTA NPs formulation provided an average size of 110 nm in dynamic light scattering with a sustained release of the drug(s). CTA NPs formulation showed a remarkable mucoadhesion and mucopenetration penetration potential in-vitro model(s). Cellular uptake studies show that CTA NPs formulation allows for effective endosomal release into the cytosol. Additionally, the G-G CTA NPs formulation showed superior *in vitro* anti-cancer activity in lung cancer cells (A549 and NCI-H1299) compared to free drugs.

Conclusions: Taken together, our results demonstrate that G-G CTA NPs formulation exhibits superior anti-cancer potential than free drug against lung cancer and could be a novel therapeutic modality for the management of lung cancer.

#2071 Pre-clinical evidence for new camptothecin-peptide conjugates in the treatment of sortilin-positive colorectal cancers.

S. Das[1], J.-C. Currie[1], M. Demeule[1], C. Charfi[1], A. Zgheib[2], A. Nayyar[1], A. Nguyen[1], B. Danalache[2], R. Beliveau[2], C. Marsolais[1], B. Annabi[2]; [1]Theratechnologies, Montreal, QC, Canada, [2]Universite du Quebec a Montreal, Montreal, QC, Canada

Limitations in current colorectal cancer (CRC) camptothecin (CPT)-based chemotherapy have mostly been attributed to low specificity and high systemic cytotoxic side effects. More effective therapies are therefore required to improve the clinical outcomes of patients with CRC. Here, we developed a selective and better anticancer drug delivery of CPT through conjugation to a peptide (TH19P01) that targets Sortilin (SORT1), a scavenging receptor expressed in various tumor tissues including CRC. In the current study, significant SORT1 expression was detected in various CRC cell lines as well as that of irinotecan analogs efflux pump (ABCG2) in LoVo and HT-29 cells. Considering this result, we used our proprietary peptide conjugation SORT1 technology to increase cell targeting selectivity and cell delivery efficacy of CPT analogs. Different peptide drug conjugates (PDCs) were generated linking the TH19P01 peptide to SN-38 (an irinotecan metabolite) or exatecan, which are two main CPT derivatives used in recent antibody drug conjugates (ADC) as payloads. *In vitro*, immunonofluorescent microscopy revealed that TH19P01 was rapidly internalized (<15 min) in a SORT1-positive human HT-29 CRC cell model. These PDCs also inhibited CRC cell proliferation at low nM concentrations (3-90 nM). *In vivo*, weekly administration of TH2101 (SN-38) and of TH2303 (exatecan) conjugates were well tolerated as they had little impact on mouse body weight but caused a more potent growth inhibition of the HT-29 CRC tumor xenograft model than did either unconjugated irinotecan or exatecan molecules. In fact, at their maximum tolerable dose, irinotecan and exatecan caused a tumor growth inhibition of only 48% and 45% whereas TH2101 and TH2303 inhibited the growth of HT-29 tumors by 83% and 91%, respectively. These results provide strong pre-clinical evidence for the future development of novel CPT PDCs therapeutics with targeting of SORT1-positive CRC cells.

#2072 Human liver patient derived organoids: Development and characterization of a new tissue mimetic model.

R. Bhowmick[1], M. Rahman[1], S. Wani[1], S. Malla[1], A. Chatterjee[2];
[1]MilliporeSigma, Temecula, CA, [2]MilliporeSigma, Burlington, MA

Liver is the largest solid organ and performs hundreds of vital functions including drug metabolism. Liver diseases, including viral infections, cancer and metabolic disorders account for about 2 million deaths annually, worldwide (1). Current models for studying liver biology and drug metabolism include 2D cultured primary cells/ cell lines, which do not represent the metabolic and structural complexity of human tissue. *In vivo* models for liver diseases are time consuming, cost prohibitive and often ineffective. Therefore, better tissue mimetic liver models are needed. Organoids are self-assembled 3D cultured cellular units that may mimic the corresponding human tissue structurally and functionally (2). Patient derived organoids (PDO) are developed from tissue of specific patients and may resemble the source tissue in molecular features, including recapitulation of patient specific responses to therapies. Here, we report development and characterization of novel liver PDO lines from vendor-sourced cryopreserved tissue. We have developed biobanks of undifferentiated as well as differentiated liver PDO models.Human cadaver-sourced liver tissue were obtained with explicit donor consent. Liver PDO were generated following modification of a previously established protocol (3). Briefly, samples were minced, digested to single cells, and filtered. Specific number of cells were mixed with diluted Matrigel (Corning) and added as small drops on cell culture plates and grown in liver PDO specific growth media. Whenever appropriate, PDO were differentiated by culturing in differentiation-specific media in multi-well plates. In all cases, PDO were monitored using brightfield microscopy (Olympus CK40) and live cell imaging (Muvicyte, Perkin Elmer); and passaged every 6-8 days. Undifferentiated PDO were cryopreserved/ thawed following in-house SOP to confirm viability. Liver-specific biomarker expression in the PDO lines were confirmed by confocal microscopy (ImageExpress, Molecular Devices). PDO lines were also assayed for ALT activity, albumin production and urea. PDO were cleared for microbial/ viral contamination and confirmed as unique lines using single tandem repeat analyses. Transcriptome profiles were analyzed using vendor services. So far, we have successfully generated 3 liver PDO lines, both undifferentiated as well as differentiated. Our liver PDO lines would be highly useful in understanding liver biology and disease models; and will have significant usage in drug testing, including DMPK and ADME/Tox studies. Future efforts would include scaling up, development of liver specific assays and developing PDO from specific liver diseases, including hepatocellular carcinoma, MASLD and NASH. #2073 Human breast patient derived organoids: Development and characterization of a new tissue mimetic model.

R. Bhowmick[1], S. Malla[1], S. Wani[1], A. Chatterjee[2];
[1]MilliporeSigma, Temecula, CA, [2]MilliporeSigma, Burlington, MA

Worldwide, breast cancer (BC), is the most frequently diagnosed cancer among women. In the US, 1 out of 8 women may expect to be diagnosed with BC In their lifetime. Current models for studying BC tumor biology and BC drug discovery include 2D cultured cell lines and patient derived xenografts (PDX). As 2D cultured cells do not represent the 3D complexity of human tissue, and PDX models are time consuming and cost prohibitive, better tissue mimetic models are needed. Organoids are self-assembled 3D cultured cellular units that may mimic the corresponding human tissue structurally and functionally (1). Patient derived organoids (PDO) are developed from tissue of specific patients and may resemble the source tissue in molecular features, including recapitulation of patient specific responses to therapies (2). Here, we report development and characterization of novel breast PDO lines from fresh (≤24h post-surgery) and cryopreserved (≤7 days post-surgery) tissue. Breast tumor and normal, tumor adjacent (NTA) tissue were sourced from consented patients. Breast PDO were generated following modifications to a published protocol (3). Briefly, tissue samples were minced, digested with collagenase, and filtered. The filtrate was resuspended in Matrigel (Corning) and small drops were added on cell culture plates. Both tumor and NTA PDO were cultured using the same media and organoids were monitored using brightfield microscopy (Olympus CK40) and live cell imaging (Muvicyte, Perkin Elmer). PDO lines were analyzed for expression and distribution of important breast-specific biomarkers using confocal microscopy (ImagExpress, Molecular Devices). PDO lines displayed hormone receptors (ER, PR), cell surface (EpCAM, CD49f), cytoskeletal (cytokeratin 14, 19, E-cadherin, vimentin) and cell proliferation (Ki67) markers. Transcriptome profiles were analyzed using vendor services (Azenta). PDO were also tested for their susceptibility to breast cancer drugs, e.g., Tamoxifen, chlorambucil and Docetaxel. We have successfully generated one NTA ER^{+}/ PR^{+}/ $HER2^{-}$ PDO line and one tumor ER^{+}/ PR^{+}/ $HER2^{-}$ PDO line from different donors. Our breast PDO lines would be highly useful in understanding tumor biology, BC progression, signal transduction, and drug discovery/ testing. Future efforts would include process scaling up and development of BC specific assays. References:1.Zhao et al., 2022. STAR Protocols 2.Bleijs, M. et al., 2019. EMBO J3.Dekkers et al., 2021. EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Targets and Pathways
Poster Session

#2077 Exploring the multifaceted efficacy of de novo lipogenesis inhibitor in cancer therapy.
D. Lowder, J. Shin, M. E. Ruiz-Echartea, J. Deng, A. Rusin, D. Skapura, M. Ittmann, S. Kaochar;
Baylor College of Medicine, Houston, TX

Cancer cells frequently exhibit altered lipid metabolism to sustain their rapid growth and proliferation.Sterol Regulatory Element-Binding Proteins (SREBPs) are key transcription factors that orchestratelipid biosynthesis and uptake in cells. Dysregulation of SREBPs is a common feature of many cancertypes, making them attractive targets for therapeutic intervention. In this study, we present acomprehensive exploration of the potential and rationale for targeting lipid metabolism in cancerthrough the use of a small molecule inhibitor that targets activation of SREBP. We illustrate that oursmall molecule inhibitor (SMI) exhibits potent anticancer activity and effectively targets SREBPsignaling in a variety of prostate cancer models as well as in non-prostate cancer models that arelipogenesis driven. Our novel SMI induces apoptosis and reduces PCa cell proliferation, suppressescell invasion and migration. Furthermore, we illustrate that in addition to suppressing the transcriptionfactor activity of SREBPs, these novel SMIs are highly effective in suppressing both the full length andvariant androgen receptor and their signaling in prostate cancer cells. Notably, in cell and organoidmodels, these novel inhibitors exhibit synergistic anticancer activity in combination with the ARsignaling inhibitor, Enzalutamide. The anticancer activity of these inhibitors extend beyond ARdependent prostate cancer and are also effective in organoid models of neuroendocrine PCa, aparticularly drug-resistant and aggressive PC subtype. Lastly, we illustrate excellent pharmacokineticsand potent anti-tumor effects of these novel SREBP activation inhibitors using *in vivo* castration-resistant prostate cancer CDX tumors. Given the urgent need for novel targets in PCa, our first-in-class inhibitor represents a promising therapeutic strategy with the potential to effectively targetdysregulated lipogenesis in cancer patients.

#2078 The imipridone ONC212 cooperates with MEK and immune checkpoint inhibition to elicit *in vivo* regression of KPC mouse pancreatic tumors.

J. Chan[1], A. J. Lannigan[1], G. Sun[1], V. V. Prabhu[2], R. Edwards IV[1], L. Zhang[1], L. Zhou[1], W. S. El-Deiry[1], A. G. Raufi[1];
[1]Brown University, Providence, RI, [2]Chimerix, Durham, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive disease with limited therapeutic options. ONC212 is a second-generation imipridone with antitumor effects in human PDAC cell lines. ONC212 has been shown to bind to mitochondrial protease ClpP, suppress ClpX, and impair oxidative phosphorylation by decreasing ATP production. While ONC212 has been evaluated in immunocompromised mice xenografted with human pancreatic tumors, ONC212 has not been evaluated, either alone or in combination with MEK and/or immune checkpoint inhibition (ICI), in immunocompetent mice bearing notoriously aggressive *Kras*$^{LSL.G12D/+}$; *Tp53*$^{LSL.R172H/+}$; *Pdx1Cre*$^{tg/+}$ (KPC) murine PDAC tumors. We hypothesized that, like human PDAC cells, KPC cells would demonstrate sensitivity to ONC212 both *in vitro* and *in vivo*. Our group has previously shown that ONC212 synergizes with trametinib to induce tumor cell death in human PDAC cells. We therefore hypothesized that this combination, together with ICI, would enhance KPC tumor cell death *in vivo*.
Methods: We determined *in vitro* sensitivity of the KPC cells to ONC212 alone and in combination with trametinib using CellTiter-Glo® luminescent cell viability assays. Results were analyzed after 72 hours of incubation using Compusyn and Combenefit. *In vivo* experiments involved C57BL/6 mice that were injected subcutaneously with $3x10^5$ KPCy cells in 100 mL of PBS/matrigel. To determine the ideal ONC212 dose, we tested five different doses/dosing frequencies (50 mg/kg; 25 mg/kg; 12.5 mg/kg given by oral gavage weekly or twice weekly) in tumor-bearing (50-75 mm^3) mice. Mouse weight and tumor size was measured every four days. Treatment was stopped once tumor volumes reached 3,000 mm^3 or if ulceration occurred. Once the ideal dose of ONC212 was determined, a study treating KPC tumor-bearing C57BL/6 mice with ONC212, trametinib, and ICI (anti-PD-1 mAb) alone and all possible doublet/triplet combinations was performed using the same methods.
Results: We found that the combination of ONC212 and trametinib exhibited synergy in the KPC cell line *in vitro*. Our *in vivo* experiments revealed that ONC212 controlled KPC tumor growth in a dose-dependent manner, however, toxicity was also noted at higher, more frequent doses. While both 25 mg/kg and 50 mg/kg twice weekly were equally effective, 25 mg/kg was better tolerated and determined to be the ideal dose. In the combination therapy study, all treatments resulted in tumor reduction, as compared to the vehicle control; however, the triple therapy group had the lowest average tumor size at day twenty. Toxicity was noted in mice receiving at least two treatments, reflected by reduced weights and mobility. Further analysis of the tumor immune microenvironment using multiplex cytokine and immunofluorescence are ongoing.

#2079 Tumor-derived fibrinogen promotes pancreatic ductal adenocarcinoma progression.

D. Liu[1], L. Brubaker[1], Y. Niu[1], E. LaPlante[1], G. Van Buren[1], A. Milosavljevic[1], C. Chen[1], C. Zong[1], M. Cruz[2], Q. Yao[1];
[1]Baylor College of Medicine, Houston, TX, [2]Michael E. DeBakey VA Medical Center, Houston, TX

Background: Hypercoagulability is a common clinical manifestation in patients with cancers, especially in pancreatic ductal adenocarcinoma (PDAC). Over 20% of PDAC patients with advanced-stage and worse prognosis undergo a venous thromboembolism (VTE) incidence. Fibrinogen (FG) may contribute to VTE due to its high expression in advanced PDAC tumors. Here, we set to determine the biological roles of tumor-derived FG in PDAC. In addition, our previous study showed that Von Willebrand Factor (VWF) A2 domain can effectively bind to FG and reduce platelet clot formation. Therefore, the functional roles of A2 on FG in PDAC were also studied.

Methods: The correlation between survival rate and FG expression in PDAC was analyzed using RNAseq profiles of 149 PDAC patient samples from the TCGA database. PDAC subtyping of Baylor College of Medicine (BCM) PDAC patient-derived xenograft (PDX) cohort was performed using RNAseq data according to Moffitt's criteria. The FG (three chains FGA, FGB, FGG) overexpression (OE) and knock-out (KO) PDAC cell lines were established. The gene expression and biological functions of FG were performed in PDX and cell lines using IHC and immunoblot assays. The FG effect on PDAC progression *in vivo* was studied in mouse models.

Results: TCGA analysis showed that elevated tumor-derived FG gene expression is significantly correlated with worse overall survival and disease-free survival rates in PDAC patients. PDX lines RNAseq analysis clearly separated BCM PDAC PDXs into two subtypes: basal-like and classical PDACs. Basal-like PDXs showed significantly stronger FG staining than that in classical ones. Compared to the classical subtype, the basal-like subtype showed significantly upregulated genes that are associated with the epithelial-mesenchymal transition (EMT), IL6/JAK/STAT3, and TNFα signaling pathways. Accordingly, basal-like subtype PDAC exposed to IL6 or TNFα significantly increased FG and FG receptor expression with activated STAT3 and AKT pathways and elevated EMT markers, whereas classical subtype cells have minimal changes. In addition, we found that the FG-OE cells exhibit enhanced cell proliferation and migration properties whereas FG-KO cells reduced the effects. Consistent with *in vitro* data, FG-OE PDAC showed significantly higher tumor burdens than that of control PDAC in both orthotopic and subcutaneous PDAC mouse models. Furthermore, A2 protein treatment can effectively block the FG function and dramatically inactivate the FG-induced EMT process and AKT signaling pathway.

Conclusions: Tumor-derived fibrinogen is upregulated in a basal-like subtype of PDAC cells and may contribute to tumor growth and metastasis by activating aberrant signaling pathways and promoting EMT. Our findings imply that elevated fibrinogen in PDAC could contribute to tumor progression and the A2 protein which target to fibrinogen may be a promising therapy for basal-like subtype PDAC.

#2080 SOS1 inhibition is an effective therapeutic strategy in SOS1-mutant cancer.

M. J. Sale[1], N. Mukherjee[1], M. Koch[1], R. Ruzicka[2], R. Jacob[2], C. Albrecht[2], T. Zanin[2], T. Madensky[2], R. L. Schenk[2], A. Baum[2], K. Kostyrko[2], D. Gerlach[2], M. H. Hofmann[2], F. McCormick[1];

SOS1 is a principal guanine nucleotide exchange factor for canonical RAS GTPases and activates RAS signaling. Mutations in SOS1 are found in several prominent cancer types, including 2-4% of NSCLC, CRC, and melanoma. The recent development of novel SOS1 inhibitors (SOS1i), including BI-3406, that block interaction between SOS1 and RAS, presents a potential therapy for SOS1-driven cancers. Here we show that the majority of SOS1 mutations observed in patients enhance RAS guanine nucleotide exchange in cells and activate RAS-MAPK signaling. We treated 11 SOS1 mutant cancer cell lines without RAS co-mutation with a SOS1i and found that 10 were sensitive to SOS1 inhibition in 2D and/or 3D cell culture. In contrast, cell lines with SOS1 and RAS co-mutations were resistant to SOS1 inhibition. In vitro treatment of SOS1 mutant cells with a SHP2 inhibitor, which is presumed to inhibit the activity of both SOS1 and SOS2, revealed a subset of four cell lines that were more sensitive to SHP2 inhibition than SOS1 inhibition. This implied that, in certain contexts, SOS2 can compensate for the loss of SOS1 activity. Accordingly, these cells exhibited a SOS2-dependent rebound in RAS-MAPK signaling after treatment with SOS1i. SOS2 knock-down further sensitized these cells to SOS1 inhibition, resulting in responses equivalent to SHP2 inhibition. Thus, upon SOS1 inhibition relief of ERK1/2-dependent negative regulation likely contributes to receptor tyrosine kinase-driven SOS2 activation that may mediate SOS1 inhibitor resistance in some contexts. In vivo, SOS1i efficiently inhibited tumor growth in four SOS1-mutant NSCLC, CRC, and AML xenograft models. The tumor-suppressive effects of SOS1i in these models were comparable to or stronger than the effects of SHP2i or MEKi. Thus, our results suggest that SOS1 inhibition could be an effective therapeutic approach in RAS wild-type cancer patients with SOS1 mutations.

#2081 Biomarkers for CLK inhibitor CTX-712 treatment response in myeloid neoplasms: Paving the way toward clinical trials.

A. Yoda[1], D. Morishita[2], Y. Ochi[1], A. Mizutani[2], H. Tozaki[2], Y. Satoh[2], T. Mori[1], J. Takeda[1], H. Makishima[1], M. Nakagawa[1], Y. Nannya[1], S. Ogawa[1]; [1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan, [2]Chordia Therapeutics Inc., Fujisawa, Japan

Dysregulated RNA splicing is a molecular feature that characterizes almost all tumor types. Splicing is altered in cancer owing to both recurrent mutations and deregulated expression of trans-acting factors that catalyze and regulate splicing. Therefore, splicing can be targeted for the development of new drugs to treat cancers, particularly those with mutations in splicing factors. In myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML), genes that encode splicing factors are among those with the highest mutation rates. These mutations are heterozygous and largely mutually exclusive, suggesting the possibility of synthetic lethality due to multiple splicing factor mutations. Such synthetic lethality can be applied as an innovative strategy to develop drugs for the treatment of MDS and AML. We have reported the development of a CLK kinase inhibitor, CTX-712, and evaluated its anti-leukemic activities both *in vitro* and *in vivo*. The mechanism of action of CTX-712 involves the suppression of the phosphorylation of multiple SR proteins, including SRSF2/3/4/6, alteration of nuclear speckle morphology, and switching of binding partners of SRSF2. RNA-seq analysis revealed that CTX-712 induced global alterations in splicing, typically resulting in exon exclusion (exon skipping) of cassette exons. Notably, the anti-leukemic effects of CTX-712 positively correlated with the degree of altered splicing, suggesting that CTX-712 inhibits RNA splicing. [Cancer Res (2022) 82 (12_Supplement): 5494., Blood (2022) 140 (Supplement 1): 489-490]. However, patient stratification markers for CTX-712 based on the above mechanism are still undefined. To identify biomarkers for CTX-712, we performed a comprehensive analysis by integrating both wet and dry DNA/RNA sequencing on more than 60 *ex vivo* primary samples from MDS/AML patients and 23 MDS/AML-derived xenografts (PDX). Unexpectedly, regardless of their splicing factor-mutation status, various types of primary AML cells and PDX models were highly sensitive to CTX-712. Both the primary cells and PDX models showed significant responses to CTX-712 and greater changes in splicing. Additionally, we performed biomarker analysis by comparing gene mutations and RNA splicing patterns between the sensitive and insensitive models and associating them with the anti-tumor effect. We identified several potential biomarkers that can indicate sensitivity to CTX-712. Mechanistic studies that aim to determine why these biomarkers could make cancer more sensitive to splicing perturbation by CTX-712 are ongoing. In conclusion, our results demonstrated a significant effect of CTX-712 on MDS/AML-derived models regardless of their splicing factor-mutation status. Additionally, we present novel biomarkers that could predict sensitivity to CTX-712.

#2082 Identification of nonsense-mediated decay inhibitors that alter the tumor immune landscape.

A. L. Cook, S. Sur, L. Dobbyn, E. Watson, J. D. Cohen, B. Ptak, B. S. Lee, S. Paul, E. Hsiue, M. Popoli, B. Vogelstein, N. Papadopoulos, C. Bettegowda, K. Gabrielson, S. Zhou, K. Kinzler, **N. Wyhs**;
Johns Hopkins University School of Medicine, Baltimore, MD

Despite exciting developments in cancer immunotherapy, its broad application is limited by the paucity of targetable antigens on the tumor cell surface. As an intrinsic cellular pathway, nonsense-mediated decay (NMD) conceals neoantigens through the destruction of the RNA products from genes harboring truncating mutations. We developed and conducted a high throughput screen, based on the ratiometric analysis of transcripts, to identify critical mediators of NMD. This screen revealed disruption of kinase SMG1's phosphorylation of UPF1 as a potent disruptor of NMD. This led us to design a novel SMG1 inhibitor, KVS0001, that elevates the expression of transcripts and proteins resulting from truncating mutations in vivo and in vitro. Most importantly, KVS0001 concomitantly increased the presentation of immune-targetable HLA class I-associated peptides from NMD-downregulated proteins on the surface of cancer cells. KVS0001 provides new opportunities for studying NMD and the diseases in which NMD plays a role, including cancer and inherited diseases.

#2083 Discovery of ETX-19477, a novel and selective PARG inhibitor with high potency against tumors with underlying replication stress.

J. P. Holleran, T. S. Rodems, S. Sharma, A. M. Santini, C. Wuerz, J. Liu, L. Tian, J. Dosch, J. Nader, R. Rivera, S. Herath, J. Marakovits, C. McBride, R. Stansfield, A. Salyards, J. M. Veal, J. A. Stafford, G. Bain;
858 Therapeutics, Inc., San Diego, CA

DNA damage response (DDR) is an important cellular process that is regulated by poly ADP ribosylation (PARylation). PARP1 binds to DNA break sites and then catalyzes PARylation, which leads to recruitment of repair factors and initiation of base-excision and single-strand break (SSB) repair. Removal of PAR chains is performed by PARG and is also critical for successful completion of DNA repair. Suppression of PAR chain hydrolysis via PARG depletion or inhibition leads to defective single-strand break repair, reduced kinetics of repair, and hypersensitivity to certain DNA damaging agents.

Cancer cells demonstrate high levels of replication stress, characterized as the slowing or stalling of replication forks during DNA replication. Replication stress generates DNA SSBs and exposes unligated Okazaki fragments which activate PARP1. PARP1 catalyzed PARylation slows replication fork progression as a protective mechanism, initiates damage repair, and promotes fork reversal. PAR chain removal, via PARG activity, enables completion of damage repair, replication fork restart, and recovery from replication stress. Under conditions of replication stress, PARP inhibition can result in unrestrained fork progression and the occurrence of DNA double strand breaks from fork runoff. In contrast, PARG inhibition causes prolonged slowing or stalling of replication fork progression, which can lead to replication catastrophe and cancer cell death. Because of these opposing roles, PARG inhibitors show distinct pharmacology as compared to PARP inhibitors in certain cancer cells including cancer cells that are *BRCA* wild type, homologous recombination proficient, and PARP inhibitor insensitive or resistant.

ETX-19477 is a novel inhibitor of PARG that demonstrates low nM, on-target activity in cells as measured by the accumulation of PAR chains. ETX-19477 induces death and/or inhibits the proliferation of multiple cancer cell types including ER+HER2- breast, serous and mucinous ovarian, lung, and gastric cancers and induces pan-nuclear γH2AX expression, a hallmark of replication catastrophe. Preclinical studies demonstrate that ETX-19477 is orally bioavailable with favorable pharmacokinetics. Oral treatment of mice with ETX-19477 is well tolerated and shows robust dose-dependent in vivo anti-tumor activity in breast and ovarian cell-line derived and patient-derived xenograft models. Efficacy is observed with either once or twice daily dosing and with a discontinuous dosing regimen. In mouse xenograft models, induction of γH2AX expression in tumor tissue correlates with tumor growth inhibition. Preclinical data show ETX-19477 demonstrates potent and specific anti-proliferative effects by exposing underlying existing replication stress vulnerabilities in cancer cells across multiple tumor types. ETX-19477 will be advanced into clinical trials in 2024.

#2084 Autocrine regulation of laryngeal cancer tumorigenesis by 24R,25(OH)$_2$D$_3$.

C. D. Dennis, D. Cohen, J. T. Dillon, B. D. Boyan, Z. Schwartz;
Virginia Commonwealth University, Richmond, VA

Vitamin D3 supplementation is becoming widely accepted as a therapeutic in many common estrogen responsive cancers. Previous studies in breast cancer showed that 24R,25-dihydroxyvitamin D$_3$ (24,25) regulates tumorigenesis via a caveolae membrane-associated signaling pathway involving phospholipase D [PLD] and palmitoylation of an unknown receptor. The goal of this study was to examine the effects of 24,25 in estrogen responsive laryngeal cancer tumorigenesis, investigate the mechanisms involved, and determine the ability of the tumor cells to produce 24,25 locally. Expression of CYP24A1 and CYP27B1 was measured in ERα66+ UM-SCC-12 (UM12) and ERα66- UM-SCC-11A (UM11A) laryngeal cancer cells. Cells were treated with 25(OH)D$_3$, and production of the vitamin D$_3$ metabolites 1,25(OH)$_2$D$_3$, 24,25(OH)$_2$D$_3$, and 1,24,25(OH)$_3$D$_3$ was measured using HPLC. The therapeutic potential of 24,25 was then assessed by treating the cells with 24,25 and measuring proliferation and apoptosis. In vivo, UM12 and UM11A cells were implanted into the cheek of NSG mice; the mice were treated with 24,25, and evaluated for survival and tumor volume. The signaling pathways involving PLD, palmitoylation, and caveolin-1 were investigated as driving mechanisms. CYP24A1 and CYP27B1 were present in ERα66+ UM12 and ERα66- UM11A cells, both of which are responsive to estrogen. When treated with 25(OH)D$_3$, UM11A cells produced more 24,25 than UM12s, comparable to the physiologically relevant levels in blood. Both cells produced similar levels of 1,25. 24,25 increased proliferation and inhibited apoptosis in ERα66+ UM12 cells in vitro, but had the opposite effect in ERα66- UM11A cells. 24,25 increased PLD activity in UM12 cells but decreased PLD activity in UM11A cells. Inhibition of PLD activity or palmitoylation, as well as silencing expression of caveolin-1, reduced the effects of 24,25 on P53 in both cell types, indicating they played a role. Mice with UM11A tumors given 24,25 exhibited reduced tumor burden and increased survival compared to vehicle-treated controls. In contrast, mice with UM12 tumors given 24,25 had an increased tumor burden and reduced survival compared to controls. The presence of CYP24A1 and CYP27B1, local production of 24,25, and demonstration that laryngeal cancer cells respond to 24,25, indicate that 24,25 acts in an autocrine/paracrine manner. 24,25 was pro-tumorigenic in ERα66+ laryngeal cancer cells while having the opposite effect in ERα66- cells, both in vitro and in vivo, demonstrating a dependence on ERα66 expression. 24,25 acts via a mechanism involving PLD, caveolae, and palmitoylation. These data show that 24,25 regulates laryngeal cancer tumorigenesis, which is mediated by membrane associated signaling pathways that may depend on ERα66 level, and suggest a major role of 24R,25-dihydroxyvitamin D$_3$ in laryngeal cancer.

#2085 Targeting the translation initiation complex component eIF4G1 in melanoma.

Y. Feng[1], M. Radaeva[2], H. Kim[1], A. Deshpande[1], A. Deshpande[1], P. Jovanovic[3], R. Murad[1], I. Topisirovic[3], S. Olson[4], A. Cherkasov[2], Z. Ronai[1];
[1]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA, [2]Vancouver Prostate Centre and Department of Urologic Sciences, University of British Columbia, Vancouver, BC, Canada, [3]Lady Davis Institute, SMBD Jewish General Hospital, Gerald Bronfman Department of Oncology and Division of Experimental Medicine, McGill University, Montreal, QC, [4]Conrad Prebys Center for Chemical Genomics at Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA

The translation initiation factor 4F (eIF4F) complex assembly is a rate-limiting step in mRNA translation. eIF4F subunits including eIF4A, eIF4E, and eIF4G, are often upregulated in cancer and neurodegeneration diseases. Elevated eIF4F level/activity has been correlated with poor prognosis and drug resistance. Leveraging our findings with the small molecule SBI-756, which interacts with eIF4G1 and impairs eIF4F complex assembly, we set to map domains that are required for SBI-756 activity. A CRISPR screen using sgRNAs that target different sequences on eIF4G1 led to the identification of the MA3 domain, as a putative binding site for SBI-756. Deletion/mutation of the eIF4G1 MA3 domain attenuated melanoma cells and spheroids growth. Polysome profiling assays confirmed attenuated translation activity, which resembled those seen with SBI-756. In silico virtual screen identified 64 small molecules (out of >10 million) that interact with the MA3 domain. Of these, we have selected four that effectively attenuated melanoma growth in culture. Analogs developed for these four compounds were more potent in impairing the assembly of the eIF4F complex, inhibition of protein translation and the 2D and 3D growth of melanoma cells. RNA-sequencing analysis highlighted altered expression of genes implicated in apoptosis, UPR, cell cycle, and ROS pathways, leading us to test possible combination with pathways that may complement the above. Among those, autophagy inhibitors synergized with our lead compound, M19-6, resulting in efficient melanoma cell death, using notably lower concentrations of these inhibitors. Our findings identify the eIF4G1 MA3 domain as an important player in eIF4F assembly and a potential target for cancer therapy.

#2086 Effect of XPO1 inhibition on colorectal cancer tumorigenesis.

A. E. Evans, D. A. Dixon;
University of Kansas, Lawrence, KS

Colorectal Cancer (CRC) is the second leading cause of cancer-related death in the U.S. A subset of individuals faces a notably higher likelihood of developing CRC within their lifetime. Hence, there is a compelling need for innovative chemopreventive treatments aimed at minimizing CRC tumorigenesis. Exportin 1 (XPO1; also referred to as CRM1) plays a pivotal role in transporting proteins from the nucleus to the cytoplasm. The overexpression of XPO1 has been identified across several cancers, including CRC. XPO1 interacts with a diverse spectrum of more than 1000 proteins. The overexpression of XPO1 leads to the excessive removal of tumor suppressors from the nucleus, rendering these proteins functionally inert. To counteract the overexpression of XPO1 in tumors, a novel class of drugs known as Selective Inhibitors of Nuclear Export (SINE) has been developed. Among these, Eltanexor (KPT-8602) has emerged as a promising therapeutic agent, demonstrating fewer side effects compared to its precursors, and is currently under evaluation in Phase 1/2 clinical trials. The treatment effects of SINE compounds on CRC remain largely unknown. We have assessed Eltanexor's ability to limit CRC tumorigenesis using a genetic CRC model in *Apc*$^{min/+}$ mice. Our findings indicate that Eltanexor substantially reduces tumor burden by approximately 3-fold and induces a significant reduction of tumors exceeding 1mm in size. Furthermore, a xenograft experiment using the human CRC cell line, HCT116, reveals nearly a 3-fold reduction in tumor size upon Eltanexor treatment. In both CRC models, Eltanexor exhibits noteworthy tolerability. Additionally, XPO1 protein levels are consistently diminished in both models, aligning with our *in vitro* observations. To further ascertain Eltanexor's specificity for CRC tumors versus normal tissue, we conducted drug sensitivity assays using organoids derived from *Apc*$^{min/+}$ tumors and wild-type mice small intestine tissue. We found that *Apc*$^{min/+}$ tumoroids have heightened sensitivity to Eltanexor-treatments, when compared to wild-type organoids. In an endeavor to elucidate Eltanexor's potent *in vivo* tumorigenesis inhibitory effects, we conducted multiple assays which revealed a reduction in COX-2 RNA and protein expression levels in Eltanexor-treated cells and reduced COX-2 protein in the tumors of Eltanexor-treated *Apc*$^{min/+}$ mice. In CRC, COX-2 is implicated in CRC development and is currently the target of multiple CRC chemopreventive agents. Our observations reveal that Eltanexor-treated CRC cells exhibit reduced COX-2 gene expression through both inhibiting COX-2's promoter and its mRNA post-transcriptional stability. Collectively, our findings underscore XPO1 as a potent target for inhibiting CRC tumorigenesis. Future studies will aim to further assess how Eltanexor is impacting COX-2's promoter, while additionally testing Eltanexor's tumorigenesis-inhibiting potential in a colitis-induced CRC mouse model.

#2087 Targeting lipid metabolism in pancreatic cancer.

C. Cheng[1], J. P. Wisniewski[1], A. Korkaya[1], B. Jackson[1], R. Mannan[1], S. Mahapatra[1], N. Rossiter[1], R. Bhattacharyya[1], P. Morlacchi[2], S. Peters[1], Y. Qiao[1], C. A. Lyssiotis[1], A. M. Chinnaiyan[1];

[1]University of Michigan, Ann Arbor, MI, [2]Agilent Technologies, Inc., Lexington, MA

Background PIKfyve is a lipid kinase that serves as the sole source of cellular PI(3,5)P2 and PI5P, critical phosphatidylinositols for autophagy and lysosome function. Pancreatic ductal adenocarcinoma (PDAC) is known to upregulate and depend on lysosomal functions such as autophagy to exist in its harsh, nutrient-disrupted microenvironment. Thus, we aimed to establish PIKfyve as a therapeutic target in PDAC. Using a PIKfyve-knockout genetically engineered mouse model of pancreatic cancer (KC and KPC), we determined that PIKfyve was necessary for PDAC development. Given these results, we hypothesized that PIKfyve was critical for maintaining metabolic homeostasis in PDAC and that inhibiting PIKfyve would be an efficacious therapeutic strategy for PDAC.
Methods and results We first validated the known role of PIKfyve in regulating autophagy using CRISPRi mediated knockdown, PIKfyve inhibitors Apilimod and ESK981, and a PIKfyve degrader, which all demonstrated that PIKfyve perturbation disrupted autophagic flux and suppressed PDAC cell growth. Little is known about the metabolic impacts of PIKfyve inhibition in PDAC beyond disruption of autophagy. Thus, we paired RNA-seq and a metabolic CRISPR screen to discover that PIKfyve inhibition obligated PDAC cells to upregulate *de novo* lipid synthesis. Specifically, PDAC cells upregulated fatty acid synthesis genes *ACACA* and *FASN* upon PIKfyve inhibition. Additionally, these genes were synthetically critical in the context of PIKfyve inhibition. We further performed metabolomics and lipidomics which revealed accumulation of sphingolipids upon PIKfyve inhibition. Given this, we concluded that PIKfyve regulates lipid homeostasis in PDAC. To further establish PIKfyve as a target in PDAC, we investigated the role of PIKfyve upon inhibition of KRAS, which drives PDAC through MAPK pathway signaling. First, KRAS/MAPK inhibition diminished expression of *FASN* and *ACACA*, genes synthetically essential upon PIKfyve inhibition. Additionally, KRAS/MAPK inhibition upregulated autophagy which was attenuated upon concurrent PIKfyve inhibition. Given this metabolic conflict between KRAS/MAPK and PIKfyve, we assessed the effects of dual inhibiting KRAS/MAPK and PIKfyve in a syngeneic orthotopic model. Encouragingly, combination therapy of trametinib (MEK inhibitor) and ESK981 eliminated tumor burden in most of mice, while single treatments only had modest effects. Further, we established a patient-derived xenograft model and showed that while the treatment with individual compounds trametinib, MRTX-1133 ($KRAS^{G12D}$ inhibitor), and ESK981 all suppressed tumor growth, the combination of ESK981 and trametinib or ESK981 and MRTX-1133 caused substantial tumor regression in nearly all mice. Taken together, targeting lipid metabolism through inhibition of PIKfyve is a promising therapeutic strategy for PDAC, particularly in combination with the numerous KRAS/MAPK inhibitors in clinical development.

#2088 Targeting transcriptional factor IWS1 as a potential treatment of advanced dedifferentiated liposarcoma.

Marina Goryunova[1], Yiran He[2], Nipin Sp[1], Elizaveta K. Titerina[1], Sayumi Tahara[1], Carson Karakis[1], Alessandro La Ferlita[1], Michael Sorkin[1], Alex Kim[1], Hua Zhu[3], Christopher M. Hadad[2], Raphael E. Pollock[1], Joal D. Beane[1]

[1]Surgical Oncology, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Department of Chemistry and Biochemistry, The Ohio State University, Columbus, OH,[3]Division of Cardiac Surgery, The Ohio State University, Columbus, OH

Introduction. Surgery remains the only curative treatment for patients with liposarcoma (LPS). The translation of novel therapies has been hampered, and there has been no significant improvement in prognosis for 30 years. Our recent findings demonstrate that IWS1, a transcription elongation and alternative splicing factor, is elevated in dedifferentiated LPS (ddLPS) patient tumor samples and is associated with worse survival and a shorter time to relapse in ddLPS. In this study, we present preliminary results on a novel treatment for advanced ddLPS: an IWS1 inhibitor, serving as a way to discover a spliceosome as a novel therapeutic target.

Methods. Utilizing computer-aided, structure-based virtual screening approaches, we identified a class of compounds that exhibited inhibitory potential. A subset of FDA-approved drugs was evaluated by molecular docking calculations, and compounds with the highest calculated theoretical potency were selected for further analysis. To assess the ability of specific compounds to disrupt IWS1/Spt6 binding, Co-immunoprecipitation (Co-IP) experiments on ddLPS cell line Lipo863 were conducted. Transwell invasion and migration assays were performed to evaluate the effect of the drug candidate on the metastatic potential of cells. Additionally, to evaluate the impact of IWS1 inhibition on spheroid formation, a matrigel extracellular matrix scaffold was employed.

Results. Through virtual screening, we identified a class of compounds characterized by a specific chemical pattern featuring a tricyclic fused-ring structure. This class of compounds includes the well-known FDA-approved drug Ketotifen, an antihistamine and mast cell stabilizer. Co-immunoprecipitation of IWS1/Spt6 complex after 48-hour treatment with Ketotifen showed a decrease of over 50% of the isolated complex. Migration and invasion of the ddLPS cell line, Lipo863, were reduced in a dose-dependent manner by 18-44% and 17-52%, respectively, when treated with Ketotifen, without affecting cell viability. In a 3D model, a 14-day treatment of Ketotifen significantly reduced spheroid formation, confirming its impact on tumor growth and cell proliferation.

Conclusion. Ketotifen effectively disrupted IWS1/Spt6 complex *in vitro*. Importantly, it did not affect cell viability while reducing the migratory and invasive potential of ddLPS. The dose-dependent effect of Ketotifen suggests that there may be an optimal *in vivo* concentration to prevent cells from invading nearby structures and/or metastasizing. We are currently testing the ability of these compounds in preclinical mouse models of ddLPS.

#2089 A pro-oncogenic RAS-GTP:RAN-GAP complex facilitates nuclear protein export and has clinical implications.

B. K. Tripathi[1], N. H. Hirsh[1], D. Hansen[1], X. Qian[1], M. E. Durkin[1], D. Wang[1], A. G. Papageorge[1], R. Lake[1], Y. A. Evrard[2], A. Marcus[3], S. S. Ramalingam[3], M. Dasso[4], K. Vousden[5], J. H. Doroshow[1], K. J. Walters[6], D. R. Lowy[1];

[1]National Cancer Institute, Bethesda, MD, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]Winship Cancer Institute, Emory University, Atlanta, GA, [4]National Institute for Child Health and Human Development, Bethesda, MD, [5]The Francis Crick Institute, London, United Kingdom, [6]National Cancer Institute, Frederick, MD

The majority of RAS oncogenic activity is thought to be mediated by its canonical signaling, mainly via RAS-GTP interactions with its effectors RAF and PI3K at the plasma membrane, which respectively activate MEK/ERK and AKT/mTOR pathways. However, in this study, we have identified a new, fundamental, pro-oncogenic, non-canonical activity of RAS-GTP that increases the Exportin 1 (XPO1)-dependent export of nuclear proteins into the cytoplasm and is independent of RAF/MEK and PI3K/AKT signaling. The nuclear protein export machinery is known to depend on a trimeric protein complex composed of RAN-GTP:XPO1:nuclear protein cargo. Unexpectedly, we have found that RAS-GTP forms a stable complex with RAN GTPase-Activating Protein 1 (RAN-GAP) at the nuclear envelope, which facilitates the release of nuclear protein cargo by increasing the hydrolysis of RAN-GTP to RAN-GDP. We have determined that RAS-GTP and RAN-GAP form this complex in primary human lung tumors, patient derived xenografts, and human lung cancer cell lines. Interestingly, the RAS-GTP:RAN-GAP complex is found at the nuclear envelope and in the cytoplasm, but not at the plasma membrane. The RAS-dependent step mediated by the RAS-GTP:RAN-GAP complex acts downstream of XPO1 by increasing RAN-GTP hydrolysis, which promotes protein cargo release. Our fundamental findings have important clinical implications. For example, in human lung cancer models that harbor a KRAS-G12C mutation, the combined inhibition of MEK and PI3K (MEKi + PI3Ki) does not inhibit tumor growth to the same degree as a KRAS-G12C inhibitor. Remarkably, adding an XPO1 inhibitor to MEKi + PI3Ki inhibits tumor growth to the same degree as the KRAS-G12C inhibitor. One critical pro-oncogenic target of the RAS-GTP:RAN-GAP complex is nuclear export of the EZH2 methyltransferase, whose increase in the cytoplasm leads to a direct methylation of the cytoplasmic DLC1 tumor suppressor protein, leading to ubiquitin-dependent proteasomal degradation of DLC1 protein. Analysis of a KRAS mutant cell line from which the DLC1 gene has been disrupted by CRISPR-Cas9 technology indicates that DLC1 makes an important contribution to the growth inhibition by inhibitors that reduce nuclear protein export. These findings establish nuclear protein export as a critical, pro-oncogenic, non-canonical RAS function that is mediated by the RAS-GTP:RAN-GAP complex and provide a mechanistic explanation for poor clinical responses to combined inhibition of MEK and PI3K, which do not regulate the nuclear protein activity identified in this study.

#2090 The GNAQ T96S mutation enhances the oncogenic properties of breast cancer.

M.-H. Wu, H.-C. Wang, W.-H. Wang, Y.-J. Lin, W.-R. Chen, S.-T. Chen, C.-W. Fu, E. Chuang;
Industrial Technology Research Institute, Hsinchu, Taiwan

Breast cancer (BC) is the most commonly diagnosed cancer in the world, and metastatic breast cancer (mBC) remains responsible for the majority of breast cancer deaths. In this study, we collected 615 cases of Taiwanese BC patient's tumor samples and used whole exome sequencing (WES) to clarify the genetic mutation landscape of this population. We have compared with various BC genomic databases such as TCGA, COSMIC, and MSKCC to identify 29 novel variants in 18 genes that were predicted to have a pathogenic effect. In these pathogenic variants, we found that the GNAQ T96S mutation (threonine 96 to serine alteration of the Gαq protein) was presented in 116 out of 615 BC patients (18.9%). To examine the effect of the GNAQ T96S mutation on BC, we transfected the MCF-7 and MDA-MB-231 cell lines with the wild-type or the mutant GNAQ T96S expression vector. Transfection with the GNAQ T96S expression vector enhanced cell proliferation, colony formation, migration, and activation of the MAPK pathways compared to wild-type GNAQ expression MCF-7 cells. We also found that the tumorigenicity, and tumor growth were significantly increased in the GNAQ T96S expressed MCF-7 xenograft model, and exhibited higher rates of lung metastasis in GNAQ T96S expressed MDA-MB-231 cells. Our data suggest that the GNAQ T96S mutation may play an oncogenic role in BC by potentiating the GNAQ signaling pathway. In this study, we also found several compounds that can inhibit in vitro cell proliferation and in vivo tumor growth of GNAQ T96S expressed MCF-7 cells. These compounds showed the potential to treat the mBC patients who have GNAQ T96S mutation.

#2091 Pharmacological inhibition of chaperone-mediated autophagy via NCoR1/RARα targeting is effective against non-small cell lung cancer.

M. McCabe, R. R. Khawaja, R. Bhattacharyya, A. Diaz, T. P. Garner, K. Lindenau, R. Sereda, O. Santiago-Fernandez, A. Cuervo, E. Gavathiotis;
Albert Einstein College of Medicine, Bronx, NY

Dysregulation of autophagy, the lysosomal degradation of intracellular components, has been universally described in cancer. While activity of macroautophagy changes in a context-dependent manner in cancers, the upregulation of chaperone-mediated autophagy (CMA) is well-described in all solid tumors studied to date. Upregulated CMA directly contributes to both tumor growth and protection against anti-oncogenic interventions in cancers. Selective degradation of anti-oncogenic and pro-apoptotic proteins, such as mutant p53 and PUMA, misfolded proteins, and glycolytic enzymes by CMA allows for increased survival, reduced cell death, increased stress resistance, and enhancement of the Warburg effect in cancer cells, respectively. As such, inhibition of CMA is an attractive target for anti-cancer therapeutics, but the field currently lacks protein targets specific to CMA and selective CMA inhibitors. We have previously demonstrated the regulatory effect of retinoic acid receptor alpha (RARα) and its coregulator, nuclear receptor corepressor 1 (NCoR1), on CMA through transcriptional upregulation of the CMA effector proteins (Bourdenx et al. Cell 2021, Gomez-Sintes et al, Nat. Commun. 2022). Here, we identified a high NCoR1/RARα expression ratio in human non-small cell lung cancer (NSCLC) tumors compared to healthy lung tissue. We further illustrated a dependency on NCoR1 expression and its interaction with RARα to maintain high CMA activity in NSCLC cell lines. Provided the reliance on NCoR1 repression of RARα for high CMA activity in NSCLC, we hypothesized that small molecule targeting of the druggable NCoR1/RARα interaction to disrupt the interaction may result in suppression of CMA effector proteins and CMA inhibition. Through a series of in-silico screens for predicted NCoR1/RARα targeting, and functional screens for CMA inhibition, we identified CIM7, a first-in-class potent and selective CMA inhibitor. We validated CIM7 function through binding to RARα and subsequent disruption of NCoR1 binding, resulting in alterations to CMA-related gene expression. CIM7 inhibits CMA *in vivo* with no observed toxicity in normal tissues. We additionally demonstrated the therapeutic potential of CIM7 through its ability to reduce tumor growth *in vivo* in mouse NSCLC xenografts. Our findings support the NCoR1/RARα interaction as a major regulator of CMA in NSCLC and demonstrate the potential of pharmacologic CMA inhibition as an anti-cancer therapeutic strategy.

#2092 Genomic and proteomic analysis of glioblastoma recurrences during TTFields exposure.

F. Cianci[1], G. Rey[1], D. Krex[2], D. Ceresa[3], P. Malatesta[3], **M. Mazzanti**[1];

[1]University of Milan, Milano, Italy, [2]Universitatsklinikum Carl Gustav Carus der Technischen Universitat, Dresden, Germany, [3]University of Genova, Genova, Italy

Glioblastoma (GB) is the most aggressive type of brain tumor, and current treatments are generally ineffective in preventing recurrence. Tumor Treating Fields (TTFields) are an innovative treatment that has been shown to improve patients' life expectancy in the last two decades. TTFields therapy has an antitumoral effect that involves different mechanisms and is an optional add-on to standard maintenance temozolomide. Although TTFields therapy initially slows tumor progression, it does not prevent tumor relapse in most patients. In the present investigation, we run a genomic and proteomic analysis of surgical material from 10 patients treated with TTFields. GB tissues were obtained from the primary tumor mass and from a second surgery after tumor relapse. All the patients, in addition to brain tumor standard therapies, were treated with TTFields for eighteen hours a day, the time span of treatment application was dependent on GB recurrence. Control samples were obtained from primary and secondary surgeries of 5 patients treated with standard therapy alone. The GB tissue extracts were analyzed with an RNAseq routine, and the results from the secondary surgery were compared with the data obtained from tumor specimens of the primary surgery. A common feature of transcripts among all the patients was the alterations of several pathways promoting the increase of intracellular oxidation and cell cycle regulation. In parallel with the analysis of patient specimens, we developed an *in vitro* GB cell relapse model. This was instrumental in investigating the beneficial contribution of TTFields action during tumor relapse, but also in uncovering the limitation of this therapeutic procedure. GB primary cultures obtained from patients' surgery were exposed for up to 12 days with 200 kHz TTFields stimulation using the inovitro™ system. After 12 days of continuous TTFields application, GB cells showed an average depolarization of the resting membrane potential, increasing oxidation, and acidification of the cytoplasm. Genomic analysis of treated cells compared with wild-type primary culture, denoted an increase of tumor stem cell markers, activation of several metabolic pathways, and upregulation of different ion channel protein transcripts. Our final goal is to identify specific molecular features enhanced by TTFields treatment to be used as a parallel therapy to fight GB recurrence.

#2093 Co-treatment with KRAS G12D inhibitor MRTX1133 plus TTFields against human pancreatic and Colorectal cancer cell lines results in synergistic up-regulation of cleaved PARP in KRAS G12D & unexpectedly in KRAS G12V as well.

V. Tajiknia, P. Srinivasan, M. PInho-Schwermann, W. MacDonald, C. Purcell, W. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Background: Both colorectal and pancreatic cancers are major global health issues and among deadliest cancers with great disease burden. The most commonly mutated oncogenic alteration in human cancers is KRAS, which is prevalent in pancreatic malignancies. The KRAS G12D mutation subtype is present in more than 40% of pancreatic ductal adenocarcinoma (PDAC). To this date there is no available targeted therapy options for patients with KRAS subtype mutations. MRTX1133 has been identified as a non-covalent, potent, and selective inhibitor of KRASG12D. This small molecule inhibitor has been shown to suppress KRASG12D signaling in cells and in vivo. Tumor Treating Fields (TTFields) therapy is a novel approach to treating cancer, the electric fields alter the behavior of cancer cells and prevent them from growing and dividing. We hypothesize that the co-application of MRTX1133 with TTFields will enhance the effects of MRTX1133 in PDAC and colorectal cancer (CRC).
Martials and Methods: PDAC cell line CFPAC1 with KRAS G12 V mutation and LS513 CRC cell line with KRAS G12D Mutation were treated with same dose of MRTX1133 (500 nM) and were co-treated with 150kHz TTFields. After 48 hours western blot was used to probe for cleaved PARP, cleaved C3, phosphor-ERK and DUSP6.
Results: In both KRAS G12D & KRAS G12V cell lines, synergistic upregulation of cPARP was observed following 48-hour co-treatment. Synergistic inhibition of pERK happened in KRAS G12D cell line but no change in pERK level following TTFields or MRTX1133 treatment was seen. Upregulation of cC3 in KRAS G12D happened in only co-treatment conditions. DUSP6 levels increased following MRTX1133 treatment in KRAS G12V cell line.
Conclusions: The surprising synergistic upregulation of cPARP in both KRAS G12V and G12D cells following co-treatment of KRAS G12D inhibitor MRTX1133 and TTFields can bring hope for other KRAS mutation subtypes as well as G12D. the increase in cPARP in KRAS G12V with no effect on pERK is particularly interesting and demonstrates the need of more studies to investigate the mechanisms of this synergy.

#2095 Peptide-based pivoting of p53 to target metastatic breast cancer.

Diana Putavet[1], Marjolein P. Baar[1], Johannes H. Lehmann[1], Antoine Khalil[1], Tao Shi[1], Thijs Koorman[1], Tobias B. Dansen[1], Patrick WB Derksen[1], Michael Teifel[2], Tobias Madl[3], Nicholas Sarlis[2], Peterus L. J. de Keizer[1]

[1]UMC Utrecht, Utrecht, Netherlands,[2]Cleara Biotech B.V., Utrecht, Netherlands,[3]Medical University Graz, Graz, Austria

The inability to target distant metastases limits the treatment of late-stage cancers. At least in part, this is due to the lack of optimal targeted therapies and treatment resistance to the remaining standard of care consisting of chemo-/radio- therapy. Here, we show that cancer cells that are irreparably damaged can withstand cell death through a process we define as “scarring”. In scarred cells, p53 is phosphorylated at Ser46 and Ser392 and localizes into progressive multifocal leukemia (PML) nuclear bodies. We have identified scarring in over a quarter of metastatic breast, colon, stomach and ovarian cancer. Thus, pivoting scarred p53 towards cell death in scarred cancer could establish a novel broad-range therapeutic opportunity against metastatic cancer. Targeting p53 with small molecules has proven challenging. We developed cell-penetrating peptides that selectively bind scarred p53. One of our lead compounds, CL04177 dissociates p53 from its PML scaffold leading to its a nuclear exclusion and initiation of the transcription-independent mitochondrial apoptosis. To examine the role of scarring as a therapeutic target, we focused on triple-negative breast cancer (TNBC). TNBC cells are marked by the expression of p53 and PML compared to other breast cancer subtypes. In cytotoxicity experiments, CL04177 specifically targeted TNBC over other breast cancer subtypes. Further investigation into how this compound can target metastatic cells revealed that scarred features are upregulated in metastasis-initiating cells of organoids when induced to invade in contact with collagen and that CL04177 can induce apoptosis specifically in these invading strands. *In vivo*, CL04177 showed favorable pharmacokinetics and -dynamics and a clear safety profile. Importantly, when dosed at 10-fold below its Maximally Tolerated Dose, CL04177 strongly reduced primary tumor mass and metastatic dissemination to the liver of TNBC cell line-derived orthotopic xenografts. This data indicates a new concept of scarred p53 in cancer progression and metastasis. Moreover, peptides that release scarring markers from nuclear structures can eliminate aggressive cancers *in vitro* and, most importantly, *in vivo*, e.g., in p53-mutated, metastatic TNBC. This ability introduces a conceptually new therapeutic option, especially for types of cancer for which there is a high unmet medical need.

#2096 A novel, orally available ferroptosis inducer targeting Fe-S assembly with significant *in vivo* anti-tumor efficacy.

Y. Song Green[1], M. Ferreira dos Santos[2], S. Ciofi-Baffoni[3], X. Liu[2], **M. Koh[1]**;
[1]University of Utah, Salt Lake City, UT, [2]Kuda Therapeutics, Inc, Salt Lake City, UT, [3]University of Florence, Florence, Italy

Background: Ferroptosis is a novel form of cell death driven by iron-dependent lipid peroxidation, which disrupts cellular membranes resulting in immune-activating death. A variety of tumor types, particularly those associated with enhanced lipid and/or iron content, or which experience increased oxidative stress (including drug tolerant persister cells), are sensitive to ferroptosis, rendering ferroptosis a promising therapeutic strategy for cancer. However, currently available ferroptosis inducers show limited activity *in vivo*, suggesting a need for novel molecular targets to validate the clinical utility of ferroptosis induction. Clear cell renal cell carcinoma (ccRCC), the most common form of kidney cancer, is typically initiated by inactivation of VHL resulting in constitutive activation of HIF-1α and HIF-2α, which contribute to disease progression, including by promoting lipid accumulation that sensitizes ccRCC cells to ferroptosis.
Methods: We performed a high-throughput screen to identify small molecule inhibitors of HIF-2α followed by structure-activity-relationship studies for validation. The molecular target of these inhibitors was identified using the Drug Affinity Responsive Target Stability assay, and target validation was confirmed using siRNA and NMR. *In vitro* efficacy was determined in a panel of cancer cell lines and *in vivo* anti-tumor efficacy was verified using mouse models of cancer.
Results: We identified a novel molecule, KD061, which decreases HIF-1/2α and induces ferroptosis *in vivo* through oral administration by targeting Iron Sulfur Cluster Assembly 2 (ISCA2). ISCA2 is a component of the late mitochondrial Iron Sulfur Cluster (L-ISC) assembly complex and ISCA2 inhibition either pharmacologically or using siRNA triggers the iron starvation response, resulting in iron/metals overload and death via ferroptosis. ISCA2 inhibition also decreases HIF-2α protein levels by blocking iron-responsive element (IRE)-dependent translation, and at higher concentrations, also decreases HIF-1α translation. These studies reveal a novel function of ISCA2 in extra-mitochondrial Fe-S assembly that may be limiting in cancer due to the increased need for these proteins in DNA replication and maintenance. Outside of ccRCC, a 92-cell line screen reveals a variety of tumor types sensitive to ISCA2 inhibition including melanoma and clear cell ovarian cancer. Treatment of tumor-bearing mice with KD061 resulted in > 65% tumor growth inhibition, associated with significantly increased lipid peroxidation, thus confirming ferroptosis *in vivo*, and with decreased HIF-1/2α. The anti-tumor efficacy of KD061 exceeded that of α-PD1 and was well tolerated at the therapeutic dose.
Conclusions: We describe the first orally available inducer of ferroptosis with significant anti-tumor efficacy in ccRCC and other tumor types.

#2097 ABT co-dose accelerated target validation with a fit-for-purpose HPK1 inhibitor tool.

J. L. Methot, J. L. Chen, E. Yu, R. D. Otte, H. Xu, Z. Xu, B. Lacey, J. Laskey, R. Mcleod, D. Smith, A. Pasternak;
Merck & Co., Inc., Rahway, NJ

Target validation can be challenging when mouse efficacy studies require achieving a high therapeutic exposure of a tool compound, ideally with a low peak-to-trough (P/T) ratio to avoid Cmax-induced toxicity. Herein, we describe the daily co-administration of the CYP inhibitor aminobenzotriazole (ABT) as a well-tolerated PK enhancer for medium-term efficacy studies in mice, enabling faster decision-making in the early space with imperfect tools. Genetic studies in mice have suggested that HPK1 inhibition would lead to enhanced effector T-cell function, decreased tumor growth and enhanced αPD-L1 efficacy. However, it remains unknown whether immune activation by pharmacological inhibition of HPK1 will recapitulate the genetic deletions. We developed a fit for purpose tool compound with picomolar HPK1 potency, excellent kinome selectivity (98% >100x, ATP-Km corrected), dose-dependent inhibition of pSLP76, sustained IL2 elevation in PBMCs, and IL6/TNFa elevation in dendritic cells. The mouse PK for this tool was inadequate, having a low exposure (AUC 16 uM-hr at 100 mg/kg po) and a high P/T ratio of 13 that could lead to an erosion of kinome selectivity in vivo; complicating efficacy interpretation and limiting overall tolerability. However, when co-dosed with ABT (50 mg/kg po 2 h prior to the HPK1 inhibitor), improved exposure of our tool was achieved (AUC 63 uM-hr at 100 mg/kg po), 90% inhibition of pSLP76 was maintained at C(trough), and the P/T ratio was reduced to 3 to avoid Cmax-induced toxicity. The inhibitor was well-tolerated co-dosed with ABT for three weeks in mice, enabling studies sooner to probe HPK1 pharmacological inhibition in cancer immunotherapy as a monotherapy as well as in combination with a mouse anti-PD-1 antibody.

#2098 A novel GCN2 kinase activator demonstrates therapeutic efficacy in preclinical PDX models of human cholangiocarcinoma.

D. M. Carlson[1], H. Kuipers[1], A. Abdelrahman[1], E. Jessen[1], J. Roldan Kalil[2], J. Sample[1], J. Tomlinson[1], M. Truty[1], R. Smoot[1];
[1]Mayo Clinic Hospital-Rochester, Rochester, MN, [2]Puerto Rico School of Medicine, San Juan, Puerto Rico

Introduction Cholangiocarcinoma (CCA) is a highly lethal, heterogenous biliary malignancy. Despite the development of targeted therapies, treatment success has been hindered by primary or acquired resistance. New therapeutic strategies are necessary to improve outcomes in these patients. NXP800 is a GCN2 small-molecule activator that phosphorylates eIF2a inducing selective ATF4 transcription which stimulates stress-induced genes leading to apoptosis. NXP800 has been previously validated in ovarian cancers with *ARID1A* mutations, well-known players in cholangiocarcinoma. We sought to determine the treatment efficacy of novel NXP800 in CCA utilizing patient derived xenograft (PDX) preclinical models. Methods In our preliminary studies, four human and two murine CCA cell lines were tested for cell viability using CellTiter-Glo to determine the maximal inhibitory concentration (IC_{50}). Immunoblot analysis of HuCCT-1 cells incubated with 1 mM of NXP800 for 6 hours vs. vehicle was performed. We also evaluated response to GCN2 activation in multiple RNA sequenced PDX models. Xenografts were expanded into the flank of NOD/SCID mice and treatment begun when tumors averaged 120mm^3. Tumor bearing mice were treated with NXP800 (35 mg/kg) or vehicle via oral gavage five days on, two days off, for 28 days. Tumor volume and animal weight were collected twice weekly. Predicted sensitive signatures were determined using multi-omics. Results IC50 dose response curves showed nanomolar activity in all six cell lines, ranging from 5-170 nM. Immunoblotting demonstrated an upregulation of phosphorylated eIF2a and in turn upregulation of ATF4 with treatment of NXP800 compared to vehicle. Five PDX tumors from patients with intrahepatic or distal CCA was established and validated by histologic analysis. Molecular characterization of the tumor identified tumor mutation and a total tumor mutational burden. RNA sequencing was completed and identified 21-gene signatures related to *YAP* activity, which were cross-referenced against our existing PDX model tumor bank. Treatment with NXP800 was associated with a statistically significant decrease in tumor size in three of five PDX models tested, which included an *ARID1A, FGFR1*, and *ATM* mutants. Preliminary multi-omics on the PDX models revealed that sensitivity mechanisms were centered around EGFR signaling. Conclusion The novel GCN2 kinase activator, NXP800, has nanomolar efficacy in both human and murine CCA cell lines *in vitro*. Additionally, NXP800 demonstrated therapeutic activity in multiple cholangiocarcinoma PDX models *in vivo*. We are opening a Phase 1b clinical trial investigating the effects of NXP800 use in patients with advanced CCA. Future studies determining the cellular effect of GCN2 activation utilizing NXP800 are being conducted.

#2099 PELP1 inhibition enhances the therapeutic efficacy of topoisomerase inhibitors in triple-negative breast cancer.

K. Nassar, J. R. Sanchez, D. Panneerdoss, B. Ebrahimi, Y. Xue, U. P. Pratap, S. C. Alejo, G. R. Sareddy, S. Viswanadhapalli, R. K. Vadlamudi;
UT Health San Antonio, San Antonio, TX

BACKGROUND: Triple negative breast cancers (TNBCs) account for 15-24% of breast cancer deaths and are characterized by aggressive clinical course, a worse prognosis, and a higher propensity to metastasize. Proline, glutamic acid-, and leucine-rich protein 1 (PELP1) is an oncogene, its expression is deregulated in TNBC, and its status is a prognostic indicator of poor TNBC survival. Recently, a small molecule inhibitor of PELP1 (SMIP34) which binds to and degrades PELP1 was developed. The *Objective* of this proposal is to define the mechanism of action of PELP1 inhibitor SMIP34 in TNBC progression and to pave the path for a novel combination therapy.

METHODS: We tested the effectiveness of PELP1 inhibitor, SMIP-34, in combination with 140 FDA-approved medications on cell survival of multiple TNBC cell lines. The effect of SMIP34 combination therapy on cell survival was measured using MTT, colony formation, and Annexin V apoptosis assays. Mechanistic studies were done using RT-qPCR, immunoprecipitation, proximity ligation, mass spectrometry, gene reporter, immunofluorescence, and comet assays. Furthermore, the preclinical utility of combination therapy was evaluated using MDA-MB-231 xenografts, patient-derived organoids (PDOs) and explants (PDEs).

RESULTS: We performed an in vitro screening of 140 FDA-approved drugs in combination with SMIP34. Results revealed that SMIP34 sensitized TNBC cells to five FDA approved drugs. Of the five drugs, the three drugs Gemcitabine, Valrubicin, and Mitoxantrone, induced DNA damage by inhibiting topoisomerase, a protein that cleaves and reconnects DNA during replication. We validated the ability of SMIP34 to enhance the efficacy of TIs using two additional TNBC cell lines and confirmed their synergistic activity using several in vitro assays including cell viability, colony formation, and apoptosis. In agreement with the role of PELP1 in DNA damage response, Western blotting analyses showed higher levels of γ-H2AX in SMIP34+TI combination therapy when compared to monotherapy. Results from the comet assays further demonstrate increased DNA damage caused by the SMIP-34 + TIs combination therapy. Mechanistic studies using Proximity labelling followed by immunoprecipitation identified topoisomerase 2A and 2B (TOP2A and TOP2B) as potential interactors of PELP1. Furthermore, gene correlation analysis using TCGA datasets revealed that PELP1 expression is positively correlated with TOP2A, and TOP2B in TNBC. SMIP34 plus Mitoxantrone (TI) combination treatment significantly reduced the growth of TNBC PDEXs, and PDOs *in vitro,* and MDA-MB-231 xenograft tumor growth *in vivo,* compared to vehicle or monotherapy treatment.

CONCLUSION: Together, these results suggest a novel targeted therapy for the treatment of TNBC, involving the combination of topoisomerase inhibitors and the PELP1 inhibitor SMIP34.

#2100 Novel LIPA targeted therapy for treating inflammatory breast cancer.

Z. Fuentes[1], R. Gopalam[1], B. A. Romo[1], K. Nassar[1], X. Yang[1], B. Ebrahimi[1], P. Ramirez[1], C.-Y. Chen[2], S. Elmore[2], H. Nagandla[3], U. Pratap[1], C. Thomas[1], **S. Viswanadhapalli**[1], J.-M. Ahn[2], G. Raj[4], R. K. Vadlamudi[1];

[1]UT Health San Antonio, San Antonio, TX, [2]UT Dallas, Dallas, TX, [3]Houston Methodist, Houston, TX, [4]UT SouthWestern, Dallas, TX

Background: Inflammatory breast cancer (IBC) is a rare but incredibly aggressive subtype of breast cancer (BC). IBC accounts for 2-4% of all occurrences of breast cancer and results in 7-10% of breast cancer-related deaths. IBC is only partially treatable with current therapies such as chemotherapy, surgery, and radiotherapy. Identification of novel therapeutic targets is urgently required. The main organelle for the synthesis, folding, and modification of proteins is called the endoplasmic reticulum (ER). Since elevated basal ER stress (ERS) is usually found in many cancers including IBC, our hypothesis was that the high basal ERS in IBC constitutes a serious vulnerability that can be targeted. Recently, we developed a small molecule ERX41 that promotes ER stress by blocking Lysosomal acid lipase A (LIPA) function in ER of cancer cells. The goal of the project is to test the utility of ERX-41 in treating IBC.

Methods: To study the effect of ERX-41, we have used three well-established IBC model cells. We evaluated the efficacy of ERX-41 as a novel therapeutic for treating IBC using cell viability assays. The long-term effects of ERX-41 on IBC cell survival were evaluated using colony formation assays. Annexin V assays were used to measure apoptosis. Reporter assays, splicing assays, RT-qPCR, and Western blotting were used in mechanistic investigations. The effectiveness of ERX-41 was examined in vivo using KPL4 cell-based xenografts.

Results: ERX-41 significantly decreased the viability of all three IBC model cells (SUM149, SUM190PT, and KPL4), with an IC_{50} of about 125 nM in MTT assay. Additionally, ERX-41 treatment significantly decreased IBC cells capacity to form colonies and promoted apoptosis. Specificity of the ERX41 mediated actions were confirmed using LIPA KO cells. Using RTqPCR based splicing assays, we demonstrated increased splicing of XBP1 as early as 6 hours after ERX41 treatment. Western analyses showed robust induction of stress markers (CHOP, PERK, ATF4) in IBC cells upon treatment with ERX-41. In KPL4 xenograft studies, ERX-41 showed significant reduction in the tumor volume. IHC analyses confirmed decreased proliferation marker and increased ER stress markers.

Conclusions: Collectively, our results suggest that ERX-41 is a novel therapeutic agent that targets the LIPA with a unique mechanism of action and implicate ERX-41 binding to LIPA induces ER stress and promotes apoptosis of IBC cells.

#2101 Patient-derived cells (PDCs) and organoids (PDOs) as critical platforms for developing next therapeutic strategies for NSCLC.

S. Park[1], Y. Joo[2], J.-h. Lee[1], M. Yun[3], M. Yu[3], S. Oh[2], E. Lee[2], D. Kim[2], S. Lee[2], K. Lim[1], M. Hong[4], S. Lim[4], J. Lee[4], B. Cho[4];
[1]JEUK Institute for Cancer Research, Gumi-City, Korea, Republic of, [2]Brain Korea 21 PLUS Project for Medical Science, Seoul, Korea, Republic of, [3]Severance Biomedical Science Institute, Seoul, Korea, Republic of, [4]Division of Medical Oncology, Department of Internal Medicine and Yonsei Cancer Center, Seoul, Korea, Republic of

Purpose : Patient-derived cells (PDCs) and organoids (PDOs) are constructed from pleural effusions to mimic the biological features of patients. In cancer research, PDC/PDOs could be a critical tool because they can recapitulate tumor mutations. Since commercial cell lines have difficulty mimicking the heterogeneity of tumors, PDC/PDOs are widely used for predicting the preclinical drug efficacy. The aim of this study is to show that the PDC/PDOs can be used as effective tools for developing new therapeutic strategy on non-small cell lung cancer (NSCLC).
Experimental design : PDC/PDO models from malignant effusions were established as following. We succeeded the establishment with samples which are positive for malignancy in cytology tests and tumor colony formation. Mutations that cell harbors are confirmed by Sanger sequencing, Whole exome sequencing, or RNA-sequencing. Following the patient treatment history, we confirmed how does established patient derived model response to drugs that patient was treated.
Results : A total of 54 PDCs and 171 PDOs were established from NSCLC patients, including models harboring EGFR mutations, KRAS mutations, uncommon EGFR mutations. 8 models of PDC and 7 models of PDO harbor various mutations of resistance mechanisms to EGFR-TKIs (T790M, C797S/C797G, MET amplification). Also, 4 models of PDC and PDO harbor uncommon EGFR mutations (EGFR G719S, L861Q, G719C/S768I, G719S/S768I) and 12 models of PDO harbors KRAS mutation.
YUO-139 and YU-1092 are patient derived models that harbors uncommon EGFR mutation G719S and L861Q respectively. The models response to afatinib sensitively. IC_{50} of YUO-139 and YU-1092 to afatinib were 2.1 nM and 23.8 nM respectively. YUO-143 is a PDO model that harbors EGFR E19del/T790M/C797S which was derived from gefitinib and mavelertinib resistant patient revealed sensitivity to BLU-945 (IC_{50}, 43 nM), a novel fourth-generation EGFR-TKI.
Conclusions : Patient derived models could be a critical tool for developing therapeutic strategies for NSCLC.

#2102 Understanding the mechanism of action of rigosertib in recessive dystrophic epidermolysis bullosa-associated squamous cell carcinoma through single cellanalysis.

A. P. South, S. Han, P. Fortina;
Thomas Jefferson University, Philadelphia, PA

The allosteric inhibitor rigosertib (an experimental therapeutic) was previously identified as an effective inducer of G2M arrest and apoptosis in squamous cell carcinoma (SCC) keratinocytes isolated from patients with the rare genetic disease recessive dystrophic epidermolysis bullosa (RDEB), both in vitro and in vivo. Early clinical trial data treating RDEB-associated SCC with rigosertib has shown remarkable efficacy in a sub-set of patients and understanding the mechanism of action of rigosertib in this lethal cancer would provide rationale for patient stratification. Multiple mechanisms of action were previously attributed to rigosertib, including polo-like kinase-1 (PLK1), PI3-kinase, activated RAS and microtubule polymerization inhibition. Our published data comparing PLK1 siRNA with PI3-Kinase inhibitors, MAPK inhibitors and microtubule disruption favored PLK1 as a mechanism of action without definitive conclusion. We therefore sought to determine the mechanism of action using transcriptomic profiling. Flow cytometry experiments identified three main categories of time to increase G2M in nine separate RDEB SCC keratinocyte populations in culture ranging from 1 to 6 hours after exposure to 1uM rigosertib. Bulk-RNA sequencing of representative populations from time to G2M groupings failed to identify consistent transcriptional change after exposure to rigosertib. However, single cell sequencing was able to identify increases in sub-populations of cells associated with G2M as well as transient emergence of unique populations that were specific to individual patient populations after exposure to rigosertib in culture. Of note a transient population of RDEB SCC keratinocytes only present after 1 hour of exposure to rigosertib was characterized by increased expression of the potassium regulator *KCNRG* which has previously been associated with apoptosis in chronic lymphocytic leukemia. Ongoing work is determining the role this gene may play in the mechanism of apoptosis induction in RDEB SCC keratinocytes after exposure to rigosertib.

#2103 Small extracellular vesicles derived from macrophages show anti-tumor effects in MDA-MB-231 cells.

P. Desai[1], A. Kumari[2], S. A. Abdullah[2], K. Dellinger[2];
[1]University of North Carolina at Greensboro, Greensboro, NC, [2]North Carolina A&T State University, Greensboro, NC

Triple-negative breast cancer is the primary cause of death in women globally due to the absence of targeted receptors on the tumor, making it hard to treat. In addition, the rapid spread of triple-negative breast cancer makes it difficult to manage using current treatment options such as lumpectomies, mastectomies, radiation, and chemotherapy. The survival rate for patients with triple-negative breast cancer is only 8-16%. Therefore, there is a critical need to develop new and effective treatment options. The objective of this study was to investigate the potential of M1 macrophage-derived exosomes to induce cancer cell apoptosis. To test this, we isolated M1 macrophage-derived exosomes to see their effects on triple-negative breast cancer MDA-MB-231 cells. We induce polarization in RAW 264.7 macrophage cells via lipopolysaccharide (LPS). Macrophage polarization was characterized using an enzyme-linked immunosorbent assay (ELISA), real-time PCR, nitric oxide production, and bright field microscopy. We characterized exosomes using nanoparticle tracking analysis (NTA) and scanning electron microscopy (SEM). The apoptosis marker, caspase 3/7 activation, was assessed using confocal microscopy in MDA-MB-231 cells. M1 macrophage-derived exosomes were isolated, characterized, and incubated with breast cancer cells to see their anticancer effects. Data showed the induction of apoptosis in 48 hours in triple-negative breast cancer cells. We conclude that exosomes derived from M1 macrophages may have the capability to induce apoptosis in triple-negative breast cancer.

#2104 Targeting stem cell proteostasis pathways sensitizes acute myeloid leukemia to proteasome inhibitors.

K. Lam, Y. J. Kim, C. M. Ong, F. J. Zhou, A. Z. Liu, B. A. Chua, J.-H. Zhou, E. D. Ball, R. A. J. Signer;
UC San Diego, San Diego, CA

Proteasome inhibitors are highly effective for treating multiple myeloma, but exhibit little efficacy in other blood cancers. In this study, we set out to determine why acute myeloid leukemia (AML) is largely refractory to proteasome inhibition and if we could sensitize human AML to this class of drugs. Efficacy of proteasome inhibitors in myeloma partly depends on disruption of protein homeostasis (proteostasis). This is driven by an accumulation of misfolded proteins that activate the unfolded protein response (UPR) and integrated stress response (ISR). Due to their highly secretory nature, myeloma cells exhibit relatively elevated baseline endoplasmic reticulum stress, and are thus sensitive to proteasome inhibition as they readily activate a terminal UPR. However, we found that proteasome inhibition fails to significantly disrupt proteostasis in human AML cells. We recently discovered that hematopoietic stem cells utilize distinct pathways to regulate proteostasis, and we hypothesized that AML cells co-opt stem cell proteostasis pathways to cope with proteasome inhibition and preserve proteostasis. To test this, we first performed RNA-sequencing which revealed that AML cells respond to proteasome inhibition by activating two distinct proteostasis pathways normally utilized by hematopoietic stem cells: autophagy and the heat shock response. Concurrent proteasome and autophagy inhibition significantly increased unfolded protein content in multiple human AML cell lines. This proteostasis disruption was sufficient to induce a terminal ISR marked by activation of the eIF2α-ATF4-CHOP signaling axis that severely attenuated protein synthesis, reduced proliferation, and induced widespread apoptosis in human AML cell lines and primary AML patient samples. In contrast to AML cells, dual proteasome and autophagy inhibition was well tolerated by healthy human CD34+ hematopoietic stem and progenitor cells, suggesting a tractable therapeutic window for treating AML. Indeed, dual proteasome and autophagy inhibition was tolerated *in vivo*, and decreased leukemia burden in mice xenografted with human AML cell lines. Similar to autophagy inhibition, disabling the heat shock response by deleting Heat shock factor 1 (*HSF1*) sensitized human AML cell lines to proteasome inhibitors. Treatment of *HSF1*-deficient AML cells with a proteasome inhibitior induced a significant increase in unfolded protein, activated the ISR, reduced growth and protein synthesis, and led to severe apoptosis. Concurrent *HSF1* deletion and proteasome inhibition dramatically reduced AML disease burden *in vivo* and extended median survival from 40 to 140 days. Overall, this study revealed that AML cells hijack stem cell proteostasis pathways to promote growth, survival, and therapeutic resistance. Targeting the unique configuration of the proteostasis network is uncovering new therapeutic strategies to eliminate AML.

#2105 Targeting the “Achilles Heel” of androgen receptor activity in castration resistant prostate cancer.

Ashish Tyagi[1], Balaji Chandrasekaran[1], Arun K. Sharma[2], Chendil Damoadaran[1]

[1]Texas A&M Health Sci. Ctr. (Bryan-Col. Station), College Station, TX, [2]Penn State College of Medicine, Hershey, PA

Background: Each year, millions of men are diagnosed with prostate cancer (CaP). The unchecked activation of the Androgen Receptor (AR) spurs CaP development and progression. Mutations or the presence of AR splice variants can add complexity to tumor ecology, leading to chemoresistance. This study aims to develop novel inhibitors targeting the “Achilles Heel” of AR activity: the N-terminal domain (NTD). This would circumvent the limitations of LBD (Ligand Binding Domain) therapies and offer a superior treatment option for patients. Though the AR-NTD is an intrinsically disordered protein, which complicates structure-based drug design, we have developed a unique small molecule inhibitor, ASR600, which specifically targets AR-NTD and promotes AR and AR-variants degradation by ubiquitination at previously unknown sites.

Methods: Mass-spec analysis was performed to identify distinct ubiquitination sites in AR's NTD. To perform spatial transcriptome analysis, CytAssist Visium (10X genomics) was used. Furthermore, we used western blotting, immunofluorescence, immunoprecipitation, and PDX mice studies in CRPC mouse models to examine the impact of ASR600 on CRPC.

Results: Four AR ubiquitination sites: K845, K847, and K913 (LBD) and K311 (NTD) are already identified. Interestingly, ASR600 continued to inhibit AR expression even with mutated ubiquitination sites. Mass spectrometry analysis of ASR-mediated mono-ubiquitinated N-terminal AR identified K16 as a unique ubiquitin acceptor. Altering this ubiquitination site rescues AR expression from ASR600-mediated degradation, emphasizing AR N-terminus as an ASR600 target. To discern the role of the K16 ubiquitination site in AR protein turnover, we evaluated AR protein stability in LNCaP cells that stably expressed ARWT or AR-K16R constructs. Our data indicates the pivotal importance of K16 for AR transcriptional activity. Invivo, ASR600, when used as a sole agent, exhibited inhibitory responses in PDX of clinically aggressive, AR-expressing tumors. Spatial gene expression analysis revealed marked expression differences in AR signature genes between control and ASR600-treated PDX tissues. Crucially, AR signaling, and related markers mainly aligned with epithelial markers rather than stromal ones. In contrast, the ASR600-treated PDX tumor showcased reduced AR signaling within epithelial cells.

Conclusion: Targeting AR-NTD has received a lot of attention, but its innately disordered structure has hindered progress. ASR600 targets AR-NTD specifically by ubiquitinating the protein at a novel location, K16. Our in vivo, PDX studies, combined with the spatial analysis, lay a strong foundation for initiating IND-enabling TOX studies, followed by a phase-I clinical trial for ASR-600 in CRPC patients.

#2106 Creating a living public oncology drug resource using PRISM cell line viability screening.

M. G. Rees, M. Kocak, C. Mapa, D. Frederick, E. Nguyen, A. Kalathungal, A. Fazio, J. F. Davis, E. Reeves, A. Tucci, R. Barry, C. Harrington, J. Eskra, M. M. Ronan, W. R. Sellers, J. A. Roth;
Broad Institute, Cambridge, MA

Cancer treatment options are rapidly expanding, with many new targeted agents and therapeutic modalities under development. However, systematic characterization of the cellular effects of emerging drug candidates is limited. Screening such agents against the approximately 900 diverse cancer cell lines in the PRISM assay can provide insights into drug specificity and cancer subtype selectivity and, leveraging the rich genomic and functional characterization of PRISM cell lines, support for annotated mechanisms of action. Our goal was to generate a large, high-quality, oncology-focused dataset that can benefit the cancer research community by characterizing new test agents of high clinical relevance. In the past year, this effort has been utilized to screen a total of 180 test agents with plans to extend testing to an additional 140 over the next year. The collection includes biologics (e.g., cytokines, antibodies, antibody-drug conjugates), targeted protein degraders, and small molecules. Supporting the quality of the screening collection and the robustness of the PRISM assay, the majority of inhibitors (including mutant-selective KRAS inhibitors, and inhibitors targeting the WRN helicase, a preferential vulnerability in cancers with microsatellite instability) tested to date closely mimic the effects of genetic knockout and/or knockdown of their annotated target, as measured by CRISPR and shRNA data available through the Dependency Map Portal (depmap.org). Further, while we observe strong modality-independent co-clustering of test agents annotated to act on the same target(s) (e.g., tucatinib with the antibody-drug conjugates T-DM1 and T-DXd for HER2), intriguing differences in efficacy and selectivity emerge in individual cell line models. All PRISM reference screening data and analyses will be made publicly available through depmap.org to serve as a benchmark for new drug development candidates and to further the efforts of researchers worldwide to match emerging cancer therapies to the patients most likely to benefit.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Pharmacodynamic Biomarkers of Drug Response
Poster Session

#2110 Characterization of the correlation between BTK degradation and tumor growth inhibition of the BTK target protein degraders using PK/PD modeling.

Y. Wu, **S. Li**, F. Wang, N. Hu, L. Yin, X. Song, J. Zhang, A. Xu, S. Yang;
BeiGene, Beijing, China

Introduction: Chimeric degradation activation compound (CDACs) are heterobifunctional molecules causing target protein degradation by simultaneously binding to the target protein as well as an E3-ubiquitin ligase. As an emerging new therapeutic modality, it is critical to understand the contribution of compound-specific parameters (e.g. drug exposure and binding potency to the target protein) and the system-specific parameters (e.g. target protein turnover) of CDACs to its in vivo effect. Method: To identify the key parameters for guiding compound optimization and to find the correlation between BTK degradation and the extent of tumor growth inhibition, a mechanistic PK/PD model was built (Phoenix WinNonlin 8.1) on a dataset generated from a BTK CDAC (Compound A). The PK/PD model was simplified mathematically compared to the full mechanistic models published previously1, since the binding affinity of Compound A to BTK was much higher than the binding affinity of CDAC to E3 ligase. This model can be linked to a tumor growth inhibition (TGI) mathematical model to find the correlation between target degradation and efficacy.Result: In mouse Rec-1 xenograft model, the BTK degradation and TGI was studied. The mice were dosed with Compound A orally at 0.3, 1, or 3 mg/kg, dose-dependent PK and BTK degradation in tumor was observed. After a single dose administration of Compound A, ~50% BTK degradation was observed in tumor at 24 h post dosing and the tumor BTK rebound to baseline at 72 hours post dosing at 3 mg/kg. The tumor BTK degradation was deeper after repeated dosing. A PK/PD model was built based on the data in this PK/PD study. The calculated BTK turnover half-life in Rec-1 model is about 16 h. In the efficacy study, Compound A was dosed orally once a day to the mice at 0.3, 1, or 3 mg/kg. The 3 mg/kg group achieved ~90% tumor growth inhibition in Rec-1 xenograft model. The PK/PD model was then linked with a mathematical model describing TGI2. A threshold level of BTK degradation in tumor to achieve tumor stasis was identified to be 96% for Rec-1 tumor model. At 90% tumor growth inhibition, average of 70% BTK was predicted to be degraded in tumor at steady state. The model was subsequently used to characterize the PK/PD relationship of BGB-16673. The efficacy of BGB-16673 was predicted using the model and it agreed with the observed value.Conclusions: The current model deepened our understanding of the PK/PD relationship of CDACs. The approach can be used to simulate different scenarios, e.g. different BTK turnover, potency or PK exposure. It can also be used in compound selection and optimization to predict repeated dose PD and efficacy from a single dose PK/PD data.1. J Pharmacokinet Pharmacodyn. 2021 Feb;48(1):149-163.2. Cancer Res. 2004 Feb 1;64(3):1094-101.

#2111 Impact of HER2 Expression on trastuzumab deruxtecan(T-DXd) efficacy.

W. Chen[1], J. Drago[2], A. Gupta[2], B. Liu[2], S. Chandarlapaty[2];

[1]Weill Cornell Graduate School of Medical Sciences/Memorial Sloan Kettering Cancer Center, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Background: T-DXd is an FDA-approved anti-HER2 Antibody Drug Conjugate (ADC), which has shown clinical efficacy in breast cancers with either overexpression or low-level expression of HER2. The benefit of T-DXd across the spectrum of HER2 expression has called into question the relevance of HER2 expression level as relevant parameter for T-DXd sensitivity. We sought to experimentally address the relevance of HER2 expression level upon the degree of T-DXd response.

Methods: A series of isogenic models was generated that expressed different levels of surface HER2 using a doxycycline-inducible promoter. These were analyzed for impact of differential expression level upon T-DXd internalization and drug response. Human breast cancer samples were analyzed for HER2 expression levels and association with clinical response to T-DXd under an IRB approved protocol.

Results: Induction of different levels of HER2 at specified doxycycline concentrations was verified in multiple models using immunoblotting and FACS. These different levels appeared to correspond to clinical breast cancer immunohistochemistry (IHC) scoring levels to 0, 1+, 2+, and 3+. The models were analyzed for T-DXd response and showed increasing levels of HER2 led to increase lysosomal uptake of T-DXd ($p<0.0001$). Moreover, elevation of HER2 levels led to lower concentrations of T-DXd needed to suppress tumor growth. Analyses of the effects of increasing levels of HER2 upon xenograft response to T-DXd are ongoing. Finally, retrospective analyses of a cohort of 50 breast cancer patients treated with T-DXd revealed that higher levels of HER2 corresponded to longer time on treatment (time to progression).

Conclusion: We observe a consistent relationship between elevated expression of HER2 and breast cancer response to T-DXd. The findings highlight the relevance of HER2 expression level as a biomarker of T-DXd response and support the potential value of therapeutic strategies that can induce HER2 surface expression levels to enhance response.

#2112 Identification of biomarkers associated with sensitivity to a novel PCNA inhibitor (AOH1996) by CRISPRi screening.

L. Gu, M. Li, C.-W. Chen, R. J. Hickey, L. H. Malkas;
City of Hope National Medical Center, Duarte, CA

Proliferating cell nuclear antigen (PCNA) plays an essential role in regulating DNA synthesis and repair and is essential for cancer cell growth and survival. We discovered a cancer-associated isoform of PCNA (caPCNA), which is ubiquitously and highly expressed in a broad range of cancer cells and tumor tissues but is not significantly expressed in non-malignant cells. Further studies of this novel caPCNA isoform as an anti-cancer drug target led to the identification of a cancer distinct region of PCNA which is partly delineated by the L126-Y133 peptide sequence and the discovery of a small molecule (AOH1996), which binds to this cancer distinct region as shown by crystallization studies. By targeting caPCNA, AOH1996 selectively kills cancer cells by interfering with the resolution of transcription-replication conflicts (TRC). Importantly, it causes no discernable toxicity at 6 times of its effective dose in mice. AOH1996 is currently in a phase 1 clinical trial for adult solid tumors at City of Hope (IND 138273). To identify genes that may be used as biomarkers for patient selection or potential targets for combination therapies, we screened a CRISPR interference (CRISPRi) library, which targets genes that are involved in cell signaling and cell cycle regulation. After culturing transduced cells in the presence of DMSO or 250 nM AOH1996 (corresponding to IC20) in triplicates for 14 generations, we measured the relative abundance of each guide RNA (gRNA) construct. Significant changes in the abundance of the gRNA constructs in AOH1996-treated cells relative to that in DMSO-treated cells were determined by the MAGeCK method. The target genes of the depleted or enriched gRNAs are predominantly involved in DNA repair, cell cycle regulation, and transcription regulation, which is consistent with the action mechanism of AOH1996. We validated the effect of these genes on sensitivity to AOH1996 and identified a panel of target proteins whose up or down-regulation is associated with sensitivity to AOH1996. Some of these proteins are targets of known chemotherapeutic drugs, which may be used in combination with AOH1996 in the clinic.

#2113 HMPL-506, a novel, highly potent and differentiated menin-MLL inhibitor for the treatment of *MLL-rearranged* and *NPM1* mutant acute leukemia in preclinical models.

M. Cheng, L. Ge, Z. Gao, Z. Zhong, A. Jiang, W. Zhang, J. Hu, S. Jiang, N. Li, N. Yang, J. Wang, Y. Sai, W. Qing, Y. Ren, W. Su;
HUTCHMED, Shanghai, China

Background: Mixed-lineage leukemia (*MLL*, or *KMT2A*) gene rearrangements (*MLL-r*) occur in 5%-10% acute leukemias and are associated with poor prognosis. *Nucleophosmin 1* mutations (*NPM1m*) are the most common genetic alterations in acute myeloid leukemia (AML). Multiple studies have illuminated that those leukemogenesis are dependent on the interaction of menin-MLL, which controls downstream gene expressions associated with cell proliferation and differentiation, e.g. *HOXA9* and *CD11b*. Herein, we introduce HMPL-506, a novel and highly differentiated small molecule compound targeting menin-MLL interaction.

Methods and Results: Biochemical assay revealed that HMPL-506 potently blocked menin-MLL binding with IC_{50} of 1.0 nM. In cell lines carrying *MLL-r* or *NPM1m*, HMPL-506 substantially down-regulated menin-MLL target genes transcription of *MEIS1* and *HOXA9* and upregulated the differentiation marker of *CD11b* by RT-PCR assay, consequently, HMPL-506 attenuated tumor cell growth, with GI_{50} ranging from 3.0 to 12.1 nM in *MLL-r* cell lines (MV-4-11, MOML-13 and RS4;11) and 22.4 nM in *NPM1m* cell line (OCI-AML-3) in CellTiter-Glo cell viability assay. Notably, compared with the other 5 menin inhibitors in clinical stage, HMPL-506 showed the strongest inhibitory potency in *MLL-r* and *NPM1m* cell line models. *In vivo* studies demonstrated the dose- and exposure-dependent target regulation of *MEIS1* and anti-tumor efficacy following HMPL-506 treatment in multiple tumor xenograft models. For instance, in MV-4-11 subcutaneous model, once daily oral administration of HMPL-506 at 5, 10 and 25 mg/kg for 4 days in BALB/c nude mice induced dose-dependent inhibition of *MEIS1* gene expression, positively correlating with compound exposures in tumor tissues; continuous dosing of HMPL-506 at 5 mg/kg for 28 days reduced the tumor growth by 86%, which was comparable to the efficacy induced by SNDX-5613 at 50 mg/kg. Treatment of HMPL-506 at 10 mg/kg and 25 mg/kg resulted in tumor shrinkage in all treated animals, with tumor regression rates of 72% and 100%, respectively. Furthermore, HMPL-506 synergistically improved anti-tumor effect of azacytidine, venetoclax and gilteritinib against *MLL-r* leukemias both *in vitro* and *in vivo*. HMPL-506 displayed favorable PK profiles and high selectivity among multiple kinases, methyltransferases and safety related targets. More importantly, the IC_{50} of HMPL-506 on hERG patch clamp was over 60 μM, indicating low risk of QTc prolongation in human.

Conclusion: HMPL-506 is a novel and highly differentiated menin-MLL inhibitor with robust anti-tumor activities, favorable ADME properties and low risk of cardiac toxicity, warranting it further clinical development for treatment of *MLL-r* and *NPM1m* acute leukemias. HMPL-506 IND is expected to be cleared in H1 2024.

#2114 Enhancing therapeutic strategies for osimertinib-resistant EGFR-mutant NSCLC: A HER3 dual-payload ADC (dpADC) with topoisomerase I and EGFR tyrosine kinase inhibitor.

L. Wang, M. Xiong, X. Gao, C. Zhou, Y. Han, Y. Li, J. Wang, L. Shi, G. Qin, P. H. Song;
GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: EGFR tyrosine kinase inhibitors (TKIs) have significantly improved the survival rate and the quality of life of the NSCLC patients with EGFR mutation in the first line setting. For example, Osimertinib, a potent third-generation EGFR TKI, has demonstrated exceptional efficacy in metastatic NSCLC with specific EGFR mutations. Despite its success, the emergence of drug resistance, often linked to elevated HER3 protein expression, remains a significant challenge. U3-1402 (HER3-Dxd), an HER3 ADC, demonstrates a promising result in managing Osimertinib-resistant NSCLC. It has been reported that combining U3-1402 with Osimertinib has shown enhanced efficacy in resistant cell lines and mouse models. Here, we explore a novel HER3 dual-payload ADC (HER3 dpADC), uniquely combining a Topoisomerase I inhibitor and an EGFR TKI within a single antibody structure using the enzymatic site-specific conjugation platform developed by GeneQuantum (GQ). This innovative approach demonstrates potent and synergistic anti-tumor effects in vitro and in vivo, presenting an alternative therapeutic strategy for EGFR-mutant NSCLC patients.

Results: GQ's dpADC platform technology employs two orthogonal enzymatic site-specific conjugations and stable linker technologies to efficiently generate the dual-payload ADC with high homogeneity and quality. For HER3 dpADC, HER3 Ab was conjugated with a novel Topoisomerase I inhibitor, TopoIx, and an EGFR tyrosine kinase inhibitor. In vitro DAR analysis revealed high linker stability, with minimal free payload release even after 96 hours of plasma incubation. Binding affinity assessments confirmed comparable affinity between HER3 dpADC and HER3 mAb in specific EGFR exon 19 deletion cell lines. Using various NSCLC cell lines in a 3D-spheroid culture system, HER3 dpADC demonstrated significant dose-dependent and synergistic anti-tumor activities. A robust bystander killing efficacy was observed in both HER3+/HER3- HEK293T cell coculture assays. Evaluation in CDX mouse models consistently demonstrated heightened in vivo efficacy by HER3 dpADC, aligning with the promising in vitro data. In NSCLC patient-derived xenograft (PDX) mouse models representing EGFR tyrosine kinase inhibitor-sensitive or resistant phenotypes, HER3 dpADC induced tumor regressions with no obvious toxicity, underscoring its potential as the next-generation HER3 targeting agent.

Conclusion: The innovative HER3 dpADC, leveraging an efficient dual enzymatic site-specific conjugation, exhibited robust anti-tumor efficacy in both in vitro and in vivo settings, surpassing single-agent treatments. Its synergistic mechanism of action presents a promising possibility for developing a more potent and the front-line therapeutic solutions in NSCLC patients who have progressed on standard therapies.

#2115 Assessing BCL2 protein complex level in peripheral blood mononuclear cells as a surrogate pharmacodynamic biomarker of BCL2 inhibitors in hematological cancers.

Hongwon Lee[1], **Byungsan Choi**[1], Saem Hong[1], Yunseo Lee[1], Tae-Young Yoon[1], Janghee Woo[2]

[1]Proteina Co., Seoul, Korea, Republic of,[2]Department of Hematology and Medical Oncology, Emory University School of Medicine, Atlanta, GA

In the last decade, cancer therapeutics have adhered to the practice of administering drugs at the maximum tolerated dose (MTD) selected from limited patient cohorts. The emergence of targeted therapies has disrupted this dose selection paradigm, as optimal efficacy may be achievable at lower dose than MTD. Recently, a regulatory agency initiated "OPTIMUS" to redefine the dose selection process, recommending quantitative assessments of drug efficacy in relation to the target protein throughout development and clinical trials.

ABT-199 is a protein interaction inhibitor that specifically disrupts the interaction of BCL2 protein. Consequently, the assessment of changes in the level of BCL2 protein complex is necessary to evaluate the ABT-199 efficacy for optimal dose selection. In this study, we adapted the Single-molecule Protein Interaction Detection platform for evaluating pharmacodynamics of BCL2 inhibitors in clinical samples.

We assessed the dissociation of two BCL2-related biomarkers, BCL2-BAX and BCL2-BIM, from a model system under various ABT-199 doses. Following one hour treatment with 300 nM of ABT-199, the BCL2-BAX complex dissociated almost by 40%, while 80% of the BCL2-BIM complex remained. The reduction of the BCL2-BIM complex was not changed when extending the treatment for 3 hours, indicating that the BCL2-BAX complex may serve as a more sensitive biomarker for assessing the target engagement of ABT-199. To determine the assay sensitivity, we evaluated the ABT-199 response across different cell numbers and found that 100,000 cells are sufficient for performing the BCL2-BAX assay. Subsequently, we validated the utility of our method in assessing clinical samples, specifically BMMCs and PBMCs. We collected 4 PBMCs and the corresponding BMMCs from hematological cancer patients and treated them with various doses of ABT-199 ex vivo. With 100,000 BMMCs and 1,000,000 PBMCs, we can generate dose-response curves for the BCL2-BAX complex at doses of ABT-199 ranging from 1 to 1,000 nM. To explore the feasibility of employing the BCL2-BAX complex in PBMCs as a surrogate biomarker for assessing ABT-199 engagement with BCL2 in BMMCs, we compared the averaged dose-response curves from 4 PBMCs with that of BMMCs. Remarkably, the two curves showed a coherent dissociation trend, indicating that the biochemical effect of ABT-199 on the BCL2-BAX complex may be conserved across different sample types.

Collectively, we have developed a target engagement assay for BCL2 inhibitors by measuring the BCL2-BAX complex. Notably, we observed a consistent dissociation pattern of the BCL2-BAX complex by ABT-199 treatment in both PBMCs and BMMCs. This molecular information offers an alternative way to assess the pharmacodynamics of BCL2 inhibitors, particularly in the case where collecting a series of BMMCs with sufficient amounts may not be feasible.

#2116 Telisotuzumab vedotin (Teliso-V)-mediated c-Met internalization, endolysosomal trafficking, and potent cytotoxic activity are unaffected by MET exon-14 skipping mutation.

I. Batth, R. Pandoy, S. Khaja, D. Maji, T. Uziel, A. Vasilopoulos, P. Ansell, P. Epling-Burnette;
AbbVie Inc., North Chicago, IL

Background: Telisotuzumab vedotin (Teliso-V) is an antibody-drug conjugate (ADC) composed of a c-Met (MET protein) antibody coupled to the microtubule inhibitor monomethyl auristatin E (MMAE). Teliso-V was granted FDA Breakthrough Therapy Designation for advanced/metastatic EGFR WT, NSQ NSCLC with high c-MET overexpression. For MMAE drug delivery, Teliso-V must first undergo receptor internalization and endolysosomal (EL) trafficking. Hepatocyte growth factor (HGF)-dependent MET EL trafficking and degradation depend on the E3 ubiquitin ligase Casitas B-lineage lymphoma (CBL). METex14 skipping and CBL-binding site mutations, which delete the binding site for CBL, occur in ~ 3% of NSCLC. The role of CBL in Teliso-V-MMAE delivery and activity was assessed in this work.

Methods: WT-human c-Met, c-Met-Y1003F/N (CBL binding site mutations in MET), and c-Met-ex14Δ (47 aa deletion to mimic ex14 skipping) or CBL-L620f, G807*, and W802* (CBL inactivating mutants) were expressed in NIH3T3, Ba/F3 cells, or A549 tumor cells using retroviral transduction. Genetically modified cells were then used to define the role of CBL in c-Met surface expression, intracellular signaling, EL trafficking (using pHrodo Red-labeled Teliso-V), and Teliso-V sensitivity in 2D/3D cell cultures.

Results: c-Met expression was required for Teliso-V cytotoxicity and intracellular payload delivery in all cell lines. While minimal changes in cell surface c-Met levels were observed, CBL binding mutants had increased phosphorylated c-Met in the absence of HGF, and ex14Δ-MET and CBL binding site mutants showed increased sensitivity to small molecule c-Met inhibitors. Compared to WT c-Met, ex14Δ and CBL-binding mutants showed similar EL trafficking and no change in sensitivity to Teliso-V. Co-treatment with a pan-CBL inhibitor also failed to alter Teliso-V EL trafficking and anti-tumor activity. Like most ADCs, EL trafficking was dependent on a dynamin-mediated process with reduced EL trafficking by co-treatment with Dyngo4a. To further understand the role of CBL in Teliso-V sensitivity, we expressed CBL inactivating mutations in A549 tumor cells. While the L602F and W802* mutants increased spheroid size, as well as activated p-MET, there was no change in sensitivity to Teliso-V.

Conclusions: Loss of CBL-binding sites on c-Met via ex14 deletion or Y1003F/N leads to increased MET-targeted TKI sensitivity and increased phospho-c-Met levels but does not impact Teliso-V sensitivity or EL trafficking. Our results indicate that Teliso-V traffics to the EL via a dynamin-mediated process. Therefore, Teliso-V delivers MMAE through a robust ADC-mediated EL-dependent mechanism that is independent of CBL, suggesting that high c-Met expression in Ex14skipping or CBL binding site mutant NSCLC patients should be further investigated for response to Teliso-V.

#2117 Elucidation of the fates of CDK2 inhibited aneuploid and residual lung cancers.

L. Tyutyunyk[1], Z. Chen[1], X. Liu[1], Y. Ng[2], A. Bhatawadekar[1], K. Narayan[1], R. Weigert[2], X. Liu[1], E. Dmitrovsky[1];
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Institute, Bethesda, MD

Genomic instability is a hallmark of cancer. Unlike normal diploid cells, cancer cells exhibit abnormal centrosome numbers and chromosomal instability. Mitosis with supernumerary centrosomes yields progeny with aberrant chromosome segregation and aneuploidy. While most progeny cells with abnormal chromosomes are eliminated through apoptosis, some have distinct fates with a growth advantage. These cancer cells can acquire resistance to antineoplastic agents. This confers an aggressive tumor biology and unfavorable clinical outcomes. Cyclin-dependent kinase 2 (CDK2) regulates cell cycle progression and the centrosome cycle. We previously reported that CDK2 inhibition prevents supernumerary centrosome clustering, causing multipolar mitosis and anaphase catastrophe in lung and other aneuploid cancers. This was associated with residual transplanted tumors in mice. To elucidate cell fates of progeny with multipolar mitosis after CDK2/9 inhibition with CYC065 (0.2 μM) treatment, a panel of murine and human lung cancer cells underwent time-lapse fluorescent microscopy. This elucidated multipolar mitotic events within the progeny. Intriguingly, distinct outcomes occurred after mitosis including formation of multipolar and multinucleated cells. Cell death of progeny is the predominant fate, but some progeny survive despite continuous CDK2 inhibition. Surprisingly, some of these cells fuse together. Those multinucleated cells can undergo multiple cell cycles without successful cytokinesis. To confirm these effects were through CDK2 inhibition, the selective CDK2 inhibitor Tagtociclib (PF-07104091, at the 2 μM dosage) was used. This treatment statistically-significantly increased multipolar lung cancer cells and increased apoptotic death during time-lapse fluorescent microscopy. Findings were independently validated by CDK2 shRNA knockdown. Focused ion beam scanning electron microscopy (FIB-SEM) and immunofluorescent staining revealed the ultrastructure of multinucleated cells. Insights into tumor biology came from intravital imaging of transplanted lung cancer cells in mice. Multipolar and multinuclear cells followed CDK2 antagonism. Incucyte® Live-Cell Analysis System and Artificial Intelligence-based imaging determined distinct growth responses in aneuploid as compared to non-aneuploid lung cancer cells after CDK2 inhibitor treatments. In summary, these findings are translationally relevant. CDK2 inhibition of aneuploid lung cancers yields distinct cell fates. This is linked to resistance to CDK2 antagonism and to formation of residual *in vivo* tumors.

#2118 SGN-CEACAM5C / SAR445953, a novel topoisomerase I inhibitor antibody-drug conjugate targeting CEACAM5, has potent anti-tumor activity in CRC, PDAC, GC and lung cancer tumor models.

Y. Baudat[1], C. Nicolazzi[1], J. Sigurjonsson[2], C. Amara[3], A. Clarke[2], R. Iyski[2], D. Meyer[2], V. Fantin[4], M. Chiron[1], S. Decary[1];
[1]Sanofi, Vitry-Sur-Seine, France, [2]Seagen, Bothell, WA, [3]Sanofi, Chilly-Mazarin, France, [4]Sanofi, Remote, NJ

Carcinoembryonic antigen cell adhesion molecule 5, CEACAM5, is a glycosylphosphatidylinositol-anchored glycoprotein expressed on the cell surface of most of the colorectal cancer (CRC) and pancreatic ductal adenocarcinoma (PDAC) and of more than 2/3 of gastric cancer (GC) and non-small cell lung cancer (NSCLC) while normal tissue expression is limited. The high prevalence of CEACAM5 expression prompted us to develop a novel CEACAM5 topoisomerase I inhibitor (Topo1i) antibody drug conjugate (ADC) with a DAR of 8, SGN-CEACAM5C / SAR445953. The anti-CEACAM5 antibody was chosen based on its high selectivity for CEACAM5 and its potential to direct cytotoxic payloads to tumor. The Topo1i payload was optimized for potency and enhanced bystander activity. SGN-CEACAM5C / SAR445953 is rapidly internalized and demonstrates *in vitro* cytotoxicity with EC50 values in the sub-nM range while it induces no toxicity on CEACAM5-negative cells. The potent anti-tumor activity is mediated by direct cytotoxicity on CEACAM5-expressing tumor cells and by a strong bystander effect due to the diffusion of the payload to the neighboring CEACAM5-negative tumor cells. Accordingly, the ADC incubated in a co-culture of CEACAM5-positive and -negative cells at a ratio of 1/1 induces a ~50% growth inhibition of CEACAM5-negative cells. Interestingly, with incubated ADC, only 1% of CEACAM5-positive cells in co-culture are sufficient to provide 11% growth inhibition of CEACAM5-negative cells. *In vivo*, SGN-CEACAM5C / SAR445953 is stable in circulation in SCID mice with a t1/2 close to 15 days. *In vivo* efficacy at 1, 3 and 10 mg/kg (single administration) was evaluated in panels of 4 CRC, 3 PDAC, 4 NSCLC and 3 GC patient-derived xenograft (PDX) models. At 10 mg/kg, the ADC elicits antitumor regression in 14/14 models. At 3 mg/kg, tumor regression occurs in 12/14 models. This potent, specific and dose dependent anti-tumor activity was further confirmed in Single Mouse Trials (SMT) of 20 CRC PDX models, 31 lung cancer PDX models and 19 gastric cancer PDX models. SMT consists in use of one animal per PDX model per treatment arm and for which the evaluation of efficacy is based on RECIST (Response Evaluation Criteria In Solid Tumors) criteria used in clinic. In CRC, gastric and lung cancer SMT, disease control rates are 95%, 84% and 87%, respectively with overall response rates of 55%, 68% and 71% including 15%, 10% and 26% of complete responses, respectively. The high anti-tumor activity across panels of PDX models of several CEACAM5 positive indications supports further evaluation of SGN-CEACAM5C / SAR445953 in patients with CRC, PDAC, GC and lung cancers (NCT06131840).

#2119 Translational research to facilitate development of novel therapeutic combinations of letrozole for the treatment of glioblastoma.

A. S. Karve, B. B. Gabani, S. N. Gadgil, S. P. Kulkarni, G. A. Gudelsky, P. B. Desai;
University of Cincinnati, Cincinnati, OH

Letrozole (LTZ), a third-generation aromatase inhibitor, appears to be a promising novel therapeutic for the treatment of glioblastoma (GBM). It synergistically enhances the efficacy of the DNA alkylating agent temozolomide, one of the few approved chemotherapeutics for GBM, against patient-derived GBM cells. RNA-seq analysis of tumor from recurrent GBM patients treated with LTZ prior to surgery in a “window of opportunity” phase 0/1 dose escalation clinical trial revealed that LTZ downregulates genes encoding for DNA-damage repair proteins (BRCA2) in a dose dependent manner. Our central hypothesis for this project is that combination of LTZ with targeted therapeutic agents that promote DNA damage results in synergistic effects against GBM. The objective of this study is to evaluate the effects of poly-ADP ribose polymerase (PARP) inhibitors in combination with LTZ against patient-derived GBM cells. Our secondary aim for this project is to delineate the blood-brain barrier (BBB) permeability of PARP inhibitors. Employing patient-derived G43, G75 and JHH-136 GBM lines we assessed the influence of PARP inhibitors (olaparib, pamiparib, veliparib and niraparib) in combination with LTZ on cell viability and neurosphere growth. We then utilized male CD-IGS rats (n=6; body wt., 250g) to assess plasma and brain extracellular fluid (ECF) pharmacokinetics (PK) of PARP inhibitors using cerebral microdialysis. The IC_{50} values for PARP inhibitors in these assays ranged from 0.06 to 11.31 µM. Treatment in combination with LTZ (0.05 µM), a non-cytotoxic concentration of LTZ in these lines, significantly decreased the IC_{50} values for PARP inhibitors (0.012 to 0.51 µM). Combination Index analysis indicated that this combination was strongly synergistic. Furthermore, the plasma and brain ECF PK analyses suggested that PARP inhibitors such as pamiparib and niraparib exhibit facile transport across the BBB barrier as reflected in $K_{p,uu,brain}$ (ratio of AUC_{ecf}/$AUC_{plasma,\ unbound}$) values of 0.98 and 0.45, respectively. Overall, these results provide a strong foundation for pursuing further development of combination therapy of GBM with LTZ and PARP inhibitors. A careful assessment of the clinical efficacy and safety profile of these agents will further guide shortlisting combination of LTZ for pre-clinical and clinical development.

#2120 Asparaginases-Treatment potential for the biomarker selected hepatocellular carcinoma (HCC) population.

E. Tyagi[1], M. Pohorecka[2], V. Duvivier[2], A. Studeny[2], D. Valour[2], N. Moulharat[2], H. Darville[2], N. Provost[2], P. Barbier Saint Hilaire[2], E. Hoeben[2], D. Simons[1]; [1]Servier BioInnovation, Boston, MA, [2]Servier, Gif Sur Yvette, France

Asparaginase is a key component of the therapeutic regimen used to treat patients with acute lymphoblastic leukemia (ALL). Calaspargase pegol (Asparlas) is composed of *E. coli* L-asparaginase and is PEGylated with approximately 5000 Da polyethylene glycol (PEG). Asparlas depletes asparagine (Asn) by deamination into aspartic acid. Asn synthetase (ASNS) is the key enzyme responsible for *de novo* Asn synthesis. In the absence of Asn in their direct environment, normal cells having adequate ASNS activity can survive with their own Asn supply while cancer cells lacking ASNS activity undergo apoptosis as they depend on extracellular sources of Asn. The *ASNS* gene has a typical CpG island in its promoter and its methylation status in tumor cells has been reported to be associated with asparaginase sensitivity clinically in T-ALL and in solid tumors preclinically. In this study we have investigated *ASNS* promoter hypermethylation as a biomarker for Asparlas activity in solid tumors and explored the feasibility of translating these results into the clinic. Analyses of the TCGA datasets indicated that a relatively high fraction of hepatocellular carcinoma (HCC) and gastric cancers are hypermethylated at the *ASNS* promoter. Testing Asparlas across a panel of HCC cell lines demonstrated that *ASNS* promoter-hypermethylated cell lines with lowest *ASNS* mRNA expression are the most responsive to Asparlas treatment in vitro. In vivo efficacy studies in mice bearing human *ASNS* promoter-hypermethylated xenograft models of HCC and gastric cancer showed that Asparlas treatment inhibited tumor growth in a dose-dependent manner and resulted in tumor rejections at the highest doses. Data from the HCC model was used to build a PK/PD efficacy model to project efficacious concentrations in patients. A panel of HCC PDX models with different levels of *ASNS* promoter methylation was evaluated to better understand the relationship between this biomarker and response to Asparlas. Treatment with Asparlas resulted in complete depletion of Asn in plasma and a partial depletion of Asn in the tumor for all models tested and strong anti-tumor activity against a model that had high methylation of the *ASNS* promoter. This activity was lost in models with lesser degrees of methylation indicating a strict threshold of promoter methylation for efficacy. These data confirm and extend previous findings that hypermethylation of the *ASNS* promoter has a synthetic lethal relationship with Asn-depleting therapies including Asparlas and highlight the need to carefully define the minimum threshold of hypermethylation to select HCC patients who could potentially benefit from Asparlas treatment.

#2122 Enhanced anticancer efficacy via ROS-dependent ferroptosis: Synergy between surufatinib and cisplatin in small cell lung cancer.

X. Li[1], Z. Zhang[1], Q. Tang[1], H. Xu[2];

[1]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]Nanjing Medical University, Nanjing, China

Objective: Small cell lung cancer (SCLC), a highly malignant subset of neuroendocrine carcinoma, accounts for 13% of lung cancer cases and is characterized by its high aggressiveness and poor prognosis. The longstanding first-line treatment, a platinum-etoposide chemotherapy regimen, is increasingly compromised by resistance issues, highlighting the critical need for new therapeutic approaches. Surufatinib, an inhibitor selectively targeting vascular endothelial growth factor receptors (VEGFR) 1, 2, and 3, fibroblast growth factor receptor type 1 (FGFR1), and colony-stimulating factor-1 receptor (CSF-1R), has demonstrated efficacy in a spectrum of solid tumors, including neuroendocrine neoplasm, thyroid cancers and biliary cancers. Recently, ferroptosis, an iron-dependent cell death pathway, offers therapeutic promise, especially by inhibiting the xCT system, effective in pancreatic and lung adenocarcinomas. Yet, surufatinib's potential for inducing ferroptosis in SCLC remains to be investigated.

Methods: Cytotoxicity assays were performed on SCLC cell lines to assess the combinatorial effect of surufatinib and cisplatin, revealing a synergistic interaction. Ferroptosis inhibitors were applied to assess the reversal of cytotoxic effects. Mitochondrial morphology, reactive oxygen species (ROS) accumulation, membrane potential dissipation (JC-1 assay), lipid peroxidation (MDA levels), and intracellular iron accumulation (Fe2+ quantification) assays confirmed ferroptosis induction. Western blot analyses were conducted to explore the mechanistic pathways, supplemented by in vivo antitumor efficacy evaluations.

Results: In vitro assays revealed that surufatinib, when combined with cisplatin, exerts a pronounced synergistic effect on small cell lung cancer (SCLC) cell lines by inducing ferroptosis. The combination therapy strategically modulated ferroptosis-related pathways: cisplatin effectively decreased the expression of glutathione peroxidase 4 (GPX4), critical for cellular antioxidant defenses, while surufatinib increased the expression of acyl-CoA synthetase long-chain family member 4 (ACSL4), which is essential for the accumulation of lipid peroxides. This dual pathway engagement significantly amplified the ferroptotic response, culminating in heightened antitumor activity. Corroborative in vivo experiments substantiated these findings, validating the combined treatment's efficacy in a living model and underscoring its potential as a robust therapeutic strategy for SCLC.

Conclusion: Our findings reveal that surufatinib triggers ferroptosis in small cell lung cancer—a novel discovery. Additionally, it also unveils that surufatinib and cisplatin together enhance anti-cancer efficacy via the ROS-mediated ferroptosis pathway, marking a significant advance in SCLC therapy.

#2123 Validation of novel histone deacetylases (HDAC) specific nanoparticles using HDACs overexpressed human embryonic kidney cells.

S. Lohana, Y. Ramakrishnan, P. Balraj, M. Khan, M. Sanku, V. Sathish, M. Quadir;
North Dakota State Univ., Fargo, ND

Introduction: Histone deacetylase (HDAC) is a major enzyme system that is upregulated in numerous disease conditions including cancer. Harnessing the upregulation of HDAC can be a viable tool to design targeted therapy for these diseases. Nanoparticle technology has emerged as a powerful workhorse to suppress the survival of diseased cells selectively. As such, we aim to design a nanoscale, drug delivery platform that responds to HDAC enzymes to initiate drug release. In this poster, we show the pharmacological evidence that HDAC-sensitive nanoparticles are interacting with HDAC enzymes in vitro in time and concentration dependent pattern.

Methods: We synthesized HDAC-responsive nanoparticles via developing a block copolymer composed of a poly (ethylene glycol) block and a poly (L-acetylated lysine) block. Abbreviated as PEG-acPLK, these copolymers self-assemble as nanoparticles with negatively charged surface. Using in vitro culture of HEK 293 cells, we showed that the formed nanoparticles interact and interfere with HDAC enzymes. Cells were grown to 80-90% confluency in DMEM media w/ 10% FBS prior to experiments. HEK-293 cells were overexpressed with HDAC 7 & HDAC 8 using Lentiviral vectors. Western blot was done to prove the successful overexpression of the HEK cells. Cytotoxicity assay was done by MTT to analyze the efficacy of HDAC specific nanoparticle on control and overexpressed HEK-293 cells.

Results: Our work showed that, PEG-acPLK systems form nanoparticles with a hydrodynamic diameter (RH) of 120-150 nm. The particles were negatively charged on their surface, as such did not produce any non-specific toxicity to cells, such as damage of cell membranes. HEK-293 cells were infected with lentivirus vectors for HDAC 7 and HDAC 8. The medium was changed 8 h after infection. Forty-eight hours after infection, the positive cells were selected with 5 µg/mL puromycin. The lentivirus stable transformants of HEK-293 cells were collected and significant overexpression were confirmed by western blot. For the cytotoxicity study, control and overexpressed cells were treated with HDAC-nanoparticle and PEG-acPLKC (5 µg/mL to 70 µg/mL) for 24hrs. Both the HDAC-nanoparticle and PEG-acPLC (free form) showed more than 60% of toxicity at the concentration of 20 µg/mL. Whereas the HDAC 7 and 8 overexpressed HEK-293 cells did not showed any effects with nanoparticle and Ae-peg-PLKC, suggesting compensating effect due to highly available HDAC system in place and confirm the effectiveness of the HDAC nanoparticle.

Summary and Conclusion: Overall, these results showed that HDAC specific nanoparticle exhibited effects in HEK-293 HDACs overexpressed cells. Further molecular mechanistic studies will help to delineate how the HDAC-responsive particles can be used for drug delivery.

#2124 Validation of the intelligent glycotransferase-dependent conjugation (iGDC) platform: A groundbreaking approach for next-generation HER2-targeting ADC GQ1012 with enhanced druggability, potency, and safety.

M. Xiong, Z. Mu, M. Xu, C. Liu, B. Dai, J. Wang, X. Gao, L. Shi, P. H. Song, G. Qin;
GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Antibody glycan remodeling has emerged as a promising site-specific conjugation technology to develop ADCs, while most reported cases suffer from complicated CMC process and scalability challenges. We report herein an innovative, streamlined one-enzyme, one-step glycan remodeling technology, i.e. intelligent Glycotransferase-Dependent Conjugation (iGDC), that enables the site-specific conjugation of various biologic modalities including monoclonal antibody, bispecific antibody and Fc fusion proteins. Employing immobilized enzymes and a continuous-flow process, iGDC efficiently tethers payloads to the *N*-297 glycan site without requiring antibody engineering. In contrast to alternative conjugation techniques, iGDC offers superior versatility, product quality, process efficiency, scalability, and cost-effectiveness. Validation of the iGDC platform is exemplified by GQ1012, a HER2-targeting ADC featuring the potent Topoisomerase I inhibitor, TopoIx. Preclinical studies demonstrated GQ1012's outstanding anti-tumor efficacy in diverse in vitro and in vivo models, displaying robust synergistic effects with anti-PD-1 therapy and excellent tolerability in pre-tox studies involving monkeys with no signs of lung diseases, surpassing those of Enhertu. **Results:** GQ1012, developed through iGDC, utilized a highly hydrophilic, stable branch linker to conjugate TopoIx to an anti-HER2 antibody, achieving high conjugation efficiency confirmed by DAR analysis. The ADC maintained comparable antigen binding affinity and internalization compared to the parental antibody, exhibiting potent cytotoxicity against HER2-positive cancer cells. Despite glycan remodeling with iGDC leading to the removal of ADCC function, GQ1012 demonstrated no off-target cytotoxicity in HER2-negative cells and displayed a robust bystander killing ability in co-culture assays. In various in vivo models, GQ1012 demonstrated similar or superior antitumor efficacy compared to Enhertu, showcasing strong synergy with anti-PD-1 therapy. Stability studies confirmed GQ1012 maintains a highly stable linker, minimizing DAR reduction. Preliminary toxicity studies in monkeys following repeated intravenous infusions of GQ1012 showcased excellent safety and pharmacokinetics at specified doses and the potential for an extended therapeutic window compared to Enhertu. **Conclusion:** The validation of the iGDC platform through GQ1012 highlights its adaptability and efficiency in producing highly homogeneous next-generation ADCs without requiring antibody engineering. GQ1012 presents promising potential as a next generation HER2 ADC with an expanded therapeutic window compared to Enhertu, supported by extensive in vitro, in vivo assessments, and preliminary toxicity studies.

#2125 The use of intestinal organoids as a preclinical screen to assess gastrointestinal (GI) toxicity and barrier integrity.

V. Ubertini, S. Hall, F. Ponthan, J. Wilson;
Epistem Ltd., Manchester, United Kingdom

Gastrointestinal (GI) toxicity is a common and often severe limiting factor in the development of antineoplastic drugs. Symptoms include diarrhoea, dehydration and ulceration which increase susceptibility to infection, partly due to damage of crypt and/or villus structures in the small intestine, impairing the barrier function. As novel targeted therapies are emerging, assessment of their potential GI toxicity remains crucial. Small intestinal (SI) organoids are 3D *in vitro* models of the epithelium which recapitulate the structure and function of the small intestine. We have further developed and validated the organoid model as a screening tool to predict GI toxicity and subsequent mucosal regeneration in four species: mouse, rat, dog and human. The culture conditions have been designed to mimic the stem cell niche and allow cell differentiation and proliferation to occur. All intestinal lineages were present in the organoids derived from each species and the epithelial hierarchy closely resembled that observed *in vivo*. The toxic effects of antineoplastic drugs on the organoids were assessed by quantification of the total cell viability upon treatment, coupled to morphometric analysis of the organoids (size, area, perimeter, and branching efficiency). Immunofluorescence and RNAseq can be used to identify the targeted cells and the toxicity mechanisms of the drugs. To further assess the effect of drugs on barrier integrity, we have developed transwell-grown cell monolayers derived from normal human small intestinal organoids. This model allows direct access to both apical and basal surfaces, which is not possible when using organoids where their geometry prevents access to the apical surface. The monolayer formation was followed by live imaging and Trans-Epithelial Electrical Resistance (TEER) measurements and treatments with toxic drugs were applied after TEER reached a plateau. The direct effect on barrier integrity was evaluated by TEER reduction, increased FITC-Dextran permeability and analysis of TJ proteins by immunofluorescence. Furthermore, effects on cell death were assessed by measuring the levels of Lactate Dehydrogenase (LDH) released into the medium by dying cells. In conclusion, our models provide an innovative *in vitro* solution to further study the toxic effects of drugs on the normal small intestine and to analyse direct effects on barrier integrity. The monolayer assay may also be useful for developing models of transient TJ impairment to improve the bioavailability of orally administered antineoplastic drugs. The model can be considered more representative of the normal intestine than transformed cell lines such as CaCo2.

#2126 Efficacy and underlying mechanisms of surufatinib in non-small cell lung cancer treatment.

Y. Zheng, B. Shan, M. Wang, X. Wu, R. Cai, F. Niu, Y. Yuan, L. Liu, X. Zhu;
Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China

Background: The prevalence and fatality of lung cancer, especially non-small cell lung cancer (NSCLC), highlight the urgency for efficacious therapies. Surufatinib, an inhibitor of tyrosine kinases like VEGF receptors (VEGFR) 1, 2, and 3, Fibroblast growth factor receptor 1 (FGFR1), and CSF-1R, shows potential in augmenting chemotherapy efficacy and reducing adverse effects. Preliminary clinical studies (NCT04922658) have indicated survival benefits for NSCLC patients treated with surufatinib. This investigation seeks to delineate the therapeutic efficacy of surufatinib, correlating clinical benefits with mechanistic insights.
Methods: To elucidate mechanisms, proliferation assays (CCK8), migration (scratch assay), and apoptosis (flow cytometry) were conducted in A549 and H1299 cell lines. Angiogenesis and macrophage polarization were examined via vascular junction points and mRNA expression profiling. In nude mice, subcutaneous tumors were induced and treated with the study drugs, with tumor growth and angiogenic markers assessed.
Results: In vitro, surufatinib potently inhibited angiogenesis and exerted a dose-dependent suppression of proliferation and colony formation in lung cancer A549 and PC9 cell lines. It also enhanced apoptosis and cell migration. Additionally, surufatinib shifted macrophage polarization towards an M1 phenotype while diminishing M2 macrophages, thereby, contributing to a more robust anti-tumor immune milieu. In vivo studies corroborated these findings, with surufatinib and vinorelbine combination therapy significantly curtailing tumor growth and reducing CD31 expression in tumor tissues, highlighting its potential for substantial therapeutic gains in NSCLC management.
Conclusion: Surufatinib achieved notable antitumor effect consistent with clinical findings in NSCLC, effectively inhibiting cellular proliferation and migration, attenuating angiogenesis, and enhancing apoptosis. Significantly, it also modulated macrophage polarization to favor an M1/M2 balance, thus activating the immune response. Therapeutic strategies with surufatinib have underscored augmented antineoplastic efficacy, meriting additional clinical investigations.

#2127 Enhancing radiosensitivity in biliary tract cancer: The dual role of surufatinib in tumor suppression and macrophage reprogramming.

N. Wang, H. Ma, X. Mei, A. Huang, Y. Xiao, J. Yao;
Wuhan Union Hospital, Wuhan, China

Background: Biliary tract cancer (BTC) is notorious for its unfavorable clinical outcomes. Radiotherapy (RT) is a crucial component in BTC treatment. This study explores the radiosensitizing potential and mechanisms of Surufatinib (SF), an oral tyrosine kinase inhibitor, distinguished by its anti-angiogenic and immunomodulatory effects.
Methods: In a NOZ mouse xenograft model, tumor growth and expressions of Ki-67, CD31 were analyzed. NOZ and TFK1 BTC cells treated with SF and/or RT underwent assessments for viability, cycle, and apoptosis using CCK8, colony formation, and flow cytometry. Macrophage polarization in SF/RT-treated tumor cell-macrophage co-cultures was studied using Elisa, qRT-PCR, and flow cytometry.
Results: In vivo, SF impeded angiogenesis and bolsters the anti-tumor effect of radiotherapy. SF combined with RT significantly reduced subcutaneous tumor growth in nude mice, and diminished Ki-67 and CD31 expressions. In vitro, SF heightened cholangiocarcinoma cells' radio-sensitivity, causing DNA double-strand breaks and apoptosis. SF and radiotherapy combined notably increased γ-H2A expression and apoptosis levels ($P<0.05$). SF induced inflammatory response changes, favoring M2 to M1 macrophage polarization. In a tumor cell-macrophage co-culture, the SF-radiotherapy group showed increased IL-6 and decreased TGF-β ($P<0.05$), with upregulated M1 markers (IL-6, CXCL10) and downregulated M2 markers (TGF-β, CCL22, Arg-1) in macrophages ($P<0.05$). Both in vivo and in vitro, SF significantly reduced CD206+ M2-type macrophages ($P<0.05$).
Conclusion: Surufatinib alters the immune microenvironment in cholangiocarcinoma, reversing the immunosuppressive macrophage polarization induced by radiotherapy and reprogramming M2-type macrophages into M1-type, thereby enhancing the radiosensitivity of cholangiocarcinoma.

#2128 Surufatinib treatment in pancreatic cancer: unveiling the role of GPR34 in TAMs and enhancing immunotherapy efficacy.

X. Guo[1], Y. Liu[1], Y. Song[1], J. Huang[1], W. Zhu[1], P. Xu[2], J. Yu[1], S. Gao[1], J. Hao[1];

[1]Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, [2]National Center for Nanoscience and Technology, Beijing, China

Background: Pancreatic cancer, often resistant due to its immunologically "cold" nature and tumor-associated macrophages (TAMs), presents challenges in chemotherapy and immunotherapy. This study uses single-cell transcriptomics to assess TAM subsets in response to surufatinib, an inhibitor targeting CSF-1R, FGFR1, and VEGFR1-3.

Methods: Surufatinib-treated patient samples were analyzed using single-cell RNA sequencing to identify altered macrophage subsets. Additional techniques, such as flow cytometry, tissue microarrays, co-culture assays, and macrophage-specific knockout mice, were used for further study. Western blot and immunofluorescence clarified the molecular functions of TAMs, and the impact of targeting these TAMs on PD-1 therapy was evaluated in a pancreatic cancer mouse model.

Results: Single-cell RNA sequencing revealed macrophage subsets with increased GPR34 expression following surufatinib treatment. The Gpr34fl/flLYZ2Cre mouse orthotopic-transplanted tumor model, treated with gemcitabine and albumin-bound paclitaxel, showed significantly reduced tumor growth compared to the control group, with notably lower percentages of exhausted T (Tex) cells and regulatory T (Treg) cells, and a significant increase in cytotoxic T cells in tumor tissue. LysoPS, produced by chronically injured pancreatic cancer cells, promotes the differentiation of bone marrow-derived monocytes (BMDM) into an immunosuppressive phenotype, an effect abolished after siGpr34 transfection. The LysoPS-GPR34 axis can significantly activate the NF-κB signaling pathway in BMDMs, potentially inducing the senescence-related secretory phenotype (SASP) and contributing to the macrophages' immunosuppressive phenotype. Combining a GPR34 antagonist with αPD-1 and PD-L1 inhibitors significantly curbed tumor growth and enhanced the immune environment in KPC mice.

Conclusions: Elevated GPR34 in TAMs enhances immunosuppression via the NF-κB pathway, affecting T cell distribution. GPR34's role could be key in optimizing surufatinib treatment for pancreatic cancer, indicating new therapeutic avenues.

#2129 Efficacy and underlying mechanisms of surufatinib combined with PD-1 monoclonal antibody and chemotherapy in pancreatic cancer.

N. Zhang, R. Jia, G. Dai;
Chinese PLA General Hospital (CPLAGH), beijing, China

Background: A phase 1b/2 study (NCT05218889) of surufatinib combined with camrelizumab, nab-paclitaxel, and S-1 (NASCA) as first-line therapy for metastatic pancreatic adenocarcinoma has shown promising results, potentially overcoming the limitations of current pancreatic immunotherapies. Animal studies are underway to further explore the synergistic effects and mechanisms of this combined therapeutic approach.
Methods: Genetically engineered KPC mouse cells were used to establish a subcutaneous transplantation tumor model in female mice, which were then divided into control group, AG group (nab-paclitaxel + gemcitabine), and NASCA group. Tumor metrics were recorded until euthanasia after 21 days. Blood and tumor samples were analyzed using Flow Cytometry.
Results: Compared with the control group, the NASCA and AG groups demonstrated tumor volume reductions of 14.7% (p=0.172) and -0.4% (p=0.972) on day 7, respectively. At day 14, the reductions were 48.8% and 29.9% (p<0.001*, p=0.002*). At day 21, the reductions were 37.4% and 21.5% (p=0.001*, p=0.144). The tumor growth inhibitions (TGIs) for NASCA and AG group were 56.7% (p<0.001*) and 21.2% (p=0.36), respectively. Compare to AG group, the tumor volume reduction in NASCA group were 15.1% (p=0.050*), 26.9% (p=0.001*) and 20.3% (p=0.116), respectively. And the TGIs for NASCA group compare AG group was 45.0% (p=0.020*). Distinguishingly, the NASCA group, when compared to the AG group, had a heightened proportion of M1 macrophages (28.5% vs. 15.5%, p=0.019*), mCD68+ Macrophages (99.7% vs. 99.1%, p=0,014*) and mPD-1+/mCD8+ T cells (24.8% vs. 9.8%, p=0.03*). Furthermore, T-regulatory cells (T-regs) in peripheral blood demonstrated uniformity across the groups, were no statistically. RNA-seq analysis revealed that the NASCA significantly suppressed multiple anti-angiogenic pathways while enhancing the cytokine pathway (p=0.005*), indicating potential immune system activation.
Conclusion: The NASCA group outperformed the AG group in controlling tumor growth and early tumor shrinkage, potentially due to macrophage polarization regulation. Further research is vital to understand the benefits of integrating targeted therapy, immunotherapy, and chemotherapy for pancreatic cancer.

#2130 Glioblastoma-derived extracellular vesicle cargo as a reporter of drug delivery and effect.

V. DeLuca[1], N. Tang[1], N. Hansen[1], A. Raju[1], C. Shaffer[1], Y. Hao[1], T. C. Burns[2], J. N. Sarkaria[2], I. Parney[2], P. Pirrotte[1], K. Van Keuren-Jensen[1], M. E. Berens[1];

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]Mayo Clinic, Rochester, MN

The selectivity of the blood-brain-barrier (BBB) can prevent therapeutics from reaching the brain, and this may contribute to the high failure rate of new drugs for tumors like glioblastoma (GBM) and brain metastasis. The capacity to detect BBB penetrance in real-time in a noninvasive manner would arguably aid the rate of therapeutic development. Extracellular vesicles, which are membrane bound particles secreted by all cell types in the body, have potential as a neuro pharmacodynamic reporter given that their protein and RNA cargo reflect the originating cell population. We hypothesized that the exposure of GBM cells to therapy results in altered EV cargo, and that the detection of this shift can be leveraged as a liquid biopsy from patients during early clinical trials to determine BBB penetrance and tumor engagement. To identify cargo shifts indicative of treatment, we exposed four short-term patient derived glioma cell lines to arsenic trioxide (an idiopathic toxin), MLN4924 (a neddylation inhibitor), and the alkylating agent temozolomide, then harvested EVs for unbiased mass spectrometry and RNA sequencing. Interestingly, we identified conserved upregulated and downregulated protein and RNA species across cell lines and across drug treatments, despite the diverse mechanisms of action. Candidate proteins were further validated by mesoscale immunoassays and exoview evaluation of tetraspanin-captured EVs. RNA species were validated by qRT-PCR. Overall, we demonstrate that GBM-derived EV cargo changes in response to therapy, supporting the development of EVs as a reporter of drug delivery in GBM. Ongoing and future work is focused on identifying enrichment handles in order to selectively evaluate GBM-derived EV cargo from patient biofluids. Thus far, B7H3, PTPRZ1, EGFRvII and IL13Ra2 have been screened as putative handles. Success in this pursuit could substantially enhance findings and accelerate drug testing in early-stage clinical trials in brain tumor patients by reporting drug accessibility to the tumor and engagement with drug targets.

PREVENTION / EARLY DETECTION / INTERCEPTION: Health Disparities Across the Cancer Continuum
Poster Session

#2134 Disaggregating breast cancer mortality trends in Asian American women from 2005-2020.

M. Marcotte[1], Y. Chauhan[1], **V. Penmetcha**[1], C. Thompson[2], C. Thompson[1], M. Srinivasan[1], G. Kim[1], X. Qi[1], R. Huang[1], A. Bacong[1];
[1]Stanford University School of Medicine, Stanford, CA, [2]University of North Caroline Chapel Hill, Chapel Hill, NC

Background: Breast cancer (BC) is the second leading cause of death among women and has disproportionately higher rates of mortality in certain racial groups, including Asian Americans (AA). While differences in BC mortality between AA and other racial groups have been identified, few studies have disaggregated nationwide AA mortality data.
Methods: Using National Vital Statistics System mortality data, BC-related deaths were analyzed among AA groups (Asian Indian, Chinese, Filipina, Japanese, Korean, Vietnamese), Native Hawiian and Pacific Islanders (NHPIs), and non-Hispanic Whites (NHWs) from 2005-2020. We calculated cancer proportional mortality ratios (PMRs), age-adjusted mortality rates (AAMRs), standard mortality ratios, and used JoinPoint regression for average annual percentage change (AAPC).
Results: Among 13677 AA, 522 NHPI, 501282 NHW descendants, 14.3% cancer deaths were due to BC. PMRs increased for all racial groups except Filipina. AAMRs significantly decreased in NHWs (AAPC -1.61; CI -1.70 to -1.48) while significantly increasing for aggregate AAs (AAPC 0.45; CI 0.08 to 0.94). Among AAs, Filipinas had the highest AAMR. AAMRs significantly increased for Asian Indians (AAPC 2.05; CI 1.20 to 3.46), Filipinas (AAPC 0.61; CI 0.15 to 1.46), Koreans (AAPC 2.72; CI 1.57 to 4.65) and Vietnamese women (AAPC 3.63; CI 2.26 to 6.20), but significantly decreased for Japanese (AAPC -1.41; CI -2.22 to -0.53).
Conclusions: We observed heterogenous and converging BC mortality trends across AA groups. These trends elucidate which populations within the broader AA group have disproportionately higher death rates and therefore should be targeted for BC prevention protocols (e.g., Asian Indian and Filipina). Identifying such trends can also help elucidate disparities in cancer care and the overall social determinants that affect women with BC. Understanding disaggregated trends can inform more inclusive screening practices and culturally tailored interventions and treatments to reduce BC deaths in vulnerable populations.

#2135 Racial disparities in symptom burden among women receiving early stage breast cancer chemotherapy.

E. Nasrollahi[1], H. Abujaradeh[2], S. Mazanec[3], J. O'Brien[2], I. M. Schlemmer[2], M. Rosenzweig[2];

[1]University of Pittsburg Medical Center, Pittsburgh, PA, [2]University of Pittsburgh School of Nursing, Pittsburgh, PA, [3]Case Western Reserve School of Nursing, Cleveland, OH

Purpose: The purpose of this study was to compare prevalent symptoms (pain, fatigue, and physical function) and changes over time between Black and White women undergoing chemotherapy for early-stage breast cancer (ESBC) employing a longitudinal, repeated measures design over the course of ESBC.

Methods: Data collected as per protocol of 1R01MD012245, comparing racial differences in chemotherapy tolerance and dose modifications during chemotherapy treatment at baseline, midpoint, and endpoint, tailored to each patient's individual chemotherapy schedule. Race was collected by patient self-report and chart review. Symptom burden (fatigue, pain, and physical functioning) was measured by the PROMIS-29 Profile v 2.0). Area deprivation was measured using the Area Deprivation Index (ADI). Linear mixed models were used to assess racial differences in symptom burden across timepoints, and changes in symptom burden over time, adjusting for ADI.

Results: A total of 147 patients participated in this study (36% Black and 64% white).

Pain: Black patients reported significantly higher pain scores than White patients at pretherapy (MD=3.7, p=.034), midpoint (MD=5.8, p: 0.002), and endpoint (MD=7.8, p<.001). Even after adjusting for area deprivation, this disparity persisted (F(1, 390)=29.43, p<.001), with Black patients having higher pain scores at midpoint (MD=4.7, p: 0.02) and endpoint (MD=7.8, p<.001). Pain scores worsened over time for Black patients, increasing significantly by the end of chemotherapy (MD_{T1-T3} =6.2, p=.010; MD_{T2-T3}=5.8, p=.024). No significant changes in pain scores were observed over time among White patients.

Fatigue: After adjusting for area deprivation, fatigue significantly increased at the endpoint (MD_{T1-T3}=8.9, p<.001) for Black patients. Among White patients, fatigue increased at midpoint (MD_{T1-T2}=5.7) and continued to worsen at the endpoint (MD_{T1-T3}=10.1, p<.001; MD_{T2-T3}=4.3, p=.017).

Physical Function: Black patients had significantly lower physical function than White patients at the midpoint (MD=4.0, p=.027). By the end of chemotherapy, physical function deteriorated significantly for Black patients (MD_{T1-T3}=7.8, p<.001), and White patients (MD_{T1-T3}=7.7, p<.001; MD_{T2-T3}=4.8, p=.002).

Correlations between the ADI and symptom severity and physical function revealed that living in more deprived areas was associated with greater pain severity (r=-.227, p=.002, 56.3 vs. 50.1) and worse physical function (r=-.190, p=-.035, 40.6 vs. 42.4) at the completion of chemotherapy.

Conclusions: The findings indicate that race and area deprivation are associated with symptom trajectories over the course of ESBC chemotherapy. Further research is warranted on how to best assess and relieve symptom burden among Black ESBC patients so that existing disparities in treatment and treatment outcomes are not perpetuated.

#2136 Genetic ancestry dependent variability in stromal cells: An unexplored player in breast cancer disparity.

P. Bhat-Nakshatri, H. Gao, C. Erdogan, Y. Liu, **H. Nakshatri**;
Indiana University School of Medicine, Indianapolis, IN

Genetic ancestry dependent variability in cancer incidence, mutation patterns, response to chemotherapy, and outcome has been documented. While an association between social determinants of health and breast cancer disparity has already been established, there is emerging evidence for genetic ancestry dependent variability in normal breast biology impacting breast cancer biology and potentially outcome. Tumor biology studies in the context of genetic ancestry and disparity have often focused on intrinsic properties of tumor cells or tumor infiltrating immune cells. However, other stromal cell types have received very little attention. Through immunohistochemistry of breast tissues from healthy women of African and European ancestry and primary cell culturing system, we had previously demonstrated enrichment of a stromal cell population called PZP cells (PROCR+/ZEB1+/PDGFRA+) with mesenchymal stem-like and fibroadipogenic properties in the normal breast tissues of women of African ancestry. In this study, we used single nuclei ATAC-seq and/or RNA-seq to further characterize stromal fibroblasts in the breast tissues of women of Ashkenazi Jewish-European, European, Indigenous American, Hispanic-European, African, and Asian ancestry. Among eight fibroblast cell clusters generated from women of African and European ancestry, only three cell clusters overlapped between two groups. While Complement Factor D (CFD, also called adipsin) expression was observed in unique fibroblast clusters of African ancestry, the expression of Insulin-like Growth Factor 1 (IGF1) was enriched in clusters unique to European ancestry. Interestingly, previous studies have demonstrated African ancestry-specific genomic variants for CFD linked to cardiometabolic disorders. Additional genes that showed genetic ancestry dependent variability in expression within fibroblasts include ABCA10, ABCA9, ABCA8, NEGR1 (enriched in African ancestry), MMP16, MAGI1, KIAA1217, PTPRK and SEMA5A (enriched in European ancestry). NEGR1 (Neuronal Growth Regulator 1) is a trans-neural growth promoting factor, whereas PTPRK (Protein Tyrosine Phosphatase Receptor Type K) is a negative regulator of EGFR signaling. These results suggest genetic ancestry dependent variability in stromal-epithelial cell communications under normal and cancerous conditions. These genetic ancestry dependent differences could impact intracellular signaling networks in epithelial cells with consequential effects on cancer incidence, mutation patterns, drug sensitivity, and outcome.

#2137 Racial disparities in triple-negative breast cancer (TNBC) mortality rates in Hampton Roads Virginia and the effects of SIAH expression on prognosis.

C. B. Piatak[1], T. N. Drake[1], A. Hannah[1], J. Baker[1], C. L. Dasom[2], E. L. Breeding[3], J. S. Winston[4], B. Samli[4], R. Jansen[5], M. Danso[6], R. A. Hoefer[7], A. H. Tang[1];

[1]Eastern Virginia Medical School, Norfolk, VA, [2]Stanford Medical, Stanford, CA, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Sentara, Norfolk, VA, [5]University of Minnesota, Minneapolis, MN, [6]Virginia Oncology Associates, Norfolk, VA, [7]Sentara Cancer Network, Norfolk, VA

Background: While high-resolution imaging and advancements in therapies have significantly improved breast cancer survival rates, 43,170 breast cancer patients will die in the United States in 2023 alone. Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype and disproportionately affects BRCA1 mutation carriers and young black women. Black/African American (AA) patients have the highest mortality and the shortest survival of any racial/ethnic group in the US. Persistent cancer racial disparities remain due to a variety of risk factors. The SEER/CDC data show an 8% lower breast cancer incidence rate and a 41% higher mortality rate in Black/AA patients compared to their white counterparts.

Methods: Chart review was conducted using Sentara MD Office/EPIC and VOA iKnowMedicine portals to update tumor relapse, metastasis, and survival in 577 TNBC patients. Supported by strong evidence in developmental, evolutionary, and cancer biology, we hypothesize that persistent EGFR/K-RAS/SIAH pathway activation is a major driving force of TNBC malignancy, racial disparity, early relapse, and high mortality. We propose to integrate SIAH expression to augment the existing clinicopathological parameters to improve patient risk stratification, therapy quantification, and relapse/survival prediction at the 1st-line neoadjuvant settings.

Results: We report that cancer disparity and high mortality rates are even more pronounced in our racially-diverse communities in Hampton Roads Virginia. We discovered that SIAH is a tumor-specific, therapy-responsive, and prognostic biomarker in TNBC. High SIAH expression in residual tumors reflects tumor-driving EGFR/K-RAS/SIAH pathway activation (ON) that will predict cancer disparity, treatment resistance, early relapse, and poor survival. Low SIAH expression in residual tumors reflect EGFR/K-RAS/SIAH pathway inactivation (OFF) that will predict tumor remission and prolonged survival.

Conclusion: We detect a major racial disparity of TNBC patients at Sentara-EVMS-VOA. Our local Black/AA TNBC patients have a 1.6-fold higher mortality rate than their White counterparts. Encouraged by our preliminary data, we aim to develop a SIAH-centered biomarker panel by measuring the EGFR/K-RAS/SIAH pathway activation (ON)/inactivation (OFF), and use SIAH as a new prognostic biomarker to risk stratify patients, detect cancer racial disparities, forecast tumor relapse, and predict patient survival at 1st-line neoadjuvant settings. By targeting SIAH, individualized treatments can be created to allow for increased survival rates in at risk individuals with more aggressive TNBCs.

#2138 Understanding the link between breastfeeding and the risk of breast cancer through comparative analysis of the murine-based model of mammary gland involution.

S. Mishra[1], N. Shinde[1], M. Cuitino[2], M. Bauer[1], D. Ahirwar[1], V. Bharti[1], K. Ormiston[1], R. Mawalkar[1], S. Alsammerai[1], G. Sarathy[1], X. Zhang[1], A. Vilgelm[1], R. Ganju[1], S. Majumder[1], B. Ramaswamy[1];

[1]The Ohio State University, Columbus, OH, [2]Medical University of South Carolina, Charleston, SC

Introduction: A meta-analysis of 47 global epidemiological studies highlights a higher breast cancer risk in women who did not breastfeed or breastfed for a short time. Further studies showed this is especially true for triple-negative breast cancer (TNBC) patients. Premenopausal AA women (AAW) have a lower prevalence of breastfeeding and a higher incidence of TNBC and mortality. Our previous study compares short-term breastfeeding, abrupt involution (AI) with prolonged breastfeeding called gradual involution (GI), revealing that AI alone induces ductal hyperplasia four months postpartum. Our current investigation delves into early events during AI *versus* GI, employing a comprehensive approach encompassing histology, gene expression, and myeloid cell involvement.
Methods: Utilizing FVB female mice, we conducted a comparative analysis of AI and GI. AI involved early pup removal, while GI was achieved through staggered weaning. The evaluation included analysis of histomorphology, gene/protein expression, and myeloid cell infiltration. Sequential mammary gland (MG) changes were monitored through H&E staining, TUNEL assay, and DNA damage analysis. 3D-organoid cultures of luminal progenitors (LPs) were employed to assess the impact of AI *versus* GI. qRT-PCR, IHC, Western blot, and flow cytometry/multiplex imaging were employed for the differential expression analysis of molecular and cellular factors associated with AI/GI.
Results: Our research showed that AI had early adipocyte repopulation, rapid cell death, DNA repair, and myeloid cell infiltration, resulting in a chronically inflamed microenvironment. In contrast, the GI triggers a controlled immune response and prolonged cell death, facilitating comprehensive remodeling of the MG. Our flow cytometric or multiplexing imaging analyses revealed that AI-affected glands exhibit an enrichment of CCL9-producing CD206+ M2-like macrophages and CD11b+Gr1+ myeloid-derived suppressor cells. Moreover, exogenous CCL9 treatment on LPs in 3D-organoid culture results in disorganized acinar-type organoids, mirroring morphological differences observed in LPs from AI mammary glands on day56 PPM. Further analysis of CCL9 treated organoids revealed the expansion of Esr1- LPs population in *ex-vivo* organoid culture which might indicate an increase in the putative cells of origin of TNBC.
Conclusion: Our studies comparing AI and GI demonstrate that AI is producing a pro-tumorigenic environment in the breast. It is important to note that prolonged breastfeeding protects the breast, although this cannot be a singular risk factor for TNBC. Therefore, understanding the mechanism will lead to prevention strategies to improve outcomes for all women but, has the potential to have a significant benefit in AAW.

#2139 Identifying molecular mechanisms in triple negative breast cancer disparities: Unveiling the role of Hedgehog signaling in non-Hispanic Black women.

J. V. Cabezas, S. Toure, M. Wilson, M. L. Stallings Mann, L. M. Pacheco-Spann, J. W. Ogony, M. E. Sherman, D. C. Radisky;
Mayo Clinic Florida, Jacksonville, FL

Triple negative breast cancer (TNBC) represents an aggressive and therapeutically challenging breast cancer subtype with higher incidence and mortality rates in non-Hispanic Black (NHB) women. This disparity persists even after adjusting for socioeconomic factors, tumor biology, and quality of care. The study aims to unravel specific molecular mechanisms underlying this disparity, with a focus on Hedgehog signaling pathways in premenopausal NHB women. Understanding these mechanisms is vital for developing targeted therapies and personalized medicine approaches to address these health disparities. Our research utilized a unique cohort of NHB and non-Hispanic White (NHW) women who underwent breast reduction surgery at the Mayo Clinic and donated breast tissue samples for our study. We isolated RNA from whole tissue sections from a cohort of 12 NHB and 40 NHW women who were parous and premenopausal at time of surgery. We performed gene expression profiling using NanoString BC360 and IO360 assays. This allowed us to identify a distinct gene expression signature characteristic of basal-like/TNBC and indicative of heightened activity in the Hedgehog signaling pathway. We also employed advanced cell culture techniques to generate tissue organoids and subculture human mammary epithelial cells (HMECs) that preserve the intrinsic characteristics of the original tissue samples. We found that significantly differential expression of IL20RA and SOX10, principal factors in the gene expression signature, were preserved in both the derived organoids and the HMECs. These results suggest a potential intrinsic difference in the activation of the Hedgehog pathway in the breast epithelial cells of NHB women. This activation may contribute to increased proliferation and transformation of basal stem cells within the breast, possibly fueling the development and progression of TNBC. The implication of activated Hedgehog signaling in NHB women opens new avenues for understanding TNBC disparities. IL20RA and SOX10 represent potential biomarkers for TNBC risk that may serve as a stratification tool for NHB women. The results of this study have the potential to improve assessment and management of TNBC risk among NHB women, thereby contributing significantly to reducing health disparities in breast cancer outcomes.

#2140 Untargeted lipidomics reveals racial differences in lipid species among women.

L. Li, G. Pourali, K. R. Getz, M. Jeon, J. Luo, C. Luo, **A. T. Toriola**;
Washington University School of Medicine in St. Louis, St. Louis, MO

Introduction: Lipids are important for many cellular processes and have been implicated in cancer development. Adopting a lipidomic approach has revealed sex-specific differences in lipid species but whether there are racial differences in lipid profiles remain unexplored. As a result, we investigated differences in lipid species between Non-Hispanic Black (NHB) vs Non-Hispanic White (NHW) women.

Methods: We performed lipidomic profiling on 705 premenopausal women who were recruited during their annual screening mammogram at Washington University School of Medicine, St. Louis, MO. A total of 982 lipid species were profiled at Metabolon (Durham, NC®). 125 lipid species missing in 300 or more women were excluded from the analysis. For the remaining missing values, we employed the nearest neighbor method for imputation. We investigated the race-differentiating lipid species concentrations using linear regression models, adjusting for age and body mass index (BMI). To satisfy the assumptions of normality and homoscedasticity, we log-transformed the lipid concentrations before performing regression analyses. The linear regression coefficients were then back-transformed as percentage differences. We accounted for multiple testings by applying the Bonferroni correction. Statistical significance was defined as a Bonferroni-adjusted p-value < 10^{-5}. Pathway enrichment analyses was conducted for differential lipid species for each sub pathway.

Results: Of the 705 women, 506 were NHW and 163 were NHB. In analysis adjusted for age and BMI, 278 lipid species were significantly lower in NHB, and one lipid specie (TAG58:10-FA20:4) was higher in NHB. These species belonged to triacylglycerols (TAG, n=213), phosphatidylcholines (PC, n=25), diacylglycerols (DAG, n=22), cholesteryl esters (CE, n=4), phosphatidylethanolamines (PE, n=4), lysophosphatidylcholines (LPC, n=3), lysophosphatidylethanolamines (LPE, n=3), sphingomyelins (SM, n=2), ceramides (CER, n=1), lactosylceramides (LCER, n=1) and phosphatidylinositols (PI, n=1) sub-pathways. The TAG sub-pathway was enriched with differential lipid species (213 significant out of 518 species, $p = 1.26\times10^{-11}$). Forty-three lipid species (42 TAGs and one DAG) exhibited an absolute percentage difference > 50% between NHB and NHW women. The top 3 TAG species with the largest absolute percentage differences were TAG44:0-FA14:0 (60.6% lower in NHB women, $p = 6.25\times10^{-8}$), TAG46:2-FA16:1 (59.8% lower in NHB women, $p = 1.11\times10^{-14}$) and TAG47:2-FA16:1 (59.4% lower in NHB women, $p = 8.66\times10^{-20}$). Conversely, TAG58:10-FA20:4 was 47.1% ($p = 5.79\times10^{-8}$) higher in NHB women.

Conclusions: Our study reveals novel substantial racial differences in lipid species among women, mostly in the TAG sub-pathway, highlighting the influence of race on the lipidome. Validation in a different study population is needed.

#2141 Prevalence of cervical high risk HPV serotypes not covered by the 9vt vaccine in a clinic-based sample of Hispanic women living in Puerto Rico.

Romaguera Josefina[1], Bianka Morales[1], Andrea Cortes[1], Ana Rosario[1], Andrea Padilla-Bou[1], Maria Frontera[1], Claudia Rosado[1], Daniela Cargas-Robles[1], Ana P. Ortiz[2], **Filipa Godoy-Vitorino**[1]

[1]University of Puerto Rico School of Medicine, San Juan, PR,[2]Comprehensive Cancer Center, University of Puerto Rico, San Juan, PR

Cervical cancer (CC) is the fourth most common female malignancy worldwide. Puerto Rico (PR) has the highest age-adjusted incidence of cervical cancer in the U.S. High-risk strains of human papillomavirus (hr-HPV) have been identified as common causative agents of CC. We aimed to characterize the prevalence of High-Risk HPV (HR-HPV) genotypes among a clinic-based sample of 368 HIV-negative women using a high-resolution approach. We used baseline data from IRB protocol 10510114. Cervical swabs underwent genomic DNA extractions followed by typification of HPV genotypes using a short-polymerase chain reaction-fragment assay (SPF10-LiPA) which detects 14 mucosal HR-HPV types (LiPA-25); 10 types (8 HR and 2LR) included in the 9-valent vaccine and 13 others not included on it. This process uses SPF10 primers to amplify a 65 bp fragment of the L1 open reading frame of HPV, followed by a reverse-hybridizationfor specific HPV genotypes by comparing the results to standardized kit controls. Cervical cytology was acquired for all participants. Data was collected from 186 women negative to intraepithelial lesions (NILM), 65 with low-grade lesions (LGSIL), 23 atypical squamous cells of undetermined significance (ASCUS) and 94 with high-grade lesions (HGSIL).Among study results, the prevalence of any HR-HPV infection was high overall (~71.5%) and higher in women who had either LGSIL or HGSIL. The top leading HR types detected were 51 (20.4%), 16 (18.5%), 52 (13.60%), 33 (13.00%) and 56 (11.00%, with other types including HPVs 35,39, 68 or 59.Nearly 34.00% of the identified cervical HR-HPV types, are not included in the 9-valent vaccine. The most common HPV types in HGSIL, included HR HPV types 16 (30.9%), 52 (18.10%), 51 (14.9%) and 33 (10.60%). In this group, only 35.20% were HPV16/18. The other 64.80% were other HR-HPV types and, based on the ASCCP guidelines, would not require a colposcopy, and could be observed in one year. Among these HGSIL (n=94) 48.9% of the HPV types were not included in the vaccine. HPV 51 was the most dominant in ASCUS (26.10%), LGSIL (20%), and women who were negative for intraepithelial lesions (NILM 22.6%). Additionally, the most prevalent HPV-HR serotypes across all cytology categories in the vaccinated cohort were 52 (11.14%), 16 (8.02%) and 31 (7.56%), whereas in the non-vaccinated cohort were HPV 16 (20.6%), 51 (17.55%), 33 (13.33%), 52 (12.29%), and 56 (11.94%).In conclusion, the high burden of other high-risk types not covered by the vaccine in women with high-grade lesions suggests that delaying immediate colposcopy might limit the identification of cervical lesions. Even though this is not a population-based study, the high prevalence of these other HR-HPV types calls for their inclusion in future generations of the vaccine.

Study sponsored by 2U54MD007600-36 (8538) Research Centers in Minority Institutions of the University of Puerto Rico (NIH/NIMHD).

#2142 Spatial distribution of high-risk human papillomavirus (HR-HPV) across 23 Chicago community areas and correlates.

G. Goba[1], J. Sun[1], Q. Class[1], J. Schwartz[1], S. Kim[1], K. Watson[1], L. Tussing-Hummphreys[1], Y. Molina[1], S. MacLaughlan[1], Z. Xu[1], B. Aldred[1], S. K. Kolar Rajanna[1], T. Alexander[1], A.-B. Moscicki[2];

[1]University of Illinois Cancer Center, Chicago, IL, [2]University of California, Los Angeles, Los Angles, CA

Background: Despite availability of effective vaccines and screening, cervical cancer claimed 4,280 lives in 2022. We explored the spatial distribution of high-risk human papillomavirus ("HR-HPV") infection across 23 Chicago Community Areas (CCAs) served by the University of Illinois Health Network (UI Health). Using a modified Warnecke et al Health Disparity Outcomes (HDO) model, we hypothesized that CCAs with higher rates of structural violence, the social, economic, and political systems exposing populations to risks and vulnerabilities, would correlate with increased HR-HPV.

Methods: Electronic medical records of patients receiving routine cervical cancer screening between January 1, 2015 and December 31, 2019 were reviewed. As per the 2014 ACS guidelines. HR-HPV test results were captured as HR-HPV positive, HR-HPV-16, HR-HPV-18 and non-16/18 HR-HPV, the latter consisting of 12 HR-HPV subtypes. Structural violence variables were used from Chicago Health Atlas (2015-2019) with percent poverty, hardship index score, easy access to fruit and vegetables, routine checkup, homicide, and primary care provider across CCAS. Univariate Poisson regression was used to compare the associations between selected structural violence factors and HR-HPV prevalence. Univariate multinomial logistic regression evaluated associations between structural violence indicators and HR-HPV subtypes Global p-values were obtained using ANOVA at 0.05 significance.

Results: 8,566 women met inclusion criteria out of 13,466 total women. 75% were Black or Hispanic. Overall prevalence of cervical HR-HPV infection was 20.3% (n=1,737), ranging from 8.7% to 27.2% across CCAs. Median age for women was 36. Percent with primary care provider was negatively associated with HPV infection (IRR = 0.99 with 95% CI (0.98, 1.00), adjusted p-value=0.023), indicating women living in CCAs with higher rates of primary care provider were less likely to have HR-HPV. Easy access to fruit and vegetables (adjusted p-value = 0.007) and percent with primary care provider (adjusted p-value = 0.009) were significantly associated with HR-HPV subtypes. Women living in CCAs with easy access to fruit and vegetables (OR = 0.99, with 95% CI (0.98,0.99)) as well as those with higher rates of primary care provider (OR = 0.98, with 95% CI (0.97,0.99)) were less likely to have non-16/18 HR-HPV.

Conclusion: HR-HPV is the most common sexually transmitted infection, and most women clear the infection naturally. As the origin of 99% of cervical cancer, understanding the reasons HR-HPV persists and progresses to cancer among certain individuals and groups is critical. Novel interventions like increasing access to fruit and vegetables could compliment widely available and effective vaccines.

#2143 Association between health insurance coverage and stage of diagnosis for cervical cancer among women in Indiana from 2011-2019.

M. Suresh Babu, M. L. Kasting, N. M. Rodriguez;
Purdue University, West Lafayette, IN

Introduction: Cervical cancer is one of the most common types of cancer among women and it is caused by infection from the human papillomavirus (HPV). The incidence rates of cervical cancer have increased in Indiana from 7.8 in 2008-2012 to 8.4 in 2013-2017. In 2020, the screening rate for cervical cancer among women in Indiana was 76% when compared to a national average of 78%. Women diagnosed at earlier stages for cervical cancer had higher relative survival of 0.98 than those diagnosed at later stages with a relative survival of 0.43. Health insurance status is an important determinant for health outcomes for patients with cancer. This study aims to assess the extent to which health insurance coverage is a contributing factor to the stage of cervical cancer diagnosis.
Methods: We examined reported cases of cervical cancer among women (N=2518) using cervical cancer registry data from the Indiana State Department of Health from 2011-2019. Using multinomial logistic regression model, we examined the associations of both race/ethnicity and insurance status with stage of diagnosis after adjusting for age at diagnosis.
Results: In this sample, the average age at diagnosis was 48.98 years (SD = 14.98). The largest proportion of the sample was between 45 to 64 years of age (41.7%), Non-Hispanic White (85.5%), had private insurance coverage (41.8%), had cervix uteri, NOS as the primary site of diagnosis (76.5%), lived in a metropolitan area (74.5%) and had squamous cell carcinoma (73.4%). The largest percentage of Non-Hispanic White patients had private insurance (50.9%), whereas the largest percentage of Black patients had Medicaid (39.3%). 20.2% of Hispanic patients were uninsured when compared to 7.7% Non-Hispanic White and 3.6% Black patients. The multivariate analysis shows that women who are uninsured (OR = 2.475) and those who have Medicaid (OR = 2.321) were significantly more likely to be diagnosed at the regional stage than the in-situ stage compared to women with private insurance. Additionally, women who are uninsured (OR = 4.432) and those who have Medicaid (OR = 3.007) were significantly more likely to be diagnosed at the distant stage than in-situ, compared to women with private insurance.
Conclusion: The findings show that insurance status is associated with the stage of diagnosis for cervical cancer and detection at regional or distant stages often leads to higher morbidity. Impact - Increased coverage for routine cervical cancer screening and preventive care services is recommended, especially for uninsured women and women with public insurance such as Medicaid or Medicare.

#2144 Disparities in gynecologic cancer survival outcome by treatment facility and region.

S. Bae[1], V. Pandya[1], C. Wang[2], H. Wang[2], R. C. Arend[1], C. A. Leath III[1], W. K. Huh[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Johns Hopkins University, Baltimore, MD

Objective: To explore five-year survival of patients with gynecologic cancers by region and treatment facility in the United States. Background: Research studies have examined the risk factors associated with gynecologic cancers, specifically cervical, ovarian, and endometrial, incidence and mortality. In addition to older age, Black/African American race, living in south, less income, less education, having comorbidity, stages of cancer, and lack of insurance have reported as risk factors for the incidence and mortality of gynecologic cancers. In addition, prior studies reported the possible effects from the distance to cancer care facilities on gynecologic cancer outcomes indicated varying results. In this study, we explore the impact of distance travelled by region and treatment facility on gynecologic cancer outcomes. Methods: This study aims to assess five-year cervical, ovarian, and endometrial cancer survival. Data were obtained from the National Cancer Database (NCDB) years 2004-2017, only from patients with a minimum 5-year follow-up. Women with races other than White or Black were excluded from the study. Demographics, region, treatment center type, distance to the treatment center, and cancer stage at diagnosis were analyzed by cancer type and 5-year survival status. Multivariate logistic regression model was used to assess the relationship between distance travelled to treatment facility by region and five-year survival. SAS version 9.4 was used for statistical analysis. Results: The distribution of the demographics across the three cancers were similar. Multivariate logistic models showed significant interactions between facility type and region on five-year survival among cervical, ovarian and endometrial cancer patients. Risk factors varied by region and treatment facility type. Age and cancer stage were significantly associated with survival among all cancers. Distance was significantly associated with survival in cervical and endometrial cancers. Conclusion: Cervical cancer patients in the South Atlantic who travel longer distances to Academic/Research Programs have poorer survival. Likewise, patients with endometrial cancer who live in New England region, and travel longer distances to Integrated Network Cancer Programs, as well as those who live in the West North Central region and travel longer distances to Community Cancer Programs have poorer survival. Further research is warranted to explore the specifics of region and treatment center types among different cancers to get a better understanding of the risk factors. Moreover, to improve the clinical outcomes, further study is needed to aim to identify which of these factors are actionable.

#2145 Genetic ancestry associations with pancreatic cancer mutational profiles from a diverse 9,274-patient real-world cohort.

B. Rhead[1], V. Vudatha[2], Y. Pouliot[1], E. Williamns[1], A. N. Riner[3], **F. M. De La Vega**[1], J. Trevino II[4];
[1]Tempus Labs, Chicago, IL, [2]Virginia Commonwealth University, Richmon, VA, [3]University of Florida College of Medicine, Gainesville, FL, [4]Virginia Commonwealth University, Richmond, VA

Pancreatic cancer is an aggressive malignancy associated with racial/ethnic disparities. Notably, Black patients have a higher incidence and mortality compared to their White counterparts. However, low representation of Black and Hispanic patients in cancer genomics studies hampers our understanding of genomic factors contributing to differential outcomes. Furthermore, comparisons between racial groups fail to capture differences in genomic ancestry. We studied the associations between genetic ancestry and race/ethnicity categories with mutational profiles, using a large, diverse real-world pancreatic cancer cohort. We analyzed 9,274 de-identified pancreatic cancer patients (8,483 with ductal adenocarcinoma, PDAC) who underwent tumor profiling with the Tempus xT 648-gene assay. We used 654 ancestry-informative markers to estimate continental ancestry for five regions: Africa (AFR), Americas (AMR), East Asia (EAS), Europe (EUR), and South Asia (SAS). We imputed Asian (ASN, n=431), Hispanic/Latino/Native American (HLN, n=593), Non-Hispanic Black (NHB, n=875) and Non-Hispanic White (NHW, n=7,309) categories from genetic ancestry using a previously published machine learning method. Associations between either race/ethnicity categories or ancestry proportions and somatic variants (copy number alterations or CNAs, small nonsynonymous, OncoKB L1/2 & R1, and predicted driver somatic mutations using boostDM) were assessed for 172 pancreatic cancer-related genes or gene sets using logistic regression models. Models with and without race/ethnicity or ancestry terms were compared with likelihood ratio (LR) tests, and p-values were adjusted to control the FDR at 5%. We tested for associations of race/ethnicity groups with TMB using a Kruskal-Wallis rank sum test. Tests of TMB and small variants used only patients with available matched normal tissue to avoid artifacts from misclassification of germline variants. Among pancreatic cancer patients, having either a CNA or small nonsynonymous mutation in a receptor tyrosine kinase (RTK) gene (*ERBB2, EGFR, MET, FGFR1*) was associated with genetic ancestry (LR adjusted p=0.027). Specifically, AMR ancestry was positively associated (OR=1.08 per doubling of ancestry proportion, p=0.004) and EUR negatively associated (OR=0.93, p=0.002). Associations in PDAC were similar but not significant. Race/ethnicity was associated with RTK changes in both groups, with ASN and HLN having more mutations than NHW, but the associations were not significant after correcting for multiple hypotheses. There was no association of race/ethnicity and TMB .Somatic changes in RTK genes were associated with AMR genetic ancestry; however, despite the relatively large cohort size, these results are modest, suggesting there is not a large somatic mutation component contributing to differences in pancreatic cancer outcomes by ancestry.

#2146 Race-related differential immunoreactivity of enolase autoantibodies in patients with prostate cancer.

K. Cheng[1], C. J. Diaz Osterman[2], K. Santiago[1], M. Reeves[3], D. Lozano[3], P. Ochoa[1], A. Duran[1], S. Mirshahidi[1], B. R. Hu[1], F. Almaguel[1], C. A. Casiano[1];
[1]Loma Linda University, Loma Linda, CA, [2]Ponce Health Sciences University, Ponce, Puerto Rico, [3]La Sierra University, Riverside, CA

INTRODUCTION AND OBJECTIVE: Enolase-1 (ENO1) and -2 (ENO2) are implicated in tumor metabolic and aggressive functions. Like prostate specific membrane antigen (PSMA), they localize to the tumor cell surface and are potential theranostics targets. ENO autoantibodies were reported by our group in prostate cancer (PCa) patients but their immunoreactivity to ENO1/2 isoforms was not defined. Differential ENO immunoreactivity in docetaxel-resistant (DR) PCa cells between African American (AA) and European American (EA) PCa patients was also reported. Our objective was to investigate the role of ENO isoforms in the race-related differential ENO immunoreactivity of PCa patients.

METHODS: PCa patient sera (41 AA, 68 EA) were obtained from Loma Linda University Biospecimen Laboratory. Western blotting (WB) analysis, using patient sera and monoclonal antibodies to ENO1 and ENO2, was done against lysates from docetaxel-sensitive (DS) and DR PCa cell lines and against recombinant (rec) ENO1 and ENO2 to assess ENO isoform expression and detect ENO autoantibodies. Scratch-wound assay was performed to evaluate AA and EA anti-ENO driven inhibition of DR PCa cell migration. Student's T-test and Chi-squared analyses were performed with $p<0.05$ deemed significant.

RESULTS: ENO1 expression was robust in all assessed DS and DR cell lines. ENO2 was detected in DS cells but was significantly reduced in DR cells. PSMA expression was lost in cells expressing ENO1 and neuroendocrine markers. Anti-ENO EA sera reacted in WB with the expected 50 kD band in both DS and DR PCa cells, but anti-ENO AA sera reacted preferentially with this band in DS cells. Strong immunoreactivity was noted against recENO1 in AA and EA sera (7% vs 28%, $p<0.01$) and against recENO2 in AA and EA sera (24% vs 35%, $p=0.23$). EA, but not AA, ENO autoantibodies significantly inhibited DR cell migration, and their pre-absorption with recENO1 diminished this inhibitory effect.

CONCLUSIONS: Autoantibodies to ENO1 and ENO2 were identified in EA and AA PCa patient sera. Weaker ENO1 immunoreactivity was seen in sera from AA PCa patients, corresponding with weaker inhibition of DR PCa cell migration compared to EA patient sera. Unlike PSMA and ENO2, ENO1 expression was robust in neuroendocrine-like DR PCa cell lines. Future studies will correlate the presence of ENO autoantibodies with clinicopathologic parameters in a larger patient cohort. Defining mechanisms underlying the race-related differential ENO immunoreactivity may identify novel biological determinants of PCa health disparities and uncover the theranostic potential of tumor surface ENO1.

#2147 Genetic ancestry associations with prostate adenocarcinoma mutational profiles: New Insights from a diverse 5,959-patient real-world cohort.

B. Rhead[1], Y. Pouliot[1], F. M. De La Vega[1], D. W. Craig[2], J. Carpten[2];
[1]Tempus Labs, Chicago, IL, [2]City of Hope, Duarte, CA

In prostate cancer, Black men face higher incidence rates, more advanced diagnoses and worse outcomes than White men. These disparities partially stem from environmental, socioeconomic, and healthcare access factors. Recent data highlight racial differences in prostate cancer molecular profiles, with tumors from Black men showing increased *SPOP* and decreased *PIK3CA* mutations and amplified androgen receptor signaling and inflammatory pathway activations. Thus, somatic mutation patterns may also contribute to these disparities. We sought to identify associations of mutational profiles in prostate adenocarcinoma (PRAD) with genetic ancestry instead of race and ethnicity categories, analyzing a de-identified cohort of 5,959 patients who underwent the Tempus xT 648-gene NGS tumor profiling test. We used 654 ancestry-informative markers to estimate genetic ancestry by calculating similarity to reference populations for five regions: Africa (AFR), Americas (AMR), East Asia (EAS), Europe (EUR), and South Asia (SAS). Associations between genetic ancestry proportions and somatic variants were assessed for 67 PRAD-related genes using logistic regression models. Analyses included copy number alterations (CNAs), oncogenic gene fusions, small splice and non-synonymous mutations (NS), OncoKB L1/2 & R1, and small missense driver somatic mutations predicted with boostDM. Likelihood ratio tests were employed to compare models with and without ancestry terms. The Benjamini-Hochberg method was utilized to adjust p-values and control the FDR at 5%. We confirmed reported associations in PRAD between AFR ancestry and *SPOP* NS mutations (OR=1.03 per doubling of AFR ancestry proportion, p=0.03) and decreased AFR with *PIK3CA* OncoKB and driver mutations (OR=0.94, p=0.02), *PTEN* CNAs (OR=0.95, p=0.0001), and *TMPRSS2-ERG* fusions (OR=0.95, p<0.0001). However, we also observed negative associations between AFR and *AR* CNAs (OR=0.95, p=0.004), EAS and *PTEN* CNAs (OR=0.96, p=0.01), and EAS and *TMPRSS2-ERG* fusions (OR=0.97, p=0.02). Additionally, a negative association was found between EAS and *TP53* driver NS mutations (OR=0.96, p=0.04), while positive associations with driver mutations in *FOXA1* (OR=1.06, p=0.03) and NS mutations in the PI3K/AKT/mTOR pathway genes (OR=1.04, p=0.01) were noted. Lastly, we identified novel positive associations between AMR and driver mutations in *PIK3C3A* (OR=1.12, p=0.0003) as well as small NS mutations or CNAs in the PI3K/AKT/mTOR pathway genes (OR=1.03, p=0.04). By analyzing a large, diverse real-world cohort and leveraging NGS-inferred genetic ancestry, our study confirms known associations between somatic alterations in PRAD cancer genes and race and ethnicity, while unveiling novel associations in understudied populations of potential significance for understanding disparities in disease outcomes.

#2148 Tumor-microenvironment from African-American prostate cancer exhibit methylation of multiple immune modulators.

S. Sankaran[1], J. Nguyen[1], T. Jennings[1], V. Kumar[1], M. B. Lilly[2], M. M. Ittmann[3], P. Castro[3], L. Song[1], T. Keane[2], W. Chu[1], X. Zi[1], O. Yazdanpanah[4], A. Rezazadeh Kalebasty[4], F. Rahmatpanah[1],

[1]University of California, Irvine, Irvine, CA, [2]Medical University of South Carolina, Charleston, SC, [3]Baylor College of Medicine, Houston, TX, [4]UC Irvine Medical Center, Orange, CA

Background: Non-Hispanic Black American patients (BA) with prostate cancer (PCa) tend to fare worse than their Non-Hispanic White American counterparts (WA), even with consideration of socioeconomic disparities. Clinically, BA face diagnosis at younger age with worse clinical outcomes. Stromal cells adjacent to the tumor, including carcinoma-associated fibroblasts (CAFs), play a critical role in tumorigenesis of PCa. Dysfunction in the tumor microenvironment play a crucial role in mediating prostate cancer tumorigenesis and is emerging as a key target for cancer therapy in solid tumors.

Methods: To investigate whether DNA methylation varies in tumor adjacent stroma (TAS) among PCa patients with different geographical ancestries, areas immediate adjacent to tumor (i.e., less than 1mm) removed for methylation analysis. A complete genome-wide DNA methylation of PCa stroma using 17 BA and 15 WA patients who had radical prostatectomy was carried out. Methyl-Captured (mCap) sequencing data was generated for TAS of prostate cancer FFPE tissues. Methylated sites were identified with the MACS2 callpeak function using a band width of 300 bp and a false discovery rate of $q < 0.05$. A consensus peak set was derived from the aligned reads of BA and WA prostate cancer stroma samples that were sequenced. Pathway analysis was performed using Ingenuity Pathway Analysis (IPA) tools. CAFs from primary tumors of BA and WA was prepared by tissue culture and treated with demethylating agent (i.e., 5-Azacytidine) for 24 hours followed by maintenance of the cells in drug-free medium for 7-10 days and subjected to mCap sequencing.

Results: We found racial disparities in genome-wide DNA methylation in TAS between the two populations in which BA PCa patients had significantly increased in global DNA methylation as compared to their WA counterpart (p value < 0.001). Hypomethylation occurred in CAFs from BA patients treated with 5-Azacytidine. We identified 1041 methylated sites corresponding to 409 unique genes that were differentially methylated in BA vs WA (p value < 0.05). Pathway analysis identified significant association between methylated genes in BA TAS and immune response pathways including IL-13, JACK/STAT, T cell receptors, NF-KB, and PD-1, PDL1 cancer immunotherapy. Evaluation of the methylome profile between patients based on the post-prostatectomy resection margins, negative (R0) vs positive (R1), showed that R0 resections had significantly greater (p value < 0.001) methylation than R1 resections. Further analysis identified 984 sites corresponding to 373 differentially methylated, unique genes (p value < 0.05).

Conclusion: Tumor-adjacent stroma of BA prostate cancer patients has a distinct methylome as compared to WA patients. Differences in immune response pathways suggests a distinct immune response in TAS in men of different races.

#2149 West African genetic ancestry and origin of the BRCA1 locus in Jamaican men with high grade prostate cancer.

S. M. Gaston, A. J. Griswold, O. N. Kryvenko, T. Gu, G.-N. Zhang, N. S. Prakash, Y. Avda, T. Ajami, C. R. Ritch;
University of Miami Miller School of Medicine, Miami, FL

Introduction: Men of West African (WA) ancestry are at higher risk for prostate cancer than men of European (EU) or Asian descent. Caribbean populations provide an opportunity to identify potential founder mutations that contribute to cancer risk. Jamaica has among the highest rates of prostate cancer incidence and mortality in the world and the majority of the population are of WA ancestry. However, there is a significant amount of genetic admixture of EU and Asian ancestry from historic migration patterns. Thus, the population provides a unique cohort for studying the complex interplay between genetic ancestry and prostate cancer. In this pilot study, we characterized the overall and gene locus-specific ancestry of Jamaican prostate cancer patients to explore potential associations with clinicopathologic disease features. We specifically focused this analysis on the BRCA1 locus based on its known association with inherited prostate cancer risk and also with breast cancer risk in patients from the Caribbean.
Methods: A retrospective cohort of 31 Jamaican men (non-US citizens/residents) who travelled to the University of Miami (2015-2020) specifically for robotic prostatectomy were included in the analysis. DNA was prepared from normal prostate tissue and analyzed using the Illumina Global Screening Array version 3 with Multi-Disease Drop-In that includes more than 650,000 genetic markers. Both overall genetic ancestry and allele specific ancestries were determined for each study subject. Clinical and pathological features (age, PSA, stage, grade group (GG)) were also recorded and analyzed using descriptive statistics.
Results: Median age was 67 years, median pre-op PSA was 6.7. The majority of patients were cT1c (91%) and GG 2 (29%) on biopsy. On final pathology most men were ≥pT3 (51%) and the proportion of GG 1, 2 and ≥ 3 was 3%, 52% and 45% respectively. The mean overall West African genetic ancestry was 51.2% (SD 28.4%). Overall % West African ancestry was not associated with pathological GG. In contrast, 50% of the men who were homozygous for African ancestry alleles at the BRCA1 locus had high-grade prostate cancer (GG 3, 4, 5) versus 37% of the men with non-African or heterozygous BRCA1 genotypes.
Conclusions: In a select cohort of Jamaican men, we found that half of patients with BRCA1 alleles derived from West African ancestry also have high grade prostate cancer. BRCA1 of African ancestral origin may contribute to the relatively high prevalence of aggressive prostate cancer in men from Jamaica. Work in progress focuses on an expanded study of associations between allele-specific genetic ancestry and prostate cancer in high-risk populations.

#2150 Spatial transcriptomic analysis of histologically matched regions adjacent to and within prostate cancer reveals RNA expression differences between African Americans and European Americans.

V. Kumar[1], D. Castaneda[1], J. A. Nguyen[1], G. A. Giannico[2], M. M. Ittmann[3], P. Castro[3], O. Yazdanpanah[2], A. Rezazadeh[2], T. S. K. Jennings[1], M. Mcclelland[1], F. Rahmatpanah[1],

[1]University of California, Irvine, Irvine, CA, [2]University of California, Irvine, Orange, CA, [3]Baylor College of Medicine, Houston, TX

Introduction. Prostate cancer (PCa) of American men of African ancestry (AA) is diagnosed at an earlier median age and more advanced stage with a poorer prognosis and significantly higher mortality than in Americans of primarily Northern European ancestry (EA). The mechanism of how ancestry contributes to aggressive PCa in AA patients is not well understood. Given the inherent heterogeneity and multifocality of prostate cancer, Spatial transcriptomics is of particular interest because it allows distinct cell populations within the tumor microenvironment to be characterized, and their possible effects on local tumors to be identified. Here we compare transcription between four AA and four EA patients in regions of peritumoral stroma, inflammation, Benign Prostatic Hyperplasia (BPH), and Gleason score patterns 3 (G3) and 4 (G4).

Methods: Formalin fixed, paraffin embedded (FFPE) prostatectomy tissue blocks were obtained from 8 patients (4 AA and 4 EA) prior to treatment of the patients and matched for clinical variables (i.e., biochemical relapse, age, Gleason score, and tumor stage). 10um tissue sections were mounted onto Visium Spatial Gene Expression Slides and processed following 10x Genomics protocol. Sample counts were processed through Space Ranger. 18000 unique genes, spatial barcodes, and clinician guided annotations were imported to the R program Seurat. Data was processed using SCTransform. Significance of each transcript differences between each tissue were calculated.

Results: Digital histologic slides of prostate cancer specimens from AA (n=4) and EA (n=4) patients were annotated by a urologic pathologist to identify regions of peritumoral stroma, inflammation, BPH, G3, and G4. Each spot was interrogated for the expression of 18000 transcripts, with an average of 17796 being detected per spot. Among the largest differences observed between AA and EA, G3 and G4 had distinct transcriptome profiles in the four AA as compared to G3 and G4 in four EA. Also, when differential expression (padj < 0.05) in peritumoral stroma was compared to G4 in AA, we identified 290 differentially expressed genes, whereas the same comparison in EA cohorts identified 600 differentially expressed genes.

Conclusion: Spatial transcriptomic analysis revealed differences in gene expression across multiple tissue types in prostate cancer patients of different ancestries.

#2151 Additional impact of genetic ancestry over self-reported race/ethnicity to prevalence of *KRAS* mutations and allele-specific subtypes in non-small cell lung cancer.

X. Wang[1], K. Hou[2], B. Ricciuti[3], J. V. Alessi[3], X. Li[1], F. Pecci[3], R. Dey[1], J. Luo[3], M. M. Awad[3], A. Gusev[3], X. Lin[1], B. E. Johnson[3], D. C. Christiani[1];
[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]University of California, Los Angeles, Los Angeles, CA, [3]Dana-Farber Cancer Institute, Boston, MA

Background: *KRAS* mutation is the most common oncogenic driver in patients with non-small cell lung cancer (NSCLC). However, the interplay between self-reported race and/or ethnicity (SIRE) and genetically inferred ancestry (GIA) on *KRAS* mutations and allele-specific subtypes is largely unknown.
Methods: A total of 3918 NSCLC patients from the Chinese OrigiMed (OM) cohort (n=2039) and Boston Lung Cancer Survival (BLCS) cohort (n=1879) were included, all of whom had baseline covariates including age, sex, clinical stage, SIRE, histology and smoking status. *KRAS* mutation and subtypes were determined by targeted NGS panels in each cohort, and *KRAS* mutation outcomes, including *KRAS* mutation, *KRAS* subtypes, and *KRAS* transversion and transition were analyzed. GIA was inferred from paired germline data for patients in the BLCS cohort. Multivariable and multinomial logistic regressions were employed to assess the associations between SIRE, GIA and *KRAS* outcomes.
Results: In the entire cohort, 804 (20.5%) patients harbored *KRAS* mutation, with a considerably higher prevalence of 31.5% observed in BLCS compared to 10.4% in OM cohort. Patients with self-identified Asian was associated with a significantly lower rate of *KRAS* mutation (OR = 0.44, 95% CI:0.22 - 0.81, P = 0.01), transversion substitutions (OR = 0.24, 95% CI:0.10 - 0.62, P = 0.003) and $KRAS^{G12C}$ (OR = 0.17, 95% CI:0.04 - 0.72, P = 0.02) compared to SIRE-White patients after adjusting for confounders including smoking status, sex and histology. The association of SIRE and *KRAS* driver mutation was further modified by sex, with Asian women demonstrating lower risk compared to Asian men, while the opposite trend was observed in SIRE-White patients. Increased European ancestry was associated with a higher risk of *KRAS* mutation (OR per 10% increase = 1.05, 95% CI:1.00 - 1.09, P = 0.03), particularly with more transition substitutions (OR per 10% increase = 1.10, 95% CI:1.01 - 1.21, P = 0.03) and $KRAS^{G12D}$ (OR per 10% increase = 1.18, 95% CI:1.04 - 1.34, P = 0.01). This association was even more pronounced in patients of increased Northern European ancestry. Furthermore, even among SIRE-White patients, a 10% increase in European ancestry was associated with an additional 6% increase in the likelihood of *KRAS* mutations (OR = 1.06, 95% CI: 1.01 - 1.12, P = 0.03), while a 10% increase in Admixed American ancestry was associated with a 6% decreased likelihood of *KRAS* mutations (OR = 0.94, 95% CI: 0.88 - 0.99, P = 0.04). Results were validated in an independent cohort of 1450 patients.
Conclusion: Self-reported race/ethnicity and genetic ancestry are both associated with *KRAS* driver mutations and allele-specific subtypes of NSCLC. This work highlights the significance of integrating both into population-based cancer research, aiming to refine clinical decision-making processes and mitigate health disparities.

#2152 Evaluating beliefs and perceived competence about tobacco cancer prevention practices in Texas local mental health authorities.

A. D. Siddiqi[1], M. Britton[2], T. A. Chen[3], I. Martinez Leal[2], A. Rogova[2], M. Z. Jafry[4], B. Kyburz[5], T. Williams[5], L. R. Reitzel[2];
[1]Rice University, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX, [3]University of Houston, Houston, TX, [4]McGovern Medical School, Houston, TX, [5]Integral Care, Austin, TX

Tobacco use is causally associated with 18 cancers and is a leading cause of preventable death. Individuals experiencing mental illness use tobacco at an elevated rate and consequently suffer from greater cancer-related morbidity and mortality. Unfortunately, local mental health authorities (LMHAs), a common setting to receive mental health services, do not prioritize tobacco dependence treatment despite robust evidence that tobacco cessation can enhance mental health in addition to reducing cancer incidence. Beliefs (Health Belief Model) and competence (Self Determination Theory) both play an integral role in shaping behavior. Consequently, this study examined employee and provider tobacco-related beliefs and competence in LMHAs to contextualize their tobacco intervention practices. The frequency of beliefs and competence related to provision of evidence-based tobacco cessation care was collected by e-survey from organizational representatives of 30 of the 39 LMHAs in Texas in 2021. Queries included if respondents agreed that patients should concurrently quit drugs/alcohol and tobacco (N=30 employees) and if they believed patients want to quit cigarette and non-cigarette (i.e., other) tobacco products (n=16 direct service providers). Providers were also asked if they thought that they had the competence to help patients quit smoking and other tobacco use, if they could tailor cessation treatment to patient needs, and about their intervention practices. Only 40% of LMHA representatives endorsed that patients should quit tobacco at the same time as other drugs. Furthermore, only 50% of providers believed that patients want to quit smoking and other tobacco use, respectively. About 70% of providers believed that they have the skills to help patients quit smoking and other tobacco use, respectively, but only 56% reported that they can tailor treatment. Finally, only 56% and 38% of providers recommend that patients stop smoking or other tobacco use, respectively, with 25% recommending smokers switch to vapes or smokeless tobacco products. Contrary to LMHA employee and provider beliefs, research indicates that most patients want to quit tobacco use and that concurrent tobacco use treatment can enhance patient sobriety for non-nicotine substance use disorders. Results demonstrate high levels of misinformation on concurrent tobacco and substance use treatment in LMHAs, which can subvert the provision of evidence-based cessation care. Educational interventions are needed to shift these beliefs, increase competence, and increase tobacco use intervention provision. This will not only help to address cancer disparities among patients but also improve mental health- a critical goal of LMHAs. Future research should investigate how to target tobacco-related beliefs, competence, and intervention behavior in LMHAs to broaden the reach of cancer prevention strategies.

#2153 The impact of socioeconomic and racial segregation on cancer stage at diagnosis, treatment and mortality among patients with small cell lung cancer.

B. B. Bekele, M. Lian, Y. Liu;
Washington University in St Louis, St Louis, MO

Background: Although studies have revealed the adverse impact of residential segregation on early detection, treatment, and survival of non-small cell lung cancer—a predominant type of lung cancers, it remains unknown regarding the role of residential segregation in treatment and outcomes of small cell lung cancer (SCLC)—a rare type of lung cancer characterized by rapid growth and poor prognosis. Therefore, we examined the associations of racialized socioeconomic segregation with risks of extensive-stage diagnosis, non-adherence to guideline-recommended treatment, and mortality among non-Hispanic White (NHW) and non-Hispanic Black (NHB) patients with SCLC.
Methods: This population-based retrospective cohort study included patients who were diagnosed with SCLC as a first primary malignancy at age 20 and older between January 2007 and December 2015, followed through December 2016, and identified from the Surveillance, Epidemiology, and End Results. County-level racialized socioeconomic segregation was measured using the Index of Concentration at the Extremes (ICE). Multilevel logistic regression accounting for county-level clustering was used to estimate odds ratios (ORs) for extensive-stage diagnosis and non-adherence to guideline-recommended treatment. Hazard ratios (HRs) for lung cancer-specific mortality and all-cause mortality were computed using multilevel Cox regression.
Results: Among 38,393 patients, 90.1% were NHW and 9.9% were NHB. Patients dwelling in the counties with the highest concentration of low-income NHB households (highest ICE quartile) had higher risks of non-adherence to guideline-recommended treatment (OR=1.23, 95% CI: 1.08-1.40; P_{trend} <0.01), lung cancer-specific mortality (HR=1.08, 95% CI: 1.04-1.12; P_{trend} <0.01), and all-cause mortality (HR=1.13, 95% CI: 1.09-1.17; P_{trend} <0.0001) as compared with patients dwelling in the counties with the highest concentration of high-income NHW households (lowest ICE quartile). These associations were comparable between NHB and NHW patients. Racialized economic segregation was not significantly associated with extensive-stage diagnosis.
Conclusions: Residing in the segregated, low-income NHB counties had adverse impacts on stage-appropriate treatment for SCLC and survival outcomes. Future research on the pathway(s) linking residential segregation to SCLC treatment underutilization and poor outcomes is warranted.

#2154 *Actívatexto:*Feasibility and acceptability of a mobile intervention that promotes smoking cessation and physical activity among Latinos.

D. Lara[1], E. I. Alaniz-Cantu[1], A. Chavez-Iniguez[1], D. Fuller[2], S. McIntosh[1], D. J. Ossip[1], A. Cupertino[1], **F. Cartujano-Barrera**[1];
[1]University of Rochester Medical Center, Rochester, NY, [2]University of Saskatchewan, Saskatchewan, SK, Canada

The purpose of this study was to assess the feasibility and acceptability of a mobile intervention that promotes smoking cessation and physical activity among Latinos. Twenty Latino adults who smoked and did not meet recommended levels of physical activity were recruited using community-based recruitment strategies. Participants received *Actívatexto*, a theory-based, culturally accommodated, 12-week text messaging intervention (available in English and Spanish) that promotes both smoking cessation and physical activity. *Actívatexto* integrates four components: 1) a text messaging program that promotes both smoking cessation and physical activity, 2) a wearable device to monitor physical activity, 3) an online dashboard where the research team manages participants' incoming and outgoing data from both the text messaging program and wearable devices, and 4) smoking cessation pharmacotherapy (i.e., nicotine replacement therapies). We assessed self-reported 7-day point prevalence smoking abstinence (not smoking any cigarettes in the past seven days) at Month 3, weekly minutes of moderate to vigorous physical activity (MVPA), pharmacotherapy adherence, self-efficacy, and satisfaction. At baseline, participants' mean age was 47.3 years old (SD 16.0), 55% of participants were female, 80% had completed high school or lower educational level, and 60% indicated that Spanish was their language of preference. Most participants (75%) smoked 1-10 cigarettes daily, 35% smoked their first cigarette within five minutes after waking up, and 60% used menthol cigarettes. At Month 3, 14 participants (70%) self-reported 7-day point prevalence smoking abstinence (90% follow-up rate). Fitbit-assessed mean minutes of MVPA per week increased from 113 (SD 127; range 0-399) at Week 1 to 177 (SD 163; range 0-513) at Month 3, although the difference was not statistically significant ($p=0.15$). Sixteen participants (88.9%, 16/18) reported NRT use in the past 90 days. Mean scores of self-efficacy for smoking cessation increased from 31.2 (SD 10.6) at baseline to 47.8 (SD 13.0) at Month 3 ($p<0.01$). Mean scores of self-efficacy for physical activity increased from 12.3 (SD 3.9) at baseline to 14.6 (SD 4.4) at Month 3 ($p=0.2$). Most participants reported being satisfied or extremely satisfied with the intervention (88.9%, 16/18). In conclusion, *Actívatexto* resulted in a noteworthy cessation rate at Month 3 (70%), increased mean minutes of MVPA per week, produced high use of NRT, increased self-efficacy for smoking cessation and physical activity, and was well received by participants. Additional testing in a formal randomized clinical trial is warranted to assess the efficacy of the intervention.

#2155 The impact of urban residence on symptom duration, treatment initiation, and survival among primary brain tumor patients: A large cohort analysis.

M. L. Stockdill, J. B. Vo, O. Celiku, Z. Karim, Y. Kim, H. Miller, E. Vera, T. S. Armstrong;
National Cancer Institute, Bethesda, MD

Primary brain tumors (PBT) are rare, accounting for less than 2% of all cancers, present acutely, and often require specialized care to determine treatment approaches. Neuro-Oncology clinics are located in densely populated urban areas resulting in additional access barriers, such as longer travel time, for those in non-urban areas. To better understand how proximity to our facility affects patient outcomes among PBT patients enrolled in the National Institutes of Health (NIH) Natural History Study (NCT02851706, PI: Armstrong), we assessed the association of population density with symptom duration before diagnosis, time to first treatment, and overall survival among a cohort of 666 adult PBT patients. More urbanized areas were defined as areas with a core population density of more than 1,000 persons per square mile. T-tests and chi-squared tests were performed to assess differences in patient and tumor characteristics based on population density (more urbanized vs. less urbanized). We used ordinal logistic regression (odds ratio [OR], 95% confidence intervals [CI]) to assess the association between duration of presenting symptoms (<6 months, 6 months-1 year, ≥1 year) and linear regression (beta coefficient, 95% CI) for time to treatment and population density. We adjusted for age at cancer diagnosis and sex (male, female), and results were stratified according to residential distance to the NIH (short distance=<200 miles, long distance=200+ miles), to control for local referral patterns. Kaplan-Meier estimates were used to assess overall survival by population density levels, overall, and by residential distance. All models were then further stratified by tumor grade (low, high). Among 666 patients diagnosed with PBTs, 401 (60%) lived in more urbanized areas, 40% were long distance, and 24% had low-grade tumors. Patients living in more urbanized areas were more racially diverse ($p<0.001$), had higher educational attainment ($p<0.001$), and were more likely to be single ($p=0.008$). In the overall cohort and when stratified by distance to NIH or tumor grade, there were no associations between population density level and symptom duration prior to diagnosis. Time to treatment for radiation and chemotherapy was longer for PBT patients living in less urbanized areas and longer distances from the NIH ($\beta=0.63$; 95%CI=0.08,1.17) compared to those living in more urbanized areas. There were no differences in the 5-year survival rates between more or less urbanized groups. In conclusion, access to care for those in less urbanized areas was demonstrated, although survival was not impacted. Future consideration should be given to novel approaches to increase access to specialized care, particularly for PBT patients living further from urban areas.

#2156 Exploring barriers to colorectal cancer screening among adult male immigrants in Salt Lake City.

O. O. Onigbogi, K. Kah, K. Okuyemi;
University of Utah, Salt Lake City, UT

Background: The United States (U.S) foreign-born population aged 65+ increased substantially between 1990 and 2010 with migrants from Africa and the Middle East being a part of these new refugee admissions. According to 2010 data, socioeconomic disparities and reduced access to health care is common in this population with 16 percent of foreign-born elderly living below the poverty threshold in comparison with 8 percent of U.S.-born elderly. Colorectal Cancer (CRC) is the second leading cause of cancer related deaths in the U.S despite being easily preventable and treatable. Studies among male African Americans reveal a CRC incidence >20% higher than what obtains among whites. Since, genetic factors are believed to contribute as much as 35% to the overall risk of CRC, male adult immigrants aged 45 years and above from Africa and the Middle East may be at increased risk of developing the disease. Determining CRC screening uptake in this population will be critical in planning interventions which may ultimately reduce disparities in CRC-related morbidity and mortality in the future.

Methods: We conducted a mixed methods study comprising administration of questionnaires and organizing four Focus Group Discussion (FGD) sessions among adult males in Salt Lake City who identified as refugees from Africa or the Middle East. The sessions were audio-taped, transcribed and coded using the Dedoose software.

Results: We had thirty-one participants who were between 45 and 64 years of age. Twenty-five of them (83%) reported awareness of the existence of CRC screening tests. Ten participants (33%) had undergone a CRC test in the past. However, only nine participants (30%) indicated that they will be willing to participate (WTP) in CRC screening if offered for free. Increased WTP was associated with younger age (OR=1.45, 95% CI: 1.23-1.81), length of stay in the United States (OR=1.41, 95% CI: 1.13-1.78) and higher education (OR= 1.26, 95% CI 1.13-1.37). Three major themes identified in the FGDs include: (1) Mistrust - distrust of the US health system (2) Fear - fear of cancer and nature of test and (3) Fatalism - the belief that screening cannot lead to cancer cure.

Conclusion: The low level of WTP in CRC screening tests among the respondents may be associated with past experiences. There may be a need to consider the correlates of increased WTP and explore culture-specific CRC prevention measures in planning interventions designed to improve screening uptake in this population.

#2157 Evaluating cervical and lung cancer risk among Hispanic and Non-Hispanic Black women in three urban Texas counties.

M. L. Chu, I. E. Jayesh;
University of North Texas Health Science Ctr., Fort Worth, TX

This study examines if there is a statistically significant difference in the risk of being diagnosed with cervical and lung cancer between Hispanic and Non-Hispanic Black (NHB) women in Tarrant, Dallas, and Bexar county.
Pulling from the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) Program, 2000-2020 trends in cancer diagnosis were measured by age-adjusted annual percent change (APC). Data was sorted by county and race/ethnicity and statistically insignificant measures were removed. APC measures were ranked relative to counties across Texas and the US. APC measures with 95% confidence intervals for Hispanic and NHB women in Tarrant, Dallas, and Bexar county were compared for a significant difference. Results from a previous study indicated that the slowest decreases in cervical cancer rates are found among Hispanic and African-American women in Tarrant and Dallas County. We built upon this study to assess if there was a statistically significant difference in the risk of developing cervical and lung cancer between these two groups. In Tarrant County (TC), the cervical cancer APC of Hispanic women was -1.8 [-3.4,0.1] and NHB women was -1.2 [-3.7, 1.3]. In Dallas County, the cervical cancer APC of Hispanic women was -2.1 [-3.4, -0.8] and NHB women was -1.8 [-3, -0.5]. This indicates that for both cities, Hispanic women saw a greater decrease in the APC in cervical cancer rates than NHB women. In Tarrant County (TC), the lung cancer APC of Hispanic women was -2.7 [-4.5, -0.9] and NHB women was -2.1[-3.1, -1.1]. In Dallas County, the lung cancer APC of Hispanic women was -2.3 [-4.2, -0.4] and NHB women was -1.8 [-2.5, -1]. This indicates that for both cities, while Hispanic women saw a greater decrease in the APC in lung cancer rates than NHB women, the decrease is not statistically significant due to the overlap of the confidence intervals. Even though the confidence interval (CI) overlaps indicates insignificance, the APC can still provide valuable information regarding diagnostic trends seen in urban cities. The results showed that there is no significant difference between these two groups, suggesting that other county-level factors may play a role in diagnostic disparities seen between these two racial groups.

#2158 Emerging epidemiological cancer trends among West African adults in Zaria, Nigeria (1972 to 2022).

F. Mohammed[1], D. J. Lee[2], K. Graef[3], A. H. Rafindadi[1], S. Ibrahim[1], S. M. Aminu[1], A. Adamu[1], A. Abdullahi[1], A. M. Suleiman[1], A. Mohammed[1], J. Idoko[4], A. L. Rafindadi[1], D. A. Ameh[1], B. A. Kumo[1], A. Bello[1], A. J. Randawa[1], O. O. Adekunle[1], U. M. Aminu[1], M. Manko[1], O. T. Tajudeen[1], L. M. D. Yusufu[1], M. D. Maigatari[1], L. Khalid[1], D. Ismail[1], A. A. Babadoko[1], A. T. Lawal[1], A. A. Mohammed[1], Y. Ukwenya[1], A. Mai[1], M. Y. Hussaini[1], A. Yahaya[1], C. Bishop[3], J. Dent[3], T. R. Rebbeck[5], Y. Iliyasu[4];

[1]Ahmadu Bello University, Zaria, Nigeria, [2]Massachusetts General Hospital, Boston, MA, [3]BIO Ventures for Global Health, Seattle, WA, [4]Ahmadu Bello University Teaching Hospital, Zaria, Nigeria, [5]Dana-Farber Cancer Institute, Boston, MA

Cancer incidence and mortality rates in Africa are increasing, with sub-Saharan Africa reporting 2.7-fold higher fatality than global averages. The incidence of cancer in Africa in 2020 was about 1.1 million new cases, with 711,000 deaths, indicating a mortality-to-incidence ratio (MIR) of 0.64. These cancer challenges in Africa necessitate a concerted approach towards effective cancer control and management. Here, we present an extensive report of emerging epidemiological cancer trends among West African adults seen between 1972-2022 in Zaria, Nigeria. We used the Zaria cancer registry of the Ahmadu Bello University Teaching Hospital (ABUTH) Zaria, Nigeria to obtain information on histologically diagnosed cancers from January 1st, 1972 to December 31, 2022. Records in the Zaria registry are indexed into a register paper-based and 2008 and transferred by CanReg4 software on the computer. We used WHO classification of tumors (WHO Blue Book) 5th edition to classify all the abstracted cancers for the purpose of this study. Time-trend analyses were performed by utilizing linear regression models. In the analysis of the Zaria cancer registry, 12,114 adults (42.2% male, 57.8% female) were diagnosed with histologically confirmed cancer between 1972 - 2022. The most common diagnosis among male cancer patients was prostate cancer, comprising a quarter of all cases. The median age of diagnosis for prostate cancer was 65 years, with an interquartile range (IQR) of 60 and 70. Among female cancer patients, the most common diagnoses were cervical cancer and breast cancer, together comprising 68.2% of all cases. Median age at diagnosis were 45 (IQR, 40-56) and 42 (IQR, 35-50), respectively. In time-trend analyses, the total number of new cancer cases diagnosed at ABUTH from 1972 to 2022 increased over time ($p<0.001$). In the analyses of individual cancers, those in which the number of new cases increased over time were neoplasms of the bones and joints, breast, cervix, prostate, colorectum and stomach, head and neck ($p<0.001$); esophagus ($p=0.006$); eye and orbit and soft tissue ($p=0.002$); and ovary ($p=0.005$). Cancers in which the number of new cases decreased over time were Hodgkin lymphoma, Non-Hodgkin lymphoma, melanoma of the skin, and non-melanoma cancer of the skin ($p<0.001$). The number of new adult cancer diagnoses recorded in the Zaria cancer registry have increased over time from 1972 to 2022. Prostate cancer accounted for a quarter of all cancer cases among males, whereas cervical cancer and breast cancer accounted for nearly 70% of all cases among females. Westernization with associated change in dietary habits, physical inactivity, obesity and reproductive behaviors and changes in the population size and life expectancy may be attributable factors to change in cancer in Zaria. Better understanding of these factors will inform cancer prevention and control strategies.

#2159 Testing of an educational tool kit for the Community Genetic Navigation Engagement Specialists, COGENES, Training Program.

Yaneth L. Rodriguez, Janet Rodriguez, Charite Ricker, Julie Culver, Daisy Hernandez, Natalia Guierrez, Yvonne Cardona, Rosa Barahona, Bianca Rosales, Mariana Stern, **Lourdes A. Baezconde-Garbanati**

Keck School of Medicine of USC, Los Angeles, CA

Introduction: There is a lack of culturally sensitive materials to educate the Hispanic/Latino/a/x (H/L) community on colorectal cancer (CRC), which is the second and third leading cause of cancer deaths among H/L men and women in the United States, respectively. For these reasons, an Educational Tool Kit was created for the Community Genetic Navigation Specialists (CoGENEs) program at the Center for Optimizing Engagement of Hispanic Colorectal Cancer Patients in Cancer Genomic Characterization Studies (COPECC) at the University of Southern California (USC). CoGENES is a train the trainer program geared towards the development of a local workforce of trained community engagement specialists, promotores de salud (community health workers) that will act as liaison agents to increase knowledge and create community awareness on genetic research, clinical genetic testing, counseling, biospecimen donation and participation in clinical trials for H/Ls CRC patients, and community at large.
Methods: The Tool Kit consisted of a newly developed educational handbook focused on CRC prevention, genetics, counseling, tumor testing, and patient navigation, as well as existing materials with resources for CRC and counseling. To test the handbook, five focus groups in Spanish/English were conducted with 44 participants, recruited via community agencies/clinics serving Los Angeles. Optimization probes focused on readability, knowledge, acceptability, barriers, and recommended changes. Content analysis was conducted with focus group transcripts to inform how to optimize the handbook. A Materials Review Optimization Scorecard was developed to evaluate materials on content, literacy, graphics, layout and typography, learning, stimulation and motivation, and cultural and language appropriateness. Fifteen pieces in the handbook were each rated by three community health workers. A final suitability score was calculated for each piece.
Results: Overall, the materials were well received, and participants understood the overall main message of the materials. Feedback included refining terminology, providing additional headings and subtitles, and clarifying images to optimize the illustration of mutations. Final suitability scores from community health educators ranged from 80 to 99% for all materials, translating into “superior materials.”
Conclusion: Overall materials were well received, and they were rated as “superior materials.” Participants’ feedback from CoGENES is shared with the Engagement Optimization Unit (EOU) and Patient Engagement Unit (PEU) to optimize ongoing education and research at COPECC. The MR-OS tool will be shared with other PEU’s at other center’s to encourage it use when developing educational materials.

#2160 Utilizing geospatial analytics to identify neighborhood cancer hot spots for recruitment of underserved populations in clinical prevention research.

M. S. Lee, R. Kaiser, R. Vyas, A. Vera, D. Flores Quetant, N. Elliott, V. Bethel, A. Rivera, S. Kumar, B. Mahal, E. Franzmann, E. Kobetz;
University of Miami Miller School of Medicine, Miami, FL

Background: The term “precision public health” has increasingly been used in literature to describe public health practices that utilize new technologies and big data to precisely target the most vulnerable populations for disease control. Following the principles of precision public health, we used geospatial technologies and population-based health data to identify the locations and socioeconomic status of neighborhoods with high cancer incidences for recruitment of participants in prevention research.
Methods: Using Florida cancer registry data, geospatial hot spot analyses were carried out to identify statistically significant clusters of census tracts with high incidences of prostate, gastric, and oral cancers within the catchment area of the Sylvester Comprehensive Cancer Center in South Florida. The locations, social determinants of health (US Census’ American Community Survey), and behavioral risk factor data (CDC’s Behavioral Risk Factor Surveillance System) of these hot spots were analyzed to identify the locations of underserved communities facing high risk for these three cancers.
Results: Hot spots with high incidences for each of these three cancers overlap in many neighborhoods with high proportions of Hispanic and Non-Hispanic Black populations and high levels of socioeconomic disparities, such as low income, low education level, rental housing, no vehicles, and no access to health insurance. These neighborhoods also have high rates for behavioral risk factors in smoking, lack of physical activity, obesity, and high incidence of cervical cancer (high risk areas for HPV-associated oral cancers). Mobile screening units called the Game Changer Vehicles have been deployed to the locations to recruit participants who were tested on-site for prostate specific antigen (prostate cancer), H. pylori (gastric cancer), or solCD44 (a soluble tumor marker for squamous cell carcinoma) and total protein levels in oral rinse specimens, which can distinguish individuals with molecular features at risk for oral cancers due to tobacco, alcohol use, and human HPV infection.
Conclusions: Geospatial analyses of population health data can be used to produce metrics that precisely target neighborhoods with high cancer risk and health disparities to recruit research participants. The same precision approach can also be applied for cancer screening purposes, such as offering cervical self-sample and fecal blood test kits in disadvantaged communities facing heightened risk for cervical and colorectal cancers.

#2161 Recruitment feasibility of Hispanic women in breast cancer survivorship research using state cancer registry procedures.

E. Lee, B. Sukhu, M. Griffin, R. Griffin, N. Mercado-Almodovar, N. Utrera, K. Bello, M. Lakshmanan;
University of Central Florida, Orlando, FL

Objectives: Hispanic populations are underrepresented in epidemiologic studies. Although the Florida State Cancer Registry's primary role is cancer surveillance and control, it can also aid in population-based epidemiologic studies of cancer survivors. This study aimed to evaluate the viability of using the Florida Cancer Data System's (FCDS) patient recruitment methods to enlist Hispanic women with breast cancer for a cross-sectional survey.
Methods: During August 2023 - November 2023**,** we recruited adult (age ≥ 20) women who were diagnosed with breast cancer at least six months ago before enrollment, self-identified themself as Hispanic, and currently living in Central Florida, using state-mandated recruitment procedure which includes two invitation letters sent via mail three weeks apart and calling to non-responders after three weeks, but up to 4 times. Potential interested participants were asked to complete a survey in English or Spanish via print or online packet, providing data on demographics, health, lifestyle, and quality of life. An Excel log was used to track the response and return dates.
Results: As of October 25, 2023, we sent the invitation letters to a total of 667 participants deemed eligible per FCDS. Most of them did not respond to the letters or follow-up telephone calls, with 364 being unreachable due to incorrect contact information, which led to 303 accessible participants. The accessible sample included 22 Cubans, 73 Puerto Ricans, 65 South/Central Americans, 20 Dominicans, 39 Mexicans, and 83 Other Hispanics, with 48.7% speaking Spanish. Among the accessible participants, 113 refused to participate, 34 were not eligible, 13 have not decided yet, 118 agreed to participate but have not completed the survey yet, and 25 agreed to participate and completed the survey as of November 15. Common reasons for not qualifying included "not being Hispanic," "dead," "not living in Central Florida," "not having cancer," or "inability to read English or Spanish." The most common reasons for refusal were "too sick," "too old," or "not interested." The average response time to the first and second invitations was 20.1 and 19.6 days, respectively, and most participants responded to the second or third call within 8.3 days of the first call.
Conclusions: The FCDS can be used to recruit Hispanics for epidemiology studies. However, the state-mandated patient recruitment procedure needs improvement. For example, the procedure should collect participants' email addresses in addition to their mail and telephone numbers, allow researchers to contact participants via email instead of written mail, and remove all dead individuals before sending the contact information to researchers.
(Supported by Florida Breast Cancer Foundation Scientific Research Grant 2023 and UCF SEED grant).

#2162 Framework and pilot testing for the recruitment of a U.S.-based prospective cohort study of 100,000 Black women.

A. V. Patel, L. R. Teras, E. Kirkland, J. McCrary, H. Vins, J. E. Bontemps-Jones, E. Larbi, M. L. Hall, P. J. Briggs, D. M. Dudas, C. Lichtman, L. E. McCullough; American Cancer Society, Atlanta, GA

Background: As of 2020, 46.9 million people in the United States (14.2% of the total population) identify as Black or African American. Collectively, Black Americans have the highest cancer death rate and shortest survival of any racial or ethnic group in the U.S. The drivers of cancer and other health conditions among Black women are likely multi-level, complex, and include contributions from environmental, behavioral, community, and system-level factors. Inadequate representation in research has limited the understanding of drivers of disparate outcomes, which, in turn, has hindered our ability to identify successful, culturally appropriate strategies for intervention.

Approach: The American Cancer Society is establishing a cohort of at least 100,000 Black women to better understand cancer risk and outcomes in this population. The cohort will include two recruitment arms: (1) an “at risk” group of 85,000 participants between the ages of 25-55 years old with no prior cancer history and (2) a “survivorship” group of 15,000 participants previously diagnosed with breast, colorectal, or endometrial cancers. Pilot enrollment of the “at risk” group launched in October 2023 and will focus on understanding the disproportionate burden of early-onset cancer among Black women. For the “survivorship” group, pilot enrollment will launch in late 2024. The cancers of focus account for 95% of the absolute cancer mortality rate difference for Black vs. White women and offer the greatest opportunity for learning how to reduce cancer mortality disparities. Enrollment will focus on Black women who reside in the District of Columbia or one of 20 U.S. states representing >90% of the U.S. Black population.

Results: Approximately 200 women were successfully consented into the cohort between October-November 2023. Study activities are conducted through an online portal optimized for mobile use. Through the portal, participants confirmed eligibility by completing an electronic survey, and reviewing and signing the informed consent. Upon consent, participants will complete a baseline survey and be sent follow-up surveys twice per year for at least 30 years. These surveys will track exposures, health outcomes, and participants’ lived experiences.

Conclusions: Pilot work in 2023 demonstrated feasibility to engage Black women into a prospective cohort study. Based on the early feasibility success, full launch of enrollment is planned for May 2024.

#2163 Socioeconomic status associates with epigenetic modulation of TET2: An emerging pathway in cardio-oncology.

Sonal Sharda[1], Yvonne Baumer[1], Alina P. S. Pang[2], Abhinav Saurabh[1], Billy S. Collins[1], Valerie M. Mitchell[1], Michael J. Corley[2], Tiffany M. Powell-Wiley[3]

[1]National Heart, Lung, and Blood Institute, National Institute of Health, Bethesda, MD,[2]Department of Medicine, Division of Infectious Diseases, Weill Cornell Medicine, New York City, NY,[3]National Heart, Lung, and Blood Institute & National Institute on Minority Health Disparities, National Institute of Health, Bethesda, MD

Introduction: Adverse social determinants of health (SDOH) are known to accelerate poor outcomes in cardiovascular disease (CVD) and cancer. Clonal Hematopoiesis (CH) is a mechanism implicated in these disease states, partially driven by epigenetic regulatory genes, including *TET2*. Yet, there is not much known about how epigenetic modulations of *TET2* itself may relate to the immune system and subsequent disease development.
Hypothesis: We hypothesize that socioeconomic status (SES), as a SDOH marker, relates to epigenetic modulation of *TET2*.
Methods: 60 African American adults (93.3% female, mean age 61) with CVD risk, living in the Washington, D.C. area self-reported their SES as household income. Immune system activity was assessed via splenic activity (SpleenA) by ^{18}FDG PET/CT. Serum cytokine levels were measured by ELISA and DNA methylation analysis evaluated the epigenetic modulations of *TET2*. Multivariable regression analysis adjusted for ASCVD 10-year risk score and BMI was used to examine associations.
Results: Out of 33 *TET2* methylation sites, we found 3 sites that were significantly related to SES. Notably, only *Tet2cg09666717* (SES β=0.310, p=0.038) was also associated with SpleenA (β=-0.453, p=0.036) and several cytokines: IL-17A, IL-1β and TNFα along with trending to significance with IFN-γ (Table).
Conclusion: Thus, we found that SES associates with hypomethylation of *Tet2cg09666717*, which further related to SpleenA and inflammatory markers. Our findings are hypothesis generating and suggest that lower SES may relate to inflammation and immune system dysregulation by the way of epigenetic modulation of TET2. These results should be examined in larger, functional studies with diverse population-based cohorts to determine the potential relationships of both SDOH and epigenetic markers in CH and cardio-oncology outcomes.

Associations between TET2 methylation sites, SpleenA, SES and Cytokines in DCCNHA cohort, 2014-17

	Tet2cg09666717	Tet2cg05094833	Tet2cg10594473
SES	0.310 **(0.038)**	-0.405 **(0.006)**	-0.283 **(0.060)**
Splenic Activity	**-0.453 (0.036)**	0.004 (0.985)	0.097 (0.654)
IL-6	-0.078 (0.558)	-0.211 (0.108)	-0.222 (0.084)
IL-8	-0.199 (0.153)	0.024 (0.865)	-0.004 (0.979)
IL-17A	**-0.373 (0.010)**	0.134 (0.370)	-0.434 **(0.017)**
IL-1β	**-0.382 (0.003)**	0.042 (0.757)	-0.143 (0.275)

Data are presented as standardized β coefficient (p-value). All data are adjusted for 10-year predicted ASCVD risk and BMI; **ASCVD** = atherosclerotic cardiovascular disease; **BMI** = body mass index; **IL-6** = interleukin 6; **IL-8** = interleukin 8; **IL-17A** = interleukin 17A; **IL-1β** = interleukin 1 beta; **TNF**α = tumor necrosis factor; **IFN-γ** = interferon gamma

PREVENTION / EARLY DETECTION / INTERCEPTION: Role of Diet, Nutrition, and the Microbiome Across the Cancer Continuum
Poster Session

#2167 Microbial bile acid, 3-oxo-LCA, inhibits colorectal cancer progression.
F. Sun, X. Dong, M. Qi, T. Fu;
University of Wisconsin-Madison, Madison, WI

Colorectal cancer (CRC) affects a significant number of individuals each year, ranking as a leading cause of cancer-related deaths in the U.S. Bile acids (BAs), natural compounds crucial for digesting dietary fats, not only influence the gut microbiota but are also involved in gut health through their interaction with the Farnesoid X Receptor (FXR). Recent findings have highlighted certain microbiota-generated BAs like 3-oxo-lithocholic acid (LCA) and IsoLCA, modulate host immunity, hinder the expansion of intestinal pathogens, and potentially anti-aging. Despite the advancements in identifying the gut microbes behind these BAs, their precise impact on intestinal cells (IECs) and their role in disease progression are largely unexplored. Our pilot investigation unveiled 3oxoLCA as an FXR agonist, restoring FXR signaling in both cancer cells and $APC^{min/+}$ mice (a classic CRC mice model). As a result, 3-oxo-LCA inhibits the growth of both human and mouse CRC cells, such as MC38, CT26 and HCT116. Additionally, 3-oxo-LCA also restrained the intestinal stem cells (ISCs)' proliferation in organoids from both wild-type and $APC^{min/+}$ mice, and patient-derived CRC organoids (PDCOs). Remarkably, treatment with 3-oxo-LCA decreased BAs levels, improved gut barrier function, reduced tumor load, and inhibited tumor progression in $APC^{min/+}$ mice. Furthermore, 3-oxo-LCA significantly suppressed tumor growth in cancer cell-derived xenograft model mice. Crucially, the 3-oxo-LCA-FXR interaction transcriptionally regulated key apoptotic genes, encouraging cancer cell death. These discoveries highlight the therapeutic promise of incorporating 3-oxo-LCA into strategies for treating CRC.

#2168 Intermittent fasting in combination with carboplatin in a pre-clinical model of obesity-driven endometrial cancer.

J. Haag, O. Lara, C. Zhou, S. D. Hursting, V. Bae-Jump;
University of North Carolina at Chapel Hill, Chapel Hill, NC

Objectives: Endometrial cancer (EC) incidence and mortality continue to rise, with obesity a well-known driver of this disease. Obesity is associated with excess estrogen, hyperinsulinemia, activation of the Akt/mTOR pathway, chronic inflammation, and a heightened capacity to harvest dietary energy, all of which contribute to the development and progression of EC. Intermittent energy restriction (IER) is thought to have anti-tumorigenic benefits and has been shown to have synergistic effects with chemotherapy and hormonal therapy in various cancer types. Thus, we evaluated the anti-tumorigenic effects of a switch from high fat diet (HFD) to either IER or low fat diet (LFD) with carboplatin treatment in a mouse model of obesity-driven endometrioid EC.

Methods: *Lkb1*$^{fl/fl}$*p53*$^{fl/fl}$ mice were fed either HFD or LFD starting at 4 weeks of age. At 12 weeks of age, the HFD-fed mice were randomized to three treatment groups: continuous HFD, HFD-LFD switch, and HFD-IER switch. The LFD-fed mice were continuously maintained on LFD. At 16 weeks of age, all mice were injected with AdCre into the left uterine horn to induce EC development. At 26 weeks of age, mice were treated with placebo or carboplatin (50 mg/kg intraperitoneally weekly) for 4 weeks (n=8-10 mice per group). EC incidence, tumor weight, and body weight were evaluated. EC gene expression was assessed by microarray analysis.

Results: EC incidence was lowest in the HFD-IER group (~60%) and highest in the HFD group (~80%); rates were similar in the other diet groups (~75%). The continuous HFD-fed mice demonstrated a 76% increase in tumor size relative to continuous LFD-fed mice ($p<0.001$). At sacrifice and after carboplatin treatment, mean body weights were significantly higher ($p<0.05$) in the HFD group (38g) than groups receiving continuous LFD (26g), HFD-LFD switch (28g), or HFD-IER switch (21g), although mean body weights were not significantly different within diet groups between placebo and carboplatin-treated mice. In placebo-treated groups, mean tumor weights were significantly lower in mice fed continuous LFD (0.62g), HFD-LFD switch (0.60g) and HFD-IER switch (0.26g) relative to continuous HFD-fed mice (1.10 g; $p<0.001$). When comparing gene expression between the HFD-LFD and the HFD-IER placebo groups, genes related to cholesterol metabolism, estrogen response, and inflammation were preferentially up-regulated in the HFD-IER group. Carboplatin treatment reduced EC tumor size 42-69% across all diet groups ($p<0.05$); tumor size was the smallest in the HFD-IER group (0.15g) relative to mice receiving continuous HFD (0.34g), HFD-LFD (0.29g) or continuous LFD (0.34g).

Conclusion: IER with carboplatin treatment may be an innovative combination treatment strategy in the management of EC, a highly obesity-driven cancer.

#2169 Dietary inflammatory potential and mortality among patients with MAFLD.

Z. Lyu, Y. Zhang, W. Li, G. Si, **K. Chen**;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Inflammation is important in metabolic dysfunction-associated fatty liver disease (MAFLD) development and progression. However, evidence regarding the influence of dietary inflammatory potential and mortality among people with MAFLD is rare. This study aimed to elucidate the association of the energy-density dietary inflammatory index (E-DII) with all-cause and cause-specific mortality among MAFLD patients.
Methods: Data were obtained from the National Health and Nutrition Examination Survey (NHANES) (1988-1994, 1999-2010). MAFLD was defined as the evidence of hepatic steatosis with ≥1 of the following: type 2 diabetes (T2DM), overweight/obesity (OW, BMI ≥ 25 kg/m^2), or lean metabolic dysregulation (MD). Dietary intake was assessed through 24-hour dietary recalls. E-DII scores and component intakes were divided into tertiles, with T1 as the reference. Through linkage to National Death Index by December 31, 2019, mortality from all cause, cardiovascular disease (CVD), and cancer were identified. Multivariable Cox proportional hazards regression model and restricted cubic splines (RCS) were used to analyze the association between dietary inflammatory potential and mortality among MAFLD and its subtypes patients.
Results: A total of 6537 MAFLD patients were included in the present analysis. During the median follow-up of 16.8 years, 2281 total deaths (534 cancer-related, 750 CVD-related) were documented. Compared to high dietary inflammatory potential, low dietary inflammatory potential presented a inverse association with all-cause mortality risk in MAFLD patients ($HR_{T2\ vs.\ T1}$ = 0.83, 95% CI = 0.72-0.95, $HR_{T3\ vs.\ T1}$ = 0.88, 95% CI = 0.76-1.01, P_{trend} = 0.092) and OW subtype patients ($HR_{T2\ vs.\ T1}$ = 0.77, 95% CI = 0.63-0.93, $HR_{T3\ vs.\ T1}$ = 0.76, 95% CI = 0.63-0.92, P_{trend} = 0.009). No significant benefit was observed among T2DM and MD subtype patients. Further component analysis found that eicosapentaenoic acid (EPA) (HR = 0.74, 95% CI = 0.66-0.83), docosapentaenoic acid (DPA) (HR = 0.72, 95% CI = 0.65-0.80), docosahexaenoic acid (DHA) (HR = 0.85, 95% CI = 0.65-0.80), and linoleic acid (HR = 0.86, 95% CI = 0.79-0.94) were linked with reduced cancer mortality risk in MAFLD patients. Further RCS analyses found that the effect pattern of EPA, DPA, and DHA on both all-cause and cause-specific mortality was presented as “J shaped” ($P_{non\text{-}linear}$ < 0.05). Similar results were observed for all-cause and CVD mortality among both MAFLD and OW subtype patients. When excluding participants who died within five years, consistent results were presented.
Conclusions: The findings of this study suggest that keep low-inflammatory dietary pattern, especially appropriate level of PUFAs component (EPA, DPA, and DHA) intake were associated with a lower risk of cancer mortality in MAFLD patients. These findings may inform future public health guidelines regarding specific dietary consumption, and liver-related health promotion.

#2170 Effects of folic acid supplementation on early stages of colitis-associated carcinogenesis.

Ariane Rocha Bartolomeu, Wen-Chi Chang, Lisa Vanderveer, Kristen N. Harvey, Mitchell Cheung, Harry S. Cooper, Margie Lee Clapper

Cancer prevention and control, Fox Chase Cancer Center, Philadelphia, PA

Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD) characterized by persistent mucosal inflammation extending throughout the colon. Due to compromised intestinal surface integrity and the prolonged use of medication, individuals with UC often develop a folate deficiency, requiring folic acid (FA) supplementation. Prior findings from this group indicate that FA supplementation, at clinically relevant levels, promotes UC-associated dysplasia. Supplementation with FA resulted in an increased multiplicity of dysplasia and a significant elevation in the expression of several inflammatory genes (e.g. IL-6, Cox-2, Iκκ-β) within the colonic mucosa of mice with UC. Genome-wide expression profiling of normal and dysplastic colonic epithelial cells from mice treated with different doses of FA revealed differentially expressed genes were enriched for members of the ERK and NF-κB pathways. Subsequent *in vitro* analyses, utilizing isogenic RKO colon adenocarcinoma cells exposed to various doses of FA, demonstrated the downregulation of ERK and p-ERK in wild type (WT) $p53^{+/+}$ cells, while an increase in expression was observed in $p53^{-/-}$ cells at the protein level. The goal of this study is to investigate the role of the MAPK/ERK pathway in the development of UC-associated neoplasms. An *in vitro* model that faithfully reproduces the inflamed microenvironment in the context of WT vs. mutant p53, the putative gatekeeper of UC-associated carcinogenesis, is needed to enhance our understanding of early changes in the colon that are induced by FA and drive tumor formation. Colon organoids are being generated by isolating crypts from WT $p53^{+/+}$ and mutant $p53^{+/515A}$ mice. These organoids are then co-cultured with mouse macrophages (RAW264.7 cells) in inserts to stimulate crosstalk between the macrophages and colonic epithelial cells, as in the inflamed colon. Analyses demonstrate that the macrophages express pivotal inflammatory cytokines characteristic of UC, including IL-1β, IL-10, TNF-α, and IL-6, irrespective of the presence or absence of LPS stimulation. Co-cultured organoids and macrophages will be exposed to different concentrations of FA for various lengths of time, and the impact of treatment on the levels of ERK, p-ERK, and p65 will be assessed. The ability of p-ERK to mediate the transcriptional activation of NF-κB and its downstream effector IL-6 will also be evaluated. Subsequent investigations employing this innovative experimental model will reveal the mechanisms by which FA supplementation promotes the progression of UC-associated dysplasia. Given the potential risks associated with FA supplementation in individuals with UC, there is an urgent need to translate these results to a clinical setting. (Supported by CA262551 and the Timothy and Aurora Hughes Cancer Research Fund).

#2171 Nutritional mediators of inflammation: A cause for increased surveillance.

J. Crook[1], E. Lee[1], R. Xie[1], O. Bolajoko[2], V. Loerzel[1];
[1]University of Central Florida, Orlando, FL, [2]Mayo Clinic, Jacksonville, FL

Background: Nutritional and inflammatory factors collected in routine cancer labs, neutrophil percentage to albumin ratio (NPAR), neutrophil lymphocyte ratio (NLR), monocyte lymphocyte ratio (MLR), and platelet lymphocyte ratio (PLR), have been shown feasible in identification of patients at risk of increased treatment complications, decreased cognition, anxiety and depression, and increased mortality. These have proven sensitive to multiple cancer types and stages, though little is known about causal pathways. The Vitamin/Mineral and Inflammatory Correlations To Understand Chronic Stress in the U.S. (The VICTUS Study) sought to elucidate a relationship between diet and food insecurity within these panels.
Methods: Using NHANES 2017/2018 surveys, adults > 18 years without renal or hepatic disorders, pregnancy, alcohol, or supplement use were included. NPAR, NLR, MLR, and PLR were categorized as quartiles and compared to demographic, food security, plasma micronutrient statuses [vitamins A, B9, C, D, E, calcium (Ca), ferritin (Fe), phosphorus (P), potassium (K), sodium (Na)], and smoking, activity level, and sun exposure, using chi-square and ANOVA. ANOVA models compared food security and poverty to NPAR, NLR, MLR, and PLR means.
Results: From 3,317 participants, 50.2% were male, 54.3% non-Hispanic White, 33.7%, food insecure, 51.1% food stamp recipients, 27.7% smokers, with a mean age of 42.5 (SD 0.44), poverty to income ratio 2.79 (SD 0.08), CRP 3.90 (SD 0.18), NPAR 14.1 (SD 0.14), NLR 2.07 (SD 0.04), MLR 0.28 (SD 0.003), and PLR 118.7 (SD 1.61). CRP was found to be statistically significantly associated with all biomarker ratios ($p < 0.018$). Significant micronutrient biomarker-inflammatory biomarker associations were identified in Fe [NPAR, MLR, PLR ($p < 0.001$)], P [NPAR, NLR, MLR, PLR ($p < 0.033$)], C [NPAR, NLR ($p < 0.008$)], E [MLR, PLR ($p < 0.016$)], K [NPAR, NLR, MLR, PLR ($p < 0.015$)], Ca [NPAR, PLR ($p < 0.04$)], A [NPAR ($p < 0.023$)] and D [NLR ($p < 0.035$)]. Significant micronutrient intake-inflammatory biomarker associations were detected in vitamin A [NPAR, PLR ($p < 0.013$)], lycopene [NLR, PLR ($p < 0.035$)], and B12 [NLR, PLR ($p < 0.031$)]. Age [NPAR, NLR, MLR, PLR ($p < 0.001$)], gender [NPAR, MLR, PLR ($p < 0.001$)], ethnicity [NPAR, NLR, MLR ($p < 0.006$)], and sedentariness [MLR, PLR ($p < 0.039$)] were also associated with inflammatory markers. Poverty was significantly associated with NPAR, NLR, MLR, and CRP ($p < 0.018$). Food insecurity was significantly associated with NPAR ($p < 0.001$) and CRP ($p < 0.001$).
Discussion: Food insecurity and poverty were significantly associated with NPAR, a ratio implicated in overall poorer cancer health outcomes. Multiple inadequate micronutrient intakes and plasma biomarkers were associated with inflammatory panels, though neither nutritional biomarker nor food insecurity statuses and their contributions to inflammatory processes are routinely surveilled within cancer disease and treatment.

#2172 Associations between plant- and animal-based dietary patterns and aggressive prostate cancer in the North Carolina-Louisiana prostate cancer project (PCaP).

J. Sainyo[1], S. E. Steck[1], L. Zhao[2], L. J. Su[3], L. Arab[4], D. Turner[5], E. N. Butler[6], J. T. Bensen[6], E. T. Fontham[7], J. L. Mohler[8];
[1]University of South Carolina, Columbia, SC, [2]Harvard Medical School, Boston, MA, [3]University of Texas Southwestern Medical Center, Dallas, TX, [4]University of California Los Angeles, Los Angeles, CA, [5]Virginia Commonwealth University, Richmond, VA, [6]Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, [7]Louisiana State University Health Sciences Center, New Orleans, LA, [8]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Objective: Results of studies examining the association between a plant-based diet or animal food intake and prostate cancer have been mixed. Few studies have focused on aggressive prostate cancer in a racially diverse population. We examined the association between healthy and unhealthy plant-based and animal-based diet scores and aggressive prostate cancer in the North Carolina-Louisiana Prostate Cancer Project, a case-only study of Black and White men in the United States.
Methods: Eighteen food groups were created and classified as healthy plant foods, unhealthy plant foods, or animal foods using dietary data collected from an interviewer-administered modified version of the National Cancer Institute Diet History Questionnaire among 909 Black and 991 White men with a histologically confirmed diagnosis of prostate cancer. High aggressive prostate cancer (n=332) was defined as Gleason sum ≥8; or PSA> 20ng/ml; or Gleason sum ≥7 and clinical stage T3-T4, and the comparison group was all other prostate cancer cases (n=1,568). Logistic regression was used to determine the odds ratio (OR) and 95% confidence intervals (95% CI) for high aggressive prostate cancer by tertiles of dietary pattern scores.
Results: A decreased odds of aggressive prostate cancer was observed among men in the upper compared to the bottom tertile for healthy plant-based diet score (OR: 0.82, 95% CI: 0.58, 1.15) and unhealthy plant-based diet score (OR: 0.89, 95%CI: 0.63, 1.25) while an increased odds was observed comparing extreme tertiles of the animal-based diet score (OR: 1.17, 95% CI: 0.84-1.65) after adjustment for multiple covariates, though confidence intervals were imprecise and not statistically significant. Associations tended to be stronger among White men than among Black men; e.g., for the animal-based diet score, ORs (95% CIs) were 1.41 (0.86, 2.37) and 1.02 (0.63, 1.66) for White and Black men, respectively.
Conclusions: Consuming a plant-based dietary pattern may be associated with lower odds of aggressive prostate cancer while an animal-based dietary pattern may be associated with higher odds, though associations were weak and not statistically significant.
Keywords: Healthy plant-based diet, unhealthy plant-based diet, animal-based diet, aggressive prostate cancer, racial disparities
Conflict of interest: None
Funding: PCaP is carried out as a collaborative study supported by the Department of Defense contract DAMD 17-03-2-0052. #2173 Effect of colored fruits and vegetables intake on gastrointestinal cancer risk: A prospective cohort study.

Y. Cho, J. Lee, M. Gunathilake, J. Kim;
National Cancer Center - Korea, Goyang-si, Korea, Republic of

Background and Aim: Diverse antioxidant compounds found in colored fruits and vegetables have been linked to various health benefits. While anthocyanins, present in purple, red, and blue pigments, and chlorophyll, responsible for green pigments, are recognized for their antioxidant properties, limited evidence exists regarding their preventive effects on gastrointestinal (GI) cancers. In the year 2020, GI cancers constituted 29% of global cancer cases. To address this gap, this prospective cohort study investigates the association between the intake of colored fruits and vegetables and the risk of GI cancer in Korea.
Methods: The Cancer Screenee Cohort, comprising adults undergoing check-ups at the National Cancer Center Korea, was analyzed for GI cancer cases diagnosed between October 16, 2007, and December 31, 2020. Of the 10,741 eligible participants, 208 developed GI cancer and 10,533 did not. General and validated semi-quantitative food frequency questionnaires were used to collect demographic data and measure dietary intake. Fruit and vegetable intake (g/day) were categorized into four groups (white, green, orange/yellow, and red/purple) based on the color of the edible parts. Analyses were conducted on total fruits/vegetables, total fruits, total vegetables, and fruits/vegetables in each color category. The intake was divided into quintiles to compare the effects of low and high intake. Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CI). HRs were adjusted for variables, including age, gender, body mass index, smoking status, alcohol drinking, education, occupation, first-degree family history of any cancer, and marital status.
Results: High total fruit and vegetable intake was associated with reduced GI cancer risk (HR = 0.64, 95% CI: 0.42-0.98, *p* for trend = 0.022). No significant associations were found for total fruits, total vegetables, fruits and vegetables together and separately in green and orange/yellow colors in this study. However, a higher intake of white fruits and vegetables was found to be effective in preventing cancer with adjusted HRs (HR = 0.51, 95% CI: 0.31-0.85, *p* for trend = 0.019). Similarly, the inverse association was observed in red and purple vegetables with adjusted HRs (HR = 0.52, 95% CI: 0.32-0.84, *p* for trend = 0.022).
Conclusions: This cohort study suggests that the consumption of fruits and vegetables in white color, as well as vegetables in red and purple colors, may have a potential protective effect against GI cancer.
Key Words: Gastrointestinal (GI) cancer; fruits and vegetables; colors of fruits and vegetables; color food; cohort studies; Korea

#2174 Sample size estimations based on human microbiome temporal stability over six months: A shallow shotgun metagenome sequencing analysis.

S. Zouiouich[1], S. Karwa[1], Y. Wan[1], E. Vogtmann[1], C. Porras[2], C. C. Abnet[1], J. Shi[1], R. Sinha[1];
[1]National Cancer Institute, Rockville, MD, [2]Costa Rican Agency for Biomedical Research-INCIENSA Foundation, San Jose, Costa Rica

Introduction: Many biological factors can influence the human microbiome; thus, it is necessary to reasonably estimate sample size to have adequate power for future population-based studies.
Methods: We evaluated the temporal stability of fecal microbial diversity, species level composition, and genes and functional pathways based on shallow shotgun metagenome sequencing from a population-based study in Costa Rica with two fecal samples separated by an interval of six months. We quantified the biological variability over six months with intraclass correlation coefficients (ICC). We then estimated the numbers of cases, assuming 1:1 or 1:3 matched case-control study, required to detect an association at significance levels of 0.05 and 0.001 with 80% power, based on the number of fecal specimens collected per participant.
Results: For most alpha and beta diversity metrics, the temporal stability of fecal microbiome in samples collected at six months of interval was low to moderate, with ICCs of 0.6 or less. We observed heterogeneity in temporal stability for the proportions of species, genes and pathways, with ICCs varying between 0.0 and 0.9. For most microbiome measures from a single fecal collection, assuming an equal number of cases and controls at significance level of 0.05 (for alpha and beta diversity) or 0.001 (for species, genes and pathways), detecting an odds ratio of 1.5 per standard deviation of microbiome metric would require hundreds to thousands of cases. Specifically, detecting an association between alpha/beta diversity metrics and an outcome would require between 1,000-5,000 cases. In addition, for low prevalent species (5% - 10%, median ICC = 0.09), 15,102 cases would be required; in contrast, for species with high prevalence (>75%, median ICC = 0.41) 3,527 cases would be necessary; the same applies to genes and pathways. For an odds ratio of 1.5, assuming a 1:3 matched case-control study based on one fecal specimen per subject, 10,068 cases would be required for low prevalent species and 2,351 cases for species with high prevalence. Using the same study setting with multiple specimens per subject over time, the required sample size would be lower. Indeed, detecting an odds ratio of 1.5 for low prevalent species would require 15,102 cases with one specimen, 8,267 cases with two specimens, and 5,989 cases with three specimens.
Conclusion: Our calculations suggest that to detect modest disease associations we would need a substantial number of cases. Repeated prediagnostic samples could decrease the number of subjects required to detect these associations as well as matching cases to a great number of controls.

#2175 Multiple exposures to antibiotics and increased risk of colorectal cancer.

N. Jani, M. Richardson, K. Hogan, M. M. Pena;
University of South Carolina, Columbia, SC

Colorectal cancer (CRC) is the second leading cause of cancer related deaths in the United States and worldwide. In 2023, approximately 153,020 individuals will be diagnosed with CRC and 52,550 will die, including 19,550 cases and 3750 deaths in patients under 50 years of age. CRC in younger patients (less than 55 years) is known as early onset colorectal cancer (EOCRC). It is a growing global phenomenon whose incidence and mortality has incidence from 11% to 20% between 1995 to 2019 and is expected to increase by 140% by 2030. While it has been linked to known and established risks for CRC, the underlying causes and mechanisms are poorly understood. Based on our current knowledge of the disease, we propose that EOCRC results from exposure of children and young adults to exposome factors that have been increasing globally in the last four decades that may impact the microbiome causing dysbiosis and inflammation in the distal colon and rectum, the anatomical site of EOCRC. Among the likely factors is the use of antibiotics, particularly in infants and children. In this study we hypothesized that early life exposure to antibiotics causes dysbiosis and inflammation in the distal colon and rectum leading to increased mutations and epigenetic events that promote EOCRC development. Specifically, we examined the effect of the most commonly prescribed pediatric antibiotics on the gut microbiota and inflammatory environment in the colon, and their impact on tumor development upon exposure to a carcinogen. We treated A/J mice with multiples rounds of antibiotics and then exposed them to azoxymethane, a carcinogen to determine the effect on tumor development in the colon. The results showed that antibiotic exposure caused dysbiosis and inflammation in the colon of antibiotic treated mice as well as systemic inflammation in mice treated with antibiotics. Treatment with azoxymethane, a carcinogen in the presence of antibiotic-induced dysbiosis led to increased tumor burden in the distal colon. These results suggest a possible involvement of antibiotics on increased risk of EOCRC.

#2176 Differences in gut microbial composition alter pancreatic tumorigenesis.

R. M. Howell, J. Enriquez Ortiz, O. Le Roux, V. Chandra, L. Li, P. K. Bhattacharya, F. McAllister;
UT MD Anderson Cancer Center, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is predicted to become the second leading cause of cancer-related deaths by 2030, and currently has a 5-year survival rate of roughly 10%. With long-term survival rates in patients being exceedingly low, understanding what factors delineate survival is imperative. When comparing spontaneous transgenic mouse models of pancreatic cancer housed in geographically distinct vivaria, regardless of a common lineage, we observed drastically different phenotype states in the respective locations. We hypothesize that the gut microbiome results in different gene expression profiles, leading to alterations in pancreatic tumorigenesis. Using various sequencing techniques, including 16s rRNA and RNA sequencing of the gut, we identified unique signatures at these respective institutions. Subsequent fecal microbiota transplantation and single bacterial species colonization experiments were performed to evaluate the ability of microbiomes/specific microbiota to alter the rate of tumorigenesis. In addition to probing the gut microbiome, circulating metabolites from individual mice were quantified, and correlated to phenotype state. Following identification of potentially tumorigenic bacterially derived metabolites, single bacteria colonization experiments were utilized to determine the downstream effects of identified metabolites as well as the ability of directly altering the metabolic landscape to drive tumorigenesis. Additionally, murine derived pancreatic cancer cells were exposed to both identified bacteria alone or bacterially produced metabolite and analyzed by metrics such as proliferation and relative expression of transcription factors associated with cancer development *in vitro*. Taken together, these data demonstrate the ability of distinct gut microbiomes to directly alter the metabolic landscape in mice, thus differentially altering the progression of pancreatic lesions. By better understanding the factors that stratify survivorship, we can begin to employ clinically actionable methodologies in the treatment or prevention of pancreatic cancer.

#2177 Postbiotic metabolites secreted by L. acidophilus reduce DNA damage in an experimental model of Barrett's tumorigenesis.

D. Joshi, C. Andl;
University of Central Florida, Orlando, FL

The origins of esophageal adenocarcinoma (EAC) are commonly attributed to the progression from gastroesophageal reflux disease (GERD) to Barrett's Esophagus (BE) and finally to esophageal adenocarcinoma. During GERD, various types of bile induce oxidative stress and generate reactive oxygen species (ROS), resulting in DNA damage and inflammation in cells. Although there has been much research documenting the shift in the esophageal microbiome from gram-positive to gram-negative bacteria during this progression, there has also been an observed increase in the presence of Lactobacillus, a gram-positive commensal bacterium with probiotic qualities, in the esophagus during the progression from GERD to BE and eventually to EAC. Our previous research has demonstrated the ability of Lactobacillus spp. to not only colonize the esophagus under *in vitro* conditions of GERD, but also their anti-inflammatory and anti-genotoxic properties on esophageal cells exposed to bile. To assess the extent of reflux-induced DNA damage and oxidative stress during the progression of BE, we exposed two BE cell lines, CP-B and BAR-T, and the EAC cell line FLO-1 to ox bile or deoxycholic acid. Both bile types demonstrated significant increases in phosphorylated H2AX, as a marker for pronounced DNA damage repair. Next, we supplemented both live *L. acidophilus* and its postbiotic metabolites to cells exposed to ox bile and deoxycholic acid. We show a significant reduction in DNA damage as measured by pH2AX with both the live treatment and the treatment with postbiotic metabolites when compared to untreated, bile-exposed cells at various stages of BE and EAC. Ongoing experiments include assessing anti-genotoxic effects of postbiotic metabolites through DNA repair protein RAD51, reductions in oxidative stress though ROS marker 8-oxo-guanine, and anti-inflammatory effects through NFkB-associated inflammation. BE and EAC cell viability and proliferation upon bile exposure and postbiotic metabolite administration will also be assessed. This study aims to determine the supplementation with Lactobacillus postbiotic metabolites in the prevention and intervention of esophageal adenocarcinoma development.

#2178 Metagenomic analysis unveils the microbial landscape of pancreatic tumors.

S. Khan[1], G. Banerjee[2], S. Setua[3], A. Dhasmana[1], P. Banerjee[2], M. M. Yallapu[1], S. W. Behrman[4], S. Chauhan[1], D. H. Jones[5], B. Chauhan[1];
[1]University of Texas Rio Grande Valley, Edinburg, TX, [2]University of Illinois at Urbana-Champaign, Chicago, IL, [3]University of Maryland, Baltimore, MD, [4]Baptist Memorial Hospital and Medical Education, Memphis, TN, [5]University of Tennessee-Knoxville, Knoxville, TN

The composition of resident microbes in the human body is linked to various diseases and their treatment outcomes. Although studies have identified pancreatic ductal adenocarcinoma (PDAC) associated bacterial communities in the oral and gut samples, herein we hypothesize the prevalence of microbiota in pancreatic tumor tissues is different as compared to their matched adjacent, histologically normal appearing tissues and these microbial molecular signatures can be highly useful for PDAC diagnosis/prognosis. In this study, we performed comparative profiling of bacterial populations in pancreatic tumors and their respective adjacent normal tissues using 16S rRNA-based metagenomics analysis. This study revealed a higher abundance of Proteobacteria and Actinomycetota in tumor tissues compared to adjacent normal tissues. Interestingly, the Linear Discriminant Analysis (LDA) scores unambiguously revealed an enrichment of *Delftia* in tumor tissues, whereas *Sphingomonas, Streptococcus*, and *Citrobacter* exhibited depletion in tumor tissues. Furthermore, we analyzed the microbial composition between different groups of patients with different tumor differentiation stages. The bacterial genera, *Delftia* and *Staphylococcus* were very high in G1 stages (well differentiated) compared to G2 (well to moderate/moderately differentiated) and G3/G4 (poorly differentiated). However, the abundance of *Actinobacter* and *Cloacibacterium* was found to be very high in G2 and G3, respectively. Additionally, we evaluated the correlation of PD-L1 expression with the abundance of bacterial genera in tumor lesions. Our results indicated that three genus such as *Streptomyces, Cutibacterium*, and *Delftia* have a positive correlation with PD-L1 expression. Collectively, these findings demonstrate that PDAC lesions harbor relatively different microbiota compared to their normal tumor-adjacent tissues, and this information might be helpful for the diagnosis and prognosis of PADC patients.

#2179 Microbiome-derived metabolites mediate carcinogenic alterations of breast tissue in the context of obesity.

M. Gaber[1], K. Neary[1], J. Holmes[1], A. S. Wilson[1], A. J. Katz[2], P.-A. Vidi[3], K. L. Cook[1];
[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Wake Forest Baptist Health, Winston-Salem, NC, [3]Institut de Cancerologie de l'Ouest, Angers, France

Obesity increases the relative risk for breast cancer incidence. Multiple molecular mechanisms linked to obesity drive breast cancer progression. Obesity shifts the gut microbiome in ways that may increase breast cancer risk. Microbial-associated molecular pattern (MAMP)-proteins and metabolites could directly affect breast epithelial cell signaling. In this study, we focused on lipopolysaccharide (LPS), a structural component of the outer membranes of gram-negative bacteria and a toll-like receptor 4 (TLR4)-agonist. Systemic LPS levels are known to increase in obesity. We hypothesize that chronic low-grade inflammation caused by LPS contributes to breast cancer initiation. To test this hypothesis, we first quantified levels of LPS, along with a panel of adipokines/cytokines, in serum samples from women (n= 33; BMI range= 18.3-45.3 Kg/m^2; Age range= 18-51 years). Women with elevated serum LPS had significantly higher BMI, leptin, and leptin/adiponectin ratio, confirming a link between systemic LPS and metabolic markers of obesity. Other biomarkers of breast cancer risk include DNA damage. Analyses of non-cancerous breast tissue sections from matched donors revealed higher densities of DNA double-strand breaks (estimated based on 53BP1 foci counts) in women with high serum LPS. Experiments with HMT-3522 S1 breast acini showed that LPS increases DNA break frequencies and oxidative stress levels in 3D structures of mammary epithelium. Moreover, LPS increases oxidative lesions in the DNA (estimated based on 8-oxoguanine fluorescence in MCF-10A cells) that may lead to increased LPS-mediated DNA damage. Patient obesity status was associated with alterations in oxidative modifications in the breast proteome. We also found that LPS disrupts epithelial polarity, a hallmark of breast tissue homeostasis. In mammary epithelium, LPS activates the nuclear factor-kappa B (NFκB) pathway by binding to the TLR4 receptor, leading to an increased expression of inflammatory cytokines such as tumor necrosis factor-alpha (TNF-α). Interestingly, TLR4 blockade prevented the loss of apical polarity and DNA damage induced by LPS. Last, but not least, we show an association between LPS immunogenicity (anti-LPS IgA concentrations) and participant BMI in non-cancerous breast tissue samples. These novel findings show that LPS is a key systemic and local mediator of the obesity-modulated microbiome that increases breast cancer risk. The outcomes of our study underscore the importance of considering the microbiome in the prevention of breast cancer.

#2180 Modulation of immune infiltration patterns in inflammation-associated colorectal cancer through rice bran-based dietary strategies.

R. Kumar[1], L. Bugata[1], M. Kabir[1], R. Agarwal[2], E. P. Ryan[3], **K. Raina**[1];
[1]South Dakota State University, Brookings, SD, [2]University of Colorado Denver-Anschutz Medical Campus, Aurora, CO, [3]Colorado State University, Fort Collins, CO

The correlation between gut microbiota dysbiosis and inflammation-associated colorectal cancer (CRC) has generated considerable interest in dietary interventions targeting immune modulation. Our prior study demonstrated the colon cancer protective effects of rice bran (RB) and ex vivo Bifidobacterium longum fermented rice bran (FRB) diet intervention against azoxymethane/dextran sodium sulfate (AOM/DSS)-induced CRC in gut microbiota-intact specific pathogen-free mice (SPF). RB showed higher levels of protection compared to FRB against CRC, as evidenced by diminished neoplastic lesion size and restored colonic epithelial integrity. The major objective of the present study was to leverage cutting-edge multispectral imaging technique for simultaneous detection of multiple immune cells markers and for a comprehensive analysis of distinct immune landscapes. We also performed spatial correlations within the tumor microenvironment of AOM/DSS-SPF mice undergoing RB and FRB dietary interventions. The primary focus was on T cell subtypes including cytotoxic T cells, helper T cells, regulatory T (Treg) cells, natural killer (NK) cells, NKT cells, B cells and macrophages (MΦ) subtypes (M1 MΦ, and M2 MΦ) to uncover the intricacies of the immune landscape and the interplay for CRC prevention through dietary intervention. The results indicated that RB intervention for 15 weeks led to reductions in overall T cell subtypes in the colonic tissue, particularly Treg cells, which are associated with protecting tumors against immune surveillance in CRC. On the other hand, FRB intervention also resulted in reductions in overall T cell subtypes but exhibited higher infiltration of NK cells and proinflammatory M1 macrophages in the colonic tissue after 15 weeks. While an increased presence of NK cells might be beneficial in countering CRC, the infiltration of M1 macrophages could potentially lessen the impact of FRB compared to RB intervention in CRC protection. The outcomes suggest that the better protective efficacy of non-fermented RB diets is linked to the modulation of Treg cell infiltration, whereas the efficacy of the FRB diet is to some extent limited by the presence of M1 macrophages. Overall, this study provides valuable insights into the complex immune landscape influenced by RB and FRB interventions in a murine model of inflammation-induced CRC, and a novel mechanism for the immunomodulatory effects of dietary RB interactions with gut microbiota. In the future, observing immune modulation throughout diet intervention would enhance our understanding of the role played by these immune cells.

#2181 Endocrine-targeting therapies modify the breast microbiome to shift metabolism and reduce cancer risk.

A. Arnone[1], Y.-T. Tsai[1], J. M. Cline[1], A. S. Wilson[1], B. Westwood[1], M. E. Seger[1], A. Chiba[2], M. Howard-McNatt[1], E. A. Levine[1], A. Thomas[1], D. R. Soto-Pantoja[1], K. L. Cook[1];

[1]Wake Forest School of Medicine, Winston-Salem, NC, [2]Duke University School of Medicine, Durham, NC

Studies indicate that breast tissue has a distinct modifiable microbiome population. However, whether endocrine-targeting therapies modify the non-cancerous breast microbiome to impact tumorigenesis is unknown. To examine this question, we performed 16S bacterial sequencing on DNA isolated from female C57BL/6 mouse mammary glands (MG) administered tamoxifen citrate for 16 weeks and breast tissue from ovariectomized non-human primates administered tamoxifen citrate (TAM) for 2.5 years. In both models, we show that TAM significantly shifted β-diversity and increased Firmicutes proportional abundance. TAM elevated the proportional abundance of *Lactobacillus spp.*, *Streptococcus luticea*, and *Staphylococcus sciuri*. Female BALB/c mice received intra-nipple injections of *Lactobacillus* and MG were harvested at 1-, 3-, 7-, and 14-days post-injection to show bacteria colonization and modulation of metabolism-associated gene and protein expression. B6.MMTV-PyMT mice were injected with *Lactobacillus* bacteria into the MG. Elevating MG *Lactobacillus* reduced tumorigenesis with an associated decrease in tumor proliferation and shifts in non-cancerous MG tissue metabolism. To elucidate the effects of combining TAM and probiotic bacteria on breast cancer outcomes, 4T1.2ER+ tumor-bearing female BALB/c mice, fed either a control or Western diet were treated with TAM, *Lactobacillus* probiotic, or a combination of TAM + *Lactobacillus*. Results indicate that oral probiotic administration in combination with TAM reduced ER+ tumor growth. Plasma metabolomics revealed combination treatment elevated L-carnitine regardless of diet, suggesting drug-bug interactions modifying metabolite profiles. Cell viability assays on human MCF7 BC cells and non-cancerous mammary HMT-3522S1 cells treated with 1% probiotic-conditioned media (Pro-CM) revealed a significant decrease in cell viability in BC cells but not non-cancerous epithelial cells. Mitochondrial fuel oxidation Seahorse assay on murine 4T1.2ER+ cells treated with 1% Pro-CM, 1µm 4-hydroxytamoxifen (4-OHT) or combination revealed changes in metabolic substrate dependency, supporting role of microbial metabolites impacting metabolism. Tumor sections from patients with ER+ BC treated with aromatase inhibitors and/or Faslodex in the neoadjuvant setting were stained for Gram-positive bacteria, Gram-negative bacteria, and Ki67. Gram-positive bacteria negatively correlated with Ki67 immunoreactivity, suggesting endocrine-targeting therapies promote tumor Gram-positive bacteria associated with a decrease in proliferation. Taken together, our data indicates that endocrine-targeting treatments modify the breast microbiome associated with a shift in tissue metabolism to decrease proliferation and reduce ER+ BC risk.

#2182 15-lipoxygenase-1 modulation of colonic resolvin production to suppress colorectal carcinogenesis.

X. Zuo[1], Y. Kiyasu[2], Y. Liu[1], M. Moussalli[2], B. Wei[1], P. Yang[1], I. Shureiqi[2];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Michigan Rogel Cancer Center, Ann Arbor, MI

Docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) are widely used dietary supplements and FDA-approved treatments. The reported impacts of fish oil, DHA, and EPA on colorectal carcinogenesis (CRC) have spurred debates, as certain studies suggest promotional effects while numerous others emphasize suppressive effects. Nevertheless, resolvins, oxidative metabolites of EPA and DHA, exhibit the ability to inhibit crucial pathways (such as TNF-α and IL-1β) that contribute to CRC. 15-lipoxygenase-1 (ALOX15) plays a crucial role in the oxidative metabolism of DHA and EPA, ultimately leading to the formation of resolvins. However, ALOX15 expression is commonly lost during human CRC. Whether loss of ALOX15 expression modulates the effects of DHA and EPA on CRC remains to be elucidated. We therefore conducted the experiments in preclinical CRC mouse models induced by Azoxymethane or *Apc* gene mutation to explore the hypothesis that ALOX15 expression in colonic epithelial cells regulates DHA and EPA metabolism to generate resolvins, subsequently influencing CRC outcomes. We found that 1) DHA and EPA exert differential effects on CRC, which can be further modified by factors such as their formulation (e.g., ethyl ester versus triglyceride); 2) targeted transgenic expression of ALOX15 in the intestines of mice (referred to as ALOX15-Gut mice) markedly augmented the production of resolvins and concurrently suppressed CRC; 3) the predominant products from the expressed ALOX15 enzymatic activity were identified as 17-HDHA and resolvin D5; and 4) the effects ALOX15 on increasing resolvin generation and suppressing CRC were consistent across various promoters used to drive ALOX15 transgenic expression in mice. These findings collectively underscore the profound importance of ALOX15 intestinal expression as a host-related factor in resolvin generation from EPA and DHA, which subsequently contributes to the suppression of CRC.

#2183 Immunomodulation by oxaliplatin is affected by the mycotoxin food contaminants alternariol and deoxynivalenol in opposite directions.

S. Hager[1], J. Gufler[1], W. Berger[2], P. Heffeter[2], D. Marko[1];
[1]University of Vienna, Vienna, Austria, [2]Medical University of Vienna, Vienna, Austria

Our diet does not only impact our risk for cancer, but might also affect the outcome of anti-cancer therapies. While interaction of natural food constituents or supplements with anticancer therapies are frequently investigated, studies on how food contaminants, such as mycotoxins, interfere with anticancer drugs is rare or lacking, despite the rise of mycotoxin occurrence in food worldwide. As the importance of the immune system during anticancer therapies is now well known, especially mycotoxins with immunomodulatory activity, such as alternariol (AOH) or deoxynivalenol (DON), which were reported as immunosuppressive and immunostimulatory, respectively, are of great concern. Thus, the aim of this study was to investigate possible disadvantageous or beneficial interactions of the mycotoxins AOH or DON with the clinically routinely-used oxaliplatin, a known stimulator of the anticancer immune response as well as immunogenic cell death inducer. Effects of the mycotoxin-oxaliplatin combinations on cell viability of different colon carcinoma cell models were analyzed via CellTiter Blue, showing a mostly additive increase of anticancer activity with both mycotoxins. As the immune system was reported to play an important role in the anticancer activity of oxaliplatin, the combined influence of mycotoxins and anticancer therapies on immune cell stimulation was analyzed. To that end, monocytic THP-1 Lucia NF-κB reporter cells were utilized and their activation, differentiation and polarization was monitored during combinatorial treatment, via luminescence, flow cytometry and qPCR, respectively. In line with its more immunostimulatory activities, oxaliplatin alone activated NF-κB signaling in monocytic THP-1 cells. However, this increase in signaling was significantly suppressed in combination with AOH, while DON further enhanced the activation significantly. In line, during polarization of THP-1 macrophages to pro- (M1) or anti-inflammatory (M2) mediators, oxaliplatin strongly induced M1 markers (IL-8, TNF-α and COX-2) on mRNA level, not altering the NF-κB activity but partly downregulating M2 marker IL-10. This M1 stimulation was potentiated in the combination with DON, whereas AOH stimulated M2 marker expression. In conclusion, AOH was able to suppress the immunostimulatory potential of oxaliplatin, whereas DON enhanced it. Consequently, mycotoxins might affect the outcome of especially immunologically-active therapies. This should not only be considered in future risk assessment of food contaminants, but might also be a chance to fine-tune the anticancer immune response.

#2184 A high-fat diet accelerates early-stage murine pancreatic carcinogenesis by influencing, in part, mesenteric adipose tissue metabolism.

A. Ead, J. Wirkus, G. G. Mackenzie;
UC Davis, Davis, CA

Increased adiposity represents a modifiable risk factor of pancreatic cancer. Multiple preclinical studies have shown that a high-fat and high-sugar diets on the acceleration of pancreatic carcinogenesis, in the context of obesity. However, the impact of diets resembling the omega-6 to omega-3 fatty acid (FA) ratio in a Western-style diet, remains unclear. Furthermore, the role of the mesenteric adipose tissue (MAT) in pancreatic carcinogenesis is poorly characterized. Thus, we aimed to determine the impact of a high-fat diet with a ratio of 9 parts omega-6 FA to each omega-3 FA, on early stages of pancreatic carcinogenesis in a genetically engineered LSL- KrasLSL-G12D; Ptf1aCre/+ (KC) model of pancreatic cancer, with an emphasis on evaluating the contribution of the MAT within the pancreatic microenvironment. For this purpose, cohorts of male and female KC mice (6-8 males and females per diet group) were randomly assigned to either a control diet (CD) group (9:1 of omega-6 FAs to omega-3 FAs) or a high-fat diet (HFD) group (9:1 of omega-6 FAs to omega-3 FAs) and fed their respective diets until three months of age. After eight weeks on their diets, HFD-fed mice had significantly increased body weight, fat mass, and elevated serum leptin levels. Furthermore, HFD-fed mice had increased acinar-to-ductal metaplasia, associated with increased PCNA expression, ERK and STAT3 phosphorylation and elevated pro-tumorigenic immune cell expression compared to CD-fed mice. Although no significant differences in MAT weight or adipocyte size were observed after 8 weeks between the groups, metabolomics analysis of the MAT revealed that HFD-fed mice had significant upregulation of many key metabolites linked to proliferative and inflammatory pathways. For instance, HFD-fed female KC mice had significant differences in α-linolenic acid metabolism and the biosynthesis of unsaturated fatty acids, while male mice had significant differences in arginine biosynthesis, amino acid metabolism, linoleic acid metabolism, and α-linolenic acid metabolism. HFD-fed female mice had a significant increase in α-linolenic acid and linoleic acid in MAT, concurrent with a reduction in inosine 5-monophosphate and α-tocopherol compared to female CD-fed mice. HFD-fed male mice displayed a more pronounced difference in metabolites, including an increase in α-linolenic acid, linoleic acid, malic acid, glutamine, isoleucine, and several other amino acids, with a concurrent reduction in lauric acid and palmitoleic acid compared to male CD-fed mice. In summary, a HFD accelerates pancreatic carcinogenesis through multifaceted mechanisms, including effects on the tumor and surrounding adipose depots. A HFD increases affects MAT metabolism in a sex-dependent manner, that might ultimately promote early-stage progression of pancreatic carcinogenesis.

#2185 Mechanism of antitumor effects of saffron in human prostate cancer cells.

M. Khan[1], **K. Hearn**[1], C. Parry,[1], M. Rashid[1], H. Brim[1], H. Ashktorab[2], B. Kwabi-Addo[1];
[1]Howard University, Washington, DC, [2]Howard University, Bethesda, MD

Prostate cancer is the most common malignancy in men in the USA and the second leading cause of cancer deaths. Several studies have suggested the antitumor properties of saffron in many types of cancers including prostate. The objective of this study was to carry out in vitro studies of saffron-treated prostate cancer cells to ascertain the effects of saffron on key intermediates in prostate carcinogenesis. Our studies demonstrate significant inhibition of cell proliferation of androgen-sensitive prostate cancer cell lines via apoptotic pathways. We also demonstrate statistically significant down-regulation of DNA methyltransferase; COMT, MGMT, EHMT2, and SIRT1 in saffron-treated prostate cancer cells. In addition, saffron-treated prostate cancer cells displayed statistically significant dysregulation of DNA repair intermediates; WRN, p53, RECQ5, MST1R, and WDR70 in a time-dependent manner. Furthermore, Western blot analysis demonstrated that saffron treatment induced changes in the expression of other key genes; DNMT1, DNMT3b, MBD2, CD44, HDAC3, c-Myc, NF-kB, TNFα, AR, N-RAS and PTEN in prostate cancer cells. Collectively, our findings demonstrate important mechanistic targets of saffron mediating anti-tumor properties in prostate cancer. These findings suggest that the use of saffron supplements alongside standard treatment protocols may yield beneficial effects for individuals with prostate cancer.

#2186 Bacterial lung cancer therapeutics from soil bacteria in New York City.

D. Deb, T. Danino;
Columbia University, New York, NY

The microbiome's diverse functions in human health have generated increasing interest in using live bacteria for cancer therapy. Due to their natural presence in colon, lung and breast tissue, bacterial therapies have been augmented using synthetic biology in order to treat infections, inflammation, and cancer. One major challenge is finding safe and effective host species and therapeutic payloads for a particular type of cancer. Here we explored the vast diversity of microbial isolates in the environment as a valuable source of novel therapeutic compounds that can be expressed by bacteria. Specifically, we isolated and identified soil bacteria from 25 local parks, and investigated their secreted compounds for anti-cancer activity using monolayer and 3D-spheroid cultures of lung cancer. Through metagenomic analysis, toxicology assays, varied growth conditions, and bacteria-cancer co-culture experiments, we found *Bacillus spp.* isolates from Manhattan parks' soil that secreted products with high, dose-dependent cytotoxicity against lung cancer models. We also demonstrate that *Bacillus subtilis*, a model organism for gram-positive bacteria, can colonize lung cancer tumor spheroids, pointing to its use as a viable strain for bacteria cancer therapy. The work presented here underscores the potential of harnessing environmental microbial diversity for the development of gram positive species and their compounds as cancer therapeutics.

#2187 Influences of high-fat diet on tumor biology in a mouse model of colorectal cancer.

A. Mahanty, **C. Wallingford**, R. Hammontree, M. Njoka, Z. Clark, M. Rekowski, M. Washburn, J. S. Davis;
University of Kansas Cancer Center, Kansas City, KS

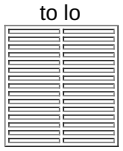
Purpose: To test the influence of high-fat diet on tumor biology in the inducible *Kras*, *Apc* and *p53* (iKAP) model (Boutin, et al *Genes & Development* 2017, 31:370).

Methods: At weening, both male and female mice were fed either a high-fat (60%) or low-fat (10%) diet for 5-6 weeks prior to tumor induction. Mutant *Kras* expression was controlled using a tet-on system. Expression of mutant *Kras* was activated by the addition of doxycycline hyclate in the drinking water. Tumor growth was monitored by bi-weekly endoscopy and calculated as percent luminal occlusion. Tumor biology was assessed with proteomics and phospho-proteomics with comparisons by sex and diet.

Results: In the absence of mutant *Kras* expression (no doxycycline in drinking water), tumors were larger in females on high-fat diet compared to low-fat diet. Tumor sizes were not significantly different in males or in the presence of mutant *Kras* expression. Proteomics analyses of tumor tissue identified significantly different patterns by diet in female mice, including altered levels of KIF4, DAB2iP, JNK cascade and JUN kinase activity (Table).

Conclusion: Based on our preliminary data, high-fat diet may alter tumor kinase activities, even in a genetically engineered mouse model. Replication and validation studies are ongoing.

Table of significantly upregulated biologic processes in female mice on high-fat diet compared to lo



#2188 Tirzepatide treatment restores antitumor immunity in a model of obesity-driven cancer.

M. F. Coleman, E. M. Glenny, T. L. McFarlane, H. M. Malian, C. E. Gates, F. Chen, A. N. Ho, V. A. Kiesel, S. D. Hursting;
UNC Chapel Hill, Chapel Hill, NC

Obesity is a widely and increasingly prevalent disease and a risk factor for several cancers. Recent work has shown that weight loss following bariatric surgery is potently protective against obesity-associated cancers. However, little is known about the potential anticancer effects of weight loss achieved through incretin-based therapies. We therefore interrogated the effects of the dual glucagon-like peptide 1 and glucose-dependent insulinotropic polypeptide receptor agonist tirzepatide (TZP) on body weight and tumor progression in a mouse model of obesity and transplanted colon cancer cells. Moreover, we tested whether TZP-mediated weight loss can reverse obesity-associated suppression of CD8+ T cell immunity. Male C57BL/6J mice were fed either 60 kcal% fat diet (D12492) or a sucrose-matched 10 kcal% fat diet (D12450J) for ≥15 weeks to generate diet induced obese (DIO) or control mice, respectively. Once DIO mice reached a body weight of 47 g they were randomized to begin TZP treatment or receive a vehicle control every other day for 3 weeks (when stable body weights were reached for TZP mice). All mice then received subcutaneous injections with $2.5x10^5$ MC38 cells and continued to receive TZP or vehicle. To determine the role of CD8+ T cell mediated tumor control in driving the effects of TZP treatment, mice received either CD8-depleting antibodies or an isotype control at days -2, 0, 2 relative to tumor cell injection and subsequently every 4 days. Tumor mass was determined by digital scale. Fasting blood glucose, body weight loss, and body composition were monitored to determine the metabolic effects of TZP. Immune cell populations were measured by full spectrum flow cytometry. We found TZP reduced body weight, fasting blood glucose, and adiposity relative to DIO mice, as was expected. These metabolic improvements were accompanied by reduction of tumor mass in TZP mice relative to DIO mice. DIO mice had increased levels of exhausted T cells which were normalized by TZP treatment. Depletion of CD8+ cells did not alter the tumor mass of DIO mice, indicating negligible CD8+ T cell-mediated tumor control. In contrast, CD8+ cell depletion in control and TZP mice increased in tumor masses to the levels comparable to those of DIO mice. These results demonstrate that TZP can mitigate obesity-associated acceleration of tumor growth and restore markers of effective antitumor T cell immunity. Critically, we find that restoration of CD8+ T cell function is essential for TZP's ability to limit tumor growth in DIO mice. Taken together, these results demonstrate that the metabolic improvements achieved by TZP treatment are accompanied by mitigation of obesity-driven immunosuppression. These findings shed important light on the potential for TZP and other incretin-based therapies to limit obesity-associated cancer progression, and are especially timely given the growing population of patients utilizing incretin-based therapies.

#2189 Tirzepatide mitigates obesity-associated metabolic dysregulation and tumor progression in a mouse model of triple-negative breast cancer.

E. M. Glenny, A. N. Ho, V. A. Kiesel, F. Chen, C. E. Gates, E. M. Paules, R. Xu, C. Holt, M. F. Coleman, S. D. Hursting;
University of North Carolina at Chapel Hill, Chapel Hill, NC

Obesity is an established risk factor for breast cancer. Dietary and surgical weight loss interventions reduce breast cancer risk but have significant limitations to their widespread use as anticancer strategies. Incretin-based pharmaceuticals safely and effectively promote weight loss, but whether these drugs exert similar protective effects against cancer is unknown. Here we test whether weight loss induced by the glucagon-like peptide 1 (GLP-1)/glucose-dependent insulinotropic polypeptide (GIP) receptor agonist tirzepatide limits tumor growth in an orthotopic mouse model of triple-negative breast cancer. Ten-week-old female C57BL/6NCrl mice were randomized to either a 10 kcal% low-fat diet (control; n=14) or 60 kcal% high-fat diet to promote diet-induced obesity (DIO; n=43). After 18 weeks on diet, DIO mice were randomized by body weight to either i) remain on the high-fat diet (DIO; n=15); ii) lose weight with tirzepatide (TZP; n=13); or iii) lose weight with 30% daily calorie restriction relative to control mice (CR; n=15). All mice were subcutaneously injected with either TZP or vehicle every other day for 13 weeks with the following escalating dosing schedule: 3 nmol/kg TZP in week 1; 10 nmol/kg TZP in weeks 2-3; 20 nmol/kg TZP in weeks 4-7; 30 nmol/kg TZP in weeks 8-11; and 40 nmol/kg TZP in weeks 12-13. Fasting blood glucose and body composition was assessed after 9 weeks of weight loss, and 35,000 E0771 cells were orthotopically transplanted into the 4th mammary fat pad. Tumors growth was monitored for 4 weeks. TZP-treated mice lost on average >20% weight loss by week 4 and remained at or below 20% weight loss for the remainder of the study. Directly prior to E0771 tumor cell injections, TZP-treated mice had lost 23.6±8.9% body weight, versus 39.7±3.6% in CR mice. Relative to DIO mice, blood glucose control was restored in both weight loss groups (DIO: 149.5±18.5 mg/dl; TZP: 124.5±15.5 mg/dl; CR: 107.6±18.8 mg/dl) and >87.5% of the lost weight was attributed to fat mass, rather than lean mass, for TZP-treated and CR mice. Notably, tirzepatide suppressed tumor growth relative to DIO, but the CR group had a greater anticancer effect than TZP. Reduced tumor mass in both weight loss groups was accompanied by a significant reduction in circulating IGF-1, insulin, and leptin relative to DIO mice. These findings are timely and important because i) obesity is a highly prevalent metabolic disease that increases risk and progression of breast cancer and >13 other cancers; ii) incretin therapies, which show promise as highly effective weight loss drugs, are increasingly being prescribed; and iii) the tumor suppressive effects of tirzepatide described herein newly suggest incretin agonism as another propitious option for breaking the obesity-cancer link.

#2190 Transcriptomic signatures of obesity-driven colon cancer: A multi-species transdisciplinary approach.

E. M. Glenny[1], T. Lin[2], V. M. Bandera[2], B. Gigic[3], A. Tan[2], B. Mirminachi[4], S. S. Khumukcham[4], A. Carpanese[4], C. A. Warby[2], O. Aksonova[2], C. Himbert[5], J. Ose[2], C. Stubben[6], D. Nix[6], K. Boucher[2], P. Schirmacher[3], I. Strehli[2], J. Jedrzkiewicz[6], A. Brobeil[3], M. A. Schneider[3], C. Kahlert[3], E. M. Siegel[7], A. T. Toriola[8], D. Shibata[9], C. I. Li[10], J. C. Figueiredo[11], J. Roper[4], C. M. Ulrich[2], S. D. Hursting[1];

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Utah, Salt Lake City, UT, [3]Heidelberg University Hospital, Heidelberg, Germany, [4]Duke University, Durham, NC, [5]Harvard T.H. Chan School of Public Health, Boston, MA, [6]Huntsman Cancer Institute, Salt Lake City, UT, [7]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [8]Washington University, St. Louis, MO, [9]University of Tennessee, Memphis, TN, [10]Fred Hutchinson Cancer Research Center, Seattle, WA, [11]Cedars-Sinai Medical Center, Los Angeles, CA

Obesity is a highly prevalent metabolic disease and an established risk factor for colon cancer. However, critical biological pathways underpinning this relationship remain undetermined. Herein, we integrate human and murine colon tumor transcriptomic data to identify obesity-responsive pathways conserved between species. Human colon cancer samples (n=155) were collected as part of the clinical ColoCare Study, a prospective cohort study of patients newly diagnosed with colorectal cancer. Enrolled patients were diagnosed with stage I-III colon cancer and treatment naïve at time of tissue collection. Patients were classified as having a BMI <30 kg/m^2 (i.e., non-obese) or BMI ≥30 kg/m^2 (i.e., obese) at baseline. Age, sex, tumor stage, and collection site were adjusted for in all analyses. Patients were 63.3 ± 13.7 years, 51% male, and 34% had a BMI ≥30. C57BL/6J adult female mice were fed a low-fat control diet (Research Diets D12450J, n= 8) or a high-fat diet-induced obesity regimen (D12492, n=7) for ~23 weeks, at which time 700 *Apc-null;KrasG12D/+;Trp53-null;Smad4-null;tdTomato* (i.e., AKPS) organoids were orthotopically transplanted into the colonic submucosa via colonoscopy-guided injection. Obese mice weighed more than controls (controls 26.4 ± 3.7 g *vs.* DIO 45.9 ± 9.7 g) and had more mesenteric fat surrounding the colon (controls 201 ± 143 mg *vs.* 1176 ± 589 mg). Tumors were excised after 4 weeks of growth. RNA was extracted from bulk human tumor samples and from the epithelial-enriched EpCAM+ cell population in murine tumor samples for RNA sequencing. Genes differentially expressed between the reference and obese groups were identified using DESeq2. For gene set enrichment analysis, genes were preranked by log2 fold change for both human and mouse datasets. There were 76 and 132 differentially expressed genes (DEGs; FDRq<0.10) identified in the human and mouse datasets, respectively. None of these 208 DEGs were common to both datasets. Thirty-five Hallmark gene sets in the human dataset and 25 Hallmark gene sets in the mouse dataset were significantly enriched in the obese group; 18 of these gene sets were common to both mouse and human datasets. These overlapping pathways were largely related to inflammation (e.g., inflammatory response, IL6 JAK STAT3 signaling, TNFα signaling) and metabolism (e.g., cholesterol homeostasis, glycolysis, and fatty acid metabolism). Additional analysis revealed 204 genes common between the leading edges of both transcriptomic datasets. These transdisciplinary data suggest that obesity induces a set of metabolic and inflammatory processes and/or pathways in colon tumors which is conserved between mice and humans. Future studies will mechanistically evaluate the role of candidate genes and pathways in obesity-associated colorectal carcinogenesis in our AKPS orthotopic organoid transplant mouse model.

#2194 Association of metabolic syndrome conditions with risk of second primary cancer of any organ in breast cancer survivors.

A. Mukherjee[1], Z. Gu[1], L. Chen[1], A. Potosky[2], R. Haque[1];
[1]Kaiser Permanente - Southern California, Pasadena, CA, [2]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington DC, DC

Purpose: Breast cancer survivors are at increased risk of developing second primary cancers; however, factors attributing to increased risk of second primary cancer in breast cancer survivors are under-studied. We evaluated the association of metabolic syndrome conditions with second primary cancer of any organ in breast cancer survivors.
Methods: In this retrospective cohort study, we included 37,222 patients diagnosed with breast cancer between 2008-2020 at Kaiser Permanente Southern California (KPSC), an integrated healthcare system. We extracted data on cancer-related variables, sociodemographic and clinical variables from KPSC's cancer registry and electronic health records. Among the metabolic conditions, we identified diabetes, hypertension, and dyslipidemia using ICD-10 diagnosis codes at or 1-year prior to breast cancer diagnosis; obesity was based on body mass index (BMI≥30kg/m^2). We included metabolic syndrome as a categorical variable: 0, 1-2, and 3+ metabolic conditions. We followed patients electronically from breast cancer diagnosis until patients developed second primary cancer of any organ, died, disenrolled from the health plan, or reached study's end (12/31/2021), whichever occurred first. Proportional hazards regression was used to report association [HR (95%CI)] between metabolic conditions and any second primary cancer.
Results: During a median (IQR) follow-up of 5.17 (2.75-8.58) years, 1701 (4.6%) patients developed any second primary cancer. More than half (53.1%) of the breast cancer survivors had 1-2 metabolic conditions at baseline; 19.4% had 3+ metabolic conditions, and the rest 27.5% did not have any metabolic condition. Hypertension was the most common metabolic condition (45.5%), followed by obesity (38.9%), dyslipidemia (36.5%), and diabetes (19.0%). Survivors with 0 and 1-2 metabolic conditions were 35% and 19% less likely to develop any second primary cancer than survivors with 3+ metabolic conditions, respectively [crude HR (95%CI): 0.65 (0.57-0.75) and 0.81 (0.72-0.91), respectively]. Reduced risk in survivors with 1-2 metabolic conditions persisted adjusting for age, race and ethnicity, breast cancer diagnosis year, breast tumor SEER summary stage, breast tumor estrogen-progesterone status, smoking status, and breast tumor treatment [adjusted HR (95%CI): 0.87 (0.77-0.99)].
Conclusion: Risk of second primary cancer of any organ was elevated in breast cancer survivors with three or more metabolic conditions.

#2195 Intrauterine device use and risk of invasive epithelial ovarian cancer: A population-based case-control study.

Minh Tung Phung[1], Yuting Wang[2], Alice W. Lee[3], Malcolm C. Pike[4], Anna H. Wu[5], Celeste Leigh Pearce[1]

[1]University of Michigan, Ann Arbor, MI,[2]Dartmouth College, Hanover, NH,[3]California State University, Fullerton, Fullerton, CA,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]University of Southern California, Los Angeles, NY

Introduction: Ovarian, fallopian tube, and primary peritoneal cancers (hereafter referred to as ovarian cancer) are the most fatal gynecologic cancers. Thus, it is imperative to identify strategies that can reduce the risk of the disease. Several contraceptive methods have been shown to be associated with a reduced risk of ovarian cancer, including combined oral contraceptives, injectable progestins, and tubal ligation. However, the use of these contraceptive methods has been decreasing in the U.S., with a growing preference for intrauterine devices (IUDs) for pregnancy prevention. Previous case-control studies on the association between IUD use and ovarian cancer risk have found inconsistent results. Notably, previous studies had small sample sizes and did not restrict to invasive epithelial tumors. The current analysis assessed the association between IUD use and risk of invasive epithelial ovarian cancer in a large population-based case-control study.

Methods: This analysis used data from 1,713 people diagnosed with primary invasive epithelial ovarian cancer (cases) and 2,348 cancer-free people (controls) participating in a case-control study conducted in Los Angeles, CA from 1992-2010. The study consisted of four waves of recruitment with similar enrollment and data collection methods. Logistic regression models were fit to assess the association between IUD use and risk of invasive epithelial ovarian cancer. All models were adjusted for age, race/ethnicity, education, first-degree family history of ovarian cancer, endometriosis, body mass index, duration of combined oral contraceptive use, parity, duration of breastfeeding, tubal ligation, and study wave. Heterogeneity across the study waves and the ovarian cancer histotypes was evaluated using standard meta-analysis techniques.

Results: There was no statistically significant association between IUD use and risk of invasive epithelial ovarian cancer (odds ratio=1.09, 95% confidence interval 0.93-1.28). This result was consistent across the study waves and the ovarian cancer histotypes (p-values for heterogeneity>0.05).

Conclusion: IUD use was not associated with the risk of invasive epithelial ovarian cancer. Analysis by IUD type (i.e., hormone-releasing vs copper IUDs) was not possible in this study as these data were not collected. Future research should examine whether the type of IUD (i.e. copper versus hormone-releasing) may have different effects on risk of ovarian cancer.

#2196 Susceptibility to tobacco use among rural adolescents: Examining the role of tobacco marketing exposure and media use intensity.

S. J. Kim[1], K. Fugate-Laus[1], J. Barsell[1], E. K. Do[2], R. Hayes[1], D. Wheeler[1], B. Fuemmeler[1];
[1]Virginia Commonwealth University - VCU, Richmond, VA, [2]Truth Initiative Schroeder Institute, Washington, DC

Background: Rural youth have higher rates of electronic nicotine delivery systems (ENDS) and tobacco product use compared to their urban counterparts. Prior literature confirms that marketing exposure increases pro-tobacco attitudes and susceptibilities, yet the extent to which tobacco product marketing and advertising messages relate to tobacco use susceptibility among rural adolescents is understudied.
Objectives: To examine the association between tobacco marketing exposure and susceptibility to tobacco use and ever tobacco use among a population of rural youth.
Methods: Youth (aged 14-18 years), enrolled in grades 9-11, able to speak and write in English, and residing in rural counties in Virginia (n = 697) were recruited to participate in the Southern Virginia - Adolescents, Place, and Behavior study. At baseline, eligible participants were asked to answer survey questions, including demographics (e.g., age, race/ethnicity, and gender), tobacco product (e.g., e-cigarettes/vapes, cigarettes, and cigars), tobacco use susceptibility (e.g., “do you think you will try any type of tobacco product in the next year?”), digital media use (e.g., “how many hours do you spend visiting social networking sites on both a typical weekday and a typical weekend day?"), and interaction and exposure to tobacco advertisements.
Results: The majority of participants were female (51.9%), White (62.4%) and non-Hispanic (86.6%), with an average age of 15.1 years old (*SD* = .96). Less than a quarter (20.7%) of participants reported ever using any tobacco products. Heavy social media users and text users were more likely to be tobacco ever-users than those who were light social media users, $X^2(1) = 12.00$, $p < .001$. Multivariate logistic regression models report that exposure to online ads promoting tobacco products (OR: 2.03, 95% CI [1.37 - 3.03]) and higher grade level (OR: 1.77, 95% CI [1.29 - 2.43]) were significantly associated with the likelihood of ever using tobacco products, while controlling for mother’s education, gender, and ethnicity. Among adolescents who never used tobacco products, higher grade levels (OR: 1.40, 95% CI [1.05 - 1.86]) were associated with greater susceptibility to initiating tobacco product use while controlling for the covariates.
Conclusions: Greater social media use and exposure to ads promoting tobacco products were significantly associated with tobacco ever use. For never tobacco users, social media use or tobacco ad exposure was not associated with greater susceptibility to tobacco use. Higher grade levels were associated with both tobacco ever use and greater susceptibility to tobacco product use. Identification of these risk factors may help inform potential targets for future tobacco prevention campaigns.

#2197 Weight history and colorectal cancer risk in the Cancer Prevention Study-3 cohort.

C. Y. Um[1], C. C. Newton[1], A. Parikh[2], M. L. McCullough[1], A. V. Patel[1];
[1]American Cancer Society, Atlanta, GA, [2]Massachusetts General Hospital Cancer Center, Boston, MA

While the link between obesity and colorectal carcinogenesis is established, limited evidence suggests that early-life overweight/obesity may be an important consideration, particularly in the development of early-onset colorectal cancer (CRC). Using data from the American Cancer Society's Cancer Prevention Study-3 (CPS-3), we investigated the association of body weight across the life course and risk of CRC.

From 2006-13, over 300,000 participants (ages 30-65) enrolled in the CPS-3 cohort and provided a baseline waist circumference (WC) measure, self-reported baseline weight and height, weight at age 18, and weight at each decade of adulthood (20s to current age). Body shape phenotype (apple, pear, other) was self-reported in 2015. Excess body mass index (BMI)-years was calculated by subtracting a reference BMI of 25 from the reported BMI for each decade of life and aggregating excess BMI for the reported years of life. Through 2018, 424 incident cases of colorectal cancer were reported, of which 94 were younger than 50 years. Associations of BMI measures and WC with incident CRC were estimated using multivariable-adjusted Cox proportional hazards regression and stratified by sex and body shape.

After exclusions (n=248,804), 78% of participants were women, 85% were non-Hispanic white, 69% were never smokers, and 8% had a family history of CRC. The mean baseline age was 47.8 (women) and 48.5 (men) years. The mean baseline BMI, WC, and age 18 BMI were 27.6 kg/m^2, 91.9 cm, and 21.7 kg/m^2, respectively, among women and 28.3 kg/m^2, 103.8 cm, and 23.1 kg/m^2, respectively, among men. Baseline BMI was associated with 8% higher CRC risk (95% confidence interval (CI) 0.99-1.18) per 5 kg/m^2 increase. However, apple body shape was associated with higher CRC risk (hazard ratio (HR) per 5 kg/m^2 BMI = 1.18, 95% CI 1.02-1.38). WC was associated with higher CRC risk (HR 1.08, 95% CI 1.01-1.15) per 10 cm increase, and the association was higher for apple body shape (HR 1.14, 95% CI 1.01-1.28). BMI at age 18 was associated with 17% higher CRC risk (95% CI 1.03-1.32) per 5 kg/m^2 increase, and the association was higher for apple body shape (HR 1.36, 95% CI 1.12-1.65). Associations for non-apple body shapes were not statistically significant across all exposures. For early-onset CRC, associations with baseline BMI, WC, and age 18 BMI were suggestive of higher risk but not statistically significant. Participants in the highest category of excess BMI-years (women ≥35, men ≥81) relative to those in the lowest had 56% higher risk of overall CRC (95% CI 1.19-2.05), but the association with early-onset CRC was not statistically significant (HR 1.92, 95% CI 0.90-4.07).

These findings suggest that while obesity is associated with higher CRC risk, excess weight gain around the waist and at younger ages may be of importance. Studies are needed to confirm these findings and further investigate the potential role of early-life obesity in the development of early-onset CRC.

#2198 Poverty, food insecurity, and nutritional inflammatory mediators of allostatic load.

J. M. Crook[1], E. Lee[1], O. Bolajoko[2], R. Xie[1];

[1]University of Central Florida, Orlando, FL, [2]Mayo Clinic, Jacksonville, FL

Background: Though widely recognized in cancer pathogenesis, inflammatory pathways of allostatic load remain vaguely understood. A partial explanation may be found within the realm of food insecurity and micronutrient inadequacies, defined as nutrient intake less than the estimated average requirement. Many micronutrient deficiencies contribute to pro-inflammatory and immunocompromised milieus. Inadequacies, however, which may present without overt symptoms, are not currently well studied. The purpose of this study was to examine relationships between known inflammation-associated nutritional biomarkers of micronutrients and biomarker variables of allostatic load.

Methods: Using NHANES 2017/2018 surveys, adults > 18 years without renal or hepatic disorders, pregnancy, alcohol, or supplement use were included. Plasma levels of vitamins A, B9, C, D, E, calcium (Ca), ferritin (Fe), phosphorus (P), potassium (K) and sodium (Na) were grouped into deficiency, inadequate and adequate groups based on clinically recognized standards. Micronutrient prevalence was assessed and variables of allostatic load [blood pressure, glucose, albumin, creatinine, red cell distribution width (RDW), high density lipoprotein (HDL), low density lipoprotein (LDL), cholesterol and triglycerides] were analyzed for mean differences among micronutrient groups, food security and poverty.

Results: From 3,317 unique participants, inadequacy prevalence percentages were quantified as: vitamins A (0.4%), B9 (12.2%), C (58.3%), D (39.6%), E (21.0%), P (11.4%), K (3.4%), Na (24.2%), Ca (59.5%), and Fe (37.4%) [$p < 0.001$]. Statistically significant differences were identified in age [C, D, E, Ca, Fe, P, Na ($p < 0.004$)], race/ethnicity [B9, C, D ($p < 0.006$)], gender [C, E, Ca, Fe, P, K, Na ($p < 0.018$)], poverty [A, B9, C, D, E, Fe, K ($p < 0.025$)], and food security [B9, C, D, E, P ($p < 0.032$)]. Associations to allostatic load were discovered in: albumin [A, C, D, Ca, Fe, P, Na ($p < 0.025$)], glucose [C, E, Fe, P, Na ($p < 0.009$)], HDL [C, D, E, Fe, P, K ($p<0.045$)], LDL [E, Ca, Fe, Na ($p<0.028$)], creatinine [C, D, Ca, Fe ($p<0.001$)], triglycerides [B9, D, E, Fe ($p<0.033$)], cholesterol [C, D, E, Ca, Fe, Na ($p<0.006$)], B/P [C, E, Fe, P, Na ($p < 0.035$)], and RDW [C, D, Ca, Fe ($p < 0.001$)]. Poverty was significantly associated with all variables of allostatic load ($F = 2.85$, $p = 0.002$). Food security was significantly correlated with albumin ($p < 0.001$), glucose ($p = 0.005$) and HDL ($p < 0.001$).

Conclusion: Allostatic load, poverty, and food security were significantly associated with subclinical micronutrient statuses, which may not present with signs of deficiency and are not currently well assessed. Similarly, poverty was significantly associated with all variables of allostatic load, though food security was only identified to be associated with albumin, glucose, and HDL, suggesting that food security may not be currently adequately defined for surveillance.

#2199 Low-carbohydrate diet score and risk of bladder cancer: Findings from the Singapore Chinese Health Study.

Y. T. Pham[1], R. Wang[1], A. Jin[2], W.-P. Koh[2], J.-M. Yuan[1], H. N. Luu[1];

[1]University of Pittsburgh, Pittsburgh, PA, [2]National University of Singapore, Singapore, Singapore

Background. Bladder cancer is a leading tumor of urinary tract with annually 570,000+ new cases and 200,000+ deaths worldwide. In the United States, the current incidence rate of bladder cancer is 15.8 per 100,000 population with more than 82,000 new cases and more than 16,000 deaths each year. Although smoking is established as a major risk factor for bladder cancer development, accounting for 30-50% cases, the role of other modifiable risk factors, including dietary in bladder cancer remains unclear. Low-carbohydrate diet (LCD) is a dietary pattern to restrict carbohydrate and to favor protein and/or fat intakes that has recently been well-accepted for weight loss. While its short-term effect to support the weight loss has been popular, its long-term effect on chronic diseases, including cancer, needs to be elucidated. In the current analysis, we sought to determine the association between LCD scores and bladder cancer risk in the Singapore Chinese Health Study (SCHS), an ongoing prospective cohort study consisting of more than 63,000 Chinese Singaporeans, 45- 74 years of age at baseline enrollment period 1995-1998.

Methods. Total, animal-based and plant-based LCD scores were derived from the baseline dietary survey data, representing summed intake of carbohydrates, fats and proteins from all dietary, animal- and plant-food sources, respectively. Bladder cancer cases were ascertained using cancer registry. Cox proportional hazard regression model was used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for different LCD score levels with risk of bladder cancer.

Results. By December 31, 2015, or after 17.6 years of follow-up, 250 bladder cancer cases were developed within the SCHS. Total LCD score was marginally associated with increased risk of bladder cancer ($HR_{Q4vs.Q1}$=1.43, 95% CI: 0.98-2.09, P_{trend} = 0.06). Animal-based LCD score was significantly associated with risk of bladder cancer. The HRs and respective 95% CIs of bladder cancer for quartiles 2, 3, and 4, compared with the lowest quartile, were 1.09 (0.76-1.56), 1.17 (0.81-1.70), and 1.53 (1.09-2.17) (P_{trend}=0.01). The positive association was only present in men, ever smokers, never drinkers and individuals without history of type 2 diabetes (All $P's_{heterogeneity}$>0.05).

Conclusions. In a prospective cohort study of more than 63,000 Chinese Singaporeans, we found that animal-based LCD score, representing a diet with lower carbohydrate and higher animal fat and protein, was significantly associated with increased risk of bladder cancer. Dietary modification is therefore suggested as an effective strategy for primary prevention of bladder cancer.

#2200 Plant-based diet and survival among patients with metastatic colorectal cancer: Findings from CALGB/SWOG 80405 (Alliance).

E. Cheng[1], F.-S. Ou[2], C. Ma[3], A. P. Venook[4], H.-J. Lenz[5], E. M. O'Reilly[6], P. T. Campbell[1], C. Kuang[1], B. J. Caan[7], K. Ng[3], J. A. Meyerhardt[3]; [1]Albert Einstein College of Medicine, Bronx, NY, [2]Mayo Clinic, Rochester, MN, [3]Dana-Farber Cancer Institute, Boston, MA, [4]University of California, San Francisco, San Francisco, CA, [5]University of Southern California, Los Angeles, CA, [6]Memorial Sloan Kettering Cancer Center, New York, NY, [7]Kaiser Permanente Northern California, Oakland, CA

Background: Plant-based diet is recommended by multiple cancer survivorship guidelines and was reported to be associated with better survival among patients with non-metastatic colorectal cancer. However, the association between plant-based diet and survival in metastatic colorectal cancer is unknown.
Methods: Using an NCI-sponsored systemic therapy trial conducted from 2005 to 2015 (CALGB/SWOG 80405), we included 1,279 patients who completed validated food frequency questionnaires at the initiation of treatment for metastatic colorectal cancer. To emphasize different impact of healthful plant foods, less healthful plant foods, and animal foods, we used 18 food groups to calculate three plant-based indexes (ranges: 18-90 points): overall plant-based diet index (PDI), healthful plant-based diet index (hPDI), and unhealthful plant-based diet index (uPDI). The primary outcome was overall survival, and the secondary outcome was progression-free survival. We estimated the associations of three indexes (quintiles) with survival using multivariable Cox proportional hazards regression.
Results: Of 1,279 patients (median follow-up: 6.1 years), mean (SD) age at diagnosis was 58.8 (11.7) years, 57.4% were men, 85.6% were White, and 1,096 deaths and 1,201 events of progression occurred. The mean (SD) points of three indexes were 51.2 (6.3) for PDI, 51.1 (6.7) for hPDI, and 51.2 (8.1) for uPDI. Compared to the lowest quintile (Q1), the highest quintile (Q5) of PDI was significantly associated with better overall survival (HR: 0.80 [0.65-0.99]) and progression-free survival (HR: 0.80 [0.65-0.98]). Similar findings were observed for hPDI, but uPDI was not significantly associated with worse survival.
Conclusions: Our findings suggest that plant-based diet is associated with better survival among patients with metastatic colorectal cancer, and plant-based dietary interventions should be considered for future trials in metastatic colorectal cancer.

Table. Adjusted Associations of Plant-Based Diet with Survival in Metastatic Colorectal Cancer

	Q1	Q2	Q3	Q4	Q5	P for trend
Overall Survival						
PDI	1.00	0.96 (0.80-1.16)	0.93 (0.77-1.14)	0.82 (0.67-0.99)	0.80 (0.65-0.99)	0.01
hPDI	1.00	0.95 (0.78-1.14)	0.94 (0.77-1.15)	0.86 (0.70-1.04)	0.84 (0.68-1.03)	0.07
uPDI	1.00	1.14 (0.95-1.39)	1.07 (0.87-1.31)	1.18 (0.97-1.45)	1.17 (0.95-1.45)	0.15
Progression-free Survival

Backgrounds: Alcohol consumption is the Group I carcinogen according to International Agency for Research on Cancer (IARC). In 2009, National Cancer Center Korea reported that 3.0% and 0.5% of total cancer incidence were attributable to alcohol consumption in men and women, respectively. Herein, we estimated population attributable fraction (PAF) of cancer incidence due to alcohol consumption as of 2020.

Methods: We organized the Consensus Committee to establish strategy and methodology of PAF estimation. Based on the consensus, cancer sites for PAF estimation were selected according to the IARC List of classification with sufficient evidence in human. PAF was calculated by using Levin's formula which incorporates exposure prevalence and relative risk (RR). Exposure prevalence was obtained from the Korea National Health and Nutrition Examination Survey (KNHANES) in 2005, assuming that latent period between exposure to alcohol consumption and diagnosis of cancer would be 15 years. Alcohol consumption was defined as non-drinking (<0.1g/day), light (0.1~30g/day), moderate (30~60g/day), and heavy (60~588g/day) drinking according to the definition by World Health Organization. We estimated RRs from the cohort data established by Korean Genome and Epidemiology Study, National Health Examination data provided by National Health Insurance Services, Korean Cancer Prevention Study-II, and KNHANES, while each cohort was linked with Korea Cancer Registry. RRs were estimated by using Cox proportional hazards model adjusted by age group and smoking status. RRs were then meta-analyzed to yield pooled RR by using random-effects model.

Results: A total of 4.1% and 1.2% of all cancer incidence were attributable to alcohol consumption in men and women. By cancer sites, 67.1% of esophageal cancer, 23.8% of oral cavity/pharyngeal cancer, 15.1% of laryngeal cancer, 12.0% of colorectal cancer, and 7.9% of liver cancer were attributable to alcohol consumption in men. In women, 54.1% of liver cancer, 10.3% of colorectal cancer, 7.8% of oral cavity/pharyngeal cancer, and 3.6% of breast cancer were due to alcohol consumption.

Conclusion: PAF of cancer incidence due to alcohol consumption has increased in 2020 compared to PAF in 2009. As alcohol consumption is an important cause of oral cavity/pharyngeal, esophageal, and laryngeal cancer in men, and liver and breast cancer in women, prevention measures are required to reduce alcohol consumption for cancer prevention in Korea. Funding Sources: This work was supported by the National Cancer Center Grant(NCC-2210840).

#2202 Association of multi-morbidity with incident cancer diagnoses.

M. C. Conroy, G. K. Reeves, N. E. Allen;
University of Oxford, Oxford, United Kingdom

Background: Multi-morbidity (MM), which is usually defined as a simple count of the number of different diseases an individual has, has previously been identified as a risk factor for some incident cancer diagnoses. This study aimed to use more sophisticated machine learning techniques to classify MM into disease clusters and to investigate their association with incident colorectal (CRC), breast (BC), lung (LC) and prostate (PrC) cancer diagnoses.
Methods: Participants in UK Biobank with a hospital (HES) record and no prevalent cancer were included in the study. Self-reported (SR), HES and primary-care (GP) recorded diseases were converted to phecodes. Sex-stratified latent class analyses (LCA) was used to identify disease clusters in the SR data. Associations between clusters and selected cancer diagnoses was undertaken using Cox proportional hazards modelling, adjusting for age, ethnicity, socio-economic status, year and region of recruitment, body mass index, smoking history, alcohol consumption and menopausal hormone therapy use (women only). The analyses were validated using HES and GP data.
Results: The analysis included 158,951 women and 127,406 men. Just over 30% (49,061) of women and 37% (48,110) of men had MM (≥2 diseases) at recruitment. LCA identified 10 disease clusters in women, the most common of which was related to respiratory disease, largely comprising asthma (9344; 19.1%). Nine disease clusters were identified in men, the most common of which was related to heart disease (9358; 19.5%), and largely comprising ischemic heart disease and hypertension. No association between disease cluster and incident CRC or BC was identified. In women, LC risk was associated with several disease clusters: respiratory (Hazard Ratio 1.57 (95% confidence interval 1.28 - 1.91) p<0.001), arthritis/gut (1.46 (1.15 - 1.85) p=0.002), hyperlipidemia (1.51 (1.19 - 1.92) p=0.001, cardiac (1.74 (1.40 - 2.17) p<0.001) and type 2 diabetes (T2DM) (1.56 (1.16 - 2.09) p=0.003). In men, LC was associated with disease clusters of hyperlipidemia/ hypertension (1.23 (1.02 - 1.48) p=0.03), cardiac (1.40 (1.18 - 1.66) p<0.001), T2DM (1.26 (1.02 - 1.56) p=0.03), respiratory (2.74 (2.21 - 3.39) p<0.001) and cardiometabolic/arthritis (1.81 (1.08 - 3.03) p=0.02). T2DM (0.80 (0.68 - 0.87) p<0.001) was associated with an inverse risk of PrC. Cluster distribution was similar in HES and GP data, with the association between the cardiac and the arthritis clusters replicated for LC in women, and the respiratory cluster for LC and T2DM cluster for PrC in men.
Conclusion: Clusters of MM were identified in a large cancer-free population, which were replicated using different sources of healthcare data. Several disease clusters were associated with incident LC and, to a lesser extent, PrC. Further work to understand the potential causal nature of these associations is needed.

#2203 Dietary patterns and prostate cancer risk in the Multiethnic Cohort Study.

W. Xiong[1], S.-Y. Park[2], A. Wang[3], P. Wan[1], L. R. Wilkens[2], L. L. Marchand[2], C. A. Haiman[1], F. Chen[1];
[1]USC - University of Southern California, Los Angeles, CA, [2]University of Hawaii Cancer Center, Honolulu, HI, [3]Harvard T.H. Chan School of Public Health, Boston, MA

Background: A growing body of research has shown the benefits of a healthy diet on a variety of cancer outcomes. Evidence is inconsistent for prostate cancer and research in diverse populations is limited.
Methods: In the Multiethnic Cohort Study (MEC), we conducted a prospective cohort analysis to investigate the association of four diet quality indices (DQIs; AHEI-2010, aMED, HEI-2015, DASH; a higher score indicates healthier diet), three plant-based diet indices (PDI, hPDI, uPDI), two inflammatory (DII, EDIP), and two insulinemic dietary indices (EDIH, EDIR) (a higher score indicates more pro-inflammatory or pro-insulinemic diet) with incidence of prostate cancer (PCa) in 79,930 men from five racial/ethnic groups (White, African American, Japanese American, Latino, and Native Hawaiian). All dietary scores were constructed from a baseline quantitative food frequency questionnaire. Outcomes examined included total PCa, high-grade PCa (Gleason score > 7), advanced PCa (regional or distant), aggressive PCa (high-grade or advanced), and lethal PCa (distant or death due to PCa). Hazard ratios (HR) and 95% confidence intervals (CI) per one standard deviation (SD) increase in the dietary score were estimated from Cox proportional hazards models, overall and by race/ethnicity. Associations were considered nominally significant at $P < 0.05$.
Results: During a mean follow-up of 18.9 years, a total of 9,759 incident PCa cases were identified, including 2,503 high-grade, 1,706 advanced, 3,430 aggressive, and 1,426 lethal PCa cases. None of the dietary scores was significantly associated with total PCa. We found a significant association between DII and advanced PCa (HR=1.08, 95% CI=1.01-1.15) overall and the association appeared to be the strongest in African Americans (HR=1.17, 95% CI=1.00-1.36) and Native Hawaiians (HR=1.29, 95% CI=0.98-1.68). We also observed weak associations of the four DQIs with advanced PCa (HR of 0.95-0.96, P of 0.07-0.10) in the overall population, among which a higher DASH score was significantly associated with a 15% (95% CI = 0.75-0.96) lower risk of advanced PCa in African Americans. In addition, we observed that several inflammatory (EDIP) and insulinemic (EDIH, EDIR) dietary scores were associated with lower incidence of advanced, aggressive, or lethal PCa (HR=0.89-0.95, P of 0.03-0.05), which requires further investigation.
Conclusions: Our findings suggest that diets with high proinflammatory potential may increase risk of advanced PCa while following a healthy dietary pattern may reduce the risk of advanced PCa. Further studies are needed to better understand the inconsistent results across studies on diet and PCa risk and whether our findings can be replicated in other populations.

#2204 Evaluating ovarian cancer risk factors in the Mexican Teachers' Cohort.

B. Trabert[1], L. Gomez Flores Ramos[2], M. Brochier[2], E. V. Bandera[3], J. A. Doherty[1], S. L. Gomez[4], L. H. Kushi[5], A. Mohar[6], **M. Lajous**[2];
[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]National Institute of Public Health, Cuernavaca, Mexico, [3]Rutgers Cancer Institute of New Jersey; Robert Wood Johnson Medical School, New Brunswick, NJ, [4]University of California, San Francisco, San Francisco, CA, [5]Kaiser Permanente Northern California, Oakland, CA, [6]National Cancer Institute (INCan), Mexico City, Mexico

Purpose: Ovarian cancer is the most lethal gynecologic cancer in North America, yet our understanding of ovarian cancer risk factors in Mexican women is limited. The aim of the present study was to prospectively evaluate associations between reproductive and lifestyle factors and incident ovarian cancer risk among Mexican women.
Methods: The Mexican Teachers' Cohort (ESMaestras) is a large, prospective, population-based cohort of women (n=115,306) living in a culturally, geographically, and economically diverse 12-state area in Mexico. Reproductive and lifestyle factors were collected on baseline questionnaires administered between 2006-2008, with additional questionnaires collected from the cohort in 2011, and 2014. During follow-up, 187 incident ovarian cancer cases were identified, including 101 via self-report on 2011 and 2014 questionnaires, as well as an additional 85 through linkage with mortality databases, and 3 via other administrative- and cancer registry-based linkages (2 of 3 were also identified via the mortality database linkage). Of the self-reported incident cases, 5 have been validated via mortality databases and 4 via linkage with an administrative database; validation of the remaining self-reported cases is ongoing. Primary analyses examined associations between established ovarian cancer risk factors and incident ovarian cancer. Age-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazards regression.
Results: Women in the Mexican Teachers' Cohort that used hormonal contraceptives (HC), were parous, or had a tubal ligation experienced reduced ovarian cancer risks during follow-up (ever HC use vs. never HR 0.70 [95% CI 0.51-0.95], parous vs. nulliparous 0.48 [0.35-0.68], ever tubal ligation vs. never 0.87 [0.59-1.28]). Ovarian cancer risk was elevated among women with a positive family history of breast cancer (1.34 [0.76-2.36]). Women with a history of endometriosis were at increased ovarian cancer risk (3.43 [1.41-8.34]). Taller adult height (>159 cm vs <150 cm) was not associated with ovarian cancer risk among women in this cohort. Risk estimates were consistent and, in some instances, more pronounced (i.e., HC use and tubal ligation) when limited to incident ovarian cancer cases confirmed via linkage with mortality databases (n=90).
Conclusions: Ovarian cancer risk factors identified in the Mexican Teachers' Cohort were generally consistent with associations reported in predominantly non-Hispanic white populations. More research is needed to better understand ovarian cancer etiology among populations under-represented in cancer research.

#2205 Modifiable risk factors are associated with clonal hematopoiesis.

C. D. Young[1], A. K. Hubbard[1], P. Saint-Maurice[2], I. Chan[3], K. L. Bolton[3], S. J. Chanock[1], C. Matthews[1], S. C. Moore[1], E. Loftfield[1], Y. Cao[3], **M. J. Machiela**[1], D. Tran[3];

[1]NCI Division of Cancer Epidemiology & Genetics, Rockville, MD, [2]Champalimaud Foundation, Lisbon, Portugal, [3]Washington University School of Medicine, St. Louis, MO

Observational studies have implicated modifiable factors like smoking, alcohol intake, physical activity (PA), and sleep to cancer risk. Clonal hematopoiesis (CH), marked by clonal expansions of mutated hematopoietic progenitors with mosaic chromosomal alterations (mCAs) or clonal hematopoiesis of indeterminate potential (CHIP), has been associated with the risk of serval cancers and may shed light the interplay between these factors and early preneoplastic hematopoietic expansion.Leveraging genotyping array and whole-exome sequencing data of leukocyte-derived DNA from 485,028 participants without hematologic malignancies in the UK Biobank (UKBB), we performed genome-wide characterization of two common forms of CH—mCAs and CHIP. To assess associations between social deprivation, self-reported modifiable risk factors, and CH risk, we employed multivariable logistic regression models adjusted for potential confounders including age, sex, smoking history, and genetic ancestry.We identified 11,826 (2.4%) individuals with autosomal mosaic chromosomal alterations (auto mCAs), 15,499 (3.2%) with loss of the X chromosome (mLOX), 43,044 (8.8%) with loss of the Y chromosome (mLOY) and 22,508 (4.6%) with CHIP. Individuals with any CH subtype were on average older than CH-free individuals ($p < 9.11\times10^{-52}$). Multivariable models identified a significant negative association between mLOY and social deprivation in England (1 SD change in score: OR = 0.968 [0.956-0.980], $p = 4.88\times10^{-7}$), suggesting modifiable risk factors could influence risk of mLOY. We observed a positive association with ever smoking and CH, which decreased with increased years since smoking cessation. Current smokers were at higher risk for auto mCAs (Odds ratio (OR) = 1.23, 95% Confidence Interval (CI):[1.16-1.31], P-value (p) = 2.63×10^{-11}), mLOY (OR = 2.25, 95%CI: [2.17-2.33], $p < 9.11\times10^{-52}$), and CHIP (OR = 1.40, , 95%CI: [1.34-1.47] $p < 9.11\times10^{-52}$); and former smokers also exhibited significant associations for mLOY (OR = 1.16, 95%CI: [1.13-1.19], $p = 2.97\times10^{-32}$) and CHIP (OR = 1.11, 95%CI: [1.08-1.15], $p = 2.75\times10^{-13}$). Alcohol consumption was associated with a significant increase in the risk of mLOX in heavy drinkers (>2-3 drinks/day) compared to non-drinkers (OR = 1.16, 95%CI: [1.09-1.24], $p = 1.21\times10^{-5}$). Moderate and high PA levels (categorized as level 2 and 3 based on total activity), were positively associated with increased mLOY frequency (moderate: OR = 1.05, 95%CI: [1.02-1.08], $p = 8.6\times10^{-2}$, high: OR = 1.06, 95%CI: [1.03-1.08], $p = 1.6\times10^{-3}$). We observed no evidence for an association between sleep patterns and CH.Our investigation in a large cohort identified associations between CH and social deprivation, smoking, alcohol consumption and PA. As CH is an intermediate marker for hematologic cancer risk, our findings imply that modifiable exposures may contribute to hematologic cancer risk through clonal mechanisms.

#2206 Obesity and cancer outcomes among patients with lung cancer and cutaneous melanoma treated with immune checkpoint inhibitors and EGFR inhibitors.

S. O. Nduaguba, L. Hazlehurst;
Mary Babb Randolph Cancer Center and School of Pharmacy at West Virginia University, Morgantown, WV

Background: Obesity is a causal factor in cancer risk and progression. Immune checkpoint inhibitors (ICI) and EGFR inhibitors (EGFRi) are indicated for the treatment of several cancers, including non-small-cell lung cancer (NSCLC) and cutaneous melanoma (CM). Improved outcomes was observed with ICI in preclinical studies. We aimed to determine the association of obesity with progression-free survival (PFS) or overall survival (OS) among patients with NSCLC and CM treated with ICI or EGFRi.
Methods: This was a retrospective study utilizing 2011-2019 SEER-Medicare data of Medicare Parts A and B enrolled patients ≥66 years diagnosed with NSCLC or CM who received ICI or EGFRi (NSCLC only) within 1-year post-diagnosis. Patients were followed from treatment commencement until death, loss to follow-up, or end of study. Descriptive statistics and survival analysis were used to achieve study objectives.
Results: Among 2393 NSCLC patients receiving ICI, obese patients (N=281, 11.7%) were younger (73.4±5.2 yrs vs 74.4±5.9 yrs, p<0.01) with higher CCI scores (2 (IQR=1-4) vs 1 (IQR=0-2), p<0.0001) compared to non-obese patients (N=2,311, 89.2%). Time to progression(TTP) was 41% faster among obese patients (392 days (95% CI=330-468) vs 493 days (95% CI=464-525), p<0.01; HR=1.41 (1.13-1.76), p<0.01) with no significant difference in time to death (TTD) (443 days (404-488) vs 491 days (462-524), p=0.35). Among 880 CM patients, those with obesity (N=91, 10.3%)) were significantly younger (74.7±6.1 yrs vs 76.3±7.3 yrs, p=0.02) with higher CCI scores (2 (IQR=0-4) vs 0 (IQR=0-2), p<0.0001). TTP was 343 days (320-400). TTD was 1,409 days (1,107-2,136) with no association between obesity status and PFS or OS. Among 2,524 NSCLC patients receiving EGFRi, obese patients (126, 5.0%) were younger (73.7±6.1 yrs) vs 75.6±6.5 yrs, p<0.01), had higher CCI scores (2 (IQR=1-3) vs 0 (IQR=0-1), p<0.0001), and longer time to treatment (3 mths (IQR=1-7) vs 2 mths (IQR=1-6), p=0.02). A higher proportion were White (76.2% vs 61.3%, p<0.001). Risk of progression was 48% higher among obese patients (664 dys (496-778) vs 1,231 dys (1,127-1,379), p<0.0001; HR=1.48, 95% CI=1.11-1.97, p<0.01) with no significant difference in TTD (559 dys (440-763) vs 673 dys (639-707), p=0.35).
Conclusion: Obesity with associated with PFS but not OS among patients with NSCLC with no association observed among patients with CM. Given that the link between obesity and NSCLC risk remains controversial, the observed association with PFS may be linked to the absence of the paradoxical effect of improve outcomes that may be seen with cancers caused by obesity such as CM.

#2207 Fiber intake and risk of lethal prostate cancer among men at increased genetic risk.

Y. Zhang[1], K. H. Stopsack[2], L. A. Mucci[1], E. Giovannucci[1], A. Plym[3];

[1]Harvard School of Public Health, Boston, MA, [2]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [3]Karolinska Institutet, Stockholm, Sweden

Introduction High fiber intake from grains may lower advanced prostate cancer risk by enhancing insulin sensitivity, lowering insulin-like growth factor 1 and systemic inflammation. Whether a high-fiber diet can lower risk of metastatic disease and prostate cancer death in men at high genetic risk is unclear.
Methods Using a new 400-SNP polygenic risk score (PRS) for prostate cancer, we quantified the genetic risk of 10,269 men with available genotype data in the Health Professionals Follow-up Study, followed between 1993 and 2019. Men in the top 50-100% PRS category were considered high-risk and included for analysis. Total fiber intake and different sources (cereal, fruits, vegetables) were assessed by validated food frequency questionnaires. Overall and lethal prostate cancer (metastatic disease/prostate cancer death) were analyzed using Cox proportional hazards models estimating hazard ratios (HRs) and 95% confidence intervals (CIs).
Results During 26 years of follow-up, we recorded 1,494 overall and 174 lethal prostate cancer events in the high genetic risk group. As expected, no associations were observed fiber intake with risk of overall prostate cancer. For lethal prostate cancer, the results varied according to the source of fiber. Higher cereal fiber intake was associated with a lower risk of lethal prostate cancer (per 3 g/d higher intake: 0.81 [0.68, 0.97], *P-trend*=0.02). We further observed a higher disease risk among men with higher fruit fiber intake (per 3g/d higher intake: 1.18 [1.02, 1.36], *P-trend*=0.03). The associations remained similar when mutually adjusted for each fiber type. No associations were observed for total or vegetable fiber intake.
Conclusion In this analysis of men at high prostate cancer genetic risk, we observed that higher cereal fiber intake was associated with lower lethal prostate cancer risk, whereas higher fruit fiber intake showed an opposite trend. Further studies in different populations and investigations into the underlying mechanisms are needed.

Fiber intake with risk of overall and lethal prostate cancer among men at high genetic risk.

#2209 Tattooing and risk of melanoma: A population-based case-control study in Utah.

R. D. McCarty[1], B. Trabert[1], M. M. Millar[2], D. Kriebel[3], L. Grieshober[1], M. E. Barnard[4], L. J. Collin[1], K. A. Lawson-Michod[1], J. A. Gilreath[1], D. Grossman[1], J. Hyngstrom[1], P. J. Shami[1], J. A. Doherty[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Massachusetts Lowell, Lowell, MA, [4]Boston University, Boston, MA

Background: Carcinogens have been observed in many tattoo inks which can form new carcinogenic compounds when exposed to ultraviolet radiation and can accumulate in the lymph nodes and other organs. Tattooing can result in short- and long-term inflammatory and immune responses. At least 38 cases of melanoma have been reported in tattoos. The incidence of melanoma in Utah is the highest in the U.S., and potentially modifiable risk factors are of public health interest. In this study, we evaluated associations between tattooing and melanoma risk.

Methods: We utilized a population-based case-control study of 514 incident *in situ* (284 men and 230 women) and 534 invasive (285 men and 249 women) melanoma cases diagnosed in Utah between 2020-2021. Controls (n=5,240) were selected from respondents to the Utah Behavioral Risk Factor Surveillance System (BRFSS) survey and frequency matched to cases in a 5:1 ratio on sex, age, race, and ethnicity. We fit logistic regression models to compute odds ratios (ORs) and 95% confidence intervals (CIs) associating ever tattooing with *in situ* and invasive melanoma risk, adjusting for age, education level, race, and ethnicity, separately for women and men. We then fit logistic models stratified by education level (< four-year college degree/four-year college degree or more) and models stratified by age (< 50 years/50+ years), separately for women and men.

Results: Among men, the prevalence of tattooing was 7% for both *in situ* and invasive cases, and 11% for controls. Among women, tattooing prevalence was 20% for *in situ* cases, 15% for invasive cases, and 18% for controls. Ever tattooing was associated with decreased invasive melanoma risk among men (OR=0.62 [95% CI: 0.37-1.02]), particularly among those who had less than a four-year college degree (0.52 [0.28-0.99]), and among ages 50+ (0.36 [0.16-0.84]). Among men, the OR for ever tattooing and *in situ* melanoma was in the same direction as invasive melanoma, but the estimate was statistically imprecise (0.73 [0.45-1.19]). Among women, we did not observe an association between ever tattooing and invasive melanoma (0.83 [0.56-1.20]), while the association between ever tattooing and *in situ* melanoma was statistically imprecise (1.25 [0.87-1.80]). However, ever tattooing was associated with a nearly two-fold increased risk of *in situ* melanoma among women with a four-year college degree (1.98 [1.21-3.26]), but not for those without a college degree (0.89 [0.52-1.50]).

Conclusion: These findings do not suggest that there is an association between tattooing and melanoma. Associations between tattooing and health-seeking behaviors, which may vary by sex and other demographic factors, may influence associations with melanoma diagnosis, particularly for *in situ* melanoma. This study is the first step in investigating whether reported cases of melanoma arising in tattoos are coincidental or whether tattoos may be associated with an increased risk of melanoma.

#2210 Healthy dietary patterns and survival among men with prostate cancer.

B. Liu, J. B. Vaselkiv, C. Himbert, C. B. McGrath, L. Lucas, E. Giovannucci, M. J. Stampfer, K. H. Stopsack, Q. Sun, L. A. Mucci;
Harvard School of Public Health, Boston, MA

Background: While prostate cancer is the second leading cause of cancer death in U.S. males, most men with prostate cancer die from other causes. We prospectively examined the potential benefits of adhering to established healthy dietary patterns on overall and cause-specific mortality among men living with prostate cancer.
Methods: We studied men with incident prostate cancer in the Health Professionals Follow-up Study from 1986-2022. Five dietary indices-Alternative Healthy Eating Index (AHEI), the Mediterranean diet, Dietary Approaches to Stop Hypertension (DASH), anti-insulinemic, and anti-inflammatory diet scores-were derived from validated food frequency questionnaires administered every 4 years. Post-diagnosis scores were cumulatively averaged, and time-varying changes in scores from pre- to post-diagnosis were calculated. We used multivariable-adjusted Cox models to estimate hazard ratios (HRs, 95% CI) for associations between adherence to dietary patterns with overall and cause-specific survival adjusting for demographics, dietary and lifestyle factors.
Results: Among 6,086 prostate cancer patients with 71,783 person-years of follow-up, 3,406 deaths occurred: 578 from prostate cancer, 918 from cardiovascular disease (CVD), and 1910 from other causes. When comparing extreme quintiles of post-diagnosis diet scores, a healthy diet was associated with lower overall mortality for AHEI (0.76, 0.66-0.88) and the Mediterranean diet (0.84, 0.73-0.97). Moreover, comparing extreme quintiles of score change, patients who increased their adherence to these diets after diagnosis had better overall survival with HRs (95% CI) that ranged from 0.79 (0.70-0.89) for AHEI to 0.89 (0.79- <1.00) for the anti-inflammatory diet. No significant associations were observed for DASH. Regarding cause-specific survival, increased adherence to anti-insulinemic diet was associated with better CVD-specific survival (0.78, 0.61-0.99). No significant associations were found between these diet scores and prostate cancer survival. Stronger associations of post-diagnosis diet scores with overall survival were seen in men diagnosed before age 70, those classified as obese at diagnosis (BMI≥30 kg/m^2), consuming less alcohol (<7.8 g/d), and with lower grade (Gleason Score ≤7) or stage (T1/T2) tumors.
Conclusions: For men diagnosed with prostate cancer, adhering to a healthy dietary pattern after cancer diagnosis, such as the AHEI and Mediterranean Diet, was associated with better overall survival. Increasing adherence to these diets after cancer diagnosis was also associated with improved overall and CVD-specific survival.

#2211 ALDH2 deficiency and alcohol intake: Opportunity for precision cancer prevention.

D. Forman[1], M. Yang[2], R. Chien[2], H. Nguyen[2], C. Wong[2], J. H. J. Kim[2], A. Ziogas[2], H. L. Park[2];
[1]University of California, Los Angeles, Los Angeles, CA, [2]University of California, Irvine, Irvine, CA

Alcoholic beverages and the main metabolite of alcohol, acetaldehyde, are known carcinogens, according to the International Agency for Research on Cancer. Many studies have shown that alcohol consumption is a modifiable risk factor for breast, esophageal, colorectal, and other cancers, and that individuals deficient in metabolizing acetaldehyde are at higher risk for alcohol-associated cancers. A genetic variant in *aldehyde dehydrogenase 2* (*ALDH2*, G>A, rs671), the main enzyme responsible for breaking down acetaldehyde, results in decreased efficiency of ALDH2, or ALDH2 deficiency. This is the most common single genetic variation in humans worldwide, mostly found in some East Asian populations. While having one or both deficient alleles can lead to adverse physical effects when drinking, including facial flushing, nausea, and palpitations, studies done in Asian countries have shown that many affected individuals still consume alcohol, increasing their risk for some cancers. We sought to explore the scope and design of potential intervention in the U.S. by examining alcohol consumption behavior in individuals with and without ALDH2 deficiency within the All of Us Research Program, a current large, diverse, national U.S. cohort. Relationships between self-reported alcohol consumption and sociodemographic factors were examined among 380,845 participants. Genomic data was available for 296,254 of them. Overall, 72.7% of the cohort reported drinking alcohol in the past year, with the majority drinking moderately (≤1 drink/day for women and ≤2 drinks/day for men). Among those who drank, 42.7% reported at least one binge drinking episode (≥6 drinks on one occasion). Among our genomic cohort who identified as Asian individuals, 23.6% had at least one deficient *ALDH2* allele compared to <4% in all other groups. 63.7% of individuals with one deficient *ALDH2* allele and 25.4% with two deficient *ALDH2* alleles reported drinking in the past year. 29.9% of individuals with ALDH2 deficiency reported binge drinking in the past year. Multivariate analysis showed that male sex, younger age, higher education level, higher household income, and being born in the U.S. were associated with alcohol consumption among both individuals with and without ALDH2 deficiency. Our study shows that ALDH2 deficiency is fairly common among Asian Americans and that many affected individuals still drink alcohol. With the growing population of Asian Americans in the U.S. (currently >7% of the total U.S. population, projected to be ~38 million individuals by 2050), our findings suggest a significant opportunity for precision cancer prevention for a substantial portion of the population.

#2212 Global cancers attributable to modifiable risk factors: Dietary factors of animal origin.

Monireh Sadat Seyyedsalehi[1], Edward Giovannucci[2], Paolo Boffetta[3]

[1]University of Bologna, Bologna, Italy,[2]Harvard T.H. Chan School of Public Health, Boston, MA,[3]Stony Brook University, Stony Brook, NY

Cancer is the leading cause of death worldwide. Modifiable risk factors including diet have been linked to a wide range of malignancies. We estimated the global cancer population-attributable fraction (PAF) to established and suspected dietary cancer risk factors according to the Human Development Index (HDI).Diet-cancer associations were selected from WCRF, GBD and IARC report. Dietary factors of animal origin include red meat, processed meat, fish and dairy products; cancers include nasopharynx, esophageal, stomach, colorectal, pancreatic, lung, prostate, breast cancer. Gender-specific PAF were calculated based on 1) the total and gender-specific 2022 country-specific population from World Bank; 2) the country-specific average daily dietary factors intake (g/day) for 2000-2005 from the Global Dietary Database; 3) relative risks from the meta-analyses and WCRF reports; 4) country-specific 2020 cancer incidence from WHO. Estimates were also stratified by Human Development Index (HDI).Table 1 provides the results. The PAF for red meat and processed meat was higher in high HDI countries, while that for low dairy product intake was higher in low HDI countries. According to results, changes in selected dietary factors can prevent cancer-related incidence, particularly depending on where development status of countries and access to the source of their intake. Table1: Population attributable fractions for incidence of cancer in 2020 by gender.

#2213 Vaping, smoking and lung cancer: A case-control study.

M. A. Bittoni, D. Carbone, R. Harris;
The Ohio State University, Columbus, OH

Introduction: Nicotine exposure through the use of electronic delivery systems (vaping) has been found to elevate the risk of certain conditions of the lungs, e.g., vaping associated lung injury. However, the potential impact of vaping on lung cancer risk remains largely unexplored. We, therefore, examined the association of vaping and cigarette smoking with lung cancer risk in a case-control study conducted at The Ohio State University in Columbus, Ohio.
Methods: Medical records examined from the James Cancer Hospital and Solove Research Institute revealed 4,975 cases with newly diagnosed, pathologically confirmed lung cancer during 2013-2021. These cases were compared to 27,294 controls without cancer that were group-matched on a 5:1 ratio to cases by age, gender, race and year of ascertainment. Descriptive statistics were calculated, and logistic regression analyses were performed to assess the associations between vaping, smoking and lung cancer.
Results: The lung cancer cases in this study were 55% male, 88% white, with mean age at diagnosis of 62 years. The adjusted odds ratio (OR) for individuals who reported vaping and smoking was OR=21.1 (95% CI=17.1, 26.1) versus OR=6.3 (95% CI=5.8, 6.8) for smoking only. Estimates for gender and histologic cell type of lung cancer, e.g., pulmonary adenocarcinoma, squamous cell carcinoma and small cell carcinoma, were consistently over threefold higher for vaping and smoking compared to smoking only ($p<0.001$), and the vaping effect persisted even after adjustment for comorbidities, COPD and cardiovascular disease.
Conclusion: Adjusted estimates of odds ratios (OR) revealed over threefold higher risk of lung cancer among individuals who had vaped and smoked compared to individuals who only smoked. Our results suggest that the addition of vaping to smoking greatly accelerates the risk of developing lung cancer. Future studies are needed to further confirm these results.

#2214 Impacts of habitual and recent alcohol intake on gut microbiome diversity and composition among Black Americans.

L. Liu, S. Nguyen, Q. Cai, M. Shrubsole, W. Zheng, D. Yu;
Vanderbilt University, Nashville, TN

Background: Alcohol intake can alter the gut microbiome, which may play a role in the development of cancer and other chronic diseases. However, there have been limited population-based studies investigating the associations of habitual and recent alcohol intake with the gut microbiome, particularly among Black Americans.

Methods: We investigated the association of alcohol intake with the gut microbiome among 538 Black American participants of the Southern Community Cohort Study (150 men and 388 women). Habitual and recent alcohol intake was assessed at cohort baseline (2002-2009) and stool collection (2018-2021), respectively. DNA was extracted from fecal samples for gut microbiome profiling using shotgun metagenomic sequencing. Generalized linear models were employed to evaluate the associations between alcohol intake and gut microbiome diversity and composition, with adjustments for sociodemographic characteristics, other lifestyle factors, and comorbidities. False discovery rate (FDR)<0.1 was considered statistically significant.

Results: The mean age at enrollment was 53.2 ± 7.7 years, with a mean interval of 13.8 years (range: 9.0-18.1 years) between baseline and stool collection. Neither habitual nor recent alcohol intake was associated with microbiome diversity indices, and recent alcohol intake was not associated with microbial taxa abundance either. However, habitual alcohol intake, both total amount and subtypes, showed significant associations with microbial taxa abundance primarily in men, including *Actinobacteria*, *Proteobacteria*, *Firmicutes*, and classes *Bacilli* and *Clostridia* within these phyla (all FDR<0.1). Specifically, total alcohol and red wine intakes were inversely associated with genus *MGYG-HGUT-02719* in class *Clostridia;* beer consumption was inversely associated with genus *Anaerostipes;* white wine intake showed negative associations with order *RF32* and genus *Eubacterium* and a positive association with genus *Paenibacillus*. Most of these associations remained significant after adjusting for BMI and history of cardiometabolic diseases or cancer.

Conclusion: We identified gut microbiome taxa associated with habitual alcohol intake among Black American men, including several with anti- or pro-gastrointestinal-cancer properties. However, the magnitudes of these associations were generally small. Further research is needed to determine if these bacteria play a mediating or modifying role in alcohol-disease relationships.

#2215 Effects of a high-fiber, high-fruit and -vegetable, low-fat dietary intervention on rectal tissue bacteria.

D. A. Byrd[1], M. Gomez[1], S. Hogue[1], A. Ortega-Villa[2], Y. Wan[2], A. Warner[3], B. Zhu[2], C. Dagnall[2], K. Jones[2], B. Hicks[2], P. Albert[2], G. Murphy[4], R. Sinha[2], E. Vogtmann[2];

[1]Moffitt Cancer Center, Tampa, FL, [2]NIH, Bethesda, MD, [3]NIH, Frederick, MD, [4]Imperial College of London, London, United Kingdom

Introduction. Emerging evidence suggests that the bacteria residing in colon and rectal tissue are plausibly associated with colorectal cancer (CRC). Prior studies investigated the effects of dietary interventions on the fecal microbiome but few assessed colorectal tissue microbiome endpoints. We investigated the effects of a high-fiber, high-fruit and -vegetable, low-fat dietary intervention on the rectal tissue microbiome in the Polyp Prevention Trial (PPT).

Methods. PPT is a 4-year randomized clinical trial, with specific goals including consuming: 1) ≥ 18g of fiber per 1,000 kcal/day; 2) ≥ 3.5 servings of fruits and vegetables per 1,000 kcal/day; and 3) <20% of kcal/day from fat. We extracted DNA from rectal biopsies using the AutoGen Animal Tissue DNA Extraction Kit and sequenced the V4 region of the 16S rRNA gene to characterize the bacteria in biopsies collected at baseline and the end of years 1 and 4 (N=233 in intervention arm and N=222 in control arm). We estimated effects of the intervention on rarefied alpha diversity and *a priori*-selected presence and relative abundance (presented as percentages summing to 100) of 10 bacteria most strongly historically associated with CRC presence using repeated-measures linear mixed-effects models. We also explored intervention effects on presence/abundance of all bacteria (with Bonferroni correction for multiple testing) and stratified the analysis among intervention arm participants who adhered to 75% of the dietary goals (super compliers) over the 4 years (N=48) and comparable participants in the control arm (N=64).

Results. The intervention did not statistically significantly modify rectal tissue alpha diversity. Compared to the control arm, relative abundance of *a priori*-selected *Porphyromonas* (absolute difference-in-difference (DiD) at T1 vs. T0 = -0.24 and T4 vs. T0 = -0.12; *P*=0.004) and *Prevotella* (absolute DiD at T1 vs. T0 = -0.40 and at T4 vs. T0 = -0.32; *P*=0.01) were more strongly decreased in the intervention arm. Other bacteria selected for exploratory analyses were not statistically significantly modified by the intervention after accounting for multiple testing. Among super compliers and comparable control arm participants, the findings were similarly weak.

Conclusion. Overall, our findings did not strongly support that a high-fiber, -fruit, and -vegetable, and low-fat diet intervention influences rectal tissue microbiome diversity nor the abundance of most bacteria, except for two oral-originating bacteria that were previously associated with CRC presence. It is possible that dietary exposures over longer periods of time (than 4 years) may more strongly influence the tissue microbiome. Future intervention studies, including tissue samples collected throughout the colon and rectum among larger, diverse study populations for longer periods of time are warranted to inform potential primary prevention strategies for CRC.

#2216 Population attributable fraction of tobacco smoking on cancer incidence in 2020 in the Republic of Korea.

S. Byoun[1], Y.-J. Choi[1], Y. Min[1], S.-K. Park[2], K. Ko[3], S. Sung[2], N. Kim[4], K. Jung[4], S. Jee[4], S.-I. Cho[5], M. Lim[6], S. Park[7], E. Park[8], H. Woo[9], K.-W. Jung[1], E. Yun[1], B. Kim[1], J.-K. Oh[1], Y. Choi[1], B. Park[1], H. Seo[1], J.-S. Im[1];

[1]National Cancer Control Institute, National Cancer Center, Goyang, Korea, Republic of, [2]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of, [3]Clinical Preventive Medicine Center, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [4]Department of Epidemiology and Health Promotion, Institute for Health Promotion, Graduate School of Public Health, Yonsei University, Seoul, Korea, Republic of, [5]Graduate School of Public Health and Institute of Health and Environment, Seoul National University, Seoul, Korea, Republic of, [6]Department of Social and Preventive Medicine, College of Medicine, Inha University, Incheon, Korea, Republic of, [7]Department of Biostatistics, Graduate School of Public Health, Yonsei University, Seoul, Korea, Republic of, [8]Preventive Medicine Department, Korea University College of Medicine, Seoul, Korea, Republic of, [9]Department of Precision Medicine, Korea National Institute of Health, Korea Disease Control and Prevention Agency, Cheongju, Korea, Republic of

Backgrounds: Cancer is the most common cause of mortality in Korea. According to International Agency for Research on Cancer (IARC), tobacco smoking is the Group I carcinogen, and the National Cancer Center Korea reported in 2009 that 20.9% and 2.3% of total cancer incidence were attributable to tobacco smoking in men and women, respectively. As of 2020, we estimated population attributable fraction (PAF) of cancer incidence due to tobacco smoking.
Methods: We organized the Consensus Committee to develop strategy and methodology for PAF estimation. From the consensus, cancer sites for PAF estimation were selected based on the IARC list of classification with sufficient evidence in human. PAF was calculated by using Levin's formula which includes exposure prevalence and relative risk (RR). Exposure prevalence was collected from the Korea National Health and Nutrition Examination Survey (KNHANES) in 2005, assuming that latent period from risk exposure to cancer development was 15 years. Tobacco smoking was defined as a categorical variable including non-smokers, past smokers, and current smokers. Pooled RRs were estimated from meta-analysis of RRs obtained from Korean Genome and Epidemiology Study, National Health Examination data provided by National Health Insurance Services, Korean Cancer Prevention Study-II, and KNHANES, each of which was linked with Korea Cancer Registry. Cox proportional hazards model were used to estimate RRs, while adjusted by age groups and alcohol consumption.
Results: For men, 17.4% of all cancer cases were attributed to smoking, compared to 1.7% for women. Specifically, in men, 57.9% of lung cancer, 36.4% of bladder cancer, 31.9% of esophageal cancer, 39.1% of laryngeal cancer , 25.4% of oral cavity/pharyngeal cancer, 19.7% of liver cancer, and 19.5% of stomach cancer were attributed to tobacco smoking. In women, 51.7% of laryngeal cancer, 15.0% of esophageal cancer, 11.6% of lung cancer, 6.0% of bladder cancer, 5.1% of oral cavity/pharyngeal cancer, 5.0% of cervix cancer, and 4.6% of liver cancer were due to smoking.
Conclusion: Tobacco smoking is an important cause of esophageal, laryngeal, and lung cancer in men, and esophageal and laryngeal cancer in women, and comprises a substantial proportion of PAF in cancer incidence. Thus, intervention measures are needed to reduce smoking prevalence for cancer prevention in Korea. Funding Sources: This work was supported by the National Cancer Center Grant(NCC-2210840).

#2217 Associations between intrauterine device use and ovarian cancer risk among 11 population-based case-control studies.

Jennifer M. Mongiovi[1], Ana Babic[2], Naoko Sasamoto[3], Lauren Peres[4], Holly Harris[5], Mollie E. Barnard[6], Shelley S. Tworoger[7], Anita Koushik[8], Joellen M. Schildkraut[9], Jennifer A. Doherty[10], Kathryn L. Terry[3], the Ovarian Cancer Association Consortium & the African-American Cancer Epidemiology Study

[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Dana Farber Cancer Institute, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Moffitt Cancer Center, Tampa, FL,[5]Fred Hutch, Seattle, WA,[6]Boston University School of Medicine, Boston, MA,[7]Oregon Health and Science University School of Medicine, Portland, OR,[8]McGill University, Montreal, QC, Canada,[9]Emory University Rollins School of Public Health, Atlanta, GA,[10]Huntsman Cancer Institute, Salt Lake City, UT

Background: Intrauterine device (IUD) use has increased while oral contraceptive (OC) use has decreased among premenopausal women. It is unknown whether IUDs offer protection against epithelial ovarian cancer (EOC), similar to OCs, or may increase risk. Therefore, we examined the association between IUD use and EOC risk.

Methods: Information on contraception use was obtained through questionnaires from 11 studies participating in the Ovarian Cancer Association Consortium and African-American Cancer Epidemiology Study. Study-specific odds ratios (OR) and 95% confidence intervals (CI) were calculated using unconditional multivariable logistic regression, and heterogeneity between studies was assessed using Cochran *Q* and I^2 statistics. There was no evidence of heterogeneity, thus data were pooled. We assessed potential effect modification by decade of birth, race, parity, and personal history of endometriosis by reporting stratum-specific estimates and tested for multiplicative interaction by comparing models with and without interaction terms via likelihood ratio test. Polytomous logistic regression was used to estimate histotype-specific associations.

Results: Results were pooled for 11,033 EOC cases and 13,358 controls. There were 2,656 (19.9%) IUD users (mostly non-hormonal) and 8,923 (66.8%) OC users among controls compared to 1,933 (17.5%) IUD users and 6,318 (57.3%) OC users among cases. IUD use was associated with lower risk of endometrioid (OR: 0.73, 95% CI: 0.62-0.86) and clear cell (OR: 0.63, 95% CI: 0.48-0.80), but not high-grade serous subtypes (OR: 1.05, 95% CI: 0.98-1.14), with significant heterogeneity by histotype (p=0.0006). Among studies that collected data on IUD type, we observed a non-significant inverse association between hormonal IUD use and EOC (OR: 0.72, 95% CI: 0.51-1.03); however, only 51 cases reported hormonal IUD use. Among those who used both IUD and OCs, there was no association with the order of contraception use and EOC. There were no major differences in the associations of age at first use, duration of use, or time since last use and EOC risk. Among parous women, IUD use before first pregnancy was associated with a non-significant reduced odds of EOC (OR: 0.82, 95% CI: 0.65-1.04). We also observed a statistically significant interaction between IUD use and endometriosis with reduced odds of EOC associated with IUD use among women with endometriosis (OR: 0.77, 95% CI: 0.60-0.98) but not those without endometriosis (OR: 0.96, 95% CI: 0.90-1.03, *p*-interaction=0.05).

Discussion: IUD use was associated with lower clear cell and endometrioid EOC risk and may be most protective among women with endometriosis. Future research should include cohorts of women with a higher prevalence of hormonal IUD use to determine the impact of changing contraceptive trends on ovarian cancer burden and identifying preventive strategies for women at high risk.

#2218 Dietary insulinemic potential and survival after breast cancer diagnosis.

A. Romanos-Nanclares[1], T. Wang[1], B. A. Rosner[2], M. D. Holmes[2], W. Y. Chen[3], W. C. Willett[2], R. M. Tamimi[4], A. Eliassen[1];
[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Weill Cornell Medicine, New York, NY

Background: Hyperinsulinemia may promote the growth and metastasis of breast cancers by activating the insulin/insulin-like growth factor 1 signaling pathways. Whether the insulinemic potential of the diet contributes to breast cancer prognosis has not been examined previously. Here, we focused on a food-based empirical dietary index for hyperinsulinemia (EDIH), an index previously designed as most predictive of fasting plasma C-peptide. We aimed to investigate whether EDIH (at different time settings) is associated with overall and breast cancer-specific mortality.
Methods: For 9,640 women with stage I-III breast cancer from the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII), we calculated the cumulative average EDIH, using repeated measures of post-diagnostic diet from food frequency questionnaires (FFQ). We also considered the pre-diagnostic EDIH score (using the last FFQ reported before diagnosis), the first postdiagnostic EDIH score, as well as a simple updated EDIH score. Information on diet and other factors was repeatedly measured in validated questionnaires every two to four years. Deaths were ascertained by report from family members or by searching the National Death Index. Multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CI) were estimated using Cox proportional hazards models.
Results: Participants were followed up for a median of 12 years after breast cancer diagnosis. We documented 1,120 deaths due to breast cancer and 2,762 all-cause deaths. Women with higher post-diagnostic EDIH had a 40% higher risk of all-cause mortality (HR for quintile 5 vs. quintile 1 [$HR_{Q5vs.Q1}$], 1.40; 95% CI, 1.22, 1.61; P-trend<0.0001). EDIH was also associated with a 19% increased risk of breast cancer mortality, although the confidence interval included the null ($HR_{Q5vs.Q1}$, 1.19; 95% CI, 0.95, 1.48; P-trend=0.17). Findings for overall mortality were similar for EDIH measured at other timings/settings: last pre-diagnosis dietary assessment ($HR_{Q5vs.Q1}$,1.21; 95% CI, 1.06, 1.39; P-trend<0.0001) and first post-diagnosis dietary assessment ($HR_{Q5vs.Q1}$,1.23; 95% CI, 1.08, 1.40; P-trend<0.0001).
Conclusions: In this large prospective study of breast cancer survivors, higher hyperinsulinemic dietary scores (reflecting higher dietary insulinemic potential) were associated with worse survival outcomes following diagnosis. Thus, dietary recommendations emphasizing the importance of avoiding high insulinemic dietary patterns (i.e., processed meat and red meat) and prioritizing low insulinemic dietary patterns (i.e., coffee, whole fruit and green-leafy vegetables) as components of a healthy diet may improve overall survival.

#2220 Associations between post-diagnostic lifestyle and dietary patterns with prostate cancer survival in the Multiethnic Cohort.

A. Wang[1], E. L. Van Blarigan[2], I. Cheng[2], J. M. Chan[2], P. Wan[3], S.-Y. Park[4], F. Chen[3], L. Le Marchand[4], L. Wilkens[4], S. A. Kenfield[2], C. A. Haiman[3]; [1]Harvard T.H.Chan School of Public Health, Boston, MA, [2]University of California, San Francisco, San Francisco, CA, [3]University of Southern California, Los Angeles, CA, [4]University of Hawaii Cancer Center, University of Hawaii, Honolulu, HI

Background: Prostate cancer (PCa) remains a leading cause of cancer-related death among men despite high 5-year survival rates for localized and regional diseases. This study evaluated healthy lifestyle and dietary patterns in relation to PCa survival in a multiethnic population.
Methods: We prospectively followed 2,603 men with non-metastatic PCa in the Multiethnic Cohort (MEC) for a median duration of 10.9 years (497 African American, 754 Japanese American, 577 Latino, 129 Native Hawaiian, and 646 White men) starting in 1993. We documented 1,321 deaths, including 196 from PCa. Lifestyle pattern was assessed after diagnosis by a previously reported PCa Behavior Score, which includes BMI, physical activity, and smoking, and a modified version including diet (based on the sum of saturated fat, whole milk, alcohol, and processed meat intake). We also evaluated six indices of inflammatory and insulinemic potential of diet and lifestyle patterns (E-DII, EDIP, EDIH, ELIH, EDIR, and ELIR); and three indices of plant-based diets: an overall plant-based diet index (PDI), a healthful PDI (hPDI), and an unhealthful PDI (uPDI). We used Cox proportional hazards models to calculate hazard ratios (HR) and 95% confidence intervals (CI) for the relationship between each index with PCa-specific and all-cause mortality. We adjusted for education, race/ethnicity, smoking, BMI, physical activity (if not part of the score), family history of PCa, and first course of treatment.
Results: Across the five racial/ethnic groups, Japanese American men exhibited healthier lifestyle and dietary patterns post-diagnosis, while African American and Native Hawaiian men tended to have less healthy behaviors. The PCa Behavior Score was statistically significantly associated with a reduced risk of all-cause mortality (HR per point=0.71, 95% CI 0.63-0.80), and a similar trend persisted when incorporating diet into the score. The PDI was statistically significantly inversely associated with all-cause mortality (HR per SD=0.90, 95% CI 0.83-0.97), while the uPDI showed a positive association (HR=1.10, 95% CI 1.12-1.18). None of the lifestyle or dietary patterns were associated with PCa mortality (p-values>0.05). No clear trends were observed for inflammatory and insulinemic dietary patterns after PCa diagnosis with all-cause or PCa-specific mortality.
Conclusion: Adopting a healthy lifestyle and diet was associated with longer overall survival among men with PCa. We did not find these practices to be associated with a lower risk of PCa-specific mortality among men diagnosed with non-metastatic disease. However, 85% of the observed deaths during follow-up were due to other causes; this underscores the importance of counseling all men, including those with non-metastatic prostate cancer on health behaviors to manage comorbidities.

#2221 Reducing cancer disparity among indigenous people by locally prepared Whey protein isolates having selective cytoprotective ability against chemotherapy induced bone marrow stem cell toxicity.

N. Das[1], L. Pathak[1], B. Pal[2], R. Das[3], P. J. Saikia[1], S. Mitra[1], T. Baishya[3], R. Bhuyan[4], H. Li[4], B. Das[1];
[1]KaviKrishna Laboratory, Research Park, Indian Institute of Technology, Guwahati, India, [2]Thoreau Laboratory for Global Health, Lowell, MA, [3]KaviKrishna Telemedicine Care, Sualkuchi, India, [4]Forsyth Institute, Cambridge, MA

Background: Cancer disparity is a major problem for the indigenous people living in the rural area of Kamrup district of Assam, a remote north eastern state of India. Often, rural people are prescribed with expensive dietary supplements during chemotherapy by urban for profit medical centers, increasing disparity, as per a study conducted by KaviKrishna Telemedicine Care (KTC) (1). We seek to reduce cancer disparity by using locally available diet/nutrition of Sualkuchi-Hajo cultural complex, including the whey protein prepared by indigenous healers practicing Vedic Jiva Upakara Cikitsha Tantra (Vejiupacita) (2,3). However, the efficacy of the indigenous Vejiupacita Whey protein is not clearly known. Here we have performed pre-clinical and clinical studies to evaluate the therapeutic efficacy of Vejiupacita Chena Pani (VCP) whey protein in reducing cancer chemotherapy induced bone marrow stem cell niche toxicity.
Methods: Using a previously described pre-clinical model of cisplatin and busalphan induced BM stem cell niche toxicities (4), the cytoprotective activity of VCP Whey protein was evaluated. Commercially available whey proteins Ensure plus, and Immunocal were used for comparisons. Next, the indigenous cancer patients (n=55) of KaviKrishna Telemedicine Care taking the whey protein (20 gm twice daily for three months of chemo and or radiation) were monitored for hemoglobin, total blood count as well as Glasgow prognostic score (ratio of serum albumin and CRP) and ECOG performance score. Third, using a Vejiupacita based Sahasa-ojash scale of well being (3) patient's quality of life was evaluated.
Results: In the pre-clinical model of cisplatin-induced BM toxicity in black 6 mice (n=10 in each group), the VCP whey protein exerted cytoprotection of BM stem cells similar to Immunocal but 2-fold higher protection compared to Ensure plus. Serum glutathione and squalene level was significantly increased only in the VCP whey protein group. The hypoxic niche of CD271+ MSCs showed enhanced stem cell niche protection. Notably, VCP and Immunocal whey protein treatment increased the hypoxic BM stem cell niche defense against cisplatin-induced toxicity. Next, 34/55 patients taking the VCP whey protein (20 gm/twice daily for three months) showed increased hemoglobin level, increased total blood count, and increased weight gain. The Sahasa-ojash scale showed significant improvement in quality of life compared to the period when they did not take whey proteins in a manner similar to Glasgow prognostic score, and ECOG performance score.
Conclusion: The Vejiupcita based whey protein concentrate therapy exerts cytoprotection against chemotherapy induced toxicity.

#2222 Knowledge of risk factors and symptoms of head and neck cancers among Arab-Americans.

E. Adjei Boakye[1], R. F. Siddiqui[1], N. Al-Antary[1], M. Gilbert[1], L. Fakhoury[1], M. Vu[2], F. Siddiqui[1];
[1]Henry Ford Health System, Detroit, MI, [2]Northwestern University School of Medicine, Chicago, IL

Background: In 2023, approximately 66000 patients with head and neck cancers (HNC) will be diagnosed in the United States (U.S.). There are approximately 3.7 million Arab-Americans living in the U.S., with large concentration in Michigan (MI). For example, Dearborn, MI has the largest percentage of Arab-Americans (40% of people having Arab ancestry). Smoking, alcohol, and human papillomavirus (HPV) are the main causes of HNC. Common symptoms of HNC are lump in the neck/mouth, nonhealing ulcers, dysphagia or odynophagia, and change in voice. Currently, there is a scarcity of research on knowledge of HNC risk factors and symptoms among Arab-Americans. We examined knowledge of risk factors and symptoms of HNC among Arab-Americans residing in MI.
Methods: This was a cross-sectional study of adult Arab-Americans (≥18 years) conducted between March and July 2023. Survey questions were adapted from the National Cancer Institute and Centers for Disease Control and Prevention and offered in English and Arabic depending on respondent preference. Awareness of the symptoms of HNCs were assessed using 14 questions while risk factors were assessed using 10 questions. The questions were in the form of “Do you know that the following can be symptoms/risk factors of HNC?” Respondents selected “yes,” “no,” or “don’t know/not sure” for each answer choice.
Results: Of the 295 Arab-Americans survey respondents, the mean age ± SD was 37.9 ± 14.6, and most were female (60.7%), had at least a college degree (57.6%), private health insurance (56.7%), and usual place of receiving care (70.7%). Majority had no history of cigarette use (81.7%) or alcohol use (91.6%). Regarding HNC symptoms knowledge, only 40-50% knew about most common HNC symptoms: nonhealing ulcers (41%), dysphagia or odynophagia (51.4%), and voice changes (48.6%); while 60.6% knew about swelling or lump in neck/throat. About half of respondents knew of persistent mass or lesion on the tongue (53.3%) and bleeding in the mouth or throat (50.3%) as symptoms of HNC. About a third knew these as HNC symptoms: teeth loosening (31.7%), ill-fitting dentures (25.9%), otalgia (37.8%), and nasal obstruction/congestion (34.9%). For HNC risk factors knowledge, tobacco smoking, chewing, and second-hand smoking were the most common recognized risk factors, identified by 78.9%, 72.8% and 66.8%, respectively. However, less than half knew HPV (40.6%) and Epstein-Barr virus (35.4%) as risk factors.
Conclusion: While there is higher knowledge about tobacco as a risk factor for HNC, knowledge about HPV as a risk factor is very low. Similarly, knowledge about HNC symptoms is suboptimal in the Arab-American community, which could result in late-stage presentation and thus lower survival. Educational programs designed for this community are needed to help close this gap and improve HNC related health outcomes among culturally and ethnically distinct Arab-Americans.

#2223 Cancer risk factors and nativity: Lifestyle and sociodemographic disparities among us-born and non-us-born residents and by length of residence in the US.

L. D. Rolle, M. Lopez-Pentecost, R. Clavon, A. Bhatti, Z. Khan, T. E. Crane;
University of Miami Miller School of Medicine, Miami, FL

Background: Previous studies have found racial/ethnic disparities in cancer and cancer-related risk factors. However, the relationship between US nativity status and cancer risk is not well understood. This study aimed to determine the relationship between cancer risk factors, including lifestyle behaviors, demographic characteristics, and nativity status, among US residents. **Methods:** We used data from the 2010 and 2015 National Health Interview Survey (NHIS). All analyses accounted for the NHIS complex survey design. Our sample consisted of 31,252 US-Born and non-US-born residents. Regression models were employed to assess the association of US nativity with various lifestyle and demographic variables, adjusting for potential confounders such as age, race, sex, education, income, and employment status. **Results:** In our sample, 25,153 (82.73%) were US-born. Among non-US-born respondents (n=6,099), 35.13% have resided in the US for less than 15 years, and 64.87% for greater than 15 years. 80.19% of US-born individuals identified as non-Hispanic White (NHW), followed by non-Hispanic Blacks (NHB) (11.71%), and Hispanics (8.10%). For non-US-born residents, 63.67% identified as Hispanic, followed by NHW (24.21%), and NHB (12.12%). Non-US-born individuals had lower odds of consuming red meat (aOR=0.60, 95% CI: 0.47-0.75), and processed meat (aOR=0.36, 95% CI: 0.31-0.43) compared to their US-born counterparts. Notably, non-US-born individuals had significantly higher odds of never smoking (aOR=1.58, 95% CI: 1.35-1.83), never drinking (aOR=2.45, 95% CI: 2.05-2.93), and consuming grains (aOR=1.45, 95% CI: 1.25-1.68) in comparison to US-born individuals. Conversely, non-US-born individuals had lower odds of meeting physical activity guidelines (aOR=0.77, 95% CI: 0.59-0.99), and consuming fruits (aOR=0.86, 95% CI: 0.74-0.99), and consuming vegetables (aOR=0.83, 95% CI: 0.71-0.97). Additionally, non-US-born respondents had higher odds of being overweight/obese compared to normal weight (aOR=1.36, 95% CI: 1.16-1.60) compared to US-born respondents. When considering the length of time in the US, non-US-born residents with greater than 15 years of residence had lower odds of being normal weight compared to overweight/obese (aOR=0.78, 95% CI: 0.63-0.97), and never drinking alcohol (aOR=0.73, 95% CI: 0.56-0.93). **Discussion:** These disparities highlight the association of nativity and length of residence on health-related behaviors and outcomes in the United States, and the need for targeted public health interventions considering nativity and residency duration to address these health disparities.

POPULATION SCIENCES: Survivorship Research

#2227 Physical activity at breast cancer diagnosis and incident cardiovascular disease in the Pathways Study.

J. K. Kresovich[1], **A. R. Richards**[1], I. J. Ergas[2], C. A. Laurent[2], R. Cannioto[3], J. S. Rana[2], J. M. Roh[2], C. Thomsen[4], S. Shariff-Marco[5], E. Rillamas-Sun[6], R. K. Cheng[7], S. Yao[3], C. B. Ambrosone[3], L. H. Kushi[2], H. Greenlee[6], M. L. Kwan[2];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]Kaiser Permanente Northern California, Oakland, CA, [3]Roswell Park Cancer Center, Buffalo, NY, [4]Zero Breast Cancer, San Rafael, CA, [5]University of California at San Francisco, San Francisco, CA, [6]Fred Hutchenson Cancer Center, Seattle, WA, [7]University of Washington Medical Center, Seattle, WA

Background: Breast cancer survivors are at increased risk of cardiovascular disease (CVD) compared to women without a history of breast cancer. Although cardiotoxic cancer treatments influence these risks, lifestyles that are associated with both breast cancer and CVD also contribute. With the number of breast cancer survivors expected to increase, a growing need exists to identify modifiable risk factors that protect against the development of CVD after diagnosis. Physical activity at breast cancer diagnosis is associated with lower cancer recurrence and mortality risk. However, associations between physical activity at diagnosis and incident CVD have yet to be investigated in detail.

Methods: The Pathways Study is a prospective cohort study of 4,504 women who were members of Kaiser Permanente Northern California (KPNC) when diagnosed with first primary invasive breast cancer between 2005 and 2013. At enrollment, women self-reported their frequency, duration, and intensity of physical activities during the previous six months using the Arizona Activity Frequency Questionnaire. This information was used to dichotomize the women's physical activity levels by the CDC's Physical Activity Guidelines for Americans (≥ 150 minutes of moderate-to-vigorous physical activity per week vs less). CVD events were obtained from electronic health records as part of the Pathways Heart Study and were defined as post-diagnostic incidence of ischemic heart disease, heart failure, cardiomyopathy, and stroke. Deaths were documented through several sources, including the National Death Index. Women were followed until the first of disenrollment from the KPNC health plan, death, or December 31, 2021. Competing risk Cox regression models were used to estimate associations between meeting CDC physical activity guidelines and CVD.

Results: In this cohort of breast cancer survivors, women who self-reported meeting physical activity guidelines at diagnosis experienced lower rates of post-diagnostic CVD events (8.6% vs 13.1%). After adjustment for socio-demographic factors, meeting physical activity guidelines remained associated with lower risk of CVD (HR: 0.78, 95% CI: 0.61, 0.98); this association appeared to be driven by reduced risk of heart failure (HR: 0.68, 95% CI: 0.50, 0.93) and cardiomyopathy (HR: 0.51, 95% CI: 0.28, 0.92). Approximately 15% of the CVD risk reduction in Pathways Study participants can be attributed to meeting physical activity guidelines (population attributable risk percent: 14.5%, 95% CI: 8%, 21%).

Conclusions: Compared to women who did not meet CDC physical activity guidelines, women who reported meeting guidelines near the time of their breast cancer diagnosis had decreased risk of future CVD, including heart failure and cardiomyopathy. Future studies investigating changes in post-diagnostic physical activity patterns and CVD risk are warranted.

#2228 Long-term trajectories of functional disability in older adults with cancer.

G. E. Nam, E. R. Mayeda, Z.-F. Zhang;
UCLA Jonathan and Karin Fielding School of Public Health, Los Angeles, CA

Background: Older individuals with cancer history have lower risk of developing Alzheimer's disease (AD). Cognitive impairment is associated with lower functioning in Instrumental Activities of Daily Living (IADL) and Activities of Daily Living (ADL). However, little is known about long-term IADL and ADL trajectories among individuals with cancer, hindering understanding of the underlying biological mechanisms between cancer and AD. We investigated the long-term functional disability trajectories of adults with cancer, comparing them with similarly aged individuals without a cancer diagnosis.
Methods: Our study included 16,006 individuals aged 50 and older without a cancer history at baseline from the Health and Retirement Study. Biennial assessments were conducted from 1998 to 2020, including self-reported cancer status, IADL, and ADL. Linear probability models with repeated measures were used to assess IADL and ADL independence probabilities, adjusting for demographic and socioeconomic covariates.
Results: Among 16,006 participants (mean [SD] baseline age, 66.1 [9.9] years; 9,169 [57.3%] female), 3,723 (23.3%) reported a cancer diagnosis during follow-up. Before cancer diagnosis, individuals who later developed cancer had a higher probability of IADL independence and experienced a slower decline in independence compared to their similarly aged counterparts who remained cancer-free. Probability of IADL independence was 0.05 lower immediately after cancer diagnosis compared to the pre-cancer phase, followed by accelerated independence losses relative to the pre-cancer period. After diagnosis, the rate of decline in probability of IADL independence remained slower for individuals with cancer than their cancer-free counterparts, but differences in the rate of decline were smaller than prior to cancer diagnosis. Similar trends were observed for ADL independence.
Conclusions: We observed a decline in both IADL and ADL independence around the time of cancer diagnosis, possibly attributed to treatments. Overall, individuals with cancer experienced a more gradual loss in functional independence compared to individuals who remained cancer-free, consistent with the documented inverse association between cancer and AD.
Funding information: The current research was supported by the National Cancer Institute of the National Institutes of Health (T32CA009142), T32 Training Grants from the NCI/NIH, and the National Institute on Aging (RF1AG059872).

#2229 Clinico-pathologic analysis and survival of patients with breast cancer diagnosed with *de novo* brain metastasis: An NCDB-based analysis.

A. Hijazi[1], M. Mohanna[1], S. Sabbagh[1], M. Herran Montes[1], B. Dominguez[1], K. Sarna[2], Z. Nahleh[1];
[1]Cleveland Clinic Florida Foundation, Weston, FL, [2]Cleveland Clinic Foundation, Weston, FL

Introduction: Patients with breast cancer with brain metastasis (BCBM) have poor survival outcomes. In this study, we aimed to explore the clinico-pathologic and therapeutic factors predicting the survival in de novo BCBM patients using the National Cancer Database (NCDB).
Methods: The NCDB was queried for patients with BC between 2010-2020. Survival analysis with Kaplan-Meier curves and log rank tests were used to find median overall survival (OS) in months (95% CI) across the different variables. A multivariate cox regression model was computed to identify significant predictors of survival. All values in the results were statistically significant at $p<0.05$.
Results: N=9,005 (0.34%) had de novo BM out of 2,610,598 BC patients with a median OS of 10.9 (10.3-11.5). A trend of decreasing median OS was observed with increasing age: highest in the ≤50 group at 18.96 (16.92-20.86) and lowest in the ≥70 group at 4.70 (4.07-5.29), Charlson-Deyo score (CDS): 12.42 (11.76-13.17) in the 0 score and 2.86 (2.17-3.78) in ≥3 score, and number of extracranial metastatic sites (EMS): 13.17 (12.02-14.36) in the 1 site and 7.59 (6.70-8.84) in the ≥3 sites group. The HR(+)/HER2(+) subgroup had the highest median OS at 22.05 (18.73-24.67) compared to the lowest in the HR(-)/HER2(-) group at 5.62 (5.19-6.18). Based on treatment regimen, surgery + whole brain radiation therapy (WBRT), chemotherapy + hormonal therapy + immunotherapy (biologic therapy including anti-HER2), and combination of BM + BC therapy achieved the highest median OS in their respective subgroups of 32.33 (23.98-40.44), 42.35 (35.48-54.14), and 16.30 (15.11-17.38), respectively. Similar trends were found in the BC subgroup analysis with immunotherapy demonstrating a survival benefit when added to systemic therapy.The multivariate cox regression model showed that age, race, ethnicity, insurance, median income, facility type, CDS, BC subtype, metastatic location sites, and treatment combinations received were significantly associated with risk of death. Age ≥70 years, CDS ≥3, ≥3 EMS, and receiving no treatment for either BM or BC had the highest risks of death with Hazard Ratio (95% CI) of 1.53 (1.31-1.79), 1.74 (1.39-2.18), 2.06 (1.78-2.38), and 2.65 (2.36-2.98), respectively. The HR(+)/HER2(+) subgroup had the lowest risk of death at 0.43 (0.38-0.49) and receiving only local treatment for BM increased the risk of death 2.3 (2.00-2.63).
Conclusions: This analysis suggests that treatment of systemic disease is the major factor influencing survival in BCBM patients and surgery + WBRT yields the best survival outcomes. Moreover, anti-HER2 therapy and biologic treatment increased survival when added to systemic therapy. To date, this represents the biggest cohort of de novo BCBM survival analysis which provides critical insights that may guide clinical management.

#2230 Connecting Black men to point of prostate cancer diagnosis (PPCD) support using precision intervention based on Virtual Reality Assistant (ViRA).

F. T. Odedina[1], C. Ngufor[1], A. Merriweather[2], D. Pereira[3], R. Dronca[1], E. Kaninjing[4], K. Ashing[5], S. Rotimi[6], V. Gordon[1], iCCaRE for Black Men Consortium; [1]Mayo Clinic Comprehensive Cancer Center, Jacksonville, FL, [2]American Legion Post 197, Jacksonville, FL, [3]University of Florida, Gainesville, FL, [4]Georgia College, Milledgeville, GA, [5]City of Hope, Duarte, CA, [6]Covenant University, Ota, Nigeria

Background: The point of prostate cancer (CaP) diagnosis (PPCD) instantly leads to a life changing experience for Black men, with diverse emotional reactions that includes fear, denial, overwhelmingness, cancer fatalism etc. Black men diagnosed with CaP expressed several needs at the PPCD, including time to reflect on the diagnosis, being comfortable, emotional support, psycho-oncology support and social determinants of health (SDOH) navigation. Given that Black men are diverse in terms of their needs at the PPCD, precision intervention is needed to support them.

Aim: The aim was to develop, implement, and establish the acceptance and usability of a Virtual Reality Assistant (ViRA) that will provide precision intervention tailored to the needs of Black men at the PPCD. This study is one of the five iCCaRE for Black Men projects focused on survivorship care.

Methodology: The development of the ViRA was guided by CaP survivors through qualitative study. Reflective, analytic, and interpretive memos were used to generate action plans for the development of the ViRA. Based on a comprehensive PPCD ViRA intervention guide created by the team, the ViRA prototype was developed with mobile immersive technologies that integrated SDOH navigation, standard CaP psycho-oncology support and emotional support. The goal was to have the intervention personalized to everyone based on participant-provided information. Alpha testing of the ViRA is ongoing and will be completed on November 20, 2023. Participants are three prostate cancer survivors and three clinicians. The assessments will confirm the accuracy of the ViRA predictions and the functionality of the ViRA.

Results: We developed the ViRA SDOH screening and navigation tool to identify participants' needs and appropriately connect them with relevant support services and resources in their communities. The emotional support intervention was based on four CaP survivors as virtual reality avatars, providing empathetic rapport through self-disclosure and sharing of survivorship stories in different settings (home, clinic, barbershop etc). The psycho-oncology support intervention was developed with the guidance of a psycho-oncologist, with her avatar providing psychoeducation about the PPCD experience, reify and concretize the PPCD experience, and foster hope using the basic tenets of Problem-Solving Therapy. The results of the alpha testing and the modified ViRA will be presented during the conference.

Conclusion: Meeting the needs of Black men at the PPCD requires a personalized and decentralized approach, which would allow Black men to access support anywhere. The presentation will unveil the iCCaRE ViRA, a smart and connected personalized AR-enabled intervention that will deliver SDOH navigation, CaP psycho-oncology support and emotional support tailored to the needs of Black men.

#2231 Impact of sociodemographic and clinical factors on symptom burden in the young adult primary central nervous system tumor population.

Kimberly Reinhart[1], Tricia Kunst[1], Jennifer Reyes[1], Alvina Acquaye-Mallory[1], Ewa Grajkowska[1], Byram H. Ozer[1], Marta Penas-Prado[1], Jing Wu[1], Eric Burton[1], Lisa Boris[2], Marissa Panzer[2], Tina Pillai[1], Lily Polskin[2], Mark R. Gilbert[1], Elizabeth Vera[1], Terri S. Armstrong[1]

[1]Neuro-Oncology Branch, NIH-NCI, Bethesda, MD,[2]Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD

Purpose: The goal of this analysis was to provide insight into differences in perceived symptom burden and general health status between young adults (YA; 18-39 years of age) and older adults (OA; ≥ 40 years of age) with primary central nervous system (PCNS) tumors. Determining differences in characteristics that impact symptom burden and general health status in YA will allow for tailored survivorship programs that meet the unique needs of this population.
Methods: Data were retrospectively analyzed from the National Cancer Institute Neuro-Oncology Branch's Natural History Study (NCT02851706 PI: T.S. Armstrong), which is an observational prospective cohort study designed to follow and collect PROs and clinical information on patients diagnosed with PCNS tumors throughout their disease trajectory. Differences in patient-reported outcomes (general health status [EQ-5D-3L], symptom burden [MDASI-BT and MDASI-SP], anxiety/depression [PROMIS], and perceived cognition [Neuro-QOL]) and demographic and clinical data were assessed using chi-square tests, one-way ANOVAs, and Students' t-tests. Linear regression with backward elimination determined which characteristics impacted perceived symptom burden and general health status as evidenced by MDASI-BT and EQ-5D-3L, respectively.
Results: The sample included 271 YA (82% with a primary brain tumor [PBT]; median age 31 [range, 18-39]) and 516 OA (88% with a PBT; median age 54 [range, 40-85]). YA were more likely to be single (P<0.001), employed (P<0.001), and make < $50,000 per year (P=0.014). More YA reported pain (P=0.008), nausea (P<0.001), drowsiness (P=0.043), and vomiting (P=0.001) than OA. More YA presented with vision problems (25% of YA, 16% of OA), whereas more OA presented with cognitive deficits (17% of YA, 25% of OA). Compared to YA, 7% more OA with PBTs and 19% more OA with primary spinal tumors (PST) were diagnosed in outpatient clinics, whereas the majority of YA with PBTs (47%) were diagnosed in an emergency room. Among demographic and clinical characteristics, only Karnofsky Performance Scale score was a predictor of general health status (P<0.001) in YA with PCNS tumors and symptom interference (P=0.014) in YA with PBTs. YA reported more affective, cognitive, neurologic, treatment-related, generalized disease, and gastrointestinal symptom burden than OA, with the affective factor being the most severe among the symptom factors reported. Among individuals with PSTs, 20% more YA reported moderate-severe anxiety (P=0.050) and 32% more YA reported moderate-severe perceived cognitive deficits (P=0.023) than OA.
Conclusion: YA patients were more likely to be single, employed, have a lower income, and report more symptom burden than OA. These findings underscore the need for tailored survivorship programs providing additional psychosocial support and resources to address symptom presentation in YA.

#2232 Association between sleep characteristics and cancer survival: Findings from the UK Biobank study.

J. Che[1], J. Lv[1], K. Pan[1], T. Sun[2], C. Cao[3], S. Li[4], T. Zhang[1], F. Xue[1], **L. Yang**[5];
[1]Shandong University, Jinan, China, [2]CancerControl Alberta-Alberta Health Services, Calgary, China, [3]Dana-Faber Cancer Institute, Boston, MA, [4]Children's Hospitals and Clinics of Minnesota, Minneapolis, MN, [5]CancerControl Alberta-Alberta Health Services, Calgary, AB, Canada

Background
Sleep characteristics have been associated with patient outcomes after cancer. We aimed to appraise the causal relationship of chronotype, sleep duration, insomnia, and snoring with cancer survival.
Methods
This large prospective cohort study enrolled 38350 cancer survivors aged ≥40 years from the UK Biobank between 2004 and 2022. Habitual sleep characteristics were obtained from the self-reported baseline questionnaire, including chronotype, sleep duration, insomnia, and snoring. Cox proportional hazards regression models were applied to evaluate the association between sleep characteristics and cancer survival, then one sample Mendelian randomization (MR) analyses were further used to validate these causal relationships. In particular, restricted cubic splines (RCS) and non-linear MR analyses were applied to assess the possible nonlinear association between sleep duration and cancer survival.
Results
Among 38350 study participants (mean [SD] age, 59.8 [7.3] years; 24150 [63.0%] males; 35534 [92.7%] White individuals), 12671 (33.1%) reported evening preference chronotype; 9050 (23.6%) reported short and 3773 (9.8%) reported long sleep duration;12274 (32.0%) reported snoring; and 30426 (79.4%) reported experiencing insomnia sometimes or usually. During up to 18 years of follow-up, 6274 deaths occurred. Multivariable regression models showed that evening preference (HR = 1.09, 95% CI: 1.03 to 1.15), short (HR = 1.14, 95% CI: 1.07 to 1.21) and long sleep duration (HR = 1.37, 95% CI: 1.28 to 1.48), insomnia (HR = 1.14, 95% CI: 1.09 to 1.21) and snoring (HR = 0.83, 95% CI: 0.78 to 0.87) were associated with death among pan to cancer survivors. Restricted cubic splines suggested nonlinear associations between sleep duration and death after cancer (nonlinear $P < 0.001$). In the one-sample MR, genetically predicted sleep duration (HR = 0.71, 95% CI: 0.56 to 0.90) and snoring (HR = 1.18, 95% CI: 1.05 to 1.34) demonstrated a reversed cancer survival pattern compared to multivariable regressions. A nonlinear U-shape association between sleep duration and cancer survival was observed in restricted cubic spline analyses ($P < 0.001$) but not evident when evaluating by nonlinear MR ($P > 0.05$).
Conclusions
Evening preference chronotype, insomnia, snoring, and short sleep duration are likely to be causally associated with a higher risk of death among cancer survivors, whilst long sleep duration does not appear to be a causal factor.

#2233 Limited adherence to clinical practice guidelines on fertility preservation for patients with early-onset cancer.

S. R. Keller[1], M. A. Lewis[2], A. Rosen[3], H. K. Park[4], R. Babyak[1], J. Feldmann[5], F. Ye[6], R. Agarwal[6], K. K. Ciombor[6], T. M. Geiger[1], C. Eng[6], M. K. Roach[1], D. R. Velez Edwards[1], M. L. Cote[7], R. Viskochil[8], **A. N. Holowatyj**[6];

[1]Vanderbilt University Medical Center, Nashville, TN, [2]Intermountain Healthcare, Murray, UT, [3]American Cancer Society, Atlanta, GA, [4]Providence Saint John's Health Center, Santa Monica, CA, [5]EGFR Lung Resisters Group, Chicago, IL, [6]Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN, [7]Indiana University Simon Comprehensive Cancer Center, Indianapolis, IN, [8]University of Massachusetts Boston, Boston, MA

Background: ASCO Clinical Practice Guidelines on fertility preservation (FP) recommend that healthcare providers discuss the possibility of infertility—including FP options—for cancer patients of reproductive-age as early as possible before treatment initiation. However, the evaluation of patient perceptions on provider adherence to these FP guidelines is largely undetermined. We sought to assess patient-reported provider adherence to FP guidelines for adults ages 18 to 49 years when diagnosed with a first primary cancer (early-onset).

Patients and Methods: The Reproductive Health After Cancer Diagnosis and Treatment (REACT) Study is a patient-partnered study in cooperation with 23 community partners and patient advocates. Adults with a first primary early-onset cancer were recruited over an 8-week period (October to December 2021). Patient-reported provider adherence to FP guidelines, reproductive health history, sociodemographic, cancer and cancer impact questions were prospectively collected via patient questionnaire using a secure, web-based application. To examine the association of provider non-adherence with patient-level factors, logistic regression models were fitted to estimate odds ratios (OR) and 95% CI.

Results: Among 647 patients diagnosed with early-onset cancer between 2006 and 2021 (mean [SD] age, 36.8 [7.8] years), a total of 376 (58.1%) reported that a healthcare professional involved in their cancer care did not discuss FP options before starting cancer treatment. Patients with thyroid, lung, ovarian and colorectal cancers reported the highest rates of provider non-adherence to FP guidelines (all ≥63% non-adherence). Females with cervical (OR 2.87, 95% CI: 1.11-7.41), colorectal (OR 2.05, 95% CI: 1.15-3.68), lung (OR 15.79, 95% CI:5.66-44.1) and ovarian (OR 10.90, 95% CI: 3.19-37.3) cancers, Hodgkin (OR 4.00, 95% CI: 1.15-13.98) and non-Hodgkin lymphoma (OR 4.65, 95% CI: 1.11-19.47) were more likely to report provider non-adherence to FP guidelines compared to breast cancer patients in models adjusted for diagnosis age and year, self-reported race/ethnicity, marital status and insurance coverage at cancer diagnosis. Similar patterns were observed for male patients with early-onset colorectal and lung cancers compared with testicular cancer patients. No overall or sex-specific associations were observed between patient-reported provider non-adherence and race/ethnicity, insurance coverage or diagnosis year.

Conclusions: Nearly six of every 10 early-onset cancer patients reported that a healthcare professional involved in their cancer care did not discuss FP options prior to cancer treatment. The development of tailored, effective strategies for implementation of clinical practice guidelines on FP and delivery of concordant reproductive healthcare to a growing population of reproductive-age individuals with cancer is needed.

#2234 Cardiovascular disease risk among men with prostate cancer: Differences by prostate cancer aggressiveness.

Caroline Himbert[1], Anna Plym[2], Jane B. Vaselkiv[3], Andreas Pettersson[2], Philip W. Kantoff[4], Lorelei A. Mucci[3], Kenneth J. Mukamal[1], Konrad H. Stosapck[1]

[1]Clinical and Translational Epidemiology Unit, Massachusetts General Hospital, Boston, MA,[2]Clinical Epidemiology Division, Karolinska Institutet, Stockholm, Sweden,[3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[4]Convergent Therapeutics Inc., Boston, MA

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality among men diagnosed with prostate cancer. We evaluated the extent to which men with prostate cancer develop CVD accounting for potential factors that may contribute to the CVD burden in this population.
Methods: We prospectively followed men diagnosed with prostate cancer and free from CVD (stroke and coronary heart disease, including myocardial infarction, coronary artery bypass graft, and percutaneous coronary intervention) before their cancer diagnosis in the Health Professionals Follow-up Study, between 1986 and 2016. Men were categorized by D'Amico prostate cancer risk groups as low-risk (stage T1-2a, Gleason score ≤6, and PSA at diagnosis ≤10 ng/mL), intermediate-risk (T2b and/or Gleason score 7 and/or PSA >10-20), or high-risk (≥T2c/N1/M1 or Gleason score 8-10 or PSA >20). Incident fatal and non-fatal CVD, defined as coronary heart disease and stroke after cancer diagnosis, were centrally adjudicated. CVD risk factors including smoking, hyperlipidemia, hypertension, diabetes mellitus, body mass index, were self-reported on biennial questionnaires. Deaths due to prostate cancer or other causes were treated as competing events when estimating cumulative incidence and cause-specific hazard ratios (HR).
Results: Among 5,707 prostate cancer patients, 1,912 had low-risk, 2,261 had intermediate-risk, and 1,534 had high-risk cancer. 1,102 CVD events were documented over up to 30 years of follow-up after cancer diagnosis. The 10-year CVD risk was 8.1% for men with low-risk cancer, 8.8% for intermediate-risk, and 10.4% for high-risk cancer. The cause-specific HRs for CVD were 1.18 (95% CI 1.03, 1.36) in intermediate-risk and 1.59 (95% CI 1.36, 1.85) in high-risk prostate cancer, both compared to low-risk prostate cancer. Men with high-risk cancer tended to be older; after age adjustment, the HRs were 1.15 for intermediate-risk (95% CI 1.00, 1.33) and 1.35 for high-risk cancer (1.35, 95% CI 1.16, 1.58). Associations between cancer risk group and CVD were essentially unchanged after further adjustment for CVD risk factors present at cancer diagnosis, primary cancer treatment modality (surgery, radiation, androgen deprivation therapy, watchful waiting/active surveillance), and calendar year of diagnosis.
Discussion: Despite the elevated risk of cancer mortality in men with intermediate-risk and high-risk prostate cancer compared to low-risk prostate cancer, CVD risk remains at least as common over time among these men as among men with low-risk prostate cancer. Incident CVD risk after cancer diagnosis among men with more aggressive cancers, which particularly occur in older men, is not primarily attributable to differences in pre-existing risk factor burden. These findings from a cohort with healthcare access and literacy indicate a need for continued clinical attention to CVD after cancer diagnosis.

#2235 Epigenetic inflammation scores for C-Reactive protein and interleukin-6 associate with adverse cardiometabolic and cardiac outcomes among survivors of childhood cancer.

Q. Dong, Y. Chen, X. Zhang, J. Easton, H. Mulder, E. Walker, G. Neale, K. Shelton, S. B. Dixon, J. Zhang, G. T. Armstrong, M. M. Hudson, K. K. Ness, Z. Wang;
St. Jude Children's Research Hospital, Memphis, TN

Background: Inflammaging, a chronic low-grade inflammation as individuals age, is measured by elevated levels of circulating markers of inflammation (e.g., C-reactive protein [CRP] and interleukin-6 [IL-6]) and is associated with age-related chronic health conditions (CHCs). We aim to evaluate epigenetic inflammation scores (EIS) for CRP and IL-6 and their associations with cardiometabolic and cardiac-based CHCs and epigenetic age acceleration (EAA) in childhood cancer survivors (CCS).
Methods: Among 2,052 CCS (47.2% female; mean [SD] = 33.7 [9.3] years of age at blood draw) from the St Jude Lifetime Cohort, EIS of CRP and IL-6 were calculated as the weighted sum of the DNA methylation (DNAm) levels of CpGs that are associated with circulating levels of CRP or IL-6, where blood DNAm data were generated with Infinium EPIC BeadChip, and weights are regression coefficients from previously published EWAS studies. CHCs with a CTCAE (Common Terminology Criteria for Adverse Events) grade ≥2 were considered except for myocardial infarction (MI) where a minimum CTCAE grade of 3 was applied. Residuals of EIS were calculated by regressing EIS on age at blood draw and sex. A multivariable Cox proportional hazard regression model evaluated the associations between the EIS residuals and each CHC adjusting for sex and cancer treatments. The timeframe was years since age at blood draw. All participants alive at the last follow-up were censored. EAA was calculated as residuals from regressing epigenetic age (both GrimAge and PhenoAge) on age at blood draw. A linear regression model evaluated the association between the EIS residual and EAA adjusting for sex and treatments.
Results: The incidence of cardiometabolic conditions (i.e., after the blood draw) included: abnormal glucose metabolism (AGM, 5.1%), hypertension (HTN, 16.6%), hypercholesterolemia (HCL, 3.9%), hypertriglyceridemia (HTG, 6.0%), and cardiomyopathy (CMP, 9.0%), MI (4.4%), and obesity (24.2%). CRP-EIS and IL6-EIS were correlated (r=0.62). The CRP-EIS residual was significantly associated with increased risk of AGM (Hazard Ratio [95% CI] = 1.33 [1.01-1.75], P=0.04) and CMP (1.44 [1.19-1.74], $P=1.58\times10^{-4}$) and suggestively associated with HTN (1.16 [0.99-1.36], P=0.07) and MI (1.55 [0.94-2.57], P=0.09). IL6-EIS residual was associated with CMP (1.25 [1.04-1.49], P=0.02). In addition, both CRP- and IL6-EIS were positively associated with PhenoAge-EAA (β = 0.53 and 0.50 years per SD increase of EIS) and GrimAge-EAA (β = 0.30 and 0.36 per SD increase of EIS).
Conclusion: The CRP- and IL6-EIS are associated with increased risk of cardiometabolic and cardiac-based CHCs and EAA among CCS, suggesting that EIS may be used as clinical tools to identify survivors at higher risk of such CHCs and inflammation may be targeted for intervention to reduce the burden of CHCs.

#2237 Determinants of time to cancer treatment initiation at a comprehensive cancer center.

N. J. Nonzee[1], M. Razavi[1], W. Dale[1], L. Cai[1], A. Mercurio[1], L. Gaytan[1], D. Lefkowitz[2], C. Kim[1], T. Hernandez[1], S. Morales[1], D. Duque[1], A. I. Tergas[1]; [1]City of Hope, Duarte, CA, [2]University of California, Riverside, Riverside, CA

Background: Delays in treatment initiation adversely impact cancer mortality and survival. To inform potential enhancements and targets for our existing oncology patient navigation program, we examined characteristics associated with timely treatment initiation among patients at a tertiary comprehensive cancer center that serves four diverse counties in Southern California.

Methods: We performed a retrospective analysis of patients newly diagnosed with non-hematological cancers between January 2020 and June 2023. Using electronic medical record data, we used a multivariable Cox proportional model to examine the association between patient demographic and clinical characteristics and time to treatment initiation (time between first encounter and start of definitive treatment) within a clinical benchmark of 3 months. A hazard ratio (HR)>1 indicates shorter (faster) time to treatment initiation while a HR<1 indicates a longer (slower) time.

Results: Our sample included 9,148 patients, who were predominantly <65 years (57%), female (61%), married or with a partner (64%), and retired or unemployed (56%); 50% were non-White. In multivariable analyses, patient's age, primary language, employment status, cancer diagnosis type, and first treatment type were significant determinants of time to treatment initiation. Faster treatment initiation was observed among patients ages >=75 vs <65 years (HR=1.36, 95% CI 1.23 - 1.52). Among the primary languages spoken in our sample (Spanish, Chinese, Korean, Vietnamese, among others), patients who spoke Armenian vs English also had shorter time to treatment (HR=1.64, 95% CI 1.32 - 2.04). By contrast, longer time to treatment initiation was associated with patients who were retired or disabled vs employed full-time (HR=0.85, 95% CI 0.78 - 0.94, and HR=0.70, 95% CI 0.59 - 0.83, respectively) and underwent radiation or oral chemotherapy vs chemo-infusion (HR=0.65, 95% CI 0.57 - 0.74, and HR=0.82, 95% CI 0.76 - 0.89, respectively). With the exception of melanoma, all diagnoses had a longer time to treatment compared with neuro-oncology. In our multivariable model, sex, marital status, race and ethnicity, and receipt of at least one navigation encounter were not significant determinants.

Conclusions: In our study, which overlapped the early stages of the COVID-19 pandemic, findings highlight opportunities to enhance navigation delivery, especially for certain subpopulations, diagnoses, and treatment types with complex scheduling and coordination needs. Future research will explore navigation intensity and other process and clinical outcomes modifiable through navigation.

#2238 Reducing cardiovascular disease risk in cancer survivors: Impact of a 16-week circuit-based interval exercise intervention.

A. J. Normann[1], R. L. Wilson[2], C. N. Christopher[3], M. K. Norris[2], S. Cuomo[4], C. M. Dieli-Conwright[2];
[1]Boston University, Boston, MA, [2]Dana Farber Cancer Institute, Boston, MA, [3]Harvard University, Boston, MA, [4]University of Turin, Turin, Italy

Introduction: Obesity and physical inactivity pose a significant health concern for cancer survivors in developing comorbid conditions such as type 2 diabetes, hypertension, and metabolic syndrome that lead to a heightened risk of cardiovascular disease (CVD). Therefore, regular physical activity plays a central role in reducing the risk of CVD. The Framingham risk score (FRS) is an established assessment of CVD risk that combines six risk factors including age, gender, high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), systolic blood pressure, diabetes, and smoking status. The objective of the study was to investigate the effects of a 16-week circuit, interval-based exercise training intervention on FRS and the 10-year FRS-predicted risk of developing CVD among breast, prostate, and colorectal cancer survivors.

Methods: This single center, pilot randomized controlled trial consisted of 90 sedentary, overweight or obese (BMI > 25.0 kg/m^2) survivors of breast, prostate or colorectal cancers, randomized to exercise (n=60) or usual care (n=30). The 16-week intervention comprised supervised moderate to vigorous intensity aerobic (65-85% of VO2max) and resistance (65-85% of 1-repetition maximum) exercise sessions conducted in a circuit-based interval fashion, occurring three times per week. Blood samples were obtained at baseline and post-intervention time points to measure fasting plasma levels of HDL-C and LDL-C, along with resting systolic blood pressure and diagnosis of diabetes. Paired t-test and repeated measure ANOVA were used to determine between-group differences.

Results: Participants (age 63.2 ± 10.8 years) were diagnosed with breast (35%), prostate (30%), and colorectal (35%) cancers and consisted of 55% female participants, participants had a mean BMI of 34.7±5.9, and 85% were obese. Chemotherapy and/or radiation therapy was completed by 75% of participants. Retention and adherence rates to exercise were high (100% and 92%, respectively). Compared to usual care, circuit, interval-based exercise significantly reduced total FRS (between group mean difference, -12.0 points p<0.001) and 10-year CVD risk (-10.0%; p<0.001).

Conclusions: This study underscores the critical role of circuit-based, interval exercise interventions in mitigating the elevated cardiovascular risk faced by sedentary, overweight, or obese cancer survivors. The significant reduction in FRS components highlights the potential of structured exercise programs to enhance cardiovascular health, thereby reducing the burden of comorbid conditions and CVD risk in cancer survivors.

#2239 Comparative effectiveness of cystoscopy surveillance strategies on mortality in non-muscle invasive bladder cancer: A target trial emulation using real-world data.

E. E. McGee[1], X. Garcia de Albeniz[2], A. Eliassen[1], K. Yim[3], B. A. Dickerman[1], M. A. Preston[3], M. A. Hernan[1];

[1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]RTI Health Solutions, Barcelona, Spain, [3]Brigham and Women's Hospital, Boston, MA

Background: More than 60,000 U.S. adults are diagnosed with non-muscle invasive bladder cancer (NMIBC) each year. These patients are recommended to undergo surveillance via repeated cystoscopies. However, the ideal frequency of post-diagnostic cystoscopy surveillance remains unknown, and efforts are underway to de-escalate surveillance given uncertainty regarding its effect on mortality. We therefore aimed to compare the effectiveness of different post-diagnostic cystoscopy surveillance strategies on bladder cancer specific mortality.

Methods: We used observational data from the Surveillance, Epidemiology, and End Results (SEER)-Medicare linkage to emulate a target trial, i.e., a hypothetical, pragmatic randomized trial that would answer our causal question. Eligible individuals were aged 66 years or older, diagnosed with NMIBC (Ta, Tis, or T1) classified as urothelial carcinoma between January 1, 2000 and December 31, 2017, and had completed their first post-diagnostic cystoscopy. We compared 10-year risks of bladder cancer specific mortality under cystoscopy surveillance every 3, 6, and 12 months separately among individuals at low, intermediate, and high risk. We estimated mortality risks using inverse probability weighted pooled logistic regression.

Results: Among 58,004 eligible individuals, the median age at diagnosis was 77 years (interquartile range: 72, 82) and 75.6% were male. Over the 10 year follow-up period, 4,977 bladder cancer deaths occurred. Among individuals at high risk, the estimated 10-year bladder cancer mortality risks were 24.5% under the 3 month strategy, 26.6% under the 6 month strategy, and 27.3% under the 12 month strategy. Compared with cystoscopy every 3 months, the risk differences were 2.1% (95% confidence interval [CI]: -0.3, 3.8) for cystoscopy every 6 months, and 2.8% (95% CI: 1.0, 4.4) for cystoscopy every 12 months. For patients in the intermediate risk group, 10-year bladder cancer mortality risks were 14.4% under the 3 month strategy, 15.1% under the 6 month strategy, and 15.9% under the 12 month strategy. The risk differences were 0.7% (95% CI: -0.6, 2.0) for 6 vs. 3 months and 1.6% (95% CI: 0.3, 2.7) for 12 vs. 3 months. Among individuals at low risk, these mortality risks were 8.3% under the 3 month strategy, 9.2% under the 6 month strategy, and 9.6% under the 12 month strategy. Risk differences were 1.1% (95% CI: -0.1, 2.5) for 6 vs. 3 months and 1.5% (95% CI: 0.2, 3.0) for 12 vs. 3 months.

Conclusions: We estimated that more frequent cystoscopy may result in clinically meaningful reductions in bladder cancer mortality among high risk patients. Among low and intermediate risk patients, more frequent cystoscopy may result in modest absolute risk reductions. Decision-makers should also consider the clinical and financial burden and risk of complications associated with more frequent surveillance.

#2240 An exploratory study of financial toxicity intervention components preferred by cancer survivors.

M. Huq[1], C. Conley[1], H. Derry-Vick[2], A. Khoudary[2], L. Sorgen[1], O. Billini[2], T. Gunning[3], C. Luck[1], S. Kaushik[1], V. Hurley[1], J. Marshall[4], B. Weinberg[4], A. Tesfaye[4], A. Ip[3], A. Potosky[1], M. D. Schwartz[1],

[1]Georgetown University Lombardi Comprehensive Cancer Center, Washington DC, DC, [2]Hackensack Meridian Health, Nutley, NJ, [3]Hackensack Meridian School of Medicine, Nutley, NJ, [4]Medstar Georgetown University Hospital, Washington DC, DC

Background: Despite growing research on financial toxicity (FT) in cancer survivors, few studies have examined cancer survivors' preferences for FT interventions. Understanding cancer survivors' preferences for specific intervention components may facilitate the development and implementation of such interventions, potentially reducing the financial burden of cancer treatment.

Purpose: The current work is an exploratory study of cancer survivors' FT intervention component preferences.

Methods: Adult survivors (N=105) of colorectal cancer (CRC; n=55) or non-Hodgkin lymphoma (NHL; n=50) from three tertiary care centers self-reported demographic characteristics (gender, race, income, employment status, insurance), clinical characteristics (comorbidities), psychosocial characteristics (PROMIS Global Health scale for mental health, Brief Health Literacy Screen scale, eHealth Literacy Scale), financial impact of cancer (the 11-item comprehensive score for financial toxicity COST scale, and life-altering and care-altering coping strategy scales), and preferences for FT intervention components. Intervention preferences were assessed through survey items on intervention timing and specific content. We employed descriptive statistics to assess overall preferences, and unadjusted linear regression and ANOVAs to identify demographic, clinical, psychosocial and financial predictors of intervention preferences.

Results: In terms of timing, 79% of participants favored initiating a FT intervention before treatment compared to during or after treatment. The majority of participants (57%) were interested in at least one FT intervention component. In terms of specific components, participants were most interested in help understanding out-of-pocket costs and insurance (49%), help applying for financial assistance (39%), financial education (32%), and help communicating with the treatment team (32%). Participants were less interested in online tools to manage cancer-related expenses (27%), finance-related stress management (25%), and budgeting (20%). Predictors of overall interest (i.e., number of components endorsed) were: having high FT (B=.413, p=<.001), adopting life-altering coping behaviors (B=.374, p=<.001), using care-altering coping behaviors (B=.241, p=.014), being a non-White survivor (B=.219, p=.024), and having poorer mental health (B=-.280, p=.004).

Conclusions: Cancer survivors may prefer FT interventions offered before treatment, and providing guidance on out-of-pocket costs and insurance. FT interventions may be particularly desired by those who experience greater financial toxicity, life and care-altering costs, are a racial/ethnic minority, or have poorer mental health, suggesting potential priority groups and target outcomes for intervention development.

#2241 Healthcare underutilization, healthcare mistrust, and quality of life among cancer survivors who use cannabis.

S. J. Kim[1], G. D. Abbasabad[1], V. Clark[2], S. Hong[1], V. B. Sheppard[1];
[1]Virginia Commonwealth University - VCU, Richmond, VA, [2]University of Rochester Medical Center, Rochester, NY

Background: An increasing number of states have legalized the use of cannabis and its derivatives. As a result, marijuana use is expected to increase among cancer survivors. Research shows that cancer survivors use cannabis to manage a myriad of cancer-related symptoms, including pain and nausea. Despite this, there is limited evidence on how cannabis use among cancer survivors impacts healthcare utilization, healthcare mistrust, and quality of life among cancer survivors. Environmental scanning is needed to inform clinical oncologic outcomes as well as the benefits and risks of cannabis use among cancer survivors.
Objectives: To examine differences in healthcare utilization, healthcare mistrust, and quality of life between adult cancer survivors who have ever used cannabis and those who have never used it.
Methods: We recruited adults with a history of cancer through Qualtrics online panels for an online survey across all the states with different levels of marijuana laws (e.g., decriminalized and/or medical use only, and fully illegal and/or CBD oil only). We assessed sociodemographic, behavioral, psychological, cancer-related, and treatment-related characteristics, as well as quality of life, healthcare utilization, healthcare mistrust, and cannabis use (e.g., types, duration of use, current/ever use).
Results: Based on a total of 747 respondents, 395 were eligible and enrolled in the survey. Nearly one-fourth of participants were non-White (n=103, 26.1%), and 240 (60.8%) were female. Two hundred and forty participants indicated they had ever used cannabis (240/395, 60.8%). Of these, 35% (n=84) were current users of cannabis. Compared to individuals who never used cannabis, ever users had greater healthcare system mistrust (t(257)=2.58, *p*=.01), underutilized healthcare systems in the last 12 months (e.g., “..had a medical problem but never sought any medical attention about my condition” and “...did not come back for a follow-up appointment that my doctor gave me”) (t(248)=2.83, p=.005), and reported worse physical (t(260)= -3.32, p<.001) and emotional well-being (t(260)= -2.36, p=.02). There was no difference between these two groups (ever users vs. never users) for functional well-being (t(260)= 1.08, p=.28).
Discussion: The present study provides empirical evidence on differences between cancer survivors who ever used and never used cannabis. Compared to never users, ever users of cannabis had greater mistrust of the healthcare system, underutilized healthcare, and reported lower physical and emotional well-being. Further studies are needed to examine how cannabis use impacts the long-term health and wellbeing of cancer survivors.

#2242 Clinical trials knowledge among Hispanic/Latino gastrointestinal cancer survivors in Puerto Rico.

Hilmaris Centeno-Girona[1], Marievelisse Soto-Salgado[1], Mariela Bournigal-Feliciano[1], Sofia F. Contreras-Fernandez[1], Karina Torres-Mojica[1], Victoria Williams[2], Arnethea L. Sutton[2], Katherine Tossas[2], Robert Winn[3], Marcia R. Cruz-Correa[4]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Virginia Commonwealth University, Richmond, VA,[3]VCU Massey Comprehensive Cancer Center, Richmond, VA,[4]School of Medicine, University of Puerto Rico, San Juan, PR

The discovery of innovative cancer prevention and treatment approaches relies on voluntary participation in clinical trials (CTs); however, participation remains low among minorities/ethnic groups. Knowledge of CTs has been reported as a barrier to CT participation. Yet, there is limited understanding regarding CTs knowledge and participation among gastrointestinal (GI) cancer survivors in Puerto Rico (PR). Colorectal cancer is the second leading cause of death in PR, accounting for 13% among men and women. We aimed to describe the knowledge and factors associated with cancer-related CTs among Hispanic/Latino GI cancer survivors in PR. We analyzed preliminary data from an ongoing cross-sectional study targeting Hispanic/Latino GI cancer survivors aged 21+ years in PR. The study employed an interviewer-administered questionnaire to assess participants' awareness, knowledge, and participation in cancer-related CTs, and the social determinants of health (SDoH) associated with CT participation. Descriptive statistics were used to describe the population. Pearson chi-square test or Fisher's exact test were used accordingly to assess significance. A generalized linear model was used to estimate the odds ratios and 95% confidence intervals (CI) for significant variables. As of November 9, 2023, 59 Hispanic/Latino GI cancer survivors had completed the questionnaire. Women accounted for 56% of the sample, and the median age of study participants was 65 years (IQR: 19). Racial identity among participants was primarily white (63%), followed by other races (18%) and African-American (18%). Most participants were in complete or partial remission from cancer (83%). A significant proportion of the respondents reported having at least 12th grade (81%) and an annual income of $20,000 or higher (67%). Most participants (76%) accurately identified the correct definition of a CT. Participants with 12th grade or more had 1.5 (95% CI:1.1-1.9) times the possibility to correctly identify the CT definition compared to to those with less than 12th grade. Similarly, respondents with an annual income equal or higher than $20,000 had 1.4 (95% CI:1.1-1.8) times the possibility to correctly identify the CT definition compared to their counterpart. Furthermore, 93.2% of respondents had a score of at least 80% of correct responses regarding their knowledge of CTs. Although nearly 100% of the respondents knew about CTs, only 20% had participated. Despite a high level of knowledge regarding CTs in PR, a significant gap remains between knowledge and participation. Factors such as education and income might play a role in understanding the CT definition. However, the barriers preventing participation, including SDoH need further exploration. Enhancing participation among Hispanic/Latino GI cancer survivors in PR is essential for advancing cancer research and improving outcomes for this at-risk population.

#2243 A multi-ethnic population-based pilot study of multiple myeloma disparities.

A. M. Rolon[1], A. P. Vang[1], J. Quino[1], A. Estrada[1], E. Stewart[2], R. D. Cress[2], L. Carvajal-Carmona[1], A. Morales Arana[1];
[1]University of California Davis, Davis, CA, [2]Cancer Registry of Greater California, Sacramento, CA

To understand multiple myeloma (MM) disparities we established the Precision MEDicine, EqUity and Disparities Research in MultipLe MyeLomA (MEDULLA) study, a population-based study in California. Our study contacted, via the Cancer Registry of Greater California (CRGC), 100 adult MM patients from four racial/ethnic groups: Non-Hispanic Black (NHB), Non-Hispanic White (NHW), Latinos, and Asians. Data collection included variables reported to the CRGC, a self-administered survey, and biospecimen saliva collection. The survey focused on demographics, risk factors, cancer treatment, family history, quality of life, and social determinants of health. Of the 400 MM patients, we had 95 patients who responded to the survey, giving a response rate of 24%. 44% of those who responded were NHW, 21% NHB, 19% Latinos, and 16% Asians. Those that provided a response tend to be living in a census tract location with lower proportions of poverty ($p=0.0004$), higher proportion of adults ages 25 years or over with a college degree ($p=0.0011$), higher median household income ($p=0.0048$), lower proportion of adults ages 25 years or over without a high school diploma ($p<0.0001$), and a lower proportion of individuals ages 16 or over who are unemployed ($p<0.006$). All respondents also have a lower comorbidity count and expressed being in good health. For minorities, we identified a trend where a higher response rate is seen if they live in an area where median household income is higher ($p=0.0108$). For every 1% increase in poverty rates, NHW living in such neighborhoods were 3% less likely to respond to the survey ($p=0.04$). For every 10% increase in the proportion of individuals having a college degree, response rate increased by 1.17 for minorities in that neighborhood ($p=0.07$). Minorities living in neighborhoods with high proportions of adults without a high school diploma and high unemployment rates are less likely to respond ($p=0.02$ and $p=0.047$, respectively). In conclusion, we found significantly lower participation rates among minority groups, with socio-economic factors affecting response rates. Our findings, therefore, suggest that future studies must develop improved community-focused and culturally tailored strategies to engage and meaningfully understand MM etiology and survivorship in such populations.

#2244 Accelerated aging associated with cancer characteristics and treatments among breast cancer survivors.

C. Wang[1], J. B. De Vis[2], K. Nguyen[1], B. Jia[1], M. Alford[1], A. Chakravarthy[2], X.-O. Shu[1];
[1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

There are currently approximately four million breast cancer (BC) survivors in the US. BC survivors may experience accelerated aging, with greater physical dysfunction and cognitive decline than cancer-free women, potentially due to the detrimental effects of BC and/or its treatments (Tx). However, the aging trajectory after BC diagnosis has not been fully elucidated. A biological age measure, PhenoAge acceleration (PAA), derived from chronological age and nine clinical blood chemistry biomarkers, has been associated with aging-related health outcomes and mortality in the general population. Our study aims to evaluate PAA among BC patients by clinical characteristics, cancer Tx, and medications (chemotherapy and endocrine therapy drugs). The study included 1264 BC patients (age 54.7±11.7) recruited at Vanderbilt University Medical Center in 2004-2021. BC-related information and lab test results were obtained from the tumor registry and electronic health records. The differences in PAA (ΔPAA) by BC stage, grade, subtype, Tx, and medications at multiple time points were evaluated using linear mixed models, with the time interval between diagnosis and PAA assessments as a natural spline, and its interaction with the exposures under study as covariates. Associations of PAA with Tx and medications were estimated with adjustment for other Tx and medications. At 10 years post-diagnosis, stage III/IV (vs 0) and intermediate- and high- (vs low-) grade BC were associated with a higher PAA of 4.48 (p<0.001), 1.26 (p=0.03), and 1.95 (p=0.001), respectively; triple-negative (vs hormone receptor+/Her2-) BC was associated with a lower PAA (ΔPAA=-1.96, p=0.004). Compared with surgery, alone or with radiotherapy, surgery plus chemotherapy was associated with a higher PAA at 1 year (ΔPAA ranging from 1.96, p=0.03 to 4.61, p<0.001), while surgery plus endocrine therapy was associated with a higher PAA at 10 years post-diagnosis (ΔPAA ranging from 1.70, p=0.04 to 2.75, p=0.006). The associations of PAA with most chemotherapy agents diminished over time, reverting to negative or null at 10 years. Antimetabolites, on the other hand, were associated with an increased PAA at 2 years (ΔPAA=2.62, p<0.001) which increased further at 10 years post-diagnosis (ΔPAA=7.26, p<0.001). Endocrine therapy and PAA association at 10 years post-diagnosis was likely driven by aromatase inhibitors (AI) (ΔPAA=1.53, p<0.001). Selective estrogen receptor modulators were inversely associated with PAA at year 10 (ΔPAA=-1.03, p=0.01). Additional adjustment for BC stage, grade, and subtype did not materially change the results for Tx and medications. Our study found that BC patients had accelerated aging up to 10 years post-diagnosis, especially those with stage III/IV and high/intermediate-grade BC. The aging trajectory varied by cancer Tx and medications; antimetabolites and AI might accelerate aging in long term BC survivors.

#2245 Awareness and participation in cancer-related clinical trials among gastrointestinal cancer survivors.

Mariela Bournigal-Feliciano[1], Marievelisse Soto-Salgado[1], Hilmaris Centeno-Girona[1], Sofia Contreras-Fernandez[1], Karina Torres-Mojica[1], Virginia Williams[2], Arnethea L. Sutton[2], Katherine Tossas[2], Robert Winn[3], Marcia Cruz-Correa[4]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Virginia Commonwealth University, Richmond, VA,[3]Massey Cancer Center, Richmond, VA,[4]School of Medicine, University of Puerto Rico, San Juan, PR

Despite significant advances in cancer prevention, early detection, and treatment, there is a persistent disparity in cancer outcomes between diverse racial/ethnic groups and medically underserved populations in the United States (US). The underrepresentation of non-white racial/ethnic groups in clinical trials (CTs) poses a critical challenge to cancer research and effective care delivery. The Hispanic/Latino population is one of the fastest-growing ethnic groups in the US and has a high rate of gastrointestinal (GI) cancer. Although Hispanics/Latinos comprise 18.5% of the US population, they have participation rates of only 1% in CTs. We aimed to describe the awareness and participation of Hispanic/Latino GI cancer survivors in cancer-related CTs. We analyzed preliminary data from an ongoing cross-sectional study that examines the social determinants of health (SDOH) associated with participation in cancer-related CTs among GI cancer survivors. As of November 7, 2023, 57 individuals aged ≥ 21 years responded to a survey assessing their awareness and participation in CTs, and other SDOH domains. Descriptive statistics were used to describe the population, including frequencies, percentages, mean, and standard deviation. The participants' mean age was 62.5 ± 12.3 years, and 56.1% were women. Most had more than a high school education (80.6%). Moreover, 59.7% of the participants had state-sponsored health insurance or Medicaid. Twenty-nine (50.9%) of the participants reported having heard about cancer-related CTs; however, only nine (31.0%) indicated that they knew how to participate in a cancer-related CT. Most of the participants had heard about cancer-related CTs from their doctor, nurse, or other health professionals (41.4%), their family/friends (20.7%), or social media/newspapers (20.7%). Furthermore, 13 (44.8%) had been invited to participate and 11 (84.6%) were eligible and participated in cancer-related CTs. Most of the participants who were eligible and participated in cancer-related CTs (90.9%) indicated that they participated because they knew CTs are important for the development of effective cancer treatments. Our preliminary findings show high levels of awareness among Hispanics/Latinos GI cancer survivors towards CTs; however, it is concerning that only a minority of those who were aware of CTs knew how to participate in them. More efforts are needed to assess the factors and SDOH that impact participation in cancer-related CTs among this population. Additionally, we will continue to recruit participants to assess the relationship between adverse SDOH and their willingness to participate in cancer-related CTs.

#2246 The impact of a waitlist control group on physical activity level in the activity after cancer treatment exercise oncology randomized pilot study.

R. Cannioto[1], E. Davis[1], K. Hulme[1], C.-C. Hong[1], C. DeNysschen[2], T. O'Connor[3], C. Ambrosone[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Buffalo State University, Buffalo, NY, [3]Moffitt Comprehensive Cancer Center, Tampa, FL

Background: In randomized clinical trials, control conditions such as blinding are essential for mitigating threats to validity. In exercise oncology trials, researchers are unable to blind participants to randomization, which may confer unintended consequences (i.e., crossover or dropout) that may threaten validity. Despite prior suggestions that a waitlist control is optimal for lessening these consequences, to date there is little agreement concerning control conditions in exercise oncology. Further, the use of a waitlist control is complicated by concerns regarding the ethical implications of instructing participants to delay healthy behavior change. Herein, we leveraged data from the Activity after Cancer Treatment (ACT) study to evaluate the impact of randomization to a waitlist control group on objectively assessed physical activity (PA) levels in breast cancer (BC) survivors.
Methods: The ACT Study (PI: Ambrosone) was a 12-week, four-arm pilot study at Roswell Park Comprehensive Cancer Center. Participants included 37 BC survivors who were randomized to either a waitlist control group (n=10), or one of three exercise interventions of varying intensities including home-based walking (n=9), home-based Zumba (n=9), or a supervised high-intensity interval training treadmill protocol (n=9) delivered by study personnel at Roswell Park Comprehensive Cancer Center. The waitlist group was asked to maintain their usual PA during the 12-week intervention. All participants received weekly phone calls to optimize engagement and ensure Fitbit data were properly synced. For the current analysis, the primary analytic exposure was randomization assignment (control or active intervention); the analytic outcomes included steps/day, moderate-to-vigorous PA (MVPA) minutes/week and total active minutes/week as measured by the Fitbit Charge 2. ANOVA was used to assess mean group differences in steps and active minutes.
Results: At study conclusion, the control group accumulated significantly fewer steps/day [6,087 (±1,353)] than the active intervention groups [8,729 (±2,585), p=0.0003]. The control group also accumulated significantly fewer MVPA minutes/week [146.2 (±114.9) vs. 264.1 (±192.3), p=0.045] and total active minutes/week [1,478 (±291.0) vs. 1,976.8 (±658.6), p=0.003] in comparison to the active intervention groups, respectively.
Conclusions: BC survivors randomized to active intervention accumulated significantly more steps, MVPA and total active minutes than the waitlist group. Although the waitlist was effective for minimizing PA relative to the active arms, waitlisted participants exceeded the national step average of 4800 steps/day by 1200 steps and nearly met the minimum PA recommendation of 150 minutes of MVPA/week, potentially assuaging ethical or public health concerns regarding the delay of health-seeking behavior.

#2247 Cellular senescence as a potential mechanism underlying differences in chemoresistance between lung cancer cell lines derived from African-American and Caucasian patients.

N. Semenova, C. C. Robertson, J. S. Yakisich, R. R. Ayscue, A. K. V. Iyer, N. Azad;
Hampton University, Hampton, VA

Lung cancer remains the leading cause of cancer-related deaths world-wide. Statistical data reveals significant difference in both lung cancer incidence and death rate between African-American (AA) and Caucasian (CA) populations in the United States. Although these disparities can be partially attributed to socio-economical reasons, the biological mechanisms underlying them are poorly understood. In this study, we compared the chemoresistance of cell lines derived from tumor tissues obtained from AA patients (H23, H292) versus CA patients (A549, H460). The cell lines were treated with FDA-approved anti-cancer drugs as well as with cardenolide analogues previously reported by our group to have anti-cancer properties. Irrespectively of drug class, cellular senescence appeared to develop more abundantly in cells derived from AA patients. However, AA-derived cell lines manifested higher drug resistance in comparison to CA-derived ones, especially to cardenolide analogues. Recovery experiments in drug-free media revealed faster and more efficient re-growth after long-term (2 weeks) drug treatment in AA-derived cell lines. Taken together, the data provides a potential role for cellular senescence as mechanism of the differential chemoresistance observed between AA and CA lung cancer cell lines, revealing new potential targets for anti-cancer therapy.

#2248 Diminished survival in patients with pancreatic ductal adenocarcinoma is linked with residence in redlined neighborhoods.

V. Vudatha, D. Freudenberger, C. Liu, L. Fernandez, J. Trevino;
Virginia Commonwealth University, Richmond, VA

Redlining refers to the practice of classifying neighborhoods with racial minorities and low-income residents as “hazardous” for investors. This discriminatory practice by the Home Owners’ Loan Corporation (HOLC) has been shown to impact patient cancer incidence and outcomes in breast, lung, cervical, and colorectal cancers. In this study, we evaluate the impact of HOLC status on pancreatic ductal adenocarcinoma (PDAC) outcomes in Virginia. The Virginia Department of Health Cancer Registry was queried for adult patients diagnosed with pancreatic ductal adenocarcinoma from 2009-2018. The HOLC grade (A: best, B: still desirable, C: definitely declining, D: hazardous) of each patient’s address was determined using the University of Richmond Inequality map. Patient demographics, treatment, and survival data were compared by HOLC Grade via descriptive statistics, bivariate and multivariate analysis. 394 patients were identified (A: 24 (6.1%), B: 54 (13.7%), C: 198 (50.3%), D: 118 (29.9%)). There was no association between patient age, sex, insurance status, receipt of therapy, or smoking history and HOLC status. Patient race was significantly associated with HOLC status with more Black patients living in areas with worse HOLC grades compared to White patients ($p<0.001$). Survival analysis demonstrated that lack of surgery and chemotherapy ($p<0.0001$), metastatic disease ($p<0.0001$), and residential status in areas of HOLC grade D ($p=0.012$) were associated with worse survival. Based on Cox regression analysis, patients who lived in areas with HOLC grade B (adjusted HR 0.70; CI 0.49-0.98) and C (adjusted HR 0.74; CI 0.58-0.95) had improved survival compared to those living in areas with HOLC grade D. Additionally, age greater than 65, metastatic disease, and lack of treatment were associated with worse survival. Residence in a redlined neighborhoods can play a significant role in pancreatic ductal adenocarcinoma outcomes. Location in a “hazardous” area in Virginia is associated with worse survival in PDAC patients. Disparities in socioeconomics, housing, education, and food accessibility in these areas likely play a role in shaping these outcomes. Future studies are warranted to further investigate this disparity in care.

#2249 Clinical outcomes of discontinuing long-term opioid therapy among older cancer survivors in nursing homes.

Y.-J. Wei[1], A. G. Winterstein[2], S. Schmidt[2], R. B. Fillingim[2], M. Daniels[2], S. T. DeKosky[2], B. Kinder[1], T.-Y. D. Cheng[1];
[1]The Ohio State University, Columbus, OH, [2]University of Florida, Gainesville, FL

Purpose: The purpose of this study is to investigate associations of discontinuing vs continuing long-term opioid therapy (LTOT) with pain, physical function, and depressive symptoms among older cancer survivors who resided in nursing homes. Pain is prevalent and use of LTOT is common among patients with cancer, including those living in nursing homes. The Centers for Disease Control and Prevention (CDC) *Guideline for Prescribing Opioids for Chronic Pain—United States* recommends tapering or discontinuing LTOT for patients with chronic pain when risks outweigh the benefits of LTOT. Despite the guideline explicitly stating that its recommendation does not apply to patients with cancer, doctors including oncologists have been prescribing fewer opioid medications for older patients, raising a question regarding the benefit and risk of discontinuing LTOT for cancer survivors who depend on opioids for pain relief.
Study Design: We conducted a cohort study using a 100% Medicare nursing home sample linked to the Minimum Data Set (MDS) from 2010 to 2021. Participants included older (≥65 years of age) long-term (≥2 years) residents with a diagnosis of cancer who received LTOT for ≥90 days in a 12-month nursing home stay. Residents entered the cohort on the 90th day of the latest LTOT episode. Residents who received palliative or hospice care were excluded. The key exposure was discontinuation of LTOT, defined as no opioid refills for ≥90 consecutive days in 1 year after cohort entry. The primary outcomes were pain (measured using a numerical rating scale or categorical verbal descriptor scale), physical function (9-item activities of daily living scale), and depression (Patient Health Questionnaire-9) from baseline to quarterly assessments during 1-year follow-up after the discontinuation of LTOT.
Results: In total, 53,141 cancer survivors who received LTOT were identified (mean [SD] age, 82.9 [8.7] years; 39,522 [74.4%] female; 46678 [87.8] Whites), consisting of 62,387 patient observations during the 10-year study period. Of 62,387 patient observations, 51,357 residents (82.3%) continued LTOT, and 11,030 (17.6%) discontinued LTOT. Residents who discontinued (vs continued) LTOT had lower odds of worsening pain (adjusted odds ratio [AOR], 0.64, 95% CI, 0.59-0.59, $P < .001$) and depressive symptoms (AOR, 0.92 [95% CI, 0.85-0.99]; $P = .033$), with no difference in physical function (AOR, 0.96 [95% CI, 0.89-1.03]; $P = .226$) during the 1-year follow-up.
Conclusion: Among older nursing home residents with cancer, discontinuing vs continuing LTOT was associated with lower odds of worsening pain and depressive symptoms. Funding source: NIH/NIA R01AG073442.

#2250 Effects of loneliness on medical expenditures among US cancer survivors.

F. Chen[1], R. Nipp[2], X. Han[3], Z. Zheng[3], R. Yabroff[3], C. Jiang[4],

[1]Tsinghua University, Dongcheng District, China, [2]University of Oklahoma College of Medicine, Oklahoma City, OK, [3]American Cancer Society, Atlanta, GA, [4]UT Southwestern Medical Center, Dallas, TX

Background: Social isolation in cancer survivors associates with diminished quality of life and worse survival. However, effects of loneliness on medical expenditure are understudied. We examined associations of loneliness with medical costs, and social/psychological/behavioral determinants of health (SDHs).
Methods: We identified 1,866 cancer survivors from the 2021 Medical Expenditure Panel Survey. One has loneliness if answering 'often' for any of: feel lack companionship/left out/isolated from others. Two-part regression models assessed marginal effect of loneliness to annual total health care expenditure (cost) in cancer survivors, aged 18-64 (young) and ≥65 years (older), adjusting for age, sex, race, region, education, health insurance, comorbid illnesses, family income, unemployment, and activity limitation. Models were sequentially adjusted for every single SDH. Ordinal regression models assessed associations of loneliness with SDHs.
Results: Over one-tenth of young (19%) and older (13%) cancer survivors reported loneliness. Loneliness was associated with higher cost in older cancer survivors (conditional coefficient (CC) 0.46, 0.12-0.81), but not young survivors (-0.14, -0.62-0.36). In both age groups, cancer survivors with loneliness more often reported stress, lack of help, as well as less time talking on the phone and getting together with support persons (Table). In older patients, sequential adjustment for stress, expected help, get-togethers, or church attendance decreased effect of loneliness to cost; among which get-togethers showed the greatest decrease (CC 0.28, -0.03-0.62).
Conclusions: Loneliness was associated with higher total medical expenditure in older US cancer survivors. Findings warrant further study of personal or community support to mitigate loneliness, in an effort to reduce healthcare costs and financial burden in older cancer survivors.

Age (year)	18-64 (648)		≥65 (1223)	
Loneliness	No (505, 81%)	Yes (143, 19%)	No (1046, 87%)	Yes (177, 13%)

Times of get together		0.34 (0.21-0.55)		0.38 (0.25-0.58)

#2252 Loneliness, quality of life, and physical and mental health among cancer patients: All of US research program.

H. Lee[1], D. Ng[2], D. Lee[1], A. Jemal[1], F. Islami[1];
[1]American Cancer Society, Atlanta, GA, [2]University of California Irvine, Irvine, CA

Background: Loneliness, as a distressing feeling, occurs with a discrepancy between an individual's social needs and one's social relationship. Cancer patients, particularly, may feel loneliness, when their expected practical and emotional support from family or friend were not met. Loneliness can impair the capacity to self-regulate lifestyle behaviors and induce systemic inflammation through dysregulation of autonomic nervous system and the hypothalamic-pituitary-adrenal axis. While a growing body of literature has found an association between loneliness and physical or mental health, quality of life, morbidity or mortality, few studies have examined this association among cancer patients and effects of loneliness by sociodemographic characteristics.
Method: We used All of US Controlled Tier Dataset v7 (summer 2017-July 1, 2022) which comprised survey and electronic health records data. Study sample included cancer patients aged ≥18 years (N=17,367). Loneliness was measured using the University of California, Los Angeles (UCLA)-3 items loneliness scale, which includes relational connectedness, social connectedness, and self-perceived isolation. Logistic regression models were used to estimate the association between loneliness and self-reported pain, fatigue, fair/poor health physical and mental health status, and quality of life, controlling for various covariates. We stratified the models by age, sex, race/ethnicity, income, education, living arrangement, and marital status.
Results: Lonely cancer patients were more likely to have fair or poor quality of life (OR=3.80; 95% CI=3.33-4.34), severe pain (OR=1.55; 95% CI=1.35-1.79), severe or very severe fatigue (OR=2.41; 95% CI=2.07-2.80), fair or poor physical health (OR=2.26; 95% CI=2.05-2.50), and fair or poor mental health (OR=4.22; 95% CI=3.72-4.80) compared to non-lonely cancer patients, controlling for all other covariates. All stratified models generally showed similar results. However, the association between loneliness and severe pain was stronger in the younger group, whereas the association with mental health was stronger in the older group. The effect of loneliness on mental health was stronger among males (OR=5.42; 95% CI=4.30-6.83) than females (OR=3.84; 95% CI=3.29-4.49; p for difference < 0.05). By living arrangements, the relationship between loneliness and severe fatigue was stronger among cancer patients living alone (OR=3.15; 95% CI=2.33-4.25) than those living with others (OR=2.16; 95% CI=1.81-2.59; p for difference < 0.05).
Conclusions: In this study, lonely cancer patients were more likely to have poor quality of life, poor mental and physical health, and severe pain and fatigue compared to non-lonely patients. These findings underscore the significance of policy and clinical interventions to alleviate negative effect of loneliness on health outcomes among cancer patients.

#2253 Cancer-related follow-up health care utilization and fertility discussion, preservation, and reproductive concerns among diverse adolescent and young adult cancer survivors: A population-based study.

J. Stal[1], K. A. Miller[1], J. E. Milam[2], M. Quinn[1], S. E. Kim[1], R. C. Ceasar[1], D. R. Freyer[3],

[1]University of Southern California, Keck School of Medicine, Los Angeles, CA, [2]University of California, Irvine, Irvine, CA, [3]Children's Hospital Los Angeles, Los Angeles, CA

Purpose: To examine cancer-related follow-up (CRFU) health care utilization associated with fertility experiences among diverse adolescent and young adult (AYA) cancer survivors.

Methods: Project Milestones is an ongoing survey study evaluating life outcomes among AYAs diagnosed with cancer at age 21-39 in Los Angeles (LA) County. AYAs had an initial 5-year survival probability of ≥50% and are currently 3-10 years post-diagnosis. A registry-based recruitment strategy through the SEER-affiliated LA Cancer Surveillance Program was used.

Results: Overall, 1442 AYAs responded (Table 1). Compared to AYAs who did not, AYAs who saw: (1) their treating provider for CRFU were more likely to report a fertility discussion (56.0% vs. 41.2%, $p<.01$); (2) another provider for CRFU were less likely to report a fertility discussion (38.1% vs. 52.0%, $p<.01$); (3) their treating provider for CRFU were more likely to report preserving fertility (14.7% vs. 8.4%, $p<.01$); (4) a primary care provider for CRFU were less likely to report preserving fertility (10.1% vs. 13.6% $p<.05$). Compared with AYAs who reported a CRFU visit 1+ years ago or never, AYAs with a visit <1 year ago: (1) had on average greater reproductive concerns (range 5-25, higher scores reflect greater concern, 13.8 vs. 13.4, $p<.05$); and were more likely to report (2) worry passing on a genetic risk for cancer to their child (55.6% vs. 47.8%, $p<.01$); and (3) caution about having children because they may not be around to raise them (23.6% vs. 16.6%, $p<.01$).

Discussion: Iatrogenic infertility concerns persistent into survivorship, yielding a need to optimize oncofertility care throughout the reproductive lifespan. Receiving CRFU care from the treating provider is related to better outcomes, and higher reproductive concerns among AYAs with a recent visit may reflect greater awareness of risk due to more points of contact with a provider.

Table 1: Sample characteristics - N (%) or M (SD)

		Total	**Hispanic**	**Non-Hispanic**
		1442	**622 (43.1)**	**820 (56.9)**
Age at survey		39.5 (5.8)	39.3 (5.8)	39.6 (5.7)
Female		1007 (69.8)	429 (69.0)	578 (70.5)
White		850 (62.4)	301 (55.0)	549 (67.3)
Had employee-sponsored insurance		909 (63.0)	347 (55.8)	562 (68.5)
Age at diagnosis		31.0 (5.2)	30.8 (5.2)	31.2 (5.1)
Cancer type	Leukemia/Lymphoma	396 (27.5)	173 (27.8)	223 (27.2)

#2254 A population-based study exploring health care self-efficacy and fertility preservation, family planning, and reproductive concerns among diverse adolescent and young adult cancer survivors.

J. Stal[1], K. A. Miller[1], J. E. Milam[2], M. Quinn[1], S. E. Kim[1], R. C. Ceasar[1], D. R. Freyer[3];
[1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]University of California, Irvine, Irvine, CA, [3]Children's Hospital Los Angeles, Los Angeles, CA

Purpose: To examine the relationship between health care self-efficacy (HCSE) and fertility experiences among diverse adolescent and young adult (AYA) cancer survivors.
Methods: Project Milestones is an ongoing cancer-registry derived cohort survey study recruiting AYAs through the SEER-affiliated Los Angeles Cancer Surveillance Program. Respondents were diagnosed with cancers prototypical for AYAs between 21-39 years and had a 5-year survival probability of ≥50% at diagnosis.
Results: Overall, 1442 AYAs responded of which 57.9% reported the highest possible HCSE (*totally confident*; score of 3; lower scores reflect greater HCSE), while 42.1% were *somewhat* or *not at all confident* in some areas (score of 4-9; Table 1). Compared to AYAs with lower HCSE, AYAs with the highest HCSE were more likely to report preserving fertility (13.8% vs. 10.3%, $p<.05$) and were less likely to report highly negative change (11.9% vs. 15.5%, $p<.01$) and more likely to report highly positive change (16.3% vs. 9.4%, $p<.01$) to family planning due to cancer. On average, AYAs with the highest HCSE had lower reproductive concerns (range 5-25, lower scores reflect lower concern; 13.3 vs. 14.2, $p<.01$) and were less likely to report worry about: passing on a genetic cancer risk to their child (49.6% vs. 56.6%; $p<.01$), telling their partner they may be unable to have children (13.8% vs. 21.5%, $p<.01$), their ability to become a biological parent (22.7% vs. 28.0%, $p<.01$), and caution having children because they may not be around to raise them (18.5% vs. 24.1%, $p<.01$) than AYAs with lower HCSE.
Discussion: Greater HCSE was associated with higher rates of preservation, lower impacts to family planning, and lower reproductive concerns in this population-based study. As one quarter of AYAs have suboptimal HCSE, accessible avenues for obtaining fertility care are needed to temper possible impacts of low HCSE on preserving fertility.

Table 1: Sample characteristics - N (%) or M (SD)

		Total	Hispanic	Non-Hispanic
		1442	**622 (43.1)**	**820 (56.9)**
Age at survey		39.5 (5.8)	39.3 (5.8)	39.6 (5.7)
Female		1007 (69.8)	429 (69.0)	578 (70.5)
White		850 (62.4)	301 (55.0)	549 (67.3)
Had employee-sponsored insurance		909 (63.0)	347 (55.8)	562 (68.5)
Age at diagnosis		31.0 (5.2)	30.8 (5.2)	31.2 (5.1)
Discussed fertility		717 (50.3)	327 (53.4)	390 (48.0)
Preserved fertility		176 (12.3)	48 (7.8)	128 (15.7)
Impacts to family planning due to cancer	Highly negative change	202 (14.3)	91 (15.0)	111 (13.7)
	Somewhat negative change	128 (9.0)	50 (8.3)	78 (9.6)
	No change	788 (55.6)	315 (52.1)	472 (58.2)
	Somewhat positive change	111 (7.8)	43 (7.1)	68 (8.4)
	Highly positive change	189 (13.3)	106 (17.5)	83 (10.2)
Reproductive Concerns After Cancer (RCAC) score		14.1 (3.9)	14.3 (4.2)	14.0 (3.8)
HCSE score		3.9 (1.4)	4.0 (1.4)	3.9 (1.3)
Could ask doctor or health care provider about things that concern you?	Totally confident	1088 (75.9)	466 (75.5)	622 (76.1)
	Somewhat confident	303 (21.1)	130 (21.1)	173 (21.2)
	Not at all confident	43 (3.0)	21 (3.4)	22 (2.7)
Could schedule and attend your doctor appointments or decide when you needed care?	Totally confident	1057 (73.8)	454 (73.5)	603 (74.1)
	Somewhat confident	310 (21.7)	130 (21.0)	180 (22.1)
	Not at all confident	65 (4.5)	34 (5.5)	31 (3.8)
Could get the cancer related follow-up care you need over the next 2 years?	Totally confident	1006 (70.6)	410 (67.3)	596 (73.1)
	Somewhat confident	328 (23.0)	149 (24.4)	179 (22.0)
	Not at all confident	90 (6.3)	50 (8.2)	40 (4.9)

#2255 Social support with physical and psychosocial quality of life in individuals with prostate cancer in the Health Professionals Follow-up Study (HPFS).

N. Chen, C. B. McGrath, B. A. Dickerman, R. C. Nethery, L. A. Mucci;
Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: Social support is associated with improved cancer survivorship, but literature on its association with prostate cancer specific physical and psychosocial quality of life (QoL) is lacking. We investigated the associations of social support with physical and psychosocial QoL in individuals with prostate cancer in HPFS. Methods: We included 1,692 men (ages 61-95 years, mean: 71 years) diagnosed with non-metastatic prostate cancer between 2008 and 2016. Social support was measured by the Berkman-Syme Social Network Index (SNI) (a composite measure of marital status, sociability, membership in religious groups or other community organizations: socially isolated, moderately isolated, moderately integrated, socially integrated) and marital status (married, not married). Physical (measured by EPIC-CP: bowel function, urinary incontinence, urinary irritation/obstruction, sexual function, vitality/hormonal function) and psychosocial (memory function and wellbeing) QoL were measured through biennial questionnaires. We fit generalized linear and ordinal mixed effect models for the associations of SNI and marital status with physical and psychosocial QoL, adjusting for age, race, employment status, body mass index, comorbidities, smoking history, and clinical factors. We conducted stratified analyses by baseline age (<70, ≥70), baseline comorbidities (yes, no), primary treatment (active surveillance, radical prostatectomy, radiation), and D'Amico Risk Classification at diagnosis (low, intermediate, high risk). Results: Among those with baseline SNI (N=1,586), 740 were socially integrated, 309 were moderately integrated, 437 were moderately isolated, and 100 were isolated. Among those with baseline marital status (N=1,663), 89% were married. Physical QoL did not differ significantly by SNI. Married individuals (compared to not married) experienced less urinary incontinence (β -0.25, 95% confidence interval [CI]: -0.55, 0.05) and urinary irritation/obstruction (β -0.26, 95% CI: -0.52, 0.00). Those who were socially integrated (compared to isolated) reported better memory function (Odds ratio [OR] 1.47, 95% CI 1.06, 2.03) and wellbeing (OR 1.74, 95% CI 1.31, 2.31). The positive association between social support and QoL was stronger among those with baseline aged <70 years (for vitality/hormonal functioning and memory function), those without comorbidities at baseline (for memory function), those with radiation as primary treatment (for urinary incontinence, vitality/hormonal functioning, memory function, and wellbeing), and those with high risk (for memory function and wellbeing). Conclusion: Prostate cancer survivors with more social support experienced better quality of life, including less urinary incontinence and urinary irritation/obstruction, and better memory function and wellbeing.

#2256 Guideline-based physical activity and physical quality of life among individuals with nonmetastatic prostate cancer: A target trial emulation in the Health Professionals Follow-up Study.

N. Chen, R. C. Nethery, L. A. Mucci, B. A. Dickerman;
Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: Randomized trials have shown that physical activity can improve quality of life (QOL) among individuals with cancer. In the absence of a randomized trial of adequate size and follow-up to comprehensively evaluate this relationship for prostate cancer, we aim to emulate a target trial of guideline-based physical activity strategies and 6-year physical QOL.
Methods: We will use observational data on individuals in the Health Professionals Follow-up Study diagnosed with nonmetastatic prostate cancer between 2010-2016 and free of conditions that could preclude following current physical activity recommendations at baseline (first post-diagnostic questionnaire). The physical activity strategies of interest are (1) engage in ≥150 minutes of moderate activity, or ≥75 minutes of vigorous activity per week, or an equivalent combination (i.e., ≥7.5 metabolic equivalent of task [MET]-hours/week of vigorous or moderate activity) and (2) no physical activity intervention. The outcomes of interest are 6-year mean physical QOL scores (based on EPIC-CP measures of bowel function, urinary incontinence, urinary irritation/obstruction, sexual function, and vitality/hormonal function). We will adjust for baseline and time-varying risk factors using the parametric g-formula.
Conclusion: These findings may help to inform clinical recommendations to improve QOL among individuals with nonmetastatic prostate cancer. Further, the proposed approach will provide a framework for future studies designed to evaluate the effectiveness of any intervention strategies to improve patient-reported outcome measures in cancer survivorship research.

Table 1. Specification and emulation of a target trial using observational data from HPFS

Protocol component	**Target trial specification**	**Target trial emulation**
Eligibility criteria	(1) Individuals diagnosed with non-metastatic prostate cancer between 2010 and 2016; (2) No history of other cancers (Except nonmelanoma skin cancer); (3) No history of conditions that could preclude high levels of physical activity: myocardial infarction, stroke, congestive heart failure, amyotrophic lateral sclerosis, or functional impairment (defined as difficulty climbing a flight of stairs or walking eight blocks due to physical impairment)	Same as for the target trial, except: We required complete data on physical activity, birth date, and other risk factors on the pre-diagnostic questionnaire and the first post-diagnostic (baseline) questionnaire.
Physical activity strategies	Each individual is assigned to one of the following strategies at baseline: (1) No intervention (usual physical activity) (2) Engage in ≥1.25 hours/week of vigorous activity or ≥2.5 hours/week of moderate activity or ≥7.5 MET-hours/week of vigorous or moderate activity (an equivalent combination). Strategies are initiated at baseline and continued over follow-up. Individuals are excused from following the physical activity intervention upon the development of myocardial infarction, stroke, congestive heart failure, amyotrophic lateral sclerosis, cancer metastasis, or functional impairment. Individuals must respond to surveys at every follow-up period to assess time-varying variables.	Same as for the target trial, except: (1) Follow-up periods correspond to the questionnaire cycles in the cohort study. (2) We assumed that each 2-year physical activity questionnaire accurately reflects the individual's (1) average physical activity over the previous 2-year period and (2) intended physical activity that the individual would have reported at the start of the current period under no intervention.
Strategy assignment	Individuals are randomly assigned to a strategy at baseline and are aware of their assigned strategy.	We assumed randomization conditional on the following baseline covariates: age; employment status; primary treatment; stage; Gleason score, and prostate-specifc antigen level at diagnosis; pre-baseline values of body-mass index and physical activity.
Outcomes	6-year mean quality of life scores in the following physical domains: (1) Bowel function, (2) Urinary incontinence, (3) Urinary irritation/obstruction, (4) Sexual function, (5) Vitality/hormonal function. Individuals self-report their physical quality of life on EPIC (The Explanded Prostate Cancer Index Composite) questionnaires at every follow-up period.	Same as for the target trial. Follow-up periods correspond to the questionnaire cycles in the cohort study.
Follow-up	For each eligible individual, follow-up starts at strategy assignment (baseline) and ends upon death, loss to follow-up, or the end of follow up in December 2018, whichever happens first.	Same as for the target trial. Loss to follow-up was defined as questionnaire non-response.
Causal contrasts	Intention-to-treat and per-protocol effect.	Observational analogue of per-protocol effect.
Statistical analysis	Intention-to-treat analysis. Per protocol analysis: Parametric g-formula to compare 6-year physical quality of life under each strategy via mean differences, with adjustment for pre- and post-baseline prognostic factors associated with adherence and loss to follow-up.	Same as for the per-protocol analysis of the target trial.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Application of Bioinformatics to Cancer Biology 2 Poster Session

#2260 Transcriptomic immuno-oncology investigation of B-cell lymphomas using a novel comparative workflow.

N. Rapier-Sharman, M. T. Told, S. Kim, K. L. O'Neill, B. E. Pickett;
Brigham Young University, Provo, UT

Patients with B-cell lymphoma currently have limited treatment options, often with serious side effects; for example, B-cell lymphoma patients undergoing chemo- and radiation therapies experience poor health from off-target toxicity. Similarly, though CD19 CAR T-cell therapy is very effective, patients suffer lifelong B-cell aplasia as a side effect. Comparing a cancer to an autoimmune disease in the same tissue type may grant us additional insights on the immune dysregulation of the cancer, leading to development of more immune-aware cancer treatments. We introduce a new data-driven comparative workflow for the analysis of immuno-oncology attributes by comparing a cancer and an autoimmune disease in the same tissue type. As an example use case, we compare primary B-cell lymphomas to primary B-cells from systemic lupus erythematosus with the goal of delineating new mechanisms that can be leveraged to treat B-cell lymphomas. Our analysis will utilize bulk RNA-sequencing (RNA-seq) of B-cells for initial discovery, followed by single-cell RNA-sequencing (scRNA-seq) of Peripheral Blood Mononuclear Cells (PBMCs) for validation. Our analytical framework incorporates differential gene analysis, GO Terms, known protein-protein interactions, principal component analysis, and machine learning for biomarker detection. Here, we describe our novel tool in detail and share the results of our lymphoma use case to gain a better understanding of the targetable immune-related attributes of B-cell lymphoma. We expect that this novel tool, along with the results of our B-cell lymphoma use case, will contribute to the continued development of immune-focused treatment options for B-cell lymphoma and other cancers.

#2261 A scalable comparison of tumor immune atlases.

J. Yang, Q. Liu, Y. Shyr;
Vanderbilt University Medical Center, Nashville, TN

Large single-cell atlases can serve as references for the analysis of smaller-scale studies. However, there are strong biases among atlases due to their varying sample sources, conditions, cell type annotation strategies and resolutions. Selecting appropriate atlas for future or smaller-scale studies is complicated due to unclear understanding of atlases, that limits the future or smaller-scale studies take advantage of the wealth of data that such atlases provide. For example, the tumor-infiltrating immune cell atlases including pan-cancer and cancer type-specific atlases provide comprehensive profiling of immune cells, which desperately facilitates future single-cell studies. However, lack of a comprehensive assessment and comparison of tumor immune cell atlases with standardized benchmarks blocked the application of the most appropriate atlas for smaller-scale study. In this study, we compared pan-cancer immune cell atlases including TICA, pan-cancer T cells and pan-cancer blueprint atlases, and cancer-type specific immune cell atlases containing ABTC, HCC and STAD atlases. We quantified the correlations of cell types and observed similar heterogeneity among atlases and unique immune cell populations in TICA as well. Then, we assessed the performance of atlases on accurately annotating immune cell types in the widely studied PBMC datasets—in which cell types were well annotated. Comparative analysis revealed the complementarity within atlases on mapping success, accuracy, clustering, annotatability and stability by benchmarking reference-based populations to reference-free de novo clustering on real immunotherapy datasets. We identified potential indicators of immune response and found that reference-based populations outperformed reference-free clusters in recognizing immunotherapy-related cell states. Our study can be easily extended to future atlases.

#2262 Genomic profiling of leukemic cell lines, responders vs. non-responders to Narazaciclib (HX301 or ON123300), a novel kinase inhibitor with activity against CSF1R and FLT3.

J. Xue[1], T. Yang[2], H. Ke[2], S. Guos[1], **H. Q. Li**[2];
[1]Crown Science, Suzhou, China, [2]Hanx Bio, Hangzhou, China

Acute myeloid leukemia (AML) is an aggressive myeloid leukemia with global annual mortality ~150,000. While standard of care (SOC) of the 1st -line treatment being mainly induction chemotherapy, available targeted therapies cover rather limited patients carrying specific driver mutations (IDH mutations and FLT3-ITR). We previously reported a novel kinase inhibitor, Narazaciclib with strong anti-CSF1R activity (IC_{50} 0.7nM) as well as anti-FLT3 (IC_{50} 7nM), and also thus anti-AML activity for certain AML experimental models, as shown *in vitro* and *in vivo* (AACR Annual Meeeting, 2023). In the present study, we assessed the impact of HX301 on the *in vitro* proliferations of a panel of leukemic cell lines (n = 54), including a panel of AML cell lines (n = 33), that have been parallelly genomic-profiled by whole-exome sequencing and whole-transcriptome sequencing. We then set out to analyze the proliferation data and the genomic data, in attempt to elucidate genes and pathways that may be associated with the treatment responses. The biomarker analysis has been performed on gene expression, mutation and copy number variation levels, and the data been presented using common methodologies, including principal component analysis, differential expression analysis, correlation analysis, Gene Ontology enrichment analysis, gene set variation analysis, somatic gene mutation analysis, and copy number variation analysis, *etc*. Some of the observations have been made: 1) differential expression analysis on all leukemic cell lines shows that 254 genes have been positively associated with the responders; while expression of 191 genes are negatively correlated with AUC, i.e. positively associated with response, as revealed by Spearman correlation analysis; 2) Gene Ontology enrichment analysis revealed these response related genes are mostly involved in myeloid leukocyte activation and defense response; 3) all FLT3-ITD AML lines are responders, presumably due to the FLT3i activity of HX301; 4) CSF1R expression levels seem not correlated to drug responses; 5) pathway analysis on non FLT3-ITD AML lines reveals that STAT5 activation downstream of FLT3 signaling, IL7 pathway and NFKB pathway are significantly associated with better response. Finally, we are also attempted to use statistics learning to reveal genes, as a potential predictive biomarker, that may be correlated to drug response.

#2263 Why does the loss of chromosomes 10 and the gain of 7 co-occur in gliomas?.

N. U. Nair[1], A. A. Schaffer[1], M. E. Gertz[1], K. Cheng[1], A. D. Sahu[2], G. Leor[3], E. D. Shulman[1], K. D. Aldape[1], U. Ben-David[3], E. Ruppin[1];
[1]National Cancer Institute, Bethesda, MD, [2]University of New Mexico, Albuquerque, NM, [3]Tel Aviv University, Tel Aviv-Yafo, Israel

Introduction: Gliomas, including aggressive forms such as glioblastoma (GBM) and lower-grade gliomas (LGG), present formidable challenges for treatment. Since the late 1980's it has been known that loss of chromosome 10 (10 loss) and gain of chromosome 7 (7 gain) often co-occur in GBM. The reasons for this frequently co-occurring event are not very clear, with some prior studies speculating on a few driver genes as culprits. In this study, we aim to study and understand the phenomenon of 10 loss and 7 gain in gliomas in a systematic, chromosome-wide level.
Methods: Our analysis consists of three main analyses, that bring independent sources of evidence to address our research question:
a) Analyzing data from Progenetix, we developed rigorous probabilistic models that elucidate the probability dynamics of 10 loss and 7 gain in gliomas.
b) Next, by analyzing hundreds of genomic and transcriptomic samples from TCGA brain cancer patients, and cell lines, we identified a category of clinically relevant genetic interactions termed 'synthetic rescues'. *Synthetic rescue (DU-SR) interactions* refer to a form of functional interplay in which the detrimental impact on cell fitness caused by the inactivation of a specific gene (termed 'vulnerable gene') is compensated by upregulation of another gene (termed 'rescuer gene'). The enrichment of rescuer genes on 7 for the vulnerable genes on 10 was then tested.
c) Utilizing large-scale *in vitro* essentiality screens via CRISPR technology in central nervous system (CNS) cancer cell lines, we sought to investigate the fitness effects of different possible sequences of chromosomal 10 and 7 loss and gains.
Results: The main results emerging from this three-pronged analysis are as follows:
1) We find that 7 gain after 10 loss is a more likely event than the opposite order of loss of 10 after 7 gain whose probability is explained by a random chance model.
2) We show that loss of 10 is enabled by the cells' ability to readily mitigate its loss, specifically through rescue interactions with genes lying on the amplified 7 chromosome.
3) These findings in the analysis of patients' tumors are further reinforced by an independent investigation in IDH wild-type CNS cancer cell line essentiality screens.
Conclusions: The co-occurrence of 10 loss and 7 gain in gliomas is the most frequent loss-gain co-aneuploidy pair occurring in human cancer. Our analysis presents a new multi-pronged approach to analyze co-occurring aneuploidy events in cancer, showing the long-contemplated chromosomal co-occurrence events in gliomas, a mystery that has persisted for decades, is likely to arise from genetic rescue interactions between many genes that lie on those chromosomes. From a future translational standpoint, it additionally points to key rescuer genes that may be potentially targeted.

#2264 Identifying and analyzing independent clonal populations in single Barrett's esophagus biopsies.

M. Kazachkova, P. He, L. B. Alexandrov;
University of California San Diego - UCSD, La Jolla, CA

Barrett's esophagus (BE) is a non-obligate precursor of esophageal adenocarcinoma (EAC), often measuring multiple centimeters in length and characterized by columnar epithelium replacing normal squamous epithelium in the distal esophagus. Early studies in BE suggested that all cells within a patient's Barrett's segment are progenies of a single founder cell. However, in recent years this previously accepted model of BE as a monoclonal disease has been retired in favor of a multiclonal model with new evidence suggesting that a patient's Barrett's segment can be composed of multiple independent clones with independent founder cells. Nonetheless, single BE samples are still routinely assumed to be monoclonal, leading to independent sets of genomic aberrations erroneously being analyzed as a single set in the case of multiclonal samples. Here, we utilize a previously generated whole-genome sequenced BE dataset and repurpose an established pipeline for detecting subclonal populations to identify BE samples that are comprised of multiple independent clones. Additionally, we present a novel approach for validating multiclonality from sequencing data by phasing pair-end sequencing reads using germline variants. We demonstrate that 20/80 patients have at least one multiclonal sample and that the independent clones contained in these single biopsies can have drastically different genomic profiles. Further, we speculate that these multiclonal samples capture a snapshot of clonal competition and evolution within BE. These findings highlight the importance of accounting for multiclonality when studying BE and provide the first systematic analysis of multiclonal BE samples.

#2265 Distinct alternative splicing patterns in genetic subtypes of diffuse large B-cell lymphoma.

Sanyeowool An[1], Youngil Koh[2], Sung-Soo Yoon[2]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University, Seoul National University Hospital, Seoul, Korea, Republic of

Advances in sequencing techniques have made molecular subgrouping of Diffuse Large B-cell Lymphoma (DLBCL) based on DNA cahnges, which has led to the development of Lymphgen classification. By the way, although alternative splicing (AS) in cancer cells contributes to proliferation, invasion and metastasis, and immune escape, their role and association with DLBCL molecular subtypes are unknown. Therefore, we analyzed whole-exome sequencing (WES) and bulk RNA-Seq data paired in the public EGA dataset (EGAD00001003600) to explore the patterns of AS events that differ between Lymphgene subtypes. The WES data of 620 DLBCL samples that passed quality control were aligned to the reference using BWA-MEM, and variants were called with Mutect2. We used the information of copy number variants provided by cBioPortal. The RNA-Seq analysis was performed using the STAR-RSEM pipeline and differential splicing events were detected using rMATS to compare subtypes. Among 620 DLBCL samples, there were 19 MCDs, 95 EZBs, 22 BN2s, and 137 ST2s (50 samples with multiple genetic classes, and 291 samples unclassified). Mutations in spliceosome complex genes (ZRSR2 and SF1) were found in 14 and 27 samples, respectively. In BN2 and MCD subtypes, splicing events with significantly different exon inclusion levels were observed at a high frequency of 29 and 16 occurrences, respectively, compared to other subtypes. (P-value < 0.05). In contrast, retained intron is the only event observed in the EZB subtype (Table 1). Samples with mutations in ZRSR2 and SF1 showed four and two aberrant events, respectively, compared to samples without these mutations. Of note, rMATS detected an alternative 3' splice site event in exon 6 of *CD37* in the MCD. *CD37* is involved in tumorigenesis in leukocytes and has been suggested as a potential biomarker in blood cancer, and its dysregulation may have influenced the poor prognosis of MCD. In summary, molecular subtypes of DLBCL had unique features in terms of alternative splicing. Functional consequences of these selective exon usages for each DLBCL subtype are being warranted.

#2266 Detection of androgen receptor splice variants from clinical sequencing.

S. Hwangbo, S. Lee, S. Kim, H. Yun;
Seoul National University Hospital, Seoul, Korea, Republic of

Background: Androgen receptor splice variant-7 (AR-v7) has been widely studied as a biomarker of resistance to AR-targeted therapy in castration-resistant prostate cancer (CRPC). Various methods have been used to detect AR-v7 in CRPC specimens, including next generation sequencing (NGS) technology. However, NGS technologies applied in clinical sequencing have focused on using blood or fresh-frozen CRPC tissue specimens. There is not yet an AR-v7 detection system tailored to formalin-fixed paraffin-embedded (FFPE) tissue specimens commonly used for clinical sequencing in hospitals.
Methods: In this respect, we propose a novel approach to identify AR-v7 in targeted RNA sequencing (RNA-seq) data derived from FFPE specimens. This approach can identify, in addition to AR-v7, all constitutively active AR splice variants (AR-Vs) that are co-expressed with AR-v7. In short, our two-step approach first gathers soft-clipped or divided reads that are adjacent to the splicing sites of AR-Vs and then yields the number of splitting reads that support the existence of AR-Vs. Next, the algorithm selects the paired-end reads whose one side and the other side are mapped to the preceding and following exons, respectively. The final number of spanning reads are calculated following to the removal of low-quality reads.
Results: We validated the proposed approach using two large-scale, independent RNA-seq datasets of prostate cancer (PC) samples: 111 samples from Seoul National University Hospital (SNUH) and 558 samples from The Cancer Genome Atlas (TCGA) dataset. The majority of both datasets were localized PC tumors, especially in the SNUH dataset, where localized PC accounted for 91% of the total. Overall, our approach successfully identified samples with putative AR-Vs, including AR-v7, AR-v3, and AR-v9. Statistical analyses of 111 SNUH PC patients suggested potential detection threshold in clinical sequencing settings (at least 200 split reads). In the SNUH dataset, the AR-v7 positive group, which included 5 patients (5%) with values above the threshold, shared the following characteristics: higher AR-v7/full length AR expression levels, AR amplification and co-expression with AR-v3/AR-v9. AR-v7 positivity was experimentally validated by Sanger sequencing. The similar pattern was also found in the analysis of TCGA dataset.
Conclusions: These results demonstrate that the detection system can successfully identify AR-v7 positivity not only for metastatic PC but also for patients with localized PC through clinical sequencing. We expect that the further in-depth analyses including larger samples and clinical outcomes can discover clinical applicability of AR-v7.

#2267 Assessment of AlphaMissense and structure-function predictions demonstrates efficient reclassification of genetic variants of unknown pathogenicity in inherited myeloid neoplasms.

A. Kurtovic-Kozaric[1], A. Campara[2], M. Jahibasic[2], A. Mujkic[2], A. Fojnica[3], **M. J. Kiel[1]**;
[1]Genomenon, Inc, Ann Arbor, MI, [2]International Burch University, Sarajevo, Bosnia and Herzegovina, [3]Technical University of Munich, Munich, Germany

Introduction: Classification of genetic variants has significant implications for clinical management. Artificial Intelligence (AI) has the potential to transform classification of genetic variants, such as AlphaMissense, which incorporates structure-function relationships and allele frequencies across large datasets of genetic variants. While this represents a promising new tool, the performance of AlphaMissense has only been compared to known pathogenic and benign variants. Therefore, the discriminatory power for variants of unknown significance (VUS) has yet to be determined. We have performed a comparison of these predictions with variants associated with inherited myeloid neoplasms: 1) to assess the accuracy of these models against VUS; 2) to enhance classification of unpublished VUS by leveraging published information about other variants; and 3) to map the predicted classification onto protein structures to examine spatial patterns.
Methods: For 83 genes associated with inherited myeloid diseases, a systematic literature review for missense variants was performed using the Mastermind Genomic Intelligence Platform and ClinVar. We used Alphamissense to characterize VUS missense variants according to predicted pathogenicity scores as pathogenic, ambiguous, or benign. Known pathogenic (n=1594) and benign (n=501) variants served as controls to evaluate the accuracy of the system. AlphaFold2 structures were visualized for structure-function rendering of reclassified VUS and known pathogenic variants to compare and identify discernible patterns of spatial distribution.
Results: This variant dataset comprised 1594 pathogenic, 501 benign, and 46676 VUS missense variants. Among VUS, AlphaMissense reclassified a majority of VUS missense mutations and established that the system was 88% accurate in predicting pathogenicity. A higher percentage of variants was classified as pathogenic among tumor suppressor genes e.g. DDX41 and RUNX1 (57.1% and 40.5%) compared to the oncogenes, GATA1 and GATA2 (25.7% and 34.9%). Furthermore, 3D models revealed a majority of variants reclassified to pathogenic were located in regions with defined tertiary structure clustered with known pathogenic variants, while benign variants were located at peripheral positions lacking definite structure.
Conclusions: These results demonstrate the discriminatory power of AlphaMissense for VUS pathogenicity prediction for both loss-of-function and gain-of-function disease mechanisms. This work may also have implications for rare or challenging somatic cancer variants and variants in rare diseases. Finally, incorporating information available from empirical and clinical studies for disease-causing variants offers the possibility of significantly enhancing the predictive power of these models.

#2268 CREDAC: Copy number-based reference-free expression deconvolution analysis of cancers.

C. Castignani[1], J. Demeulemeester[2], O. Pich[1], T. Lesluyes[1], R. E. Hynds[3], D. R. Pearce[3], E. Larose Cadieux[1], S. C. Dentro[4], T. Consortium[1], N. Kanu[3], C. Swanton[5], P. Van Loo[6];

[1]The Francis Crick Institute, London, United Kingdom, [2]VIB-KU Leuven Center for Cancer Biology; Department of Oncology, KU Leuven, Leuven, Belgium, [3]University College London Cancer Institute, London, United Kingdom, [4]Wellcome Sanger Institute & European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, United Kingdom, [5]The Francis Crick Institute & Universtity College London Cancer Institute, Cancer Research UK Lung Cancer Centre of Excelence, London, United Kingdom, [6]Departments of Genetics and Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Analyses of bulk RNA sequencing data are central to most large-scale tumor sequencing studies. Bulk expression data represent population averages and its interpretation is confounded by both normal cell contamination and somatic copy number alterations. Several computational methods to deconvolve have been developed recently. However, these methods often rely on a set of cell-type-specific reference signatures and ignore the effect of copy number changes. Methods: To address these issues, we have developed a method that formalizes the relationship between allele-specific copy number, expression and sample purity to deconvolve the expression profiles of tumor and normal cells from bulk RNA-seq in an unbiased manner. Our method was applied to sequencing data produced by the TRACERx consortium, a longitudinal study with multi-region whole-exome and RNA-seq of non-small-cell lung cancers. A total of 414 primary tumor regions and 140 adjacent normal tissue samples from 140 patients with matched DNA and RNA-seq data were processed. Results: We were able to directly deconvolve a median of ~2,000 genes per sample and indirectly infer tumor and normal expression profiles of ~10,000 genes using an scaled and weighted mean approach. The accuracy of the deconvolution was validated using (1) *in-silico* mixtures of patient-derived tumor and normal cells, (2) pseudo-bulk scRNAseq and (3) in regions with loss of heterogeneity (LOH) directly on the bulk sequencing data, where the total fraction of expression attributed to tumor cells can be computed directly using somatic mutations. CREDAC allows for single sample bulk-level tumor-normal differential expression analysis and revealed a strong and constitutive genome-wide overexpression in cancer compared to admixed normal cells, with a more pronounced overexpression in lung squamous cell carcinoma than lung adenocarcinoma ($p<0.001$). CREDAC adjusts for variations in copy number, thus facilitating the investigation of cancer-specific dosage compensatory responses triggered by aneuploidy. We revealed that a majority of genes (~65%) exhibit proportionality to copy number alterations, while a substantial proportion (~35%) shows anti-scaling or dosage compensation strategies. We show an enrichment of genes involved in cell cycle and expression processes within the dosage compensated group and revealed methylation as a key mechanism driving this compensatory process.

Conclusion: Overall, our results suggest that CREDAC is able to accurately disentangle the expression of tumor and normal cells from bulk RNA-seq without any previous knowledge. It has potential applications in many studies that include matched RNA-seq and copy number data and can provide new insights functional characterization, the taxonomy of cancer, and tumor evolution.

#2269 Dual targeting of the PI3K-AKT pathway in triple-negative breast cancer.

G. Colley, A. Eustace, D. AlSultan;
Dublin City University, Dublin 9, Ireland

PIK3CA mutations occur in ~15% of triple-negative breast cancers (TNBCs) and aberrantly activate the PI3K-AKT pathway, resulting in uncontrolled cell proliferation. Alpelisib is approved for hormone receptor-positive (HR+), HER2-negative BC patients with a PIK3CA mutation; however, not all PIK3CA-mutated (MUT), HR+ patients respond to alpelisib and others acquire resistance following exposure, suggesting adaptive mechanisms of PI3K activation. It has been proven that in TNBC, there exists a cohort of mutated genes which activate PI3K-AKT signaling. We hypothesize that testing alpelisib in combination with repurposed approved drugs, targeting alternative mechanisms of PI3K-AKT pathway activation, may be used to treat a cohort of TNBC patients. TNBC patient genetic data from the MSK (N=168), METABRIC (N=209), and TCGA (N=171) datasets were analyzed using cBioPortal to identify frequently occurring mutations. Differential expression analyses based on mutational status were performed on CCLE cell line (N=705) microarray and TCGA BC patient (N=981) RNA-sequencing data using R. Dysregulated genes were functionally analyzed using DAVID Ontology and those associated with poorer survival in TNBC were identified using KM-Plotter. STRING database was used to investigate protein interactions. The antiproliferative effects of targeted drugs tested alone and in combination in a panel of 6 TNBC cell lines were determined using acid phosphatase assays. Reverse-phase protein array analysis was carried out on protein lysates from cells following 24 hour treatment with drugs used alone and in combination.TP53 is the most frequently mutated gene in TNBC and mutations were associated with significant genetic dysregulation. A comprehensive analysis of upregulated genes in TP53-MUT TNBC led to the identification of 5 potential therapeutic targets - MET, S100A9, LCN2, CA9, TACSTD2, and KLK5 - based on their association with poorer survival in TNBC, protein interactions with TP53 and PIK3CA, and availability of targeted drugs. MET was selected for *in vitro* analysis based on its strong correlation with PI3K-AKT signaling. The presence of a TP53 mutation was associated with decreased antiproliferative effects in TNBC cell lines treated with alpelisib. Treatment with alpelisib in combination with a MET inhibitor, crizotinib, demonstrated greater antiproliferative effects in TP53-MUT/PIK3CA-MUT cell lines when compared to TP53 or PIK3CA MUT only models.TP53 mutations are associated with genetic dysregulation in TNBC and may confer resistance to alpelisib. Targeting upregulated proteins in a cohort of TP53-MUT/PIK3CA-MUT patients may improve sensitivity to alpelisib via dual inhibition of PI3K-AKT pathway activation. Protein analysis will uncover the mechanisms of synergy observed between alpelisib and crizotinib, and the therapeutic potential of the combination will be experimentally investigated *in vivo*.

#2270 UALCAN Mobile, An app for cancer gene expression data analysis.

S. Varambally[1], D. Shimoga Chandrashekar[1], G. Puli[2], S. Karthikeyan[1], U. Manne[1], C. J. Creighton[3], S. Kumar[4];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Kattech Systems Inc . Full-time, Philadelphia, PA, [3]Baylor College of Medicine, Houston, TX, [4]University Illinois, Illinois, IL

Cancer is a complex disease effecting different organs and a major cause of death and a burden on the society. Multiple molecular alteration occur during cancer initiation and disease progression and metastasis. Recent advances in technology led to generation of large amount of molecular data including transcriptome. These large datasets can be used to analyze and identify sub-class specific cancer biomarkers and targets. However, there is a need for the development user friendly tools for its analysis and dissemination of the large scale cancer molecular data. Earlier, we had developed and upgraded web based comprehensive proteogenomic platform UALCAN (ualcan.path.uab.edu), which allows users to analyze and integrate the disparate data to better understand the gene, proteins, and pathways perturbed in cancer and make discoveries. UALCAN web platform enables intuitive analysis and discovery by cancer research community. In the current study, we describe the development of UALCAN Mobile application (App) that will provide cancer transcriptomic data obtained from The Cancer Genome Atlas (TCGA) project, to evaluate protein-coding gene expression based on various stratification including stage, grade, race, gender and molecular-subtypes across over 30 types of cancers. The UALCAN Mobile app aims at providing large cancer dataset on the go. In order to find causative gene expression changes, identify biomarkers and therapeutic targets, UALCAN Mobile will assist as the data will be easily mobile and transportable with this App. Here, we describe the development of UALCAN Mobile and its utility to the cancer research community. UALCAN Mobile App can be found at both iOS/Apple and Android play store and is free to download and use.

#2271 Conservation and faithful representation of circular extrachromosomal DNA in orthotopic patient-derived medulloblastoma xenografts.

R. Kenkre[1], O. Chapman[1], J. Luebeck[2], V. Bafna[2], R. Wechsler-Reya[3], J. Mesirov[4], L. Chavez[1];

[1]Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA, [2]UC San Diego, San Diego, CA, [3]Columbia University Medical Center, New York City, NY, [4]UC San Diego School of Medicine, San Diego, CA

Background: Extrachromosomal DNA (ecDNA) is a driver of tumor heterogeneity and is associated with poor survival in many different adult and childhood cancer types. Patient-derived xenograft (PDX) models facilitate preclinical drug testing in an in vivo environment that enables analysis of tumor growth and survival and molecular tumor profiling. These models, combined with single-cell profiling, can be used to study intratumoral heterogeneity under therapeutic pressure and the emergence of drug resistance. Here we investigate the abundance and conservation of ecDNA in PDX models with the aim of assessing the faithful representation of ecDNA compared to the tumors from which they are derived.

Methods: Whole-genome sequencing (WGS) was applied to 27 medulloblastoma (MB) PDX models and their tumors of origin using Amplicon Architect, a tool used to reconstruct focally amplified regions of DNA to provide insights into the landscape of cancer genomes. The frequency of ecDNA in these models was also compared to that of ecDNA in the MB patient population. Optical genome mapping enabled accurate and reliable ecDNA sequence reconstructions. Multiome single-cell RNA and ATAC-sequencing of a PDX tumor enabled analysis of ecDNA conservation and intratumoral heterogeneity compared to similar data previously obtained from the primary tumor.

Results: Comparative analyses revealed that ecDNA is largely conserved in PDX models, emphasizing their relevance as faithful models of the primary tumors. In addition, we find that ecDNA is significantly more frequent in MB PDX models (16 out of 27 analyzed patient-derived tumors) as compared to their frequency in the overall patient population (~18% of all medulloblastoma tumors contain ecDNA), suggesting ecDNA as a driver for successful establishment of MB PDX models. Single-cell analysis revealed that ecDNA is omnipresent in almost all PDX tumor cells, while its presence was limited to only ~9% of tumor cells in the primary tumor.

Conclusion: Analysis of ecDNA in medulloblastoma primary tumors and in PDX models revealed that ecDNA is preserved in PDX models. This is an important characteristic that renders patient-derived mouse xenografts as faithful models of their primary tumors. These results emphasize the relevance of PDX models for preclinical in vivo studies aimed at analyzing the role of ecDNA under therapeutic pressure and for analyzing clonal selection along with molecular evolution of ecDNA during the development of therapeutic resistance.

#2272 Unlocking the potential of miRNA sequencing for early detection and monitoring of pancreatic cancer progression and recurrence.

R. N. Fuller, A. Morcos, D. Escalera, N. R. Wall;
Loma Linda Univ. School of Medicine, Loma Linda, CA

Pancreatic cancer (PC) is an elusive and deadly disease. Many patients with PC are diagnosed with metastatic or locally advanced tumors, limiting surgical resection, and increasing the risk of relapse after treatment. Relapse is recorded to be as high as 75% in the first 2 years after clinical intervention, resulting in a mean 5-year survival of 12% in the US, and as low as 2% worldwide. It is vital to develop diagnostic and monitoring techniques for PC. MicroRNAs (miRNAs) are robustly expressed in patient tumors and provide a rich source of biomarkers for disease detection and status. miRNA are short nucleic acid strands that bind to catalytic proteins to guide the regulation of large RNAs within the cellular space. This system is altered in tumors, leading to abhorrent expression of miRNA. Due to significant advancements in sequencing technology, miRNA-seq has become more accurate and affordable in detecting profile changes. To identify biomarkers for PC progression, we developed from the Gemcitabine-sensitive MIA-PaCa-2 (MP2) cell line the Gemcitabine and FOLFIRINOX resistant MP2-GR cell line. MiRNA-seq was conducted on the parental MP2 and resistant MP2-GR cells to identify those miRNAs that were differentially expressed between the cell lines. These miRNAs were analyzed via pathway analysis and gene ontology to find predicted functions followed by annotations from the miRNA Enrichment Analysis and Annotation tool (miEAA) to identify differentially expressed miRNAs associated with PC progression. This comparison indicated several miRNAs related to PC resistance. This dataset was then compared to *The Cancer Genome Atlas* (TCGA), which contains data from over 300 PC patients. The miRNA set was used to predict both PC progression after treatment, and recurrence. We are currently refining this data set to increase its predictive sensitivity and widen our patient data set comparison to further elucidate this approach in a clinical setting.

#2273 Development of a prognostic biomarker for ovarian cancer based on a high-resolution digital pathology platform for spatial statistical analysis of platelets and blood vessels.

J. Ahn[1], W. Carlos-Alcalde[2], M. Vasquez[1], M. Cho[2], V. Afshar-Kharghan[2], S. T. Wong[1];
[1]Houston Methodist Research Institute, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: A third of ovarian cancer patients have elevated platelet counts that are associated with poor prognosis. However, the exact mechanism by which platelets preferentially extravasate into tumor microenvironment is unknown, partly owing to lack of effective tools that can accurately segment and measure platelet counts found in tumor tissues. In this study, we developed a high-resolution digital pathology (DP) platform with whole tissue confocal imaging and deep learning model that can be used to automatically segment out platelets and blood vessels to perform spatial statistics (SA) of platelets with high precision and consistency. We utilized our SADP platform to study an interaction between tumor secreted SDF-1 and CXCR4 on platelets which initiates platelet chemotaxis towards tumor microenvironment.
Methods: A deep learning algorithm to accurately segment out platelets was developed based on the U-Net structure using our original datasets from the murine ovarian cancer model. Tumor-bearing mice were injected with 5 mg/kg of Plerixafor, a CXCR4 inhibitor, daily for 4 weeks. Then, tumor nodules were resected, stained with CD41a and CD31 antibodies, and imaged using a whole slide confocal microscopy. We performed manual annotation of these images to generate the mask dataset and performed further data augmentation to increase the diversity of datasets. We trained our model using 85% of these images and performed validation using the remaining 15%.
Results: Using our SADP platform, the validation dataset achieved pixel-wise accuracy of 98.8%. A receiver operating characteristic (ROC) curve demonstrated an area under the ROC curve (AUC) of 0.99 with high sensitivity and specificity. Intersection over union (IoU) score of 0.765 was obtained. A statistically significant ($p=0.0467$), 7.03% reduction in the platelet density was shown in the Plerixafor-treated mouse ovarian tumor tissues ($n=8$) compared to the control tumor tissues ($n=9$). We also found that platelets are spatially concentrated near blood vessels in the control tumor tissues compared to the Plerixafor-treated tumor tissues ($p=0.0377$).
Conclusions: We developed a SADP platform to segment and quantitate tens of thousands of platelets from whole slide mouse ovarian cancer tissues automatically with high accuracy and consistency and incorporated spatial statistics to understand their spatial relationships and patterns that would not be apparent in non-spatial analyses. Applying the SADP platform, we demonstrated that treatment with Plerixafor leads to overall reduction in platelet infiltration within ovarian murine tumors. Our ongoing effort is to utilize our SADP platform on human tumor tissue images from a whole slide digital scanner to further characterize spatial distribution of platelets as a potential prognostic marker for ovarian cancer.

#2274 Genomic and transcriptomic analyses of chemical hepatocarcinogenesis aggravated by loss of oncoproteins in hepatocytes.

X. Wang, J. Zhang, Y. Liu, S. Zhang, Y. Liang, M. Zong, X. Lin, M. Karin, G. Feng;
University of California San Diego - UCSD, San Diego, CA

Hepatocellular carcinoma (HCC) is one of the most common causes of cancer-related death without effective treatment. Oncogenic drivers, including PTPN11/Shp2, Ikkβ kinase (IKK), c-Met and β-catenin, as well as tumor microenvironment as illustrated by a carcinogen or diethylnitrosamine (DEN)-treated models, have combined contribution to cancer progression that have distinct prevalence in human HCC progression. We previously found that disruption of Ras/Erk by Shp2 deletion combined with deletion of NF-κB unexpectedly dysregulated circadian clock genes which leads to further cancer progression. Except for this, limited reports investigated how various other oncogenic genes aberration would incorporate with DEN to induce HCC. Further, no reports investigated the dynamic evolution of transcriptomic aberration incorporating genetic changes and the differential functional pathways involved in DEN plus oncogene triggered-HCC progression. Thus, we here sought to investigate the context-dependent contribution of PTPN11/Shp2, IKK, c-Met and β-catenin to HCC using hepatocyte-specific deletion models (SKO, IKO, MKO, BKO) combined with DEN treatment. Exome sequencing and RNAseq were used to identify dynamic changes of the genomic and transcriptomic variations of HCC development under the influence of both genetic deletion and DEN-treatment. We found that upregulated epithelial-mesenchymal transition (EMT), cancer metastasis/migration and downregulated fatty-acid and cholesterol metabolism were highly involved across models. Macrophages together with genes including *Spi1*, *Clec7a*, and microRNA networks including *miR-122* and *miR-155* etc. were also deregulated. Specifically, upregulated IL2-STAT5 signaling in DEN-SKO liver tissues, upregulated myogenesis, KRAS signaling and EMT as well as apoptosis in DEN-MKO, downregulated xenobiotic metabolism and bile acid metabolism in DEN-IKO and -BKO were identified to be distinct to oncogenic deletion in relation with HCC development.

#2275 Reducing artifactual somatic variant calls from formalin-fixed paraffin-embedded specimens by using DEEPOMICS FFPE, a bioinformatic approach based on deep neural networks.

D.-h. Heo, I. Kim, H. Seo, S.-G. Kim, M. Kim, J. Park, H. Park, S. Kang, J. Kim, S. Paik, S.-E. Hong;
Theragen Bio Co., Ltd., Seongnam-si, Korea, Republic of

Formalin-fixed, paraffin-embedded (FFPE) tissue specimens are routinely used in pathological diagnosis. However, formalin induced artificial mutations make it challenging to accurately analyze next-generation sequencing data. Existing FFPE filtering tools tend to categorize all low-frequency variants as artifacts, making it difficult to identify true variants with low allele frequencies, compromising analysis of tumors with low tumor cell content. To address this issue, we developed DEEPOMICS-FFPE, an AI model designed to distinguish true variants from artifacts. We gathered paired exome genome sequencing data from both fresh frozen and FFPE samples of 24 tumors from public sources. These data were used to train and validate the model, with a split of 70% for training and 30% for validation. The deep neural network model, comprising three hidden layers, was trained using input features derived from the outputs of the MuTect2 caller. We employed the SHapley Additive exPlanations algorithm to identify relevant features, and then fine-tuned them based on the training outcomes. We assessed the performance of the final DEEPOMICS FFPE model in comparison to existing models (MuTect filter, FFPolish, and SOBDetector) using well-defined test datasets. Our findings revealed 43 distinguishing characteristics for FFPE artifacts. Refining the quantification of these characteristics resulted in improved model performance. DEEPOMICS FFPE successfully filtered out 99.6% of artifacts while retaining 85.2% of true variants, achieving an F1-score of 87.8 in the validation dataset, surpassing the performance of existing tools. Furthermore, the model demonstrated consistent performance even for variants with low allele frequencies, exhibiting a specificity of 0.998, suggesting its capability to identify subclonal variants. Future enhancement of the model will include the ability to use other variant callers and analysis of whole genome sequencing data. This newly developed tool has potential applications in designing capture panels for personalized circulating tumor DNA assays and identifying candidate neoepitopes for personalized vaccine development. DEEPOMICS FFPE is freely accessible for research purposes on the web at http://deepomics.co.kr/ffpe.

#2276 Comprehensive analysis of the genomic landscape of thyroid cancer.

SooHyun Im[1], Jong-Lyul Park[1], Jae-Yoon Kim[1], Chan-Kwon Jung[2], Seon-Young Kim[1]

[1]Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of,[2]Department of Hospital Pathology, College of Medicine,, The Catholic University of Korea, Seoul, Korea, Republic of

Thyroid cancer, the most common endocrine malignancy, has a high incidence worldwide. Meanwhile, the incidence of thyroid cancer ranks first in Korea. To assess the possible influence of ethnicity on the molecular profile of thyroid cancer, we compared the genomic features of South Korean thyroid cancer with European thyroid cancer. In this study, we performed whole genome sequencing profiling (WGS) for 459 Korean thyroid cancer patients, including papillary thyroid carcinoma (PTC, n = 274), noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP, n =18), follicular thyroid carcinoma (FTC, n = 16), follicular thyroid adenoma (FTA, n = 63), Hürthle cell adenoma (HCA, n = 22), and invasive encapsulated follicular variant papillary thyroid carcinoma (IEFVPTC, n = 19). We assessed the single nucleotide variant (SNV) and insertions and deletions using Mutect2, Varscan2, and Strelka2. For mutation signature and copy number alterations analysis, we used the Maftools and GISTIC2.0 packages, respectively. Our results revealed that most somatic mutations were similar between the Korean thyroid cancer dataset and the cancer genome atlas program (TCGA). However, the Korean cohort (1%) had a much lower NRAS mutation frequency than the TCGA cohort (8%). Mutation signature analysis showed that SBS6 and SBS2 were highly associated with the TCGA and Korean cohort. SBS6 is related to defective DNA mismatch repair, and SBS2 is characterized predominantly by CC > TT doublet base substitutions. In addition, we identified the NIFTP-specific somatic mutations such as KEAP1 and ZFP36L2. This study presents insights into the genomic landscape of Korean thyroid cancer and reveals some similarities and differences with European thyroid cancer at the molecular level.

#2277 Understanding the impact of clonal hematopoiesis on multiple myeloma: Insights from exosomal RNA analysis and survival analysis.

J. Park[1], G. Ryu[1], D. Nachun[2], M. Maurer[2], S. Jaiswal[2], D.-Y. Shin[3], J. Byun[3], J. Hong[3], Y. Koh[3], S.-S. Yoon[3];

[1]Seoul National University College of Medicine, Seoul, Korea, Republic of, [2]Stanford University School of Medicine, Stanford, CA, [3]Seoul National University Hospital, Seoul, Korea, Republic of

Clonal Hematopoiesis of Indeterminate Potential (CHIP) is a trait characterized by the accumulation of somatic mutations in hematopoietic stem cells in certain adults. It has been observed that the presence of CHIP can have significant implications for the development and prognosis of various blood cancers. Multiple myeloma (MM), a cancer involving the abnormal proliferation of malignant plasma cells in the bone marrow, is one such condition. Exosomes, a type of extracellular vesicles, play a role in cell communication by carrying information between cells. Analysis of UK Biobank data confirmed the poor prognosis of multiple myeloma patients with CHIP and identified a potential of paracrine effect on plasma cancer cells. To gain deeper insights into this paracrine effect on plasma cells, we attempted to analyze cell-to-cell interaction, such as the expression of miRNAs in exosomes, through exosome RNA sequencing. In our research, exosomes were extracted from bone marrow samples of 30 multiple myeloma patients, and exosome RNA sequencing was performed. Differential expression of miRNAs was identified. A total of 14 down-regulated miRNAs were identified based on adjusted p value < 0.05, log2 fold change < -1. We found that hsa-let-7f-5p, hsa-let-7a-5p, and hsa-miR-148a-3p, which are mainly miRNAs targeting MAP kinase, were significantly down-regulated in the CHIP cases. A computational tool was used to predict and integrate the target genes and pathways regulated by these DE miRNAs. The results suggested that certain inflammatory and oncogenic pathways including the MAPK signaling pathways, were not effectively suppressed in cases with CHIP (KEGG, $p < 0.005$). In addition, the chemokine signaling pathway and cytokine-cytokine receptor interaction (KEGG, $p < 0.005$) related to the paracrine effect, integrins in angiogenesis (PID, $p < 0.005$) related to poor prognosis and metastasis of cancer were also not adequately inhibited in the CHIP cases. Using UK Biobank data, we called somatic CHIP variants excluding those with VAF < 0.02 and analyzed them against ICD-10 codes. Hazard ratios (HR) were computed through Cox proportional regression with covariates. CHIP presence significantly correlated with MM diagnosis (HR: 1.64, CI: 1.35-2, $p < 0.001$), notably in *TET2* mutation carriers (HR: 2.35, CI: 1.63-3.4, $p < 0.001$). *TET2* mutations intensified MGUS to MM progression (HR: 5.0, CI: 2.27-11.0, $p < 0.001$). CHIP in MM impacted EFS (HR: 1.61, CI: 1.25-2.1, $p < 0.001$), with TET2 mutation carriers facing higher hazards (HR: 1.66, CI: 1.05-2.6, $p = 0.031$). CHIP, especially *TET2* mutations, significantly contribute to adverse MM outcomes and MGUS to MM evolution. Our findings provide insight into how CHIP influences the tumorigenesis and cancer progression of MM.

#2278 Unraveling immune dynamics of CD4+ in non-small cell lung cancer through single-cell analysis and gene expression profiling.

Hyunmin Woo[1], JiHye Yang[1], Siyoung Yang[2], Seong-il Eyun[1]

[1]Chung-Ang University, Seoul, Korea, Republic of,[2]Sungkyunkwan University, Seoul, Korea, Republic of

Non-small cell lung cancer (NSCLC) is a type of epithelial lung cancer other than small cell lung cancer and represents the majority of cases in lung cancer. The immune response against NSCLC relies significantly on the vital role by $CD4^+$ T cells, contributing to the regulation of immune system and the suppression of tumor growth. Various $CD4^+$ T cell subtypes, such as T conventional cells (T_{conv} cells) and T regulatory cells (T_{reg} cells), perform distinct functions within the immune system. T_{conv} cells boost immune responses against specific pathogens, while T_{reg} cells play a role in suppressing immune reactions. Investigating the correlation between T_{conv} cells and T_{reg} cells in NSCLC could serve a valuable biomarker for evaluating the immune status of lung cancer patients. We examine the connection between particular $CD4^+$ T cells in the lung and specific gene expressions associated with NSCLC. Through single-cell analysis, we classified the proportions of T_{reg} cells and T_{conv} cells within $CD4^+$ T cells in both the lungs and spleen of mice. Our discovery revealed that the proportion of T_{conv} cells in the lungs exceeded that in the spleen. From the differential gene expression (DEG) analysis using RNA-Seq data for T_{reg} cells and T_{conv} cells in NSCLC, compared to the control group of Peripheral Blood Mononuclear Cells (PMBC), we identified 1823 genes uniquely expressed in NSCLC T_{reg} cells and 711 genes in T_{conv} cells. Within these genes, we verified the expression of IL2RA and CTLA4, known to be expressed in NSCLC. Additionally, we identified high expression of genes TM4SF1 and KRT6A. By comparing the genes specific to T_{conv} and T_{reg} cells in the lungs with those significantly expressed in NSCLC, we were able to identify 114 co-expressed genes in T_{reg} cells and 71 in T_{conv} cells. We conducted GO and KEGG pathway analyses on these genes and examined the interaction networks among the associated genes. Furthermore, we found receptor interactions between T_{conv} cell subtypes (Th1, Th2, Th17, and Tfh) and T_{reg} cells through cell-cell interaction analysis. We explored the mouse phenotypes associated with these genes. These discoveries unveiled connections within lung-specific gene networks of T_{reg} and T_{conv} cells associated with NSCLC, highlighting candidate genes for targeted therapy in cancer.

#2279 Evaluating the metabolic status of gioma microenvironment at single-cell resolution.

F. P. Carcanholo, L. M. M. Fonseca, R. L. Simoes, S. A. Uyemura, **T. M. Malta**;
University of Sao Paulo, Ribeirao Preto, Brazil

Gliomas are brain tumors with low therapeutic response, markedly heterogeneous, and very proliferative. Mutations in the isocitrate dehydrogenase 1 (IDH1) and 2 (IDH2) genes are present in most lower-grade gliomas and less frequent in high-grade gliomas. The reprogramming of energy metabolism marks cancer to support rapid tumor growth and tumor survival. The remodeling of the epigenome in gliomas with and without IDH1/2 mutations is associated with changes in the energy metabolism, which has implications for the evolution of the tumor and for patient outcomes. Comprehending the metabolic reprogramming of different subtypes of gliomas is crucial to understanding tumor development and for the identification of better treatment targets. In this research, we explored the cell-to-cell metabolic variability using public single-cell RNA-seq (scRNA-seq) data of IDH wild-type (IDHwt) and IDH-mutant (IDHmut) gliomas. We analyzed 13,000+ single cells from four datasets [IDHwt (n=7,930), IDHmut codel (n=3,304), IDHmut non-codel (n=6,333), and IDHwt/K27M mutant (n=4,084)]. Data was processed using Seurat. CopyKat was used to distinguish malignant from non-malignant cells. Known marker genes were used to identify normal cell populations (macrophages, T cells, oligodendrocytes). Finally, ssGSEA was used to create a score of activity of 70 important metabolic pathways extracted from KEGG, for each individual cell. Our exploratory analysis revealed a metabolic heterogeneity among malignant cells even within the same patient. Steroid biosynthesis and valine/leucine/isoleucine biosynthesis are the top contributors to metabolic heterogeneity. Oxidative phosphorylation (OXPHOS), fatty acid metabolism (FA), and tricarboxylic acid cycle (TCA) are among the highest metabolic activities. Comparing the distinct glioma subtypes, IDHmut codel showed the lowest OXPHOS, TCA, and glycolysis/gluconeogenesis (GLYCO) activities, suggesting a potential link between low metabolic activity and better prognosis. Comparing astrocytomas IDHmut and IDHwt we observed lower TCA, GLYCO, and FA activities in mutant tumors. Overall, malignant cells showed higher metabolic activity than non-malignant cells of the same tumor. The metabolic microenvironment of IDHmut differed the most compared to the other subtypes. Immune and normal cells could also be distinguished by their metabolic features. We observed subpopulations of T cells and macrophages presenting distinct metabolic activity which may reflect distinct immune activation stages. Collectively, we covered the heterogeneity in energy metabolism of gliomas with potential prognostic value. Understanding the metabolic status of cells in the tumor microenvironment could shed light on intratumoral heterogeneity and aid in identifying therapeutic vulnerabilities.

#2280 HPV integration identifies emerging oncogenes and carcinogenic mechanisms, potentially indicating tumor recurrences.

S. Li[1], S. Xia[1], M. Lawas[1], T. Qin[1], B. Grab[1], N. D'Silva[1], L. Rozek[2], M. Sartor[1];
[1]University of Michigan, Ann Arbor, MI, [2]Georgetown University, Washington, DC, WA

HPV integration events in Head and neck squamous cell carcinomas (HNSCC) are strongly associated with carcinogenesis and tumor progression. Previous studies have elucidated the mechanisms and structures of HPV-human fusion events, pinpointing potential integration “hotspots” (i.e. genes with nearby HPV integration in recurrent patients). However, none has comprehensively investigated the effects of HPV integration on both HPV and human gene expression, nor assessed the clinical implications of these bidirectional expression changes.

In this study, we conducted bulk RNA sequencing on 67 Formalin-Fixed Paraffin-Embedded Oropharyngeal Squamous Cell Carcinoma (OPSCC) tumor samples from the University of Michigan hospital, and analyzed them in conjunction with bulk and single cell RNA-seq from another >200 HPV(+) HNSCC patients from four previous studies. Among the 117 samples confidently identified as HPV integration positive, we recaptured all previously known integration “hotspot” genes as well as several novel ones that have altered expression in the integrated samples.

Exploring the impact of HPV integration on the expression of human and HPV genes, we found that HPV integration in HNSCC is strongly associated with keratinization, immune response, and the development of HPV(+) HNSCC subtypes. Upon HPV integration, expression of non-oncogenic HPV genes is often lost. We hypothesized that the expression ratio of these potentially HPV immunogenic genes (E1-E5, L1,L2) to the HPV oncogenic genes E6 and E7 (termed the ImmunOnco Score) would predict clinical outcomes. Survival analysis of 70 University of Michigan patients showed low ImmunOnco Score is associated with tumor recurrence.

#2281 A tumor-intrinsic signature involving immunosuppression via MIF-CD74 signaling is associated with overall survival in ICT-treated lung adenocarcinoma.

R. Erbe, M. M. Stein, T. A. Rand, J. Guinney;
Tempus, Chicago, IL

Introduction: Immune checkpoint therapies (ICT) have changed cancer care, yielding robust and durable responses in a subset of patients. Identifying patients who are likely to respond to ICT remains an ongoing challenge. In addition, only a portion of patients with clinical biomarkers respond to therapy. Signatures of RNA expression have been developed to predict response, the majority of which focus on T-cell and cytotoxicity markers, yet have been unable to substantially improve outcome predictions. Here, we present a RNA signature that instead describes tumor-intrinsic immune resistance and a potential mechanism of immunosuppression via tumor signaling on macrophages, derived from single-cell RNA-sequencing (scRNA-seq).
Methods: We performed dimensionality reduction using a Variational Autoencoder (VAE) on 30 scRNA-seq samples from 15 lung adenocarcinoma (LUAD) patients, comprising a total of 183,873 cells from the Cell Ranger pipeline. The VAE model was trained on each sample for 250 iterations, yielding 20 signatures from each patient, for a total of 300 signatures. The relationship of each signature with real-world overall survival (rwOS) across 1,983 bulk RNA-sequenced LUAD patients treated with an FDA approved ICT was assessed via a Cox proportional hazards model with risk set adjustment, using TMB and line of therapy as covariates. The NATMI python package was used to identify putative active ligand-receptor interactions between tumor cells and the immune environment.
Results: Among the VAE encodings, we identified an immune resistance signature significantly associated with decreased rwOS across the patient cohort (HR = 4.2 [2.8-6.3], adjusted p = 4.3e-10). This signature was derived from a small cluster of neoplastic cells (4.4% of cells) in a patient sample that was otherwise dominated by immune cells, including a substantial fraction of cytotoxic CD8 T cells (24.5%). The strongest predicted ligand-receptor interactions were found between the neoplastic cells and macrophages, via the MIF-CD74 interaction, an interaction we found upregulated in multiple single-cell tumor samples. Further, MIF RNA expression alone was significantly associated with rwOS across the 1,983 patient LUAD cohort (HR = 1.5 [1.1-2.1], p = 0.004).
Discussion: MIF-CD74 is a known immunosuppressive interaction and MIF signaling from tumor cells on macrophages has been previously shown to have immunosuppressive effects in a mouse model of melanoma that were largely reversible via MIF-CD74 blockade. Taken together, these results identify a signature of tumor intrinsic immune suppression that can indicate patients likely to experience reduced benefit from ICT. In addition, this signature provides evidence to support blockade of the MIF-CD74 axis as a means to enhance anti-tumor immune responses in LUAD.

#2282 Predictive association of tumor cells hijacked NFATC2 activities with resistance to immune checkpoint inhibition in melanoma patients.

B. Lawal, Y. Wang, P. Lotfinejad, X. Wang;
University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Immune checkpoint blockade (ICB) has emerged as an effective cancer therapy. However, only a small fraction of patients receives benefits whereas a significant subset of patients experienced severe or even lethal autoimmune diseases. Stratifying patients that would benefit from immunotherapy remain a highly unmet clinical need. Dysregulations of transcriptional programs have been implicated in cancer initiation and progression. To date, there is a paucity of studies on the predictive values of transcriptional factors on ICB response based on the most recently emerged ICB clinical trial datasets. We reasoned that cancer cells may hijack key transcriptional programs in hematological cells to evade the attack from immune cells and acquired tolerance to immunotherapy.

Method: Herein, we used an R package singscore/1.14.0 to compute the TFs activity scores based on their validated gene targets (TGs). Leveraging melanoma clinical trial datasets, we analyzed the predictive association of the TF scores with resistance to anti-PD1 ICB. The R package, iGenSig was used to evaluate the potential confounding variables.

Results: Our landscape correlation analysis revealed NFATC2 (Nuclear Factor Of Activated T Cells 2)-TGs as the most significant predictor of anti-PD-1 ICB resistance in melanoma. NFATCT-TGS as a predictor of anti-PD1 resistance is confounded by liver metastasis and achieved AUC range between 0.71 to 0.74 in three datasets (PRJEB23709, GSE160638, and Phs000452). In addition, prior anti-CTLA4 exposure (AUC=0.87 and 0.89) is associated with higher predictive efficacy of NFATC2-TGS than anti-CTLA4 naïve tumor (AUC=0.61 and 0.69) in phs000452 and GSE91061 datasets. Survival analysis revealed that NFATC2 is a better predictor of progressive-free survival (PFS; HR=5.95), and overall survival (OS; HR= 3.28-3.38) in anti-CTLA4 exposed tumor than anti-CTLA4 naïve tumor (PFS: HR=1.92, and OS; HR=1.64-2.17). Finally, NFATC2-TGS show strong inhibitory correlation with B cells and T cells infiltration, but strongly correlated with tumor purity.

Conclusion: We demonstrate that NFATC2 TGS predicts ICB benefits in melanoma patients, and thus may guide the recruitment of melanoma patients for anti-PD1 ICB. Our data provide support to the hypothesis that melanoma acquired NFATC2 transcriptional program to avoid immune cells evasion and acquired tolerance to ICB immunotherapy

#2283 A targeted mutation calling workflow - end to end - from FASTQ to clinical report for single cells.

Adithi Ravikumar Varadarajan[1], Thomas Ragg[2], Jonas Grote[2], Vadim Dechand[1], Steffi Treitschke[1], Clara Chaiban[3], Christoph Klein[3], Zbigniew Czyz[3], Jens Warfsmann[1]

[1]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Regensburg, Germany,[2]Quantiom Bioinformatics GmbH & Co. KG, Weingarten, Germany,[3]Experimental Medicine and Therapy Research, University of Regensburg, Regensburg, Germany

Molecular profiling of rare cancer cells derived from liquid biopsy holds promise to monitor systemic cancer progression and guide personalized therapy interventions. However, this necessitates reliable and comprehensive profiling of samples at the single cell level and requires whole genome amplification (WGA), which adds amplification errors and bias to common sequencing errors. Therefore, we established a single-cell mutation calling workflow that can identify clinically actionable somatic mutations in rare single cell DNA with high sensitivity and accuracy. Our workflow is an end-to-end solution which can take FASTQ reads from any Panel Sequencing (PanelSeq) data and gives out single nucleotide variations (SNVs), insertion-deletions (InDels), and copy number variations (CNVs) in single cells alongside with mutation specific information from ClinVar, OncoKB, pathogenicity scores, conservations scores as well as known association to drug response and resistance. We incorporated a Bayesian Neural Network (NN) based Classifier algorithm that assigns a single statistical confidence score to the mutations, enabling prioritization of the mutations in a robust manner. On the training dataset including MDA-MB-453, BT474, BT549 and ZR-75.1 cell lines, the classifier achieved 91% sensitivity and 96% specificity (AUC=0.98), while on the independent test collective including HCC1395/HCC1395BL cell lines it achieved 84% sensitivity and 96% specificity (AUC=0.90). We applied the workflow to patient samples suffering from advanced metastatic Triple Negative Breast Cancer (TNBC) assayed with in-house single-cell Integrated Mutation Profiling of Actionable Cancer Targets (scIMPACT) and single-cell Whole Exome Sequencing (scWES). Using our method, we detected clinically actionable SNVs with pathogenic relevance in primary tumor, metastatic specimens, circulating tumor cells (CTCs) from blood and disseminated cancer cells (DCC) from pleural effusions, as well as the matched CTC-derived *in vivo* models (CDX). Notably, functional *in vitro* drug screens performed on CDX models uncovered susceptibility to approved drug treatments conferred by mutations detected in the samples. In summary, we introduce a novel mutation calling workflow facilitating detection of SNVs, Indels and CNVs in rare single cells with high sensitivity and precision. Confident scores assigned by the NN classifier enables identification of functionally actionable mutations. The workflow was executed in GDPR compliant fashion and follows all data protection standards imposed by the European laws. Accordingly, the method is well suited for molecular profiling, therapeutic target selection and longitudinal monitoring of liquid biopsy specimens in diagnostic environments.

#2285 Mass spectrometry-based proteomics profiling reveals differential proteome composition in tumor and normal tissues, with implications for normalization.

Y. Zheng[1], L. Olita[1], M. Nivens[1], A. Chiang[1], S. Ahuja[1], M. Glover[1], J. Bullen[1], E. Hurt[1], W. Zhong[2];
[1]AstraZeneca US, Gaithersburg, MD, [2]AstraZeneca US, New York, NY

The composition of the proteome varies significantly across different tissues and disease states creating a challenge of how best to compare expression levels of each protein across these tissue types. Traditionally, a median approach to normalization has been used, but this could obscure meaningful biological differences between tissues. Here, we present a quantitative proteomic study analyzing proteome composition across tumor and normal tissues in order to assess normalization methods. Human proteomes covering 7 cancer indications (244 samples) and 12 normal tissue organs (370 samples) were analyzed by data-independent acquisition mass spectrometry. On average, over 8,000 proteins were quantified across the study cohorts. Comparison of proteomes revealed an average of 11.4% higher protein identification in tumors compared to matched normal tissues (6 tumor types all $p<0.003$). Tissue origin strongly influenced proteome composition, most notably in bone marrow, while cancer tissues displayed less proteomic composition variation than normal tissues. Compared to global median normalization, riBAQ and tissue-specific quantile normalization reduced technical variances while maintaining biological differences between tissue types. By revealing tissue-specific proteome signatures as well as systemic proteomic alterations in tumors, this study lays the groundwork for appropriate comparative approaches accounting for tissue origins, and establishes a framework for discovery of tissue-specific biomarkers, which may facilitate the development of novel diagnostic and prognostic tests, and guide therapeutic interventions for cancer.

#2286 Clonal sweep dynamics: A marker of tumor fitness and predictor of clinical outcomes.

L. E. Lara Gonzalez[1], S. Loi[1], A. T. Papenfuss[2], D. L. Goode[1];

[1]Peter MacCallum Cancer Centre, Melbourne, Australia, [2]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Cancer evolution is a complex process driven by cellular adaptations to environmental pressures. Understanding a tumor's evolutionary path is crucial for tailoring therapeutic strategies based on its genomic profile. We developed a method that estimates tumor 'fitness' (w) by analyzing the time of every clonal sweep. This is quantified by driver copy number or point mutations through analytical solutions derived from the branching process of tumor evolution. The method incorporates tumor size and growth rate, assessed through *in-vivo* BrdU staining, to determine the tumor's age, diversity, and aggressiveness. Using our method in the Yates et al. 2015 multi-region study, we analyzed 303 breast cancer tumors from 45 patients using whole-genome and exome sequencing (WES), focusing on ER+ (N=26) and ER- (N=19) subtypes. A negative correlation was observed between clonal cytoband alterations and fitness (ER+, R=-0.41; P=0.04; ER-, R=-0.72; P<0.001). Expanding the analysis with the METABRIC study (Curtis et al. 2012), clonal cytoband alterations (CA) were linked to survival outcomes for both ER+ and ER- subtypes. Additionally, in the TRACERx NSCLC study (Jamal-Hanjani et al. 2017) of 327 tumors from 100 patients who underwent WES, the median tumor fitness was associated with a higher risk of recurrence or death. Survival analyses are detailed in Table 1 below. Multivariate analysis was adjusted for tumor size, nodal status, and CD8α expression in the breast cancer study, and according to the authors' methodology in the TRACERx study, respectively.

Table 1 Survival Analysis

Study and Endpoint	Parameter	Univariate HR (95% CI)	Multivariate HR (95% CI)
METABRIC: ER- (N=128) on RFS	CA > 3 (Ref: CA ≤ 3)	0.61 (0.40, 0.93), P=0.02	0.49 (0.32, 0.75), P<0.001
METABRIC: ER- (N=128) on OS	CA > 3 (Ref: CA ≤ 3)	0.68 (0.47, 1), P=0.05	0.60 (0.4, 0.88), P=0.01
METABRIC: ER+ (N=458) on RFS	CA > 3 (Ref: CA ≤ 3)	1.61 (1.33, 1.94), P<0.001	1.51 (1.25, 1.82), P<0.001
METABRIC: ER+ (N=458) on OS	CA > 3 (Ref: CA ≤3)	1.44 (1.23, 1.68), P<0.001	1.38 (1.18, 1.61), P<0.001
TRACERx NSCLC (N=43) on RFS	Med. w > 1.031 (Ref: w ≤ 1.031)	3.24 (1.38, 7.62),P=0.007	4.11 (1.12, 15.1), P=0.033

The observed tumor growth rates in both studies align with known doubling times, demonstrating our method's accuracy. This approach successfully identifies tumor profiles linked to worse outcomes in breast and NSCLC cancers. Our findings suggest that analyzing clonal composition in tumors can improve patient stratification, particularly in infiltrated tumors, potentially enhancing immunotherapy response due to increased neoantigen exposure.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Liquid Biopsy and Precision Oncology Poster Session

#2290 Integration of cell-free DNA end motifs and fragment lengths can improve identification of active genes in liquid biopsies.

C. T. Maansson[1], L. S. Thomsen[1], P. Meldgaard[1], A. L. Nielsen[2], B. S. Sorensen[1];
[1]Aarhus University Hospital, Aarhus N, Denmark, [2]Aarhus University, Aarhus C, Denmark

Multiple studies have shown that the plasma cell-free DNA (cfDNA) from cancer patients differs from healthy individuals in both fragment length and fragment end motifs (FEMs). Yet, there is a lack of understanding regarding how the two factors combined can be associated with cancer and gene transcription. In this study, we evaluated cfDNA fragmentomics in plasma from lung cancer patients (n = 17) and healthy individuals (n = 7) using targeted sequencing (lung cancer: n = 12, healthy: n = 7) and whole-genome sequencing (WGS) (lung cancer: n = 5). A personal gene expression profile was established with H3K36me3 cell-free chromatin immunoprecipitation sequencing (cfChIP-seq). cfChIP-seq isolates nucleosomes with histone marks of active transcription directly from plasma, meaning cfDNA enrichment with cfChIP reflects gene activity in the cells of origin. Short cfDNA fragments were isolated using *in vitro* size-selection. Somatic mutations were identified from input cfDNA through the AVENIO pipeline. The findings were validated in an external public dataset comprising of WGS-cfDNA data from healthy individuals. Cancer patients contain a larger fraction of short (<150bp) cfDNA fragments compared to healthy individuals. Cancer patients also demonstrate an enrichment of distinct FEMs compared to healthy individuals. Investigating the association between gene activity and fragment lengths revealed that genes with high expression display an enrichment of short cfDNA fragments (median = 19.99%, IQR: 16.94% - 27.13%, $P < 0.0001$) compared to genes with low expression. Furthermore, distinct GC-rich FEMs are enriched in active genes. Combining the frequency of short cfDNA fragments with the presence of distinct FEMs results in a further enrichment of the highest expressed genes (median = 37.85%, IQR: 30.10% - 39.49%, $P < 0.0001$). *In vitro* size selection of short cfDNA also results in enrichment of GC-rich FEMs. *In vitro* size-selection can isolate cfDNA representing active genes and *in vitro* size-selection enrichment correlates with the cfChIP-seq enrichment (Spearman's ρ range: 0.499-0.882). This study expands the knowledge regarding cfDNA fragmentomics. We document how cancer patients and healthy individuals have different fragmentomic features. In addition, we shed new light on how gene activity in the cells of origin is associated with cfDNA fragment lengths and FEMs. Together, the results can increase the utility of liquid biopsies by determining gene activity in cancer patients.

#2291 Bravo automation of Agilent Avida targeted enrichment for high-throughput detection of genomic alteration and DNA methylation.

A. Wahba, T. Ho, S. Johns, A. Aravind, H. Wang, N. V. Mehendale, G. P. Amparo, K. Win, M. Gomez, G. Zhao, **D. N. Roberts**;
Agilent Technologies, Inc., Santa Clara, CA

Background: Current genomic and epigenomic profiling of cancer tissue DNA or cfDNA (cell-free DNA) in liquid biopsy relies upon separate, time- and sample-consuming technologies for somatic variant detection or methylation analysis. Here we describe workflow and performance of the Agilent Bravo automated liquid handling platform with the Agilent Avida targeted enrichment solution for next generation sequencing of somatic variants and methylation profiling. This solution can effectively analyze low-input tumor DNA or cfDNA samples. The Avida Duo workflow enables highly sensitive detection of single nucleotide variant (SNV), insertions and deletions (INDEL), copy number variation (CNV) and DNA methylation profiles from a single sample, without any sample splitting. Methods and Results: Panels, reagents, and automated workflows for Avida DNA, Avida Methyl, and Avida Duo Methyl (combined DNA & methylation) kits were developed to accommodate up to 96 samples on the Bravo NGS workstation. The automated solution supports independent single-day workflows for somatic variants or methylation sample preparation. The Avida Duo analysis combines both workflows without sample splitting, streamlining the process and reducing sample consumption. Leveraging a focused cancer hotspot panel, we demonstrate excellent reproducibility and low allele frequency (SNV at sub 1%) variant detection in cfDNA samples and reference standards with as little as 10ng DNA input. We exhibit similar performance with a larger ~300 kb target region tumor profiling panel. Finally, we demonstrate DNA methylation detection in the standalone or combined (“Duo”) workflows across differentially methylated regions (DMRs) with a panel of ~3400 targets. Conclusions: Automation of the Avida targeted enrichment solution with the Bravo NGS workstation enables a sensitive, high-throughput, end-to-end analysis for detection of genomic alterations and DNA methylation changes from a single low-input cfDNA or tumor DNA sample.

#2292 Impact of delayed processing on cfDNA quantity and quality using STRECK cfDNA tubes: Connect Pilot Study.

J. Bess[1], D. Hopkins[1], N. Diaz Mayoral[2], H. Cooley[2], A. de Palatis[2], D. T. Wong[3], S. Weinstein Oshinsky[1], C. Abnet[1], M.-J. Horner[1], A. Black[1], M. Brotzman[1], K. Wyatt[1], L. Sorbara[1], M. Young[1], M. Gaudet[1], N. Wentzensen[1], M. Williams[2], C. Karlovich[2], E. Greenbank[2], D. Elashoff[3], F. Wei[3], F. Li[3];
[1]National Cancer Institute, Rockville, MD, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]University of California Los Angeles, Los Angeles, CA

Interest in cell-free DNA detection for multi-cancer early detection and tumor monitoring is growing.1 Prospective evaluations of liquid biopsy assays are critical, and knowledge gaps in standard collection and preparation practices must be addressed for adequate assay execution.2 The NCI Connect for Cancer Prevention Cohort Study (Connect) aims to study new approaches in early detection. A pilot study was conducted with the STRECK Cell-Free DNA BCT tube to determine the impact of processing time on cfDNA quantity and quality utilizing two complementary quality control assays. 4 STRECK DNA BCT tubes were drawn from 40 donors. Plasma samples were analyzed, with half processed immediately and the other half stored for five days before processing. Two QC assays were performed to compare results at the two processing time points. The Alu EFIRM assay measured Alu element concentration (copies/mL). The Cell-free DNA ScreenTape assay evaluated Qubit DNA concentration (µg/mL) and %cfDNA. Descriptive statistics and paired sample t-tests were performed to compare mean concentrations at the two processing time points, with and without identified samples with cytolysis.

Median, mean, and range were recorded for each assay measure (Table 1). A reduction in cfDNA quantity was observed at the 5-day processing time point. Five 5-day processing samples were identified with high DNA quantity and a high Alu element concentration. The five samples experienced hemolysis and clotting as a result of handling and processing at odds with standard protocol. There was a significant difference between the mean DNA quantities of the processing time points following exclusion of the five samples. There was no change in significance between the mean Alu concentration and %cfDNA following exclusion (Table 2).

Both assays successfully detected samples with high nuclear DNA, a major contaminant for cfDNA assays, and identified a reduction in cfDNA at the 5-day processing time point. Proper handling and processing procedures are necessary to avoid cell lysis and maximize cfDNA quality and yield. This pilot establishes a starting point for future evaluations of liquid biopsy tube types, processing delays, and preanalytical cfDNA quality variables.

#2293 Comparisons of saliva versus plasma cfDNA and exosomal DNA as potential biomarkers for head and neck cancer.

M. Barbirou, A. Miller, D. Baek, A. Hameier, A. Wetzel, A. Linnenbach, K. Nunes, P. Llerena, V. Bar-Ad, A. Luginbuhl, U. M. Outschoorn, R. Myers, J. Curry, C. Wang, H. Yang;
Thomas Jefferson University, Philadelphia, PA

Purpose: Liquid biopsy approaches are revolutionizing cancer monitoring and have been considered potential mediators for therapeutic efficacy in multiple cancers. The investigation of different liquid biopsy biomarkers may lead to a better understanding of the cancers they are designed to detect and facilitate optimal management. This study aimed to identify and compare the epigenomic and genomic profiles of tumor biomarkers in circulation using cell-free DNA (cfDNA) and exosomal DNA (exoDNA) in plasma and saliva samples collected from patients with head and neck squamous cell carcinoma (HNSCC).
Methods: In a prospective trial, we performed whole-genome bisulfite sequencing on paired cfDNA and exoDNA from saliva versus plasma of 16 HNSCC patients. cfDNA was directly extracted from plasma and saliva, while exoDNA was extracted from purified exosomes after characterization. DNAs were then converted by Zymo EZ DNA Methylation-Direct kit and libraries were constructed with xGen™ Methyl-Seq Kit and sequenced on the Illumina NovaSeq platform. Sequencing data analyses were performed using Bismark, GATK, and methylKit for methylation pattern and cfTools for Tumor Fraction Estimation (TFE).
Results: Methylation data demonstrated heterogeneities across sample types. Comparisons of ctDNA as a reference for exoDNA showed 7147 hypermethylated and 9984 hypomethylated regions for plasma samples but showed 131 hypermethylated and 123 hypomethylated regions for saliva samples. Comparisons of plasma as a reference for saliva, 37 hypermethylated and 95 hypomethylated regions were noted in exoDNA, while 117 hypermethylated and 262 hypomethylated regions in ctDNA. The mean level of tumor-derived DNA was above 3%, the lower limit of sensitivity to indicate the presence of tumor cutoff as suggested by the cfTools. There were 3.24%, 3.14%, and 3.14% tumor-derived DNA in plasma cfDNA, plasma exoDNA, and saliva exoDNA, respectively. However, the tumor fraction in saliva cfDNA was below this cutoff (2.88%). A statistically significant ($P < 0.001$) difference in TFE was observed between combined cfDNA and exoDNA data from plasma and saliva, but the difference between combined sample types cfDNA and exoDNA did not reach statistical significance ($P = 0.306$). The linear mixed-effects model for TFE influence between the different groups revealed a significant interaction between sample sources (plasma and saliva) and sample types (cfDNA and exoDNA) ($P = 0.005$), as well as a significant effect of sample source on TFE ($P < 0.001$).
Conclusions: This pilot investigation provides evidence that exoDNA and cfDNA have different molecular profiles in plasma and saliva samples from the same HNSCC patient, and indicates that saliva carries additional tumor markers for HNSCC. These results help to advance our understanding of the potential impact of different liquid biopsy sample types in cancer management.

#2294 Monitoring glioma treatment response through longitudinal analysis of cell-free DNA in cerebrospinal fluid: Insights from a comprehensive study using next-generation sequencing.

R.-C. Cecile[1], **X. Dong**[2], C. Dai[2], W. Mo[2], P. Du[2], S. Jia[2], T. Burns[1];
[1]Mayo Clinic, Rochester, MN, [2]Predicine Inc., Hayward, CA

Background: Assessing treatment response in gliomas with high fidelity remains challenging. Cell-free DNA (cfDNA) is increasingly recognized as a liquid biomarker in plasma and cerebrospinal fluid (CSF), showing promise in optimizing therapeutic regimens for various cancers. While CSF has been explored as a source of cfDNA for gliomas, understanding the dynamics of cfDNA abundance and sequencing changes during treatment and recurrence is essential. Leveraging our biobank of longitudinal CSF specimens obtained through CSF access devices, we aimed to determine the potential utility of CSF cfDNA as a monitoring tool for treatment response in glioma patients.
Materials and methods: Longitudinal CSF specimens were collected through Ommaya reservoirs (NCT04692337) or ventriculoperitoneal shunts (NCT04692324) from patients with brain tumors, including gliomas. cfDNA was extracted from 1-5 mL of CSF based on available sample volumes and quantified using Qubit. Next-Generation sequencing using PredicineCARE or PredicineSCORE low-pass whole genome sequencing (LPWGS) was performed based on the available cfDNA.
Results: CSF collected before versus after resection showed an increase in quantified cfDNA (2.97x, range: 1.58-5.26x), indicating the impact of increased parenchymal disruption and closer contact with CSF. Subsequently, CSF cfDNA decreased during chemoradiation and adjuvant treatment and increased at recurrence, even in patients co-enrolled in immunotherapy trials for IL-7 agonists and pembrolizumab. Notably, copy number burden (CNB) increased at recurrence in three patients with known disease progression and decreased throughout immunotherapy treatment in one patient despite concerns of pseudoprogression. In a patient with a hypermutated glioblastoma, CSF cfDNA revealed over 59 genomic alterations, including MAP2K1, KIT, and PDGFRA. Another patient with a progressing EGFR-amplified GBM showed over 200 new variants in the final sample, with EGFR copy number increasing from 2 to over 30.
Conclusion: Analysis of cfDNA throughout a patient's disease course, encompassing resection and treatment with standard-of-care and experimental therapies, may aid in disease monitoring and treatment response. Further evaluation in a larger patient cohort is needed to determine the sensitivity of changes in mutations, CNB, and cfDNA quantity for glioma disease burden.

#2295 Circulating T cell receptor repertoire analysis improves cancer early detection.

Y. Li[1], M. Nahas[1], D. Stephens[1], K. Froburg[1], E. Hintz[1], D. Champagne[1], A. Lochab[1], M. Brown[1], J. Abhyankar[1], J. Braun[1], M. Dinh[2], M. Fortuno[3], M.-d. Ocon[3], A. Pasquier[3], I. Luque[4], C. W. Seder[5], J. A. Borgia[5], L. Seijo[4], L. M. Montuenga[3], **R. Yelensky**[1];
[1]Serum Detect, Inc., Newton, MA, [2]Rush University, Chicago, IL, [3]Clinica Universidad de Navarra, Pamplona, Spain, [4]Clinica Universidad de Navarra, Madrid, Spain, [5]Rush University Medical Center, Chicago, IL

Background: Cancer screening by liquid biopsy promises to detect cancer early when it can be cured. However, current liquid biopsy approaches based on circulating tumor DNA (ctDNA) detect only a minority of early-stage cancers, because these tumors shed little ctDNA and plasma sample volume is limited. For liquid biopsy to realize its potential for the early detection of cancer, sensitivity for the earliest stage disease must be improved.
Methods: We set out to improve sensitivity of liquid biopsy for cancer early detection by exploiting tumor recognition by T cells through sequencing of the circulating T cell receptor repertoire. Using gDNA extracted from blood buffy coats, we studied a cohort of 451 lung cancer patients (86% with stage I disease) and 525 subjects without cancer, enriched for older individuals with a history of smoking. We performed genomic DNA TCR beta chain sequencing to yield a median of 81,088 TCR clonotypes in cancer patients and 112,588 clonotypes in non-cancer controls. We built a TCR sequence similarity nearest neighbor graph to cluster >68M distinct TCR clonotypes into TCR repertoire functional units (RFUs). The TCR frequencies of RFUs were tested for association with cancer status and significantly associated RFUs were combined using a support vector machine model into a TCR RFU cancer score. This model was evaluated by 10-fold cross-validation (CV) and compared to a ctDNA panel of 237 mutation hotspots in 154 lung cancer driver genes (IDT™) and to a panel of 17 lung cancer related protein biomarkers (Olink®) in 87 subjects.
Results: We identified 177 cancer-associated TCR RFUs at FDR≤0.10, including 83 RFUs that were enriched in cancer samples with a TCR count log2-fold change between 0.05 and 1.31, and 94 that were enriched in controls with a log2-fold change between 0.07 and 0.40. We observed 56 of the 83 cancer-enriched RFUs had decreasing TCR counts with increasing age across the cohort, coupled with higher counts in cancer patients relative to age-matched controls. The TCR RFU cancer score achieved a cross-validated ROC AUC of 0.69 for cancer status prediction, with the AUC for stage I cancers similar to that of stage II-IV (0.69 vs. 0.70). 44% of stage I cancers (test samples of each CV fold) were detected by the TCR model at a specificity of 80%. We saw a substantial gain in sensitivity for stage I cancer when TCR RFUs were added to ctDNA and proteins, with a ~15-20%-point increase seen at the 90% target specificity level typical for cancer screening tests. Likewise, sensitivity increased at the 99% specificity level used in multi-cancer early detection, with 35% of stage I lung cancers detected, which could not be achieved by any analyte alone.
Conclusion: We demonstrate detection of a significant fraction of early lung cancer cases from blood by analyzing the circulating TCR repertoire and show that this signal is complementary to established analytes such as proteins and ctDNA.

#2296 Liquid biopsy of cerebrospinal fluid in breast to brain metastases.

S. N. Shishido[1], A. Marvit[1], S. Priceman[2], J. Portnow[2], P. Kuhn[1];
[1]University of Southern California, Los Angeles, CA, [2]City of Hope, Duarte, CA

Up to 30% of patients with breast cancers will develop brain metastases, and this risk is especially high with HER2-positive cancers. For patients with central nervous system metastases, cerebrospinal fluid (CSF) liquid biopsies are a promising opportunity to monitor disease, inform treatment, and predict prognosis. This study explores the CSF liquid biopsy analytes from 3 patients with central nervous system metastases analyzed with the third generation non-enrichment high-definition single cell assay (HDSCA3.0) workflow. The detection of cellular analytes was compared between the CSF and matched peripheral blood (PB) samples. Circulating tumor cells (CTCs) were detected in the CSF but not the PB and were subsequently molecularly characterized by single cell genomics and targeted multiplexed proteomics to reveal a clonal population of phenotypically heterogeneous cells. There was a lack of concordance between CTCs and cfDNA of the CSF in the copy number alteration profiles. In an extracellular vesicle surface marker analysis of the CSF, there was a high signal among tetraspanin CD9/CD63/CD81, with CD81 signal the highest across all 3 patients. The data indicates that the CSF may be used as a diagnostic or potentially prognostic tool to measure and characterize disease burden.

#2297 Longitudinal monitoring of HPV circulating tumor DNA in cervical cancer.

Preetiparna Parida[1], Krishna Sharan[2], Shirley Lewis[2], **Rama Rao Damerla**[1]

[1]Department of Medical Genetics, Kasturba Medical College Manipal, Manipal Academy of Higher Education, Manipal, India,[2]Department of Radiotherapy and Oncology, Kasturba Medical College Manipal, Manipal Academy of Higher Education, Manipal, India

Introduction

Detecting circulating tumor DNA (ctDNA) in the blood using minimally invasive techniques known as a "liquid biopsy", is gaining tremendous popularity in oncology research. Integration of human papillomavirus (HPV) DNA and the overexpression of the E6 and E7 oncogenes are crucial steps in the development of cervical cancer. We investigated the potential utility of HPV ctDNA as a biomarker for monitoring treatment outcomes in patients with cervical cancer.

Material and Methods

We use droplet digital PCR (ddPCR) to measure the amount of HPV16/18 ctDNA in plasma of cervical cancer patients. The HPV standard GP5+/6+ primers were used to determine HPV positivity in our patients. Specific primers were designed to amplify specifically the E6 oncogene of HPV16 and HPV18. Plasmid constructs were made using the PCR-purified products of HeLa and SiHa cell lines which would act as a positive control for the assay. HPV16 and 18 plasmids were serially diluted and then tested in qPCR as a template using different primer sets. Standard curves were made from the recombinant plasmids. This will serve as a positive control and will also provide a correlation between the sensitivity and specificity of qPCR vs ddPCR.

Results and Discussions

We hypothesize that our dPCR test will be able to detect minute quantities of HPV ctDNA in plasma of cervical cancer patients as ctDNA levels are expected to be decrease as treatment progresses. The assay sensitivity and specificity will be obtained by comparing results to QPCR. The study samples involve a tumor biopsy and a blood sample at the baseline prior to the therapy and serial blood sampling in different stages of treatment and follow-ups. These samples will also serve for treatment monitoring of these patients through ddPCR. Tumor samples are used to confirm the HPV status of patients using HPV-specific GP5+/GP6+ qPCR. We have recruited 75 cervical cancer patients with majority of them being squamous cell carcinoma and stage IIB disease. The qPCR results from tumor biopsy revealed HPV 16 was most prevalent (32/43), followed by HPV18 (6/43) and HPV 33(2/43).

Conclusion

we will now use Qiagen digital PCR system to understand HPV ctDNA levels in our patient cohort. we believe that our comprehensive sample collection after every treatment milestone and thorough follow-up for upto 2 years after diagnosis will allow us to study the utility of this sensitive test in monitoring disease and relapse.

#2298 Optimization of high-volume cell free DNA extraction and end-to-end automation for TSO 500 ctDNA library prep.

N. Prasad, R. Rock, R. Beatty, M. Robinson, D. Wildman, M. Sykes, B. Umylny, T. Halsey;
Discovery Life Sciences, Huntsville, AL

Liquid biopsy such as plasma, has emerged as one of the most valuable sample types for profiling circulating tumor DNA (ctDNA) for screening, response to treatment, and monitoring relapse in oncology patients. Due to the diffuse nature of ctDNA however, both extraction and library preparation must be optimized for the efficient downstream next-generation sequencing (NGS) application. We initially addressed the optimization of quality and quantity of cfDNA recovery from healthy and various oncology patients by evaluating QIAsymphony DSP Circulating DNA Kit and Apostle MiniMax cfDNA isolation kits. Overall, the cfDNA yields from Apostle MiniMax kit were approximately 12X higher. We then optimized high-volume automated cfDNA extraction from 1ml, 3ml and 6ml plasma samples using the Biomek i7 for Apostle MiniMax kit. Colorectal, Gastric and Ovarian cancer gave the highest yield of cfDNA whereas, Esophageal, Lung and Kidney cancers were the lowest cfDNA yielding samples. We then analyzed ctDNA from plasma from healthy donors, colorectal, kidney, Breast, and endometrial cancer patients along with Oncospan and Seraseq ctDNA mutation mix (5-0.5% AF) to evaluate the mutation detection efficacy, repeatability, and reproducibility by targeted NGS using TSO 500ctDNA assay ay 10ng, 20ng, and 30ng inputs. For library preparation batches of 48 samples were prepared using a fully automated processes for the library prep, Hybridization capture and post capture enrichment on the Beckman i5 robot. Libraries were sequenced on NovaSeq 6000 at 600M Paired-end depth. This method demonstrates an overall concordance of inter-run and intra-run accuracy of variant detection to be 90% demonstrating that this method run as described produces highly repeatable and reproducible variant detection to sub-1% allele frequencies. The inter-run, lot-to-lot, and operator-to-operator variability was ≥99%. Down-sample analysis demonstrated high levels of assay performance with sample inputs of 30 ng with ≥96% sample passing Illumina cut-off metrics at 150M PE read depth as compared to Illumina recommended 420M PE reads. Taken together, we provide a high-volume automated solution for cfDNA extraction from plasma samples, additionally these data demonstrate a robust, reproducible, and highly accurate targeted DNA sequencing method that can be used for low allele frequency variant detection in cfDNA.

#2299 More information from limited DNA: simultaneous measurement of genetics, 5hmC and 5mC in cell-free DNA.

T. J. Charlesworth, F. Puddu, R. Crawford, A. Johansson, E. Lleshi, A. Modat, J. Scotcher, M. Wilson, N. Harding, J. Teyssandier, J. Fullgrabe, W. Gosal, P. Creed;
Biomodal, Cambridge, United Kingdom

Liquid biopsy for profiling of cell free DNA (cfDNA) in blood holds huge promise to transform how we experience and manage cancer by early detection and identification of residual disease and subtype. While early work in liquid biopsy focused on the identification of actionable somatic variations at specific loci, the past decade has seen an expansion into non-genetic features, notably methylation. 5-methylcytosine (5-mC) profiles of cancer are differential from non-cancer at many more loci and so provide a stronger signal. Moreover, recent research has suggested that 5-hydroxymethylcytosine (5-hmC) profiles in cfDNA can be a marker for early cancer. However, a standard blood draw yields an average of only 10ng of cfDNA, presenting the dilemma of how to use limited sample to obtain maximum information. Existing methods for measuring methylation using next-generation sequencing cannot distinguish between 5-mC and 5-hmC and are limited in their ability to detect mutations, with approaches that measure both 5-mC and 5-hmC requiring two separate workflows. Hence, to measure complete genetics, 5-mC and 5-hmC using existing technologies requires three separate workflows, each of which require separate DNA input. We will present a technology which sequences at single base resolution the complete genetic sequence of input DNA fragments integrated with the modification status (unmodified, 5-mC or 5-hmC) for each CpG from low nanogram input quantities of DNA. A hairpin construct is used to create a copy of the original DNA strand. Enzymatic conversion followed by next-generation sequencing enables coupled decoding of bases across the original and copy strand, uniquely reporting one of A, C, G, T, 5-mC, or 5-hmC for each position in the input DNA fragment. Using this technology, we generated whole genome 6-letter data (measuring A, C, G, T, 5-mC, and 5-hmC at single-base resolution across the genome) on cell-free DNA extracted from plasma of healthy volunteers and patients with colorectal cancer at various stages of progression. We demonstrate how the technology can be used to compare 5-mC and 5-hmC methylomic profiles, genomics, and fragmentomics, across different stages of colorectal cancer. In particular, we show how disease progression can be marked by changes in 5-mC and 5-hmC across several loci. We propose that the ability to measure 5-mC and 5-hmC at high accuracy and single base resolution, alongside genomic and fragmentomic profiles, from a limited quantity of DNA will enable greater insight into the ctDNA in plasma and help advance the field of liquid biopsy towards fulfilling its promise.

#2300 AI enabled whole exome & transcriptome liquid biopsy addressing MCED, MRD, and therapy selection on a single platform.

J. Abraham[1], V. Domenyuk[1], M. Borderias[2], T. Yoshino[3], E. I. Heath[4], E. Lou[5], S. Liu[6], J. Marshall[6], W. S. El-Deiry[7], A. Shields[4], M. Dietrich[8], Y. Nakamura[3], T. Fujisawa[3], D. D. Halbert[1], D. Sacchetti[2], S. Stahl[2], A. Stark[2], S. Klimov[1], S. Antani[1], C. Nabhan[1], J. Swensen[2], G. Poste[9], M. Oberley[2], M. Radovich[1], G. W. Sledge, Jr.[1], D. Spetzler[2];

[1]Caris Life Sciences, Irving, TX, [2]Caris Life Sciences, Phoenix, AZ, [3]National Cancer Center Hospital East, Chiba, Japan, [4]Karmanos Cancer Institute, Detroit, MI, [5]University of Minnesota, Minneapolis, MN, [6]Lombardi Comprehensive Cancer Center, Washington, D.C., DC, [7]Brown University, Providence, RI, [8]AdventHeath Orlando, Orlando, FL, [9]Arizona State University, Phoenix, AZ

Effective clinical management of cancer patients requires an accurate and early diagnosis, highly sensitive monitoring of minimal residual disease (MRD), and precise therapy selection. There are multiple tests available that attempt to address each of these needs independently with varying degrees of clinical utility. Caris Assure is a proprietary circulating nucleic acid sequencing platform that couples whole exome and transcriptome (WES/WTS) sequencing on white blood cells and plasma with advanced machine learning techniques to satisfy all three testing needs on one platform. This test detects SNVs, INDELs, structural variants, copy number, gene expression, tumor mutational burden (TMB), microsatellite instability (MSI), fragment length, and aneuploidy of both somatic (tumor and clonal hematopoiesis) and germline origin. Caris' extensive database of over 350,000 tissue WES/WTS from solid malignancies was used to train deep learning neural networks to identify the molecular underpinnings of cancer. These networks were then deployed on WES/WTS data from plasma and buffy coat in pursuit of signals that can inform early detection, MRD and therapy selection.

Validation studies were performed to characterize the analytic and clinical performance of Assure on over 3000 patient blood samples. These samples include ~1000 non-cancer patients (controls), ~1700 newly diagnosed patients where blood was collected at surgery (early detection), ~500 early-stage patients during adjuvant therapy at multiple time points (MRD), and ~200 locally advanced/metastatic patients where matched tissue testing was also performed (therapy selection).

For early detection, stratification of blood samples from patients with stage I-IV cancer versus those with no reported cancer resulted in an AUC > 0.99 and included over 30 types of solid tumors. Notably, at 99.5% specificity, the sensitivities for stages I-IV (n= 119, 54, 50, 27) were 73%, 80%, 76%, and 89%. In the MRD setting for high-risk patients, the disease-free survival of patients whose cancers were predicted to recur was significantly shorter (39.6 mo) than those predicted not to recur (93.4 mo) (HR: 5.18, 95%CI: 2.94-9.09, p<.00001). This performance was observed across multiple lineages of cancer including but not limited to breast, colon, lung, and bladder. Lastly, for therapy selection, detection of driver mutations where blood was collected within 30 days of matched tissue demonstrated high concordance with a PPA of 93.8% and PPV of 96.8%. CHIP correction proved to be essential as ~35% percent of patients had CHIP mutations, including KRAS, BRAF, ATM, BRCA1/2, findings that could lead to improper therapy selection.

Herein, we demonstrate for the first time a single liquid biopsy assay that addresses the entire continuum of care in clinical oncology with optimal diagnostic, prognostic, and predictive utility for patients and physicians.

#2302 Innovative blood-based cell-free RNA whole transcriptome sequencing for comprehensive RNA profiling in patient plasma samples and its clinical applications.

F. Liu, Y. Huang, M. Wang, X. Sun, B. Xiang, S. Jia, P. Du, S. Luo;
Predicine, Inc., Hayward, CA

Background: Plasma cell-free RNA (cfRNA) holds promise for non-invasive cancer biomarker discovery, particularly in diseases like prostate cancer where specific biomarkers (AR splicing variants and TMPRSS2:ERG fusion) are detectable at the RNA level. Despite its potential, the technical challenges posed by blood cell-originated cfRNA abundance necessitates the development of robust and reliable assays for non-invasive cancer diagnostics. This study establishes and demonstrates the clinical utility of an innovative protocol for isolating and identifying tumor-originated cfRNA in plasma samples.
Methods: A novel methodology was developed for the simultaneous extraction of cfDNA and cfRNA from a single blood sample tube, enabling whole transcriptome sequencing (WTS) analysis with minimal input as low as 1ng. A proprietary method was developed to selectively deplete blood cell-originated transcripts in the library. An enrichment-based WTS assay was conducted, and a customized RNASeq analysis pipeline was employed to enable expression profiling and cancer biomarker testing from the cfRNA samples.
Results: The developed extraction method yielded substantial amounts of cfDNA and cfRNA from a 4 mL blood sample. Efficient depletion of blood cell-originated transcripts, achieving over 99% removal, enhanced the detection of a broader range of gene expressions in plasma. Implementation of the cfRNA WTS assay across healthy donor and cancer samples demonstrated consistency with documented biomarker status. The assay revealed significant differential clustering between cancer samples and healthy donors, with characteristic cancer genes contributing to the distinction. Reproducibility and analytical sensitivity of the developed cfRNA WTS assay were successfully validated.
Conclusions: This study introduces Predicine's proprietary cfRNA WTS assay, enabling concurrent expression profiling and RNA biomarker detection in plasma samples. Overcoming technical challenges associated with blood cell-originated cfRNA, this assay represents a significant advancement in liquid biopsy-based cancer diagnostics.

#2303 Identifying and stratifying circulating tumor cell cluster subtypes in metastatic breast cancer patients and evaluating their clinical outcomes.

D. L. Adams[1], C. Reduzzi[2], A. Aryasomayajula[3], R. Alpaugh[4], S. Chumsri[5], C.-M. Tang[6], G. Del Priore[7], W. V. Williams[8], M. Cristofanilli[2];
[1]Creatv MicroTech, Inc., Monmouth Junction, NJ, [2]Weill Cornell Medicine, New York, NY, [3]Rutgers University, Piscataway, NJ, [4]Fox Chase Cancer Center, Philadelphia, PA, [5]Mayo Clinic Cancer Center, Jacksonville, FL, [6]Creatv MicroTech, Inc., Potomac, MD, [7]BriaCell Therapeutics Corp, Philadephlia, PA, [8]BriaCell Therapeutics Corp, Philadelphia, PA

Background: Circulating tumor cell clusters (CTCCs) are aggregated groups of tumor cells that detached from primary tumors and circulate the bloodstream. However, while Circulating Tumor Cells (CTCs) are a well studied phenomenon, CTCCs remain relatively unexplored and ill-defined, with only a few descriptive investigations evaluating their clinical utility. Adding to CTCC complexity is that various subtypes exist, including homotypic clusters consisting of a homogenous population of tumor cells and heterotypic CTCCs made of CTCs with immune/stromal white blood cells (WBCs). Furthermore, CTCs can undergo Epithelial-Mesenchymal Transition (EMT), a process characterized by loss of epithelial traits and upregulation of mesenchymal traits, and can form clustered EMTs (CEMTs). Moreover, CTCs can fuse with macrophages forming Tumor Macrophage Hybrid Cells, aka Cancer-Associated Macrophage Like cells (CAMLs) when in circulation. We enumerated all these types of cells and complex aggregates in the peripheral blood of patients with metastatic breast cancer (mBC).
Methods: We enumerated the 6 populations from patient samples enrolled in IRB aproved prospective pilot studies. Whole peripheral blood (7.5mL) was filtered and stained with cytokeratin (CK) & CD45/CD14 to identify CTCs. CTCs were defined as an intact DAPI nuclei and strong filamentous CK. Homotypic CTCCs were defined as ≥2 CTCs attached together. Heterotypic CTCCs were defined as ≥1 CTC attached to ≥1 WBC. EMTs were defined as having DAPI nuclei and weak non-filamentous CK. CEMTS were defined as ≥2 EMTs. CAMLs were defined as having an enlarged polynucleated DAPI, and positive for CD45/CD14 or non-filamentous CK. Median progression free survival (mPFS) and median overall survival (mOS) over 24 months (m) were evaluated.
Results: We evaluated the blood of 79 mBC patients. Single CTCs were found in 57% of patients (n=34/79), homotypic CTCCs 15% (n=12/79), heterotypic CTCCs 66% (n=27/79), EMTs 56% (n=44/79), CEMTs 23% (n=18/79) and CAMLs 97% (n=77/79). Over 24 ms, patierns with detectable heterotypic CTCCs & homotypic CTCCs had the shortest response times at mPFS=2.8 & mOS=5.8 ms, or mPFS=2.1 & mOS=4.3 ms, respectively. This was followed by CTCs mPFS=3.7 & mOS=13.7 ms, EMTs mPFS=4.3 & mOS=14.4 ms, CAMLs mPFS=4.3 & mOS=14.4 ms, and CEMT mPFS=4.7 & mOS=13.2 ms. Additionally, CTCCs were rare in HER2+ patients at 4.4% (n=1/23), but no associations to other hormone statuses were found.
Conclusion: CTCCs appear to represent an array of subtypes with different biological and clinical meanings. Here we enumerated CTCC subtypes in the blood of mBC patients and stratified the various types to clinical outcomes. These data suggest CTCCs are clinically important and further understanding of their biology in the context of tumor pathogenesis is needed.

#2304 Detection of early-disseminated cancer cells with deep learning-enabled holographic imaging.

N. Heller[1], K. Mallery[1], N. Bristow[1], Y. Travadi[2], E. Lee[2], J. Hong[1];
[1]Astrin Biosciences, Inc., St Paul, MN, [2]University of Minnesota, Minneapolis, MN

Recent research increasingly validates the early dissemination of tumor cells in peripheral blood during the nascent stages of cancer, often preceding clinical identification of the primary tumor. This emerging evidence emphasizes the potential of Circulating Tumor Cells (CTCs) as early indicators for cancer. Despite their significance, CTCs are exceptionally rare compared to normal blood cells, which presents a considerable challenge in detection, particularly during early stages of cancer. Traditional detection methods, such as those based on nucleated cell enrichment, antibody labeling and fluorescence imaging, encounter notable limitations when applied in the context of early detection. These limitations arise from the inherent heterogeneity of CTCs, and the multistep process involved in labeling and manual enumeration, compromising cell viability and resulting in cell loss. This loss becomes particularly problematic in the context of early cancer detection scenarios where the tumor burden is extremely low, and any cell loss can significantly impact assay sensitivity. To overcome these challenges, we propose an innovative CTC detection approach employing a deep learning framework combined with holographic imaging. This technique utilizes coherent light to generate holograms from cell samples, capturing detailed 3D morphological and optical properties of individual cells. We developed a custom convolutional neural network designed to facilitate high-throughput cell sorting in real-time. Trained on healthy blood samples and diverse cancer cell lines, the dataset consists of more than 50 million cellular holograms enhanced by proprietary Gaussian annotation and image augmentation strategies. Moreover, by combining the morphological signatures from holography with antigen signatures (e.g. HER2/ER/PR) in real-time, our model demonstrates the ability to detect less than 1 false positive per 1 million nucleated cells, highlighting its potential as a robust tool for targeted early-stage breast cancer detection. Our technology represents highly sensitive alternative to traditional screening methods, with the promise of enhancing patient outcomes.

#2305 Label-free high dimensional single cell morphological profiling of different hematological malignancies by ghost cytometry.

A. Tsubouchi[1], J. J. Miettinen[2], K. Wagatsuma[1], S. Akai[1], Y. An[1], M. Uematsu[1], P. Sergeev[2], D. Tsallos[2], M. J. V. Vaha-Koskela[2], S. Ota[3], C. A. Heckman[2]; [1]ThinkCyte K.K., Tokyo, Japan, [2]University of Helsinki, Institute for Molecular Medicine Finland - FIMM, Helsinki, Finland, [3]The University of Tokyo, Tokyo, Japan

Characterizing the heterogeneity in human leukemias is critical for understanding mechanisms of disease onset, uncovering biomarkers for disease diagnosis, and guiding research into novel treatment approaches. While extensive research focus has been placed on characterizing the molecular heterogeneity in leukemia by modern omics technologies, comparatively less emphasis has been placed on studying the diversity in holistic morphological changes that occur in single cells in the context of disease. Here, we report on a novel approach to understanding and characterizing different hematological malignancies using ghost cytometry, a recently developed high-content flow cytometric method that leverages high-speed, artificial intelligence (AI) driven morphological characterization and analysis of single cells. We performed morphometric profiling on human bone marrow samples from patients with T and B-cell acute lymphoblastic leukemia (ALL, n=5), acute myeloid leukemia (AML, n=5), multiple myeloma (MM, n=5) and healthy bone marrow mononuclear cell (BM-MNC) controls (n=6). Morphological profiles from individual cells were analyzed by unsupervised machine learning (universal manifold approximation and projection, UMAP) and compared within disease subsets and against controls. We identified disease-specific cell populations from a mixture of healthy control and disease samples without any labeling, based on completely label-free information. For validation of the specific cell subsets, we overlaid known cell surface markers (e.g. CD45 for blast cells, CD10/CD19 for B-ALL, CD33/CD34 for AML, CD38/CD138 for MM). The intensity of CD45 was dimmer and disease-specific markers were highly expressed in the disease-specific cell population. We also identified a unique cell subpopulation in the disease-specific cell population that could not be distinguished by existing markers. We also analyzed three human myeloma cell lines (AMO1, KMS, and L363) for comparison to the primary MM samples. In the UMAP analysis using LF-GC data, in all three types of cell lines, Bortezomib-resistant cell lines exhibited different distributions from the control parental cell lines. In addition, we observed distinct morphological profiles between primary myeloma samples and myeloma cell lines.
Here we present a novel cell characterization approach for human hematological diseases that leverages AI-based, label-free, high-speed morphological characterization of single cells. We demonstrate that the approach can be used to identify subtle morphological differences in blast cells from a range of blood cancer subtypes. Application of morphological profiling and AI can be used to identify measurable, disease-related changes in these diseases that have diagnostic, drug screening, and therapeutic monitoring potential.

#2306 A deep learning framework for automated segmentation and analysis of 3D breast cancer spheroid invasion dynamics.

T. Ngo, T.-H. Nguyen, F.-Y. Lin, T.-Y. Tu;
National Cheng Kung University, Tainan, Taiwan

Invasion of neighboring tissues is a cardinal feature of malignancy, notably observed in aggressive cancers like breast cancer, where it can lead to significant morbidity. To explore cancer invasion dynamics, the implementation of a three-dimensional (3D) tumor spheroid invasion assay offers a swift approach to mimicking a tumor micro-region or micro-metastasis. Differential Interference Contrast (DIC) time-lapse imaging was chosen for its fluorescence-free and non-destructive advantages in capturing live spheroid movement. However, the subsequent analysis posed challenges, including out-of-focus cells and a voluminous dataset with diverse microscope planes and time points. Our study introduces a segmentation framework featuring in-focus spatial stacking algorithm and novel training architecture that enabling in-depth automated analysis of 3D spheroid invasion behaviors within a microenvironment. Firstly, the MDA-MB-231 breast cancer spheroids were cultured in a microwell dish and then incorporated into a collagen type I matrix for the 3D spheroid invasion assay. Capturing spheroid invasion dynamics involved acquiring 15 z-plane images (spaced at 20 µm intervals) per timepoint for each spheroid using DIC microscopy at 15-minute intervals over a 28-hour period, employing a 20X objective lens. We refined the Focus Stacking framework into Multiple Slices Blurry Stacking (MSB-Stack) by pre-filtering blurred areas before stacking images. This process produced 6390 slices consolidated into 426 labeled stacked images, highlighting Invasive area, Spheroid core, and Invasive cells post-invasion. We then enhanced Mask R-CNN (Region based-Convolutional Neural Networks) with a weak-to-strong augmentation mechanism, leveraging well-segmented samples from MSB-Stack for training on both fully stacked and blurred images. Blurry Consistency Mask R-CNN (BCMask R-CNN) demonstrates overall improvement across feature extractors, outperforming Mask R-CNN. Using Mean average precision (mAP) as the main metric for instance segmentation and detection, our proposed model achieves 73.0% and 65.2% on mAP @[0.5, 0.95], showcasing robustness. Notably, our best results for mAP @0.5 reach 96.6% and 96.7% on both tasks, underscoring the effectiveness of consistency training in mitigating unclear boundary issues during preprocessing. In conclusion, our proposed method, MSB-Stack, effectively addresses the challenge of unclear boundaries in 3D breast cancer cell DIC microscopy datasets. The integration of weak-to-strong consistency training in our model, BCMask R-CNN, not only mitigates biases but also enhances performance across different backbones, setting the stage for future advancements in cell-tracking tasks and broader migratory analyses.

#2307 State-transition modeling of blood transcriptome predicts disease evolution and treatment response in chronic myeloid leukemia (CML).

D. E. Frankhouser, **R. C. Rockne**, D. Zhao, S. Branciamore, L. Uechi, D. O'Meally, Y.-H. Fu, Y.-H. Kuo, B. Zhang, G. Marcucci;
City of Hope National Medical Center, Duerte, CA

Chronic myeloid leukemia (CML) is initiated and initially maintained by BCR-ABL which is clinically targeted using tyrosine kinase inhibitors (TKIs). Although TKIs can induce long-term remission, they are frequently not curative. Thus, CML is an ideal system to test our hypothesis that transcriptome-based state-transition models accurately predict cancer evolution and treatment response. We collected time-sequential blood samples from tetracycline-off (Tet-Off) BCR-ABL-inducible transgenic mice that recapitulates human chronic phase CML and wild-type controls. From the transcriptome, we constructed a CML state-space and a three-well leukemogenic potential landscape that describes CML state-transition from health to disease. The potential's stable critical points were used to define three distinct disease states. The Early state was characterized by anti-CML genes (n=35) that opposed leukemia progression, whereas an expanding number of pro-CML genes characterized the Transition state (n=357) and Late states (n=1,858). Gene modules that were co-regulated at the unstable points in the potential landscape were identified as the drivers of transition between stable disease states. To investigate CML therapies we used two treatments: silencing of BCR/ABL by readministering Tet (Tet-on, Tet-off [TOTO]) which represented a best-case scenario of disease being cured, and TKI (nilotinib) therapy which represents current clinical practice. TOTO returned the diseased mice transcriptomes to a near health state, without reaching it, suggesting partly irreversible transformation. TKI, however, only reverted the transcriptome to an intermediate disease state, without approaching health, and disease relapse occurred soon after treatment. Finally, using only the earliest time-point as initial conditions, our state-transition models accurately predicted both disease progression and treatment response to both therapies for each individual mouse. In conclusion, these results show state-transition analysis is a valuable approach to gain real time insights into CML development, progression and ongoing treatment response that can also be applied to other type of leukemia and cancers in general. We predicted disease evolution and treatment response in a murine model that recapitulates human disease, supporting this as a potentially valuable approach to time clinical intervention even before phenotypic changes become detectable.

#2308 Semi-automated Ki-67 index assessment using top-k hotspot recommendation in Ki-67 IHC stained WSIs.

H. Yang[1], Y. Hwang[1], Y. Lee[1], K. Jung[2], M. Sung[2], T.-Y. Kwak[1], S. Kim[1], H. Chang[1];
[1]Deep Bio Inc., Seoul, Korea, Republic of, [2]Samsung Medical Center, Seoul, Korea, Republic of

Ki-67 index is commonly used as a breast cancer proliferation marker. However, it is a laborious and time-consuming task for a pathologist to directly measure the Ki-67 index. Recently, automation techniques using machine learning techniques such as deep learning have been proposed. In this study, we propose a top-*k* hotspot recommendation method to help Ki-67 index assessment based on nuclei detection detected by a deep learning model. The dataset included a total of 32 diaminobenzidine-hematoxylin (DAB-H) Ki-67 IHC whole slide images (WSIs) of breast cancer obtained by core biopsy. Each of these WSIs was evaluated by a pathologist using the interval of the Ki-67 index estimate and the scores of 1+, 2+, 3+, and 4+. Additionally, the search area was manually designated to exclude internal control. We developed a Ki-67 index analysis model based on deep learning and image analysis. Nuclei segmentation used the StarDist model. The detected results were filtered based on nucleus size and nucleus eccentricity. The filtering threshold was determined experimentally. To recommend top-*k* hotspots, a coarse search is performed to move the circle region horizontally and vertically in specific units, and the top *k* regions based on Ki-67 index are found among areas containing more than 500 cells. Next, a fine search is performed around the *k* areas in detail. Finally, the top-*k* hotspots and each detected positive and negative cells, count of positive cells and negative cells, and predicted Ki-67 index are provided. It was confirmed that the Ki-67 score estimated for the detected top-1 hotspot and the pathologist's Ki-67 score had a correlation of Pearson correlation coefficient=0.8153, R^2=0.6648. As *k* increased, the top-*k* accuracy was observed to increase from 68.75% when $k = 1$ and 3 to 75.00% when $k = 5$, based on the pathologist's score. When a pathologist reviewed 10 cases where the Ki-67 score differed from the prediction, 6 cases were judged to be worth reexamining considering the proposed hotspot and Ki-67 index, and 2 cases included stromal cells in cell detection. In two cases, the WSI was judged to be blurry. Cell analysis and top-*k* hotspot recommendation using deep learning and image analysis were performed on Ki-67 IHC stained WSIs and compared with the pathologist's Ki-67 score. Through semi-automatic top-*k* hotspot recommendation, the reliability of diagnosis can be increased as an auxiliary test to Ki-67 index assessment.

#2309 3D spatial quantification of lymphocyte infiltration and collagen features in the tumor microenvironment using a novel assay: 3D I/O Pro™.

C. Stoltzfus[1], J. Wilson[1], N. Grant[1], A. Alvarsson[1], A. DeWitt[1], D. Simmons[1], B. Olin[1], B. Phillips[1], L. A. Dillon[2], G. Clifton[2], **N. P. Reder[1]**;
[1]Alpenglow Biosciences, Inc., Seattle, WA, [2]Incendia Therapeutics, Inc., Boston, MA

Background: The composition of the tumor microenvironment (TME) is a major determinant of response to therapy in many solid tumors. To-date, characterization of the TME has been based on limited analysis of thin tissue sections. Here we demonstrate the utility of an end-to-end 3D spatial biology workflow, the 3D I/O Pro™, based on whole tissue imaging, to identify and quantify tumor cells, lymphocytes, and collagen features in human FFPE tissue samples.
Methods: Five human colorectal cancer FFPE blocks were deparaffinized, stained with nuclear (TO-PRO-3) and general protein (eosin) dyes, and cleared using a modified iDISCO protocol. Entire samples were imaged at 2 µm/pixel resolution with a hybrid open-top light-sheet microscope, the 3D*i*™. Regions of interest (ROIs) with a volume of 0.5 mm^3 were re-imaged at 0.33 µm/pixel. Cell nuclei and collagen were segmented and 3D spatial relationships between tumor cells, lymphocytes, and collagen fibers were quantified. Analyses were performed within select ROIs using 3D*a*i™ tools including U-Net, CytoMAP, CT-FIRE, CurveAlign, and custom Python scripts.
Results: The ratio of stromal to tumor parenchymal lymphocytes (lymphocyte infiltration ratio) varied from 1.4 up to 9.1 in 3D volumes and 1 to 25 in 2D virtual sections taken throughout all 5 CRC samples. The ratio of the collagen fibers within 100 µm of the tumor border-oriented perpendicular to the tumor-stromal boundary compared to those oriented parallel to the tumor-stromal boundary was 0.37 in a proof-of-concept evaluation of a 2D virtual section with a lymphocyte infiltration ratio of 12. Qualitatively, areas with perpendicular collagen had more lymphocyte infiltration into the tumor parenchyma than areas with parallel collagen orientation.
Conclusions: We demonstrated that the 3D I/O Pro™ pipeline can quantify lymphocyte density in tumor parenchyma and stroma and analyze collagen features, including orientation, within 3D ROIs in the TME. This workflow allows us to characterize tumors based on many complex spatial relationships and could have broad applicability in research and development of novel cancer therapies that target tumor fibrosis or other features of the TME. In the future, we plan to correlate features from the 3D TME with response to immunotherapy and use these features to refine histologic definitions of immune spatial phenotypes.

#2310 Integrating real-world histopathological and clinicogenomic data from 1799 lung cancer patients by applying unsupervised deep learning.

S. Wu[1], Y. Zhao[2], H. Luo[1], K. Kolahi[1], T. Bui[1], X. Shi[1], A. Shrotre[1], A. Liede[1], X. Zhao[1], J. Samayoa[1], W. Zhao[1];
[1]Abbvie South San Francisco, South San Francisco, CA, [2]Johns Hopkins University, Baltimore, MD

Hematoxylin and eosin (H&E) stained histologic sections contain invaluable information that remains largely untapped because of its complexity. To this end, AI applications employing deep learning (DL) can facilitate the translation of image data to enable human interpretation and yield novel oncological insights that would have otherwise remained imperceptible. DL-based methodologies are multimodal, capable of integrating imaging with clinicogenomic data to furnish a more holistic perspective and affording more accurate predictions in oncology. Here, we developed an unsupervised DL workflow to analyze 1,799 H&E images of lung cancer (NSCLC n = 951; SCLC n = 50; others n = 798) incorporating comprehensive patient-level clinical data (electronic health records [ConcertAI]) integrated with genomics (WES and RNA-seq [Caris Labs]). There are three steps in our approach: (1) image preprocessing and filtering, yielding > 30 million image patches; (2) utilizing pretrained SimCLR models from 57 public oncology histopathology datasets with ResNet-18 as a backbone structure to extract 512-dimensional-feature vectors for each patch; (3) using three unsupervised clustering methods (kmeans, DBSCAN, Leiden clustering) to cluster patches and selected Leiden clustering. We identified 635 primary imaging clusters using an elbow method and generated an image feature matrix by calculating correlations between each patch and cluster centroids; these were aggregated and mapped back to source slides. In this proof-of-concept, distinct image feature patterns characterized SCLC and NSCLC samples. For SCLC, one of the salient features was the presence of hemorrhage, which may be associated with higher rates of fine-needle aspiration biopsy procedure for SCLC compared with NSCLC which was confirmed in the EHR data (p = 0.032). Derived morphological clusters were correlated with tumor-immune genomic features (Tumor Mutational Burden [TMB], Immunologic Constant of Rejection [ICR], and Miracle scores[1]) serving as predictors of response to immune-checkpoint inhibitor therapy. By applying linear models, we detected 11, 96 and 249 significantly associated imaging clusters, respectively, highly enriched with immune cells e.g., plasma cells, macrophages, lymphocytes, and supporting an infiltrated and inflamed tumor-immune microenvironment. In summary, a multimodal, unsupervised deep learning workflow combining H&E imaging with clinicogenomic data was developed to identify histologic feature clusters associated with well-established tumor-immune genomic signatures of NSCLC immune infiltration and molecular phenotypes. These studies demonstrate enormous potential to yield histopathological and translational insights in NSCLC and SCLC that can empower clinicians to make better therapeutic response predictions.

#2311 Precise assessment of cancer cell growth and survival by artificial intelligence.

C. Wong[1], N. Khazamipour[1], S. Alibagi[2], J. Saade[2], D. Golanarian[2], N. Farivar[2], M. Daugaard[1], **N. Al Nakouzi**[1];
[1]Vancouver Prostate Center, Vancouver, BC, Canada, [2]SnapCyte Solutions Inc., Vancouver, BC, Canada

Introduction: Cancer research requires accurate methods for measuring analytical parameters like cell culture confluence, cell count, colony numbers, viability, and motility. These methods must be unbiased and user-independent for reproducible data. Cell analytics involves manual processes (e.g., manual cell counting) or reagent-based approaches (e.g., viability kits). In recent years, semi-automated systems have been introduced that can either count cells, measure cell growth by density tracking, and/or determine cell viability. However, these methods are often time-consuming, require reagents and labeling, and may involve costly instrumentation. Artificial Intelligence (AI) has made strides in clinical and laboratory research, holding promise for swift integration into cancer research. Here, we present the development and validation of SnapCyte™, an AI performing accurate, unbiased, label- and reagent-free cell analytics from basic cell culture images, independent of specialized instrumentation.
Materials and Methods: Cell images were generated using diverse cell lines (MCF7, PC3, Hela, Raji⋯) cultured in various vessels with and without treatments (Taxane, Cisplatin, Heatshock⋯). For the cell count dataset, adherent cells were detached using trypsin, stained with trypan blue and loaded into a standard hemocytometer. Images were acquired using the SnapCyte™ adaptor and diverse microscopes (Leica, Hund, Zeiss, Nikon) and cell phones. Multiple datasets of 500 annotated images each were created, with images masked for confluency or for singular live and dead cells by experienced scientists. Object segmentation utilized the UNet architecture for localizing cells in cell culture images and iterative training was applied to achieve the required accuracy.
Results: After multiple training iterations, SnapCyte™ AI detection models achieved 99% precision for confluency and >95% precision and recall for cell count. SnapCyte™ surpassed standard methods (Crystal Violet, WST1, MTT, Presto blue, CyQuant, Incucyte®, and Bio-Rad TC20 cell counter), displaying high accuracy and smaller standard error variation than reagent-based assays. Compared to IncuCyte® Bio-Rad TC20, SnapCyte™ demonstrated similar accuracy and greater user-independent results. Furthermore, SnapCyte™ acquired data in under 10 minutes, with non-invasive measurements, allowing direct use of cells in downstream assays.
Conclusion: We have developed and validated an AI model for advanced cell analytics. Our data show that the SnapCyte ™ AI is *at par* or better than existing reagent and instrument-based solutions in assessing cell confluency, number, and viability. This technology offers a fast, accurate, and unbiased cell analytics platform that is resistant to user variations, and independent of reagents and costly equipment.

#2312 Integrating spatial multi-omics data with spatial quantitative pharmacology (spQSP) model to simulate human neoadjuvant immunotherapy clinical trial of hepatocellular carcinoma.

Shuming Zhang, Atul Deshpande, Babita K. Verma, Hanwen Wang, Haoyang Mi, Long Yuan, Won Jin Ho, Elizabeth M. Jaffee, Qingfeng Zhu, Robert A. Anders, Mark Yarchoan, Luciane T. Kagohara, Elana J. Fertig, Aleksander S. Popel

Johns Hopkins University School of Medicine, Baltimore, MD

Human clinical trials provided tremendous insights to advance novel systemic therapies and to improve treatment outcomes for cancer patients. The few durable treatment options have led to a critical need to advance new therapeutics in hepatocellular carcinoma (HCC). Recent human clinical trials have demonstrated that new combination of immunotherapeutic regimens provide augmented clinical response in a subset of patients. Computational methods that can simulate tumors from mathematical equations describing cellular and molecular interactions are emerging as promising tools to simulate the impact of therapies entirely *in silico*. To facilitate designing dosing regimens and selecting potential predictive biomarkers, we developed a new computational model to track tumor progression at organ scale while reflecting the spatial heterogeneity in the tumor at cellular and molecular scale in HCC. This computational model is called a spatial quantitative systems pharmacology (spQSP) platform and it is also designed to simulate the effects of combination immunotherapy. The model is first calibrated using clinical outcomes and measured immune cell densities based on recent neoadjuvant HCC clinical trial combining anti-PD-1 immunotherapy and a multitargeted tyrosine kinase inhibitor (TKI) cabozantinib (NCT03299946). Then, we validate the results from the spQSP model by leveraging real-world spatial multi-omics data from the same clinical trial. The model output is compared with spatial data from Imaging Mass Cytometry (IMC). Both IMC data and simulation results suggest closer proximity between CD8 T cell and Arginase 1 (Arg1) positive macrophages among non-responders while the reverse trend was observed for responders. We also compared the model output with Visium spatial transcriptomics analyses of samples from post-treatment tumor resections in the original clinical trial. Both spatial transcriptomic data and simulation results identify the role of spatial patterns of tumor vasculature and TGFβ in tumor and immune cell interactions. To our knowledge, this is the first spatial tumor model for virtual clinical trials at a molecular and cellular scale that is grounded in high-throughput spatial multi-omics data from a human clinical trial.

#2313 Multi-modal deep learning to predict cancer outcomes by integrating radiology and pathology images.

Z. Li, Y. Jiang, **R. Li**;
Stanford University, Palo Alto, CA

Purpose: Cancer patients routinely undergo radiologic and pathologic evaluation for their diagnostic workup. These data modalities represent a valuable and readily available resource for developing new prognostic tools. Given their vast difference in spatial scales, effective methods to integrate the two modalities are currently lacking. Here, we aim to develop a multi-modal approach to integrate radiology and pathology images for predicting outcomes in cancer patients.
Methods: We propose a multi-modal weakly-supervised deep learning framework to integrate radiology and pathology images for survival prediction. We first extract multi-scale features from whole-slide H&E-stained pathology images to characterize cellular and tissue phenotypes as well as spatial cellular organization. We then build a hierarchical co-attention transformer to effectively learn the multi-modal interactions between radiology and pathology image features. Finally, a multimodal risk score is derived by combining complementary information from two images modalities and clinical data for predicting outcome. We evaluate our approach in lung, gastric, and brain cancers with matched radiology and pathology images and clinical data available, each with separate training and external validation cohorts.
Results: The multi-modal deep learning models achieved a reasonably high accuracy for predicting survival outcomes in the external validation cohorts (C-index range: 0.72-0.75 across three cancer types). The multi-modal prognostic models significantly improved upon single-modal approach based on radiology or pathology images or clinical data alone (C-index range: 0.53-0.71, $P<0.01$). The multi-modal deep learning models were significantly associated with disease-free survival and overall survival (hazard ratio range: 3.23-4.46, $P<0.0001$). In multivariable analyses, the models remained an independent prognostic factor ($P<0.01$) after adjusting for clinicopathological variables including cancer stage and tumor differentiation.
Conclusions: The proposed multi-modal deep learning approach outperforms traditional methods for predicting survival outcomes by leveraging routinely available radiology and pathology images. With further independent validation, this may afford a promising approach to improve risk stratification and better inform treatment strategies for cancer patients.

#2315 AI-enabled precision oncology era: Advanced and interactive interpretation of next-gneneration sequencing (NGS) reports.

H. Chen, Z. Xu, L. Chen, M. Wang, P. Zhang, F. Pang, K. Wang;
Shanghai OrigiMed Co., Ltd, Shanghai, China

Background: Next-generation sequencing (NGS) has been widely adopted in clinical practice, but there are still unmet needs among physicians regarding the interpretation and application of NGS reports. These needs include selecting multi-targeted and combination therapies, keeping up with evolving treatment options and clinical trial results, and incorporating personalized medicine based on real clinical cases.
Methods: To address these challenges, we propose using large language model (LLM) to analyze and interpret clinical questions, perform semantic searches in a high-quality database, and provide customized prompts and logical outputs. Our knowledge base includes diagnostic and treatment details for 600+ tumor subtypes, 620,000+ entries, 2,000+ drug details, and 440,000+ clinical trials. The database is updated automatically using a fact engine and medical literature sources. Personalized gene interpretation is incorporated using pretraining, cosine similarity, and context learning prompts.
Results: Our tool, named "SmartMTB", enables personalized interpretation of genomic testing reports for precision oncology. Users input the latest clinical features using a selection-based or question-and-answer approach. The tool identifies the treatment stage and genomic variations, provides information on mutation frequencies, sensitivity and resistance of targeted and immunotherapies, and priority selection strategies for multi-gene mutations. It matches similar clinical cases and provides real-time updates on treatment options and clinical trial literature. It also facilitates patient matching for clinical trials and considers economic factors.
Conclusion: We present a groundbreaking artificial intelligence (AI) tool in cancer care that revolutionizes precision oncology. This AI system, trained on extensive datasets, swiftly and accurately analyzes and interprets complex genomic and clinical data. It enables clinicians to make informed decisions about personalized treatment strategies, significantly improving patient outcomes in cancer therapy.

#2316 A deep Gaussian process (DGP)-based prediction model for immunecheckpoint inhibitor (ICI) response in gastric cancer (GC).

S. Park, M. Kim, C. Hong, T. Hwang;
Mayo Clinic, Jacksonville, FL

Background: Immune checkpoint inhibitors (ICIs) targeting PD-1 or PD-L1 have dramatically improved survival of patients with gastric cancer (GC). However, recent clinical trials, including KEYNOTE-059, KEYNOTE-061, and ATTRACTION-2, show that the objective response rate (ORR) for ICIs is still less than 20% in patients with advanced GC. Therefore, predicting who will respond to ICIs in advance is essential to make better treatment plans for GC patients. There are potential biomarkers to predict ICI response, but most of them can only be applied to a limited population of patients. For example, Kim ST., et al., (PMID: 30013197) show that patients with MSI-high or EBV-positive responded well to ICIs, but these subtypes account for less than 30 percent of GC patients (PMID:25079317). In this study, we propose a prediction model of ICI response using the 32 GC-specific genes that we identified from mutation data (PMID: 26635139) and showed their close association with survival and ICI response in GC (PMID: 35140202; PMID: 36508166). In addition, since the number of available GC-ICI samples is small, we design our prediction model in Bayesian and ensemble learning frameworks which are robust to small sample size problems.

Methods: We collected mRNA sequencing data from GC-ICI treated patients from our institutions and publications (PMID: 30013197; PMID: 35254400; PMID: 33846173). We used 108 samples previously included in our previous work (PMID: 36508166) as the training data and 27 samples (13 responders and 14 non-responders) from (PMID: 3384617) as the test data. We built and trained a classifier to separate responders from non-responders using the expressions of the 32 genes. We proposed to use a Deep Gaussian process (GP) model, a multi-layered extension of a GP that is itself a Bayesian method. We optimized the parameters of each GP model in variational inference. To implement ensemble learning, we trained multiple DGP models with different initializations of the model parameters and data splitting (training/validation sets). For each training run, the best model was selected based on the prediction performance on the validation set, measured by AUC. The final prediction for a test sample was made by combining the prediction results of all the DGP models by taking the average.

Results: We implemented the DGP-based prediction model using PyTorch in Python, and the codes will be publicly available on the GitHub repository (https://github.com/hwanglab/GC_ICI_response_prediction). We achieved a prediction performance of 0.813 AUC on the test data (sensitivity = 0.769 and specificity = 0.714).

Conclusion: We propose the prediction model of ICI response, which can handle small sample size problems in the framework of Bayesian and ensemble learning. The experimental results using the GC-ICI data demonstrate that the 32 genes can be used as predictive markers for ICI response in GC.

#2317 Development and validation of a colorectal cancer prediction model: A nationwide cohort-based study.

S. Hayek;
Tel Aviv University, Tel-Aviv, Israel

Background: Colorectal cancer (CRC) ranks as the third most prevalent cancer globally and is a major cause of cancer-related mortality. Early diagnosis is critical to increase survival rates. While CRC screening has shown significant benefit, adherence remains low, and there is a need for better tools to identify high-risk patients. Risk prediction models were demonstrated to identify such patients.
Aim: To establish an individualized risk prediction model for CRC diagnosis based on Electronic Health Records (EHR).
Methods: This is a retrospective cohort study utilizing EHR data of Clalit Health Services (CHS) members aged 50-74 that were eligible for CRC screening, from January 2013 to January 2019. The model was trained to predict CRC diagnosis within two years using approximately 20,000 EHR features including socio-demographic information, laboratory results and medical history. Model performance, as a complementary screening method, was evaluated.
Results: The study included 2679 subjects with CRC diagnosis and 1,133,713 subjects without CRC diagnosis. The model was trained on subjects from 2013-2017, and performance was validated on subjects from 2019 and a cohort of subjects that underwent fecal occult blood test (FOBT). Incidence values of CRC among subjects in the top 1% risk scores were higher than baseline (2.3% vs. 0.3%; lift 8.38; P-value <0.001). Characteristics of subjects by risk scores percentiles are presented in Table1. Cumulative event probabilities increased with higher model scores, indicating a correlation between predicted and actual risk of CRC diagnosis. Model-based risk stratification among subjects with a positive FOBT, identified subjects with more than twice the risk for CRC compared to FOBT alone.
Conclusions: We developed an individualized risk prediction model for CRC that can be utilized as a complementary decision support tool for healthcare providers to precisely identify patients at high risk for CRC and refer them to confirmatory testing.

#2318 Multimodal machine learning for the automatic classification of recurrent cancers.

P. Krawczuk[1], **Z. Fox**[1], D. Murdock[1], J. Doherty[2], A. Stroupe[3], S. M. Schwartz[4], L. Penberthy[5], E. Hsu[5], S. Negoita[5], V. Petkov[5], H. Hanson[1];
[1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]Huntsman Cancer Institute, Salt Lake City, UT, [3]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, [4]Fred Hutchinson Cancer Center, Seattle, WA, [5]National Cancer Institute, Washington, DC

The National Cancer Institute's (NCI) Surveillance, Epidemiology, and End Results (SEER) registries maintain and organize cancer incidence information allowing researchers to derive valuable insights into cancer epidemiology. While significant attention has been devoted to identifying cancers either from clinical text or through tabular data collected by SEER registries, there has been less emphasis on integrating these distinct modes of data. In our multimodal deep learning approach, we use longitudinal tabular data from the Consolidated Tumor Case (CTC) database that encompass a patient's past diagnoses. This tabular information can augment clinical text to aid in the classification of pathology reports indicative of recurrent cancers. Four NCI SEER registries (Louisiana, New Jersey, Seattle and Utah) have manually labeled 61,150 pathology reports with one of six categories, which we refine into a four-class classification problem. Each pathology report is identified as either positive for recurrence, negative for recurrence/not disease free, new tumor, or an "other" (no malignancy/uncertain) class. Natural Language Processing techniques can extract meaningful information from clinical pathology reports, aiding in the identification of subtle indicators of recurrence by using relevant context. We use a hierarchical self-attention model (HiSAN) to construct document embeddings and classify the pathology report. To further enhance the predictive accuracy of our modeling approach we fuse the textual information from a pathology report with categorical data about patient's cancer history. For each report, we create a patient context vector that encapsulates tumor-level information from patient's previous cancer(s). The selected CTC records are associated with cancers diagnosed more than 120 days before the date of biospecimen collection stated in the pathology report. The patient context vector is crafted based on diverse categorical features; including cancer staging, patient age, treatment and sites of metastasis at the time of diagnosis. Features are represented using a combination of one-hot encoding and binning. Additionally, we employ patient and feature-level normalization to maintain proportional significance of features for individuals with multiple past diagnoses. We present preliminary results corresponding to different approaches for classifying cancer recurrence; first, we observe that using only the pathology reports as input yields an accuracy of 68%. Secondly, when using only CTC features with an XGBoost model, we achieve an accuracy of 49%. Finally we show that leveraging multiple data modalities, i.e. HiSAN generated pathology report embeddings and CTC data, significantly improves the model's predictive accuracy to 76%. This research demonstrates a promising path forward in enhancing classification of clinical text by incorporating longitudinal patient history data.

#2319 Deep learning-enabled dynamic infiltration and response to NK therapies in solid tumor organoids.

L. Lonini[1], S. Khare[1], T. D. Lopez[1], S. Szydlo[1], M. Streit[1], O. A. Karginova[1], M. K. Flaherty[1], A. Salhaudeen[2], A. Kunert[3], A. Oja[3], K. Sasser[1], M. C. Stumpe[1], C.-S. Ho[1];

[1]Tempus Labs, Chicago, IL, [2]University of Illinois Chicago, Chicago, IL, [3]Sanofi, Amsterdam, Netherlands

Patient-derived organoid co-culture models have become a state of the art platform to evaluate the effectiveness of immunotherapeutic agents in preclinical studies. However, preclinical development as well as quantification of therapeutic potency and resistance require differential labeling of cells with fluorescent dyes or transgenic fluorescent proteins, which may dysregulate the effector cell function or produce undesired cytotoxicity. Deep learning-based image analysis allows the use of brightfield images to co-localize tumor organoids (TOs) with effector cells, and measure TO-specific responses to novel candidate immunotherapies in a label-free manner; this can accelerate their evaluation as therapeutic candidates in cancer patients and shed light on tumor-immune interaction mechanisms.

Here we record multi-day time-lapse confocal microscopy images of TOs co-cultured with NK cells at increasing concentrations of target to effector cells. Two pre-trained U-Net convolutional neural networks are used to separately segment tumor and immune cells from the brightfield channel, and quantify immune cell infiltration over time. TO segmentation masks are registered with a vital dye (caspase 3/7) channel to selectively quantify TO cell death and correlate it with estimated immune cell infiltration across a large cohort of patient-derived TO models (including breast, colorectal, endometrial, gastric, head and neck, liver, lung and pancreatic cancer), at increasing concentrations of 6 different NK cell types (identified as A through F).

We find that the estimated density of infiltrating immune cells is highly correlated with TO death, as quantified by fluorescence intensity of caspase over time (median Pearson's r=0.89, P<0.001). Higher ratios of effector to target cells lead to higher activation of NK cells as measured by infiltrating cell density. Differential infiltration dynamics are observed across TOs and immune cell lines, as peak infiltration density is affected by co-culture time, ratio of target to effector cells, TO line, and NK cell type. These findings highlight that the paired segmentation models are able to measure varying degrees of infiltration across different types of immune cells and TO models.

The approach described here is highly scalable and only requires capturing brightfield images of the assay, therefore eliminating the need to label cells and avoiding phototoxic effects or alteration of the immune cells activity. Time series measurements enable quantification of patterns of immune cell activation, including infiltration, migration and co-localization dynamics, which provide insights into the pharmacokinetics and mechanisms for specific immune therapies. Overall, this methodology enables high throughput screening of many therapeutic candidates across dozens to hundreds of unique TO-models, thereby facilitating targeted precision therapy.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: New Algorithms, Software, and Models Poster Session

#2323 Deciphering RNA degradation: Insights from a comparative analysis of paired fresh frozen/FFPE total RNA-seq.

W. Choi[1], M. Yeon[2], H. Choi[1], D. N. Hayes[1];

[1]University of Tennessee Health Science Center, Memphis, TN, [2]Florida State University, Tallahassee, FL

Background: Fresh frozen (FF) and formalin-fixed paraffin-embedded (FFPE) samples are primary resources for archival tissues in cancer studies. Despite the advantages of easy storage and cost-effectiveness, FFPE samples have the disadvantage of inevitable chemical-induced RNA degradation. Although, in mRNA-seq data, the 3' bias due to the characteristics of the mRNA-seq platform allows the measure of RNA degradation levels, for total RNA-seq and FFPE samples, there is still no clear measure for RNA degradation.

Methods: Our study, utilizing The Cancer Genome Atlas (TCGA) pilot data comprised of 26 paired samples of fresh frozen mRNA-seq [FFM], fresh frozen total RNA-seq [FFT], and FFPE total RNA-seq [PET], investigated RNA degradation patterns in FFPE samples. Upon investigating the read coverage of transcripts in FFPE data, we observed increased noise parameters in selected samples compared to others, suggesting a method for assessment of RNA degradation in FFPE. To measure these noise patterns, we developed a method called windowCV (wCV) utilizing coefficient of variance (CV) along the transcript length. Also, based on reports that membrane-surrounded RNA such as lncRNA and mitochondrial RNA (mtRNA) might be less affected by formalin fixation, we developed the simple measure dividing expression value of other proteins with certain lncRNA or mtRNA inferring the degree of RNA degradation.

Results: We first compared the shape of transcript read coverage from 3 different RNA-seq data and observed 3'bias pattern in FFM which was not observed in FFT and PET. For FFT and PET, we applied wCV and executed hierarchical clustering. We observed that a subset of samples and genes were clustered by high wCV value suggesting notable RNA degradation. To support the hypothesis of RNA degradation, we utilized Trimmed Mean of M values (TMM) expression ratio of paired FFT and PET to determine which samples and genes were associated with underestimation of expression in PET. Interestingly, we observed that PET/FFT TMM ratio showed negative correlation with wCV. Additionally, when we investigated hierarchical clustering result of PET/FFT TMM ratio, we found that lncRNA and mtRNA were less affected by FFPE. We then calculated expression ratio between membrane-surrounded RNA and a set of protein coding genes largely affected by FFPE. As a result, we found that this ratio positively correlated with paired PET/FFT TMM ratio. We conclude that this simple measurement can provide information of FFPE induced underestimated expression with limited transcriptome data as well as RNA degradation.

Conclusion: Our method can provide gene-level CV while avoiding false positive variance signal originating from transcript model and simple way to detect the degree of RNA degradation across FFPE samples.

#2324 Leveraging a comprehensive genomic data library for detecting clonal hematopoiesis in liquid biopsy.

A. Sonnenschein, M. Hasan, S. Hui, B. Tell, H. Nimeiri, J. Freaney, K. Sasser, W. Zhu, C. Lo;
Tempus Labs, Chicago, IL

Background: Clonal Hematopoiesis (CH) is a well established confounder in next-generation sequencing (NGS)-based liquid biopsy cancer diagnostics. Misclassification of CH variants as tumor variants can lead to false positive actionable variant detection, potentially resulting in incorrect interpretation of results and therapy selection. Moreover, CH variants may also interfere with quantitative variant monitoring leading to inaccurate assessment of treatment response. While filtering of CH variants is possible via matched sequencing of white blood cell and plasma DNA, emerging algorithmic approaches may enable a more resource-effective, time-sensitive approach with high precision.

Methods: A random forest classifier was trained and validated on 1321 advanced, pan-solid tumor cancer samples (training n=660, validation n=661) sequenced using both the Tempus xF+ (liquid biopsy) and Tempus xT (solid tumor with matched buffy coat) NGS assays. Variants were labeled as CH or tumor-derived based on solid-tissue results in 39 genes that are known to be associated with CH (e.g., DNMT3A, TET2, TP53). The classifier was trained to classify SNV and indel variants detected via liquid biopsy as circulating-tumor or non-tumor (CH + germline) in origin. Features used by the classifier include the fragment size of reads overlapping each variant, prevalence in solid-tumor samples from the Tempus multimodal database, and variant allele fraction relative to estimated tumor fraction. Model classifications were validated against Tempus xT.

Results: Our training set (n=660 liquid biopsy samples) included 680 pathogenic variants. 50% (n=342/680) were determined to be tumor-derived, while 50% (338/680) are likely due to CH.

Our independent validation (n=661 samples) included 600 pathogenic variants. Model prediction accuracy on these validation set variants was 91.7%, with an ROC-AUC of 0.97. Sensitivity was 88.3% (n=257/291 true positives correctly labeled as non-tumor variants), specificity was 94.8% (n=293/309 true negatives correctly labeled as tumor variants), and precision was 94.1%.

The model ranked “gene” as the most informative feature for variant classification, followed by measurements of fragment distribution and historical prevalence of individual variants within the Tempus Database.

Conclusion: A novel classifier trained on multiple orthogonal bioinformatics features can reliably distinguish CH from tumor-derived variants using only liquid biopsy data with high accuracy, including high sensitivity and high specificity.

#2325 NUWA-ms: A network-based method to infer quantification of missing proteins using multi-cohort proteomics profiles.

Lihua Cao, Yuhao Xie, Jiale Chen, Man Wang, Tingting Zhao, Heli Yang, Yang Du, Yang Yang, Zhaode Bu, Jiafu Ji, **Jianmin Wu**

Peking University Cancer Hospital & Institute, Beijing, China

Although mass spectrometry is powerful for proteomic quantification, the inherent issue of missing values remains a significant challenge. We found a prevalent lack of quantification of valuable proteins (e.g., immune cell markers and drug targets) in published datasets, limiting the functional utilities of quantitative proteomic profiles. This was exemplified by the substantial lack of quantification of immune cell marker, which impede the dissection of tissue-infiltrating immune cells by deconvolution analysis of cancer proteomic profiles. Thus, we introduce a network-based method NUWA-ms for robust abundance inference of missing proteins using multi-cohort proteomic profiles. By evaluating 561 tumors with paired proteomic and transcriptomic profiles, a significant improvement of deconvolution performance was shown with the aid of NUWA-ms. This was further validated by the comparison between scRNA-seq and proteomic analyses of a same gastric cancer tumor tissue. NUWA-ms applications to cancer proteomic profiles facilitated the inference of CD8+ T cell markers and effector proteins, enabling the associations of CD8+ T cell infiltration with MSI status in colorectal cancer and anti-PD-1 therapy response in melanoma. These findings demonstrated the utilities of NUWA-ms in depicting infiltrating lymphocytes in the tumor microenvironment using proteomic profiles. Furthermore, based on the proteomic profiles of six patient-derived tumor organoids (PDOs), NUWA-ms application helped identifying PDOs sensitive to a targeted therapeutic agent including the ones neglected by the raw MS quantification, and aided in revealing the resistant mechanism. Together, NUWA-ms could enable a robust inference of protein abundance, to help identifying protein biomarkers and therapeutic targets for cancer and other complex diseases.

#2326 Integrating single nucleotide variants (SNVs), copy number alterations (CNAs), and structural variants (SVs) into single-cell clonal lineage inference.

N. Bristy, X. Fu, R. Schwartz;
Carnegie Mellon University, Pittsburgh, PA

Background: We extend algorithms for clonal lineage inference (``tumor phylogenetics") from single-cell DNA sequence (scDNA-seq) data to accommodate broader classes of genetic variants, including single nucleotide variants (SNVs), copy number alterations (CNAs), and structural variants (SVs).
Methods: We develop a computational method based on constrained optimization, posing a problem of inferring cellular lineage trees consistent with a given scDNA-seq data set constrained to follow a Dollo parsimony model for SNVs and SVs. We then seek an optimal tree consistent with these constraints so as to optimize for a CNA minimum evolution model balanced against measure of consistency of the different data types with one another relative to the reconstructed set of clones. We pose this problem as an integer linear program (ILP) that we solve heuristically via a coordinate descent algorithm. We tested the resulting method on a combination of synthetic scDNA-seq data and publicly available real data.
Results: Results on synthetic data show the method to be effective at constructing lineage trees under a variety of parameter domains, including variations in noise levels, clone numbers, single cells, and mutation rates. We further show it to yield improved accuracy over widely used prior models that operate on only subsets of these variant types. Application to previously published scDNA-seq data demonstrate the method to be effective at inferring clonal lineage trees incorporating all three variant types. The results further show how the different kinds of variants can contribute in tandem to progression along single cell lineages or to the emergence of clones exhibiting hallmarks of distinct mechanisms of progression.
Conclusion: The results support the effectiveness of our method in resolving accurate trees from scDNA-seq data including diverse variant types, as well as the value of considering these mutation types collectively in developing a comprehensive understanding of how various forms of somatic mutability together shape clonal evolution in cancers.

#2327 MADVAR: An algorithm that improves the relevance of computational biology output, while reducing compute time and space requirements.

G. Silberberg[1], **M. Ritchie**[2];
[1]Champions Oncology, Hackensack, NJ, [2]Corellia AI, Rockville, MD

High-throughput methods implemented in biology research produce a continuously growing array of data input that are used to produce data output with an increasing abundance of features. While growth in the volume and diversity of data input can be highly valuable for studying biological systems, it presents the challenge of managing enormous quantities of features, many of which are not relevant to the specific research question being asked. This excess data input burdens storage and computation of downstream clustering and machine learning tasks. A common approach used to manage this data input relies on filters applied to the features by their variance across the sample set, while applying random cutoffs. Our proprietary algorithm (“MADVAR”) enables the prioritization of variable features from high-throughput continuous data, by automatically finding an optimal cutoff for the distribution of the data. Based on the right-skew nature of biological data distribution, MADVAR finds and excludes the "0 variance peak" using the median of the distributions and the median absolute deviation (MAD). MADVAR enables a faster analysis with a reduced memory requirement, and dramatically improves clustering results with minimal loss of relevant features.

#2328 Next-generation sequencing-based regression algorithm to determine homologous recombination deficiency scores in a pan-cancer cohort.

B. Choi, Y. Choi;
Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Background: Homologous recombination deficiency (HRD) inhibits double strand breaks from being repaired in DNA, leading to cancer cells failing to recover themselves and cell death. Previous studies found that HRD-positive ovarian cancer patients had more significant clinical benefits from poly ADP-ribose polymerase inhibitors (PARPi) treatment. For accurate detection of HRD, next-generation sequencing (whole exome, whole genome) was used to identify large-scale genomic aberrations including telomeric allelic imbalance (HRD-TAI score), loss of heterozygosity profiles (HRD-LOH score), and large-scale state transitions (HRD-LST score). So far, many studies (HRDetect, SigMA, CHORD and shallowHRD) have been conducted to accurately determine HRD in a pan-cancer cohort. As the study progressed, it has been revealed that PARPi is effective when applied to patients with HRD in not only ovarian cancer but also breast cancer, prostate cancer, and pancreatic cancer.
Purpose: To develop an algorithm that accurately predict HRD score in patients with ovarian cancer, breast cancer, prostate cancer, and pancreatic cancer utilizing a machine learning algorithm.
Methods: We used whole-genome sequencing (WGS) data of 710 samples from 309 patients, whole-exome sequencing (WES) data of 4,650 samples from 2,193 patients from the pan-cancer cohort of the TCGA (TCGA-OV, TCGA-BRCA, TCGA-PRAD, and TCGA-PAAD). The HRD-TAI/HRD-LST/HRD-LOH scores were calculated through structural variation analyses. After data cleaning processes, machine-learning models were trained and tested on 228 out of 2,502 samples, and validation was performed on 1,248 out of 2,502 samples from the TCGA dataset.
Results: To assess the performance of the machine-learning regressor, the concordance between predictions and annotations was quantified by calculating the R squared (R;;;^2). As a result of training using machine learning algorithm, we achieved a high R;;;^2 (0.904) with a RMSE (root mean squared error) score (7.649) for a pan-cancer cohort.
Conclusions: Our regressor was robust and accurate when applied to 4 cancer types. Using our systematic pan-cancer analysis, we found novel insights into the mechanisms of HRD across cancer types with potential contribution to clinical practice.
Figure 1. Functional HRR genes can repair DNA breaks, but deficient HRR genes will decrease rates of DNA repair leading to cell death via apoptosis.HRR, Homologous recombination repair; HRD, Homologous recombination deficiency
Figure 2. Receiver operating characteristic (ROC) and under the curve (AUC) values showing the performance of machine-learning algorithm. TPR, true positive rate; FPR, false positive rate

#2329 Cancer region definition using spatial gene expression patterns by super resolution reconstruction algorithm for spatial transcriptomics data.

Jeongbin Park[1], Seungho Cook[1], Dongjoo Lee[1], Jinyeong Choi[1], Seongjin Yoo[1], Hyung-Jun Im[2], Daeseung Lee[1], Hongyoon Choi[1]

[1]Portrai, Inc., Seoul, Republic of Korea, Seoul, Korea, Republic of,[2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background: Spatially resolved transcriptomics (ST) has enabled a variety of cancer research on the heterogeneity of tumor microenvironment. However, when identifying cancer boundaries based on ST, the limited resolution of ST such as Visium hinders the accurate identification of cancerous regions. To address these issues, we have developed a novel approach for accurately classifying regions of the tumor by using deep image prior (DIP) algorithm to convert Visium data into high-resolution images.

Methods: We proposed SuperST, which utilizes deep image prior to transform low-resolution ST data into high-resolution images, providing more accurate spatial marker expression patterns. This method was used to define cancer regions by combining with a pre-trained deep learning algorithm that recognizes spatial patterns. ST data of hepatocellular carcinoma (HCC) patients were used to apply SuperST. Firstly, 400 spatially variable genes were identified. SuperST leverages the deep image prior (DIP) algorithm and a U-Net neural network to transform ST data into high-resolution ones without needing ground-truth high-resolution data. The final high-resolution images of gene expression data were used to extract 512-dimensional feature vectors for each gene via a pre-trained convolutional neural network model (VGG16). Subsequently, we apply K-means clustering to these features to identify transcriptionally distinct tissue regions considering spatial information and compared with the human-labeled cancer regions.

Results: The cancer region detection using spatial gene expression data and our algorithm yielded results that substantially align with the human annotations on the H&E images. Furthermore, compared to the cancer definition obtained using the CopyKat and SPACET algorithms, our results were more spatially consistent for cancerous regions as well as providing high-resolution image-level definition of cancer region margin. This indicates that our algorithm better utilizes spatial information and more effectively overcomes the low resolution of ST data.

Conclusion: This research demonstrates the effective application of our SuperST algorithm to the challenging problem of cancer region detection only using spatial gene expression data. It suggests that our algorithm could be utilized for a variety of problems in spatial biology in cancer research.

#2330 CTD2 "Connects the Dots" to capture disease genes in complex networks and its application on the Cancer Genomics Cloud.

V. Petrosyan[1], V. Kovacevic[2], P. Obradovic[3], C. Fisher[4], Z. Worman[4], D. Sain[4], J. DiGiovanna[4], B. Davis-Dusenberry[4], A. Milosavljevic[1];
[1]Baylor College of Medicine, Houston, TX, [2]Persida Bio, Brooklyn, NY, [3]University of Belgrade, Belgrade, Serbia, [4]Velsera, Charlestown, MA

We have developed CTD2 (an algorithm to "Connect the Dots") to capture biological signals and identify candidate genes in complex networks. CTD2 extends the functionality of its predecessor CTD by providing ranked lists of genes that are “guilty by association” and significantly linked to other genes of interest. With the explosion of large scale multi-omics studies in the cancer field, novel approaches are needed to interpret these valuable datasets. Both CTD and CTD2 are information-theoretic algorithms that allow identification of highly connected sets of genes in complex networks without the need for permutation testing. CTD has been previously used to interpret perturbations in different subtypes of breast cancer. Additionally CTD has been used to identify biomarkers of chemotherapy response in Triple Negative Breast Cancer (TNBC) murine PDX models to both platinum and taxane agents. These small multigene biomarkers of response were shown to be informative for the response of both patients and PDXs. CTD2 was developed to expand the utility of the CTD package by also capturing genes that are "guilty by association". These genes are significantly connected to genes of interest (such as disease genes), and are ranked by their connectedness to these informative gene sets. To demonstrate its utility, we investigated if CTD2 could identify known breast cancer genes. Using TCGA breast cancer expression data, we built case/control graphs over 5,000 variable genes for each subtype of breast cancer. Genes previously associated with breast cancer were identified with DisGeNET and split into a training set discovered pre-2015 and test set discovered post-2015. The genes that were discovered pre-2015 that overlapped with our networks (n = 680) were then used as an input for CTD2 along with the case/control graphs. We then ranked the connectedness of all the genes in these graphs to the training set and found that the test set of breast cancer genes that were discovered post-2015 were significantly enriched in these ranked lists.We have shown that CTD2 and CTD can be utilized to discover biologically informative signals in complex networks. Furthermore we have deployed these tools on the Cancer Genomics Cloud to make them easily accessible for users without a bioinformatics background. The democratization of these in silico tools will allow for their adaptation by a wider audience and aid in the interpretation of large multi-omic datasets.

#2331 Uncovering gene co-regulation networks in spatial transcriptomics data.

P. Danaher, D. McGuire, M. Patrick, D. Kroeppler, J. Schmid, J. M. Beechem;
NanoString Technologies, Inc., Seattle, WA

Single-cell spatial transcriptomics measures thousands of genes *in situ* over potentially millions of cells. These rich datasets pose the best problem in genomics: how can an analyst possibly uncover all the biological insights contained within them? Careful analysis can uncover intricate biological relationships, but only if the analyst knows where to look. One useful set of “places to look” is genes sharing spatial correlations, i.e. that tend to be expressed in the same regions as each other. When genes are expressed together in space, it suggests causality, either by one gene acting on another, or by some latent variable impacting all the genes. These causal relationships have only become detectable en masse with the advent of spatial transcriptomics data, making them rich in potential for previously unknown findings. Unfortunately, spatial correlation has largely fallen short of its promise for one reason: genes expressed by the same cell type are usually highly spatially correlated. These trivial correlations overwhelm results driven by interesting biology.

Here we present an algorithm designed to discover spatial correlations arising from causal relationships and not from the cell type landscape. We compute genes’ conditional correlations over space, looking at the residuals of spatial expression after accounting for the cell type landscape.

In a 6,000-plex Spatial Molecular Imaging (SMI) analysis of colon cancer, we find that approximately 80% of the strongest spatial correlations can be attributed to cell type; the remaining 20% suggest underlying causal relationships. 96 distinct modules comprising up to 46 spatially correlated genes were discovered. The expression within these modules is driven by between 1 and 19 different cell types. Notable modules include those related to IFNG signaling, antigen presentation, B-cell chemotaxis and activation, and microenvironmental remodeling. Further, our study delves into the spatial correlations among ligand-receptor pairs, revealing spatial co-regulation in a limited subset of the 555 ligand-receptor pairs examined in the 6,000-plex panel.

This approach enables us to discern spatial correlations that hint at biological causality, thereby beginning to delineate the "spatial interactome" of cancer. Leveraging a growing collection of 6,000-plex CosMx™ SMI cancer datasets that span various cancer types including breast, liver, kidney, lung, color, skin, and pancreatic cancers, we are systematically documenting the spatial dependencies of genes. This includes identifying correlations that are consistent across different tumors, as well as those unique to specific tumors or tumor types. Early observations have highlighted modules of chemokines (CCL3/CCL4/CCL3L, CXCL1/CXCL2/CXCL3), genes indicative of CAF phenotype (FN1 and collagens), and those involved in cell adhesion and collagen formation.

For research use only. Not for use in diagnostic procedures.

#2332 Enhanced analysis of CO-Detection by indEXing (CODEX) imaging through a novel image processing technique utilizing two-dimensional Fourier transform for stitching artifact detection.

Afrooz Jahedi[1], Aliya Khan[2], Kasthuri Kannan[1], Krishna Bhat[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]College of Osteopathic Medicine, Sam Houston State University, Conroe, TX

Objective: The objective of this study is to address the challenge of stitching artifacts in CODEX imaging, which hinders the accurate spatial quantification of positive cell locations—a critical step for reliable spatial analysis in computational pathology.
Methods: Our algorithm applies 2D-FT and inverse transformations to process pathological images. We tested the algorithm on 16 different histology images, each containing 5 or more regions. Within these regions, we evaluated 29 protein markers, culminating in the analysis of over 2800 images.
Results: The algorithm demonstrated a recall rate of over 85 percent, indicating a high likelihood of accurately identifying true positive regions with stitching artifacts. However, the precision varied, suggesting further investigation is needed to understand the variability and improve consistency.
Conclusion: The proposed method significantly improves CODEX imaging reliability by detecting and quantifying stitching artifacts. The method's high recall rates are promising, but the variable precision indicates the necessity for ongoing refinement to ensure consistent diagnostic accuracy across diverse and extensive image sets. Keywords: Computational pathology, Fourier transform, Image stitching, CODEX, Spatial analysis, Diagnostic precision, Recall.

#2333 Methylation based phylogeny and timing in cancer.

N. Guteneva, E. Lichter, **I. Leshchiner**;
Boston University, Boston, MA

Knowing the chronological sequence of genetic alterations during cancer development and progression is crucial for understanding the process of transformation of normal tissue into malignant tumors. This can offer insights into the etiology and intrinsic cellular mechanisms of the process, presenting opportunities for early detection and treatment of initial disease stages, as well as highlight key events as potential therapeutic. Current methods of establishing progression histories of cancers rely either on direct sequencing of premalignant lesions, which are seldom available for tumors or on computational inference timing methods capable of reconstructing the history from primary tumor data. These methods require genome or exome sequencing data from a relatively large cohort of tumors and provide limited resolution due to overall scarcity of somatic mutations. We utilize a different source of genetic information, genome methylation, that also “records” historic information about acquisition and development of mutations. Over 28 million methylated CpG sites exist in the genome with several percent of them differentially methylated (DMS) between tissue types and tumor vs adjacent normal tissue. The several orders of magnitude higher density of distinctly methylated sites provides unprecedented resolution, needs fewer tumors, can be merged with driver mutation data and co-analyzed with “methylation clock” information that allows to establish early development, phylogeny and progression at unprecedented resolution. We developed methods for whole genome bisulfite sequencing (WGBS), reduced representation bisulfite sequencing (RRBS) and Oxford Nanopore Technologies native methylation sequencing data. Somatic DMS sites have distinct properties from somatic point mutations, can appear and disappear in the process of tumor evolution and development allowing for unique configuration of methylated islands. Our tools perform single sample and cohort level “timing”, multi-sample phylogeny reconstruction and cancer population reconstruction by integrating methylation and mutation information from the same sample. These new methods will significantly contribute to our understanding of cancer initiation and progression at a resolution not available previously.

#2334 Computational methods for optimizing marker selection, clonal lineage reconstruction, and longitudinal tracking of clonal dynamics via circulating tumor DNA (ctDNA).

X. Fu[1], Y. Deng[1], Z. Luo[1], W. Laframboise[2], D. Bartlett[3], R. Schwartz[1];
[1]Carnegie Mellon University, Pittsburgh, PA, [2]Allegheny Health Network and Drexel University College of Medicine, Pittsburgh, PA, [3]Allegheny Health Network, Pittsburgh, PA

Background: Technologies for blood-based profiling of tumor DNA (“liquid biopsy”) have offered great prospects for non-invasive early cancer diagnosis, treatment monitoring, and clinical guidance, but further advances in computational models and data analysis to optimize monitoring protocols and develop liquid biopsy as a robust quantitative assay of tumor clonal evolution.
Methods: We propose new computational methods to improve our ability to characterize tumor clonal dynamics from circulating tumor DNA (ctDNA). Our methods address how to apply ctDNA assays most effectively to two distinct questions in profiling tumor clonal dynamics: 1) How to apply longitudinal ctDNA data to refine phylogenetic tree models of clonal evolution, and 2) how to most effectively characterize changes in clonal frequencies that may be indicative of treatment response or tumor progression. We pose these questions computationally in terms of a probabilistic framework for optimally identifying maximum likelihood markers for the preceding tasks and applying measured marker concentrations to their solution. We apply this framework by first evaluating the distribution of plausible clonal lineage models using bootstrap samples over pre-treatment tissue-based genetic variation data, then refining these lineage models and the clonal frequencies we can infer from them over successive longitudinal samples of selected markers.
Results: We tested our method on synthetic data under various model assumptions and showed the method to be effective at refining distribution tree models and clonal frequencies over longitudinal samples so as to minimize measures of tree distance relative to the ground truth. We further apply the methods to a real ovarian cancer case and show their ability to develop and refine a clonal lineage model and assess clonal frequencies.
Conclusion: Our methods show the power of ctDNA assays in conjunction with computational optimization to lead to improved marker selection, clonal lineage reconstruction, and tracking of clonal dynamics, with potential for more precise and quantitative profiling of tumor progression enabling improved clinical decision-making.

#2335 MultiNMF: multiview factorization for joint modeling of spatial multi-omics and histology images.

W. Bowie, S. Wang, B. Strope, **Q. Zhu**;
Baylor College of Medicine, Houston, TX

An increasing number of cancer research studies employ spatially resolved transcriptomics (SRT) to investigate the composition of tumor microenvironment in a cancer type of interest. These studies have defined tumor microenvironment (TME) states and spatial domains based on clustering spatial gene expression patterns in SRT in an unbiased manner, yet a more thorough delineation of TME states requires the incorporation of the tumor's histology image. Here, we develop MultiNMF, a multiview factorization approach that is suitable for cancer research studies where joint profiles of spatial multi-omics and tumor histology images are available. We apply MultiNMF to analyze a set of TNBC SRT primary tumor samples and reveal TME states in the stromal, epithelial, and immune enriched compartments, defined by distinct histomorphological features. We further illustrate the ability of the approach to extend to paired spatial ATAC-seq and histology dataset that is recently published on HER2 breast cancer. MultiNMF thus permits an automated and data-driven decomposition of SRT and spatial ATAC data supported by histomorphological evidence.

Context

In SRT by 10X Visium, the hematoxylin eosin (H&E) staining image is automatically aligned to the slide where the tissue section is mounted. Image patches can be easily extracted from areas under the SRT barcoded spots. For these images, I will apply a pre-trained convolutional neural network (CNN) model to extract high dimensional features from spot images. The image features can be added as a second view after gene expression view for joint analysis under MultiNMF.

Results

MultiNMF can factorize the SRT data into components well-supported by histological evidence. It has identified T-cell infiltrating regions, and EMT-enriched regions with distinct immune and stroma morphological characteristics. The T-cell infiltration neighbors a region that has an appearance of necrosis according to the pathologist evaluation. These domains further demonstrate enrichments of modules with motif enrichment (known as regulons) according to SCENIC analysis. Analysis of spatial ATAC illustrates not only HER2 but also its amplicon amplification. From MultiNMF components of spatial ATAC, we derive regulatory regions for T-cell/B-cell marker genes. Overall, MultiNMF is a novel model that has not been applied to SRT field. It provides an multiomic extension to the traditional NMF.

#2336 A prototype for a machine-learning assisted image analysis tool for preclinical *in vivo* studies.

A. M. Aji[1], T. M. Kierski[1], J. D. Rojas[1], H. Morilak[1], O. J. Kelada[1], K. H. Gessner[2], A. S. Gdowski[2], L. Kim[2], W. Y. Kim[2], R. C. Gessner[1], **T. J. Czernuszewicz[1]**; [1]Revvity, Durham, NC, [2]UNC Chapel Hill, Chapel Hill, NC

The purpose of this study was to build a software tool to test the feasibility of machine-learning (ML) assisted analysis of *in vivo* 3D images in oncology research studies. Conventionally, *in vivo* image segmentations are performed by hand, and are a bottleneck for data analysis, taking time and introducing both inter and intra-user variability. Recently, advances in ML have shown promise in accelerating similar clinical image analysis tasks. Our objective was to work toward making this technology accessible to preclinical cancer researchers. 3D image data across multiple mouse models, organs, modalities, and imaging systems were used. ML segmentation models were trained with user-defined masks on images of mouse bladders (N=134), kidneys (N=131), livers (N=65), and lungs (N=26) from either ultrasound or micro-computed tomography (uCT) scanners. Models were developed using PyTorch / MONAI, hosted in an AWS cloud environment, and served to users via a custom extension for 3D Slicer (www.slicer.org). Performance was assessed as the difference between the human vs. ML organ volumes on a test set unseen by the models during training. Lastly, the functionality of on-the-fly segmentation improvement tools through iterative user feedback was assessed. Results demonstrated that generating segmentations with the prototype ML software took 2-6 seconds per image running on a modern GPU (NVIDIA RTX 3090), compared to 3-7 minutes if performed manually by an expert user (>30x improvement). The Dice scores between the ML generated and human segmentations ranged from 0.81 (liver ultrasound) to 0.84 (bladder ultrasound) but could be improved using ML-based on-the-fly mask improvement tools. Using data from this pilot study, we estimate that the threshold to achieve 90% accuracy on first-pass segmentations is between 200-300 training images, depending on the variance observed in the image data. In summary, the prototype software was able to decrease the manual analysis time across a variety of preclinical *in vivo* image modalities, which is broadly relevant to preclinical oncology research. The next steps for this project will be to extend the platform to additional orthotopic tumor models (e.g. pancreatic, liver, prostate, etc.) and deploy to the field to enable access to this toolset by preclinical imaging scientists across the world.

#2337 Accelerated optical genome mapping analysis with Stratys Compute and Guided Assembly.

D. Senol Cali, T. Anantharaman, M. Muggli, S. Al-Saffar, C. Schoonover, N. Miller;
Bionano Genomics, San Diego, CA

Background

Optical genome maps (OGM) from Bionano enable the detection of genomic structural and copy number variants that cannot be detected by next-generation sequencing (NGS) technologies and are often missed by conventional cytogenetic techniques. Bionano has developed bioinformatics pipelines for calling structural and copy number variants including the Bionano Solve *de novo* assembly pipeline for constitutional analysis and the Rare Variant Analysis (RVA) pipeline for low-allele-fraction cancer applications. Both pipelines are computationally intensive and currently take 5-10 hours on the latest generation of the Bionano Saphyr® Compute which is deployed as a four-node compute cluster and requires significant IT resources.

Methods

To increase throughput and simplify the deployment of the compute resources needed to support the Stratys™ optical genome mapping instrument, Bionano has developed Stratys™ Compute. Stratys Compute improves both compute and analytical performance by adapting compute-intensive stages in the Solve pipeline to run on GPUs and by developing the Guided Assembly pipeline.

Stratys Compute is powered by state-of-the-art NVIDIA RTX 6000 Ada generation cards and CUDA-optimized refinement, alignment, and structural variation detection kernels to accelerate OGM analysis. Stratys Compute is a standalone workstation placed adjacent to Stratys instrument. This will minimize the IT footprint and bypass the integration with the customer site's data center.

We have incorporated these optimizations into the new Guided Assembly pipeline, which aims to combine the low-allele fraction detection capability of the RVA pipeline with the whole genome coverage and ability to detect smaller structural variants enabled by the *de novo* assembly pipeline. The Guided Assembly pipeline uses the reference genome as an initial seed followed by extension, refinement, and structural variant calling. This new analysis method has been evaluated through comparison to previous results from both existing pipelines and standard benchmarking datasets used to estimate structural variant calling performance and is deployed on Stratys Compute for both constitutional and low allele-fraction applications.

Results

Guided Assembly has been adapted to run on GPU hardware in a simplified compute tower that can be deployed to a lab along with the Stratys instrument without the need for a dedicated server room. We found concordance between the guided assembly results and our previous *de novo* and RVA pipeline results. We also found increased sensitivity at low allele fractions for detecting insertion variants smaller than 5 kb and larger than 200 kb while finding equivalent performance for other variant types with the updated methods. The accelerated Guided Assembly for constitutional and low-allele-fraction applications will be available to early access customers in Q4 2023 with full commercial release in Q2 2024.

#2338 Benchmarking long- and short-read somatic structural variation callers using a multi-technology panel of six tumor/normal cell lines.

A. Keskus[1], **A. Bryant**[1], T. Ahmad[1], A. Donmez[1], I. Rodriguez[2], N. Rossi[2], Y. Xie[2], B. Yoo[3], R. Milano[2], H. Lou[4], J. Park[5], J. Gardner[5], B. McNulty[5], K. Miga[5], M. Dean[2], M. Farooqi[3], B. Paten[5], M. Kolmogorov[1];

[1]Center for Cancer Research, National Cancer Institute, Bethesda, MD, [2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD, [3]Children's Mercy Hospital, Kansas City, MO, [4]Leidos Biomedical Research, Inc., National Laboratory for Cancer Research, Frederick, MD, [5]UC Santa Cruz Genomics Institute, Santa Cruz, CA

Better structural variation (SV) detection could improve cancer diagnosis, treatment and prevention. Yet many cancer genomics studies have only reliably detected single nucleotide variants and small indels due to technological limitations of short-read sequencing. While structural variants can be inferred from discordant short read pairs, as much as 70% of SVs remain undetected because of the mappability difficulties. This is especially true for SVs in regions where GC content is greater than 45% or regions which harbor tandem repeats and segmental duplications.

Advances in long-read sequencing enabled direct observation of SVs with recall and precision over 95% across a larger portion of the genome. To harness this technology, we developed Severus - a long-read SV caller that provides phased detection of both simple germline SVs as well as complex rearrangements commonly found in cancer genomes. Such rearrangements are built into a breakpoint graph to reconstruct derived tumor chromosome structure.

To benchmark Severus and other long-read SV calling methods, we sequenced six tumor/normal cell line pairs using Nanopore, HiFi, short-read and Hi-C sequencing technologies. We combined the calls from multiple tools and technologies to generate benchmarking sets of somatic SV for each tumor cell line, and evaluated short- and long-read tools against this benchmark set.

Current tools for SV merging and comparison (such as truvari) were primarily designed for long indels, rather than breakends that are more common in somatic SVs. Another challenge is that different tools may represent the same variants differently in a VCF output. To enable robust somatic SV outputs comparison, we developed a tool called Minda that translates an input VCF entries into a unified representation, and then compares the calls in either pairwise or multi-tool mode.

As expected, in our benchmarking of cell six tumor cell line pairs, short-read methods had substantially lower recall and precision, compared to long-read methods. Among the long-read methods, Severus consistently had substantially better recall and precision, compared to Sniffles2, nanomonsv and SAVANA. An analysis of publicly available long-read sequencing of a melanoma cell line (for which curated benchmark SV set is available) produced consistent results.

#2339 GPNotebook: A toolkit for identifying cancer-related glycosylation alterations in glycoproteomic analysis.

H. Zhang[1], T. Hoang[2], **Y. Hu**[1];

[1]Johns Hopkins University, Baltimore, MD, [2]University of Maryland at College Park, College Park, MD

This study is dedicated to the development and application of 'GPNotebook', an innovative Python-based data analysis tool, specifically designed to enhance glycopeptide research in cancer studies by enabling the detailed investigation of glycosylation patterns and their correlation with various clinical cancer phenotypes. In our study, we recognize the critical role of protein glycosylation in biological processes and its relevance in cancer. To address the lack of specialized tools for glycoproteomic analysis, we developed GPNotebook, a comprehensive Python package designed for detailed investigation of intact glycopeptides (IGPs). This tool integrates multiple functionalities, including statistical profiling, differential expression analysis, categorization of glycosylation subtypes, and exploration of the interactions between glycosylation and phosphorylation. It also encompasses survival analysis and assessments of glycosylation enzymes. We applied GPNotebook in a research project focused on 10 cancer types collected from Clinical Proteomic Tumor Analysis Consortium (CPTAC) projects to validate its efficacy and demonstrate its wide-ranging capabilities. Through this application, we were able to analyze and interpret complex glycoproteomic data, revealing potential IGPs as biomarkers for cancer detection and differentiation of cancer subtypes. We identified hundreds of cancer-specific IGPs, with several showing promise as early-stage cancer biomarkers. In addition, our analysis revealed unique glycosylation patterns linked to specific molecular subtypes and immune cell distributions in tumor microenvironments. We also clarified the roles of certain glycosylation enzymes across different cancer types, highlighting their potential significance in cancer progression. GPNotebook has proven to be a critical tool in glycopeptide research. Our findings not only enhance the understanding of glycosylation in cancer but also demonstrate GPNotebook's potential in identifying novel biomarkers and providing insights into cancer subtype differentiation. This study positions GPNotebook as a valuable resource for exploring the complex relationships between protein glycosylation and cancer phenotypes.

#2340 STRUMP-I: Structure-based binding prediction of MHC class I.

A. Voshall[1], W. Park[2], E. A. Lee[1], Y. Choi[3],

[1]Boston Children's Hospital and Harvard Medical School, Boston, MA, [2]Samsung Medical Center, Seoul, Korea, Republic of, [3]Chonnam National University Medical School, Gwangju, Korea, Republic of

The presentation of short peptides derived from endogenously expressed proteins within the Major Histocompatability Complex-I (MHC-I), together known as the pMHC, allows the adaptive immune system to monitor the internal functioning of a cell and surveil for foreign or mutated self-proteins. With the rising importance of immunotherapies targeting neoantigens in cancers, the ability to accurately predict which peptides will bind to the diverse population of MHC alleles is critically important. Computational methods for predicting MHC/peptide interactions fall into two broad categories: sequence-based methods that utilize machine learning or deep learning to predict binding from information about the MHC and peptide sequence alone, and structure-based methods that leverage the computed structure and energetics of the pMHC to predict binding. While sequence-based methods have outperformed structure-based methods, their performance varies with the quantity and quality of training data for each MHC allele. The pMHC structure also provides additional insights into downstream analyses, such as predicting the immunogenicity of cancer neoantigens, that cannot be determined from the sequence alone. We developed a STRUMP-I (STRUcture-based pMHC Prediction (for class I)), a novel pMHC binding prediction tool that combines structural modelling with a machine learning-based classifier to discriminate binders from non-binders. STRUMP-I has comparable performance to the state-of-the-art sequence-based methods on data taken from IEDB, the HLAthena training set, TESLA, PRIME, and an in-house cancer neoantigen dataset. However, it generalizes better to alleles with low representation or a lower proportion of positive examples in the training data than the sequence-based methods. Additionally, we demonstrate how STRUMP-I can be used in conjunction with PRIME, a sequence-based immunogenicity prediction method, to use structural information about the peptide to filter out false positive predictions and increase the precision of immunogenicity predictions, increasing the precision by up to 2-fold. Further, on a set of 10 experimentally validated peptides from the in-house cancer neoantigen dataset containing only a single immunogenic peptide, STRUMP-I filtered all false positive predictions and retained only the true positive prediction. By leveraging structural information about the pMHC, STRUMP-I provides robust binding predicting performance across MHC alleles and increases the precision of immunogenicity prediction for neoantigen screening.

#2341 Morph: A feature extraction toolset for spatial transcriptomics.

A. N. Targino da Costa, J. Liu, C.-K. Mo, E. Storrs, A. N. Southard-Smith, R. G. Jayasinghe, J. T. Wang, M. D. Iglesia, M. Wendl, S. Chen, A. Houston, A. Karpova, Y. Li, L. Ding;
Washington University In St. Louis, Saint Louis, MO

Accurately defining spatial characteristics of tumors has been a challenge in cancer research. Specifically, there is still a lack of spatial transcriptomic (ST) bioinformatic methods that infer tumor boundaries, a necessity for tumor microenvironment (TME) analyses, that are fully automated and handle non-rectangular grids (like the one found in Visium). Here we introduce Morph, a toolset that not only addresses these limitations, but also accurately extracts tumor regions, layers surrounding them, and distances related to such regions. Morph was tested on a dataset composed of 117 ST slides across 6 different cancer types, including primary and metastatic tumors. More broadly, Morph is a computationally efficient tool based on mathematical morphology that is designed to work without any approximations on ST slides (that can be composed of spots in a hexagonal lattice) of any resolution. The toolset accepts a variety of input types, such as tumor purity and manual annotation, and can perform a diverse set of morphological operations, such as erosion, dilation, opening and closing, using a number of structuring elements with different shapes and sizes, such as a hexagon of side 1. Moreover, Morph runs quickly (seconds per sample). Its main focus is to unveil the aforementioned features of any spatially distinct tumor region (here defined as microregion) for various downstream analyses, such as spatially-varying copy number variations, cell-type distribution, and tumor-microenvironment interaction. Overall, we developed a spatial transcriptomics toolset that is not limited to any specific technology platform, and that can accurately extract ST features facilitating the discovery of spatial transcriptomic and interaction patterns.

#2342 BARTsc: A transcription factor analysis suite for single-cell omics data.

H. Zhang, J. Wang, Z. Wang, C. Zang;
University of Virginia, Charlottesville, VA

In Eukaryotic cells, the expression of a small set of transcription factors (TFs) is usually sufficient to set up a cell-type-specific gene expression program. The underlying complicated epigenetic mechanisms that explain how cells change their states in response to intra- and extra-cellular signals in different scenarios remain to be fully understood. Importantly, epigenetic regulation of gene expression has been considered a central regulatory mechanism of cell fate determination and cellular plasticity. Insights into it will also profoundly impact our understanding of misregulation of gene expression in diseases such as cancer. However, the functional TFs of many cell types remain unclear, which greatly hinders the study of epigenetic regulatory mechanisms.
The rapid development of single-cell technology is a promising opportunity that enables us to infer functional TFs for different cell types. Some computational methods have been published in this area. However, existing methods have various pitfalls. For instance, some methods use transcription factor binding motifs (TFBMs) as the reference of TF binding, overlooking widespread non-specific binding. Some other methods hold strict criteria for training data and thus can only predict a small number of TFs. To overcome these issues, we propose to leverage publicly available high-quality ChIP-seq data to predict TFs functional in single-cell omics data. Here, we present BARTsc, a comprehensive suite for a series of TF analysis functionalities, including inference of signature TFs of given cell types/clusters, cross-cell-type/cluster TF activity comparative analysis, and TF clustering based on their cross cell-type distributions. The input of BARTsc can be either scRNA-seq, scATAC-seq, or scMultiome data. We demonstrate that BARTsc outperforms several existing tools in both sensitivity and specificity in identifying key cell type regulators in single-cell datasets of well-studied systems. Applying BARTsc to a scRNA-seq dataset for cancer-associated fibroblasts (CAFs), we identified distinct regulatory activities of some TFs in different subtypes of CAFs, but the TF genes are universally expressed in these subtypes. In addition, by time course BARTsc analysis, we identified a list of TFs that may either promote or suppress CAF differentiation, offering a new approach to find potential candidate therapeutic targets.

#2343 Adapting gene set enrichment analysis to single cell data.

A. T. Wenzel, J. Jun, J. P. Mesirov;
UC San Diego, San Diego, CA

Gene Set Enrichment Analysis (GSEA) is a method for quantifying the activation of pathways and processes in gene expression data. GSEA works by ranking genes and testing if genes in annotated gene sets representing molecular pathways are overrepresented at the top or bottom of the ranked list. Standard GSEA assumes a gene-by-sample matrix with samples falling in two phenotype class labels and ranks genes based on correlation of expression and sample class labels. Single sample (ssGSEA) uses a similar approach to enrichment scoring but ranks genes in a single sample based on their expression. There has been recent interest in using the ssGSEA modality to measure pathway activity in individual cells from single cell RNA-sequencing (scRNA-seq) data. However, we have observed that ssGSEA scores in scRNA-seq cells are prone to uncertainty due to the characteristic sparsity of scRNA-seq data. This is because sparse data leads to large groups of tied genes, that is, genes with equal expression and subsequently equivalent positions in the ranked list. Because ssGSEA, which was designed for bulk gene expression technologies which yield much less sparse data, breaks ties arbitrarily, these ties can lead to variability in enrichment scores that is purely algorithmic and not a result of the underlying biology. To address this issue, we performed benchmarking to characterize the stability of scores using different enrichment scoring statistics, normalization methods, and aggregation of similar single cells. We have implemented the best practices identified using this analysis as Single Cell GSEA (scGSEA), a software tool which we will make freely available to researchers as open-source software to enable robust gene set enrichment scoring in scRNA-seq data.

#2344 Federated image quality assessment of prostate MRI scans in a multi-institutional setting.

Mohsen Hariri[1], Prathyush Chirra[1], Malhar Patel[2], Tal Tiano Einat[2], Ittai Dayan[2], Alex Tonetti[2], Yuval Baror[2], Tristan Barrett[3], Nikita Sushentsev[3], Joshua D. Kaggie[3], Shuaiyu Yuan[3], Dufan Wu[4], Baihui Yu[4], Zhiliang Lyu[4], Cheyu Hsu[5], Weichung Wang[6], Smitha Krishnamurthi[7], Satish E. Viswanath[1]

[1]Department of Biomedical Engineering, Case Western Reserve University, Cleveland, OH,[2]Rhino Health, Boston, MA,[3]Department of Radiology, Addenbrooke's Hospital and University of Cambridge, Cambridge, United Kingdom,[4]Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[5]Division of Radiation Oncology, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan,[6]Institute of Applied Mathematical Sciences, National Taiwan University, Taipei City, Taiwan,[7]Cleveland Clinic Foundation, Cleveland, OH

Introduction: Reliability of machine and deep learning models on medical images can be compromised by the presence of image artifacts of variability in image acquisition. This is further exacerbated when validating model performance across multiple institutions, where multiple acquisition protocols and scanner equipment may result in significant numbers of outlier scans. We developed a privacy-preserving outlier identification algorithm via federated MR imaging quality evaluation of a distributed multi-institutional cohort of prostate MRI scans.

Methods: This retrospective study utilized T2-weighted prostate MRI scans from 1 public collection (used as a template) and 3 federated institutions. An open-source MR image quality evaluation tool (MRQy) was implemented via Docker within the RhinoHealth Federated Computing Platform (FCP). This enabled remote extraction of 9 specific metadata values and remote computation of 15 quality measurements from each scan, while ensuring confidentiality of patient data by avoiding direct access to patient images and information. Centralized analysis of extracted image quality attributes utilized a rule-based classifier to determine whether individual metadata or measurement values for a given MRI scan fell within or outside predefined bounds: (i) ±20% of template metadata values, (ii) 5th - 95th percentile range of template measurement values. Scans were considered outliers if more than 60% of their image quality attributes fell outside predefined bounds.

Results: In total, 630 MRI scans from 3 institutions were analyzed in a federated manner. 344 MRI scans from 1 public collection formed a benchmark cohort to calibrate the rule-based classifier and determine predefined bounds for outlier detection. Centralized analysis of federated image quality attributes showed marked differences in the number of outliers per institution (3%, 19%, 79% for Institutions 1, 2, 3, respectively). Further analysis of Institution 3 determined significant intensity and resolution differences compared to other institutions, requiring extensive post-processing prior to downstream analysis.

Conclusion: Federated image quality assessment can allow for distributed, privacy preserving analysis of outliers and thus curate multi-institutional cohorts of consistent quality for downstream machine learning tasks. Further analysis of the impact of quality-based curation on federated machine learning applications is currently underway.

#2345 Docking and molecular dynamic simulations of mithramycin against Sp1, Sp3, and survivin.

C. B. Lambring[1], S. K. Behera[2], R. Basha[1];

[1]University of North Texas Health Science Ctr., Fort Worth, TX, [2]Department of Biotechnology, Institute of Pharmaceutical Education and Research, Ahmedabad, India

Purpose: Therapeutic targeting of transcription factors, Specificity protein (Sp)1 and Sp3 and their downstream effectors, such as survivin, are studied in various cancers. Due to role in in poorer cancer prognoses in several cancers their downregulation has been investigated as an effective treatment approach. Mithramycin (Mit) showed innate anti-cancer properties by targeting Sp proteins through GC/GT DNA binding interference. Recent studies have given new insights into further mechanisms of action of Mit, however in-depth binding and mechanistic studies are lacking. Our objective is to investigate Mit's specific binding interactions with Sp1, Sp3, and survivin.

Methods: Protein structures and sequences for Sp1, Sp3, and survivin (ID: P08047, Q02447, and O153392, respectively) were retrieved from UniProtKB database. Experimental predicted structures for Sp1 and Sp3 were obtained from AlphaFold. Sequence lengths of Sp1 and Sp3 were 785 and 781 amino acids (aa), domain regions of Sp1 (619-785) and Sp3 (461-781) were note. Survivin structure was obtained from PDB and was comprised of 142 aa. Co-crystallized compounds were removed during analyses using BIOVIA Discovery Studio 4.5 Visualizer. Prediction of binding sites and docking were performed using CASTp, GHECOM, DEPTH tools, glide, and AutoDock 4.2 software. Energy minimization and Molecular dynamics simulations were performed in the Schrödinger suite.

Results: Binding sites were identified for Sp1, Sp3, and survivin. Simulated docking demonstrated multiple binding complexes and varying binding energies. The most efficient binding was seen with Sp1 and Sp3. RMSF and RMSD simulations revealed stabilization of Sp1-, Sp3-, and survivin-Mit complexes. This shows Mithramycin can potentially inhibit all three proteins, with slightly more stability with Sp1 and Sp3. Radius of gyration (rGyr), H-bond analysis, and solvent accessible surface area (SASA) support docking findings with Mit-protein complexes remaining stable in the binding pocket, forming new H-bonds, and altering hydrophilic and hydrophobic interaction areas.

Conclusion: Our findings warrant further in vitro testing of the ability of Mit to interact with a wider range of oncogenic targets. While we only tested the ability of Mit to interact with Sp1, Sp3 and survivin, similar model can be used to evaluate the interaction with other critical proteins associated with cancer and to further elucidate mechanisms of action. These finding are crucial to understanding base mechanistic abilities and can be useful to test additional agents for their ability to interact with Sp1 or survivin.

#2346 Meningioma molecular classification predict response to surgical resection and adjuvant radiotherapy: An integrated clinicomolecular analysis.

J. Z. Wang[1], A. P. Landry[1], V. Patil[2], A. Ajisebutu[2], C. D. Wilson[3], A. Cohen-Gadol[4], G. Tabatabai[5], S. Chotai[6], J. Barnholtz-Sloan[7], R. Yakubov[2], M. Wilson[2], R. Kaloti[2], A. Rebchuk[8], D. A. Almiron Bonnin[9], E. C. Holland[9], S. Yip[8], F. Sahm[10], K. Aldape[11], The International Consortium on Meningiomas, F. Nassiri[1], G. Zadeh[1];

[1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Ascension St. John Medical Center, Tulsa, OK, [4]Indiana University, Bloomington, IN, [5]Eberhard Karls University Tubingen, Tubingen, Germany, [6]Vanderbilt University, Nashville, TN, [7]Center for Biomedical Informatics and Information Technology, Bethesda, MD, [8]University of British Columbia, Vancouver, BC, Canada, [9]Fred Hutchinson Cancer Center, Seattle, WA, [10]University Hospital Heidelberg (DKFZ), Heidelberg, Germany, [11]National Cancer Institute, Bethesda, MD

Importance: Meningiomas are the most common primary brain tumor and a heterogeneous disease with a need to study response to surgery and adjuvant RT in the context of contemporary molecular classifications.

Objective: The gold standard for treatment of symptomatic meningiomas has been surgical resection including complete removal of tumor and its surrounding dural margin, although the necessity of different degrees of marginal resection is controversial. Adjuvant radiotherapy (RT) is generally reserved for aggressive or subtotally resected (STR) meningiomas. However, uncertainty exists regarding optimal case selection for RT and response to treatment is variable. We aimed to examine the effects of treatment (surgery/RT), molecular, and clinical factors on meningiomas in the context of molecular classifications.

Design, Setting, and Participants: In this retrospective analysis, a 20-year cohort of 2490 patients with meningiomas were assembled across 10 institutions. Molecular data (DNA methylation, RNA sequencing) was generated for 1645 cases. Propensity score matching (PSM) was performed for key baseline covariates including WHO grade and molecular classifications, mimicking a randomized, molecular pathology informed clinical trial.

Main Outcome and Measures: Progression-free survival (PFS), and overall survival (OS) were assessed based on extent of resection (EOR), Simpson grade, and receipt of adjuvant RT.

Results: Gross total resection (GTR) was associated with improved PFS across all molecular groups. The PFS benefit of GTR was lessened in molecularly-defined proliferative meningiomas (HR 0.69, 95%CI 0.50-0.95), but OS benefit was enhanced (HR 0.52, 95%CI 0.30-0.93). Surgically treating the dural margin (Simpson grade 1/2) was associated with improved PFS compared to removal of tumor alone (Simpson grade 3) particularly for immunogenic (HR 0.16, 95%CI 0.03-0.82) and NF2-wildtype meningiomas (HR 0.24, 95%CI 0.11-0.53). Adjuvant RT was associated with improved PFS across all molecular classifications. Molecular groups could reliably predict response to RT, even when controlling for WHO grade and EOR with immunogenic and NF2-wildtype meningiomas benefitting most while proliferative meningiomas are largely RT-resistant (HR 0.96, 95%CI 0.67-1.37).

Conclusion: This study is the first to investigate interactions between contemporary molecular classifications and response to both surgical resection and adjuvant RT in a large, multi-institutional cohort of molecularly defined, clinically annotated meningioma cases.

#2347 Zuclopenthixol as an inhibitor of glioblastoma-induced neuronal hyperexcitability.

M. B. Negussie, S. Krishna, Y. Wei, C. Nava Gonzales, M. Mehari, S. L. Hervey-Jumper;
UCSF School of Medicine, San Francisco, CA

Introduction
Drug repurposing serves as a promising avenue for glioblastoma treatment, especially as new evidence emerges about the role of neuronal activity dependent tumor proliferation. Structure based drug discovery with virtual screening requires highly accurate 3D information about the target of choice. Recent developments in machine learning based protein structure prediction have allowed for the exploration of chemical space with virtual screening tools not previously accessible via traditional methods. Netrin-G1 (NTNG1) is an axonal guidance molecule implicated in glioblastoma with high functional connectivity to the cortex. In this study, we explore pharmacologic inhibition of NTNG1 with a clinically approved compound.
Methods
We perform protein structure predictions with AlphaFold2, followed by structure relaxation in an explicit solvent environment with NAMD 2.14. A final confirmation of NTNG1 was used as input to an AutoDock Vina based virtual screening platform. Zuclopenthixol (ZP) was chosen from a list of hits for microelectrode array (MEA) experiments in a mouse neuron/ patient-derived tumor cell co-culture environment.
Results
A list of clinically approved compounds were returned from our virtual screen. ZP was chosen for validation studies, as it readily crosses the blood-brain barrier and occupies the entire TSP1 binding site in NTNG1. Preliminary results from MEA studies suggest ZP reduces tumor-mediated hyperexcitability and adequately modulates a protein-protein interaction between NTNG1 and TSP1.
Conclusion
By demonstrating that ZP decreases tumor-mediated hyperexcitability, this study offers evidence for the novel application of ZP to reduce glioblastoma proliferation. Further work will focus on survival analyses in mice treated with ZP and validation of experimental compounds that are structurally similar to ZP.

#2348 A global multiscale map of protein assemblies from integration of protein interactions and images.

L. V. Schaffer[1], M. Hu[1], E. L. Huttlin[2], G. Qian[1], A. Pal[3], N. Soni[3], A. Latham[3], L. Vaites[2], T. Le[4], Y. Qin[1], C. Churas[1], D. Pratt[1], I. Echeverria[3], A. Sali[3], J. Harper[2], S. P. Gygi[2], E. Lundberg[4], T. Ideker[1];

[1]University of California, San Diego, La Jolla, CA, [2]Harvard Medical School, Boston, MA, [3]University of California, San Francisco, San Francisco, CA, [4]Stanford University, Palo Alto, CA

Cells regulate growth and function through a hierarchical structure of subcellular protein assemblies, in which alterations can result in cellular dysfunction leading to disease such as cancer. Much of this structure remains uncharted, resulting in recent efforts to map subcellular organization at different physical scales. Here, we report a global architectural map of human cancer cell protein assemblies spanning 10^{-9} to 10^{-5} nm, based on integration of near-proteome-wide affinity purification mass spectrometry-based protein interactions and immunofluorescent imaging in U-2 OS osteosarcoma cancer cells. The U-2 OS multi-scale integrated cell map places >5000 proteins into 270 distinct subcellular protein assemblies across biological scales, representing approximately half of expressed proteins. There are known organelles and protein complexes recovered in the map, as well as 152 putative assemblies, such as a putative interferon signaling complex consisting of a serine protease and STAT transcription factors. The map also incorporates 128 previously uncharacterized proteins into protein assemblies, such as C18orf21 association with a canonical RNAse complex. Protein subsystems in the U-2 OS map were evaluated for the potential for downstream integrative structural modeling, where available structural data (e.g. crosslinking, Protein Data Bank structures, AlphaFold predictions) are combined in a Bayesian framework to model the physical structures of protein complexes. Using this framework, we created an integrated structural model of new proteins interacting with the Rag-Ragulator complex, which regulates MAPK and mTOR signaling. In summary, the global proteome architecture map provides a resource for cellular biology discovery and the systematic determination of protein functions and structures.

#2349 A phenotypic model for cancer metabolism.

Javier Villela-Castrejon[1], Jason T. George[2], Dongya, Jia[3], Herbert Levine[4], Jose N. Onuchic[5], Benny Abraham Kaipparettu[6]

[1]Center for Translational Cancer Research, Texas A&M University, Houston, TX,[2]Department of Biomedical Engineering, and Department of Translational Medical Sciences, Texas A&M University, Houston, TX,[3]Immunodynamics Group, Laboratory of Integrative Cancer Immunology, Center for Cancer Research, National Cancer Institute (NCI), Bethesda, MD,[4]Center for Theoretical Biological Physics and Depts. of Physics and Bioengineering, Northeastern University, Boston, MA,[5]Center for Theoretical Biological Physics; Dept. of Physics and Astronomy; Dept. of Chemistry, Rice University, Houston, TX,[6]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX

Understanding cancer metabolism is crucial for deciphering various cancer hallmarks, including metastasis and immunosuppression. This study investigated the intricate interplay of catabolic processes involving glucose, fatty acids, and glutamine in cancer cells. Recent evidence highlights the dual reliance of cancer cells on glycolysis and oxidative phosphorylation (OXPHOS), challenging the simplistic Warburg effect. Fatty acids and glutamine also emerged as vital contributors to tumorigenesis. Despite these advances, a comprehensive model encompassing both catabolic and anabolic processes, especially glutamine metabolism, is lacking. A metabolic network model integrates catabolic and anabolic modes for glucose, fatty acids, and glutamine, incorporating genetic regulation involving AMPK, HIF-1, and MYC. Equations capture the temporal dynamics of regulatory proteins (pAMPK and HIF-1) and metabolites (mtROS and noxROS), modeling metabolic flux for glucose and glutamine uptake, fatty acid, acetyl-CoA utilization, and activities of glucose oxidation, glycolysis, and FAO. The regulatory network outlines competition for resources, gene regulation, chemical intermediates, cross-regulation among gene regulators, and regulation of metabolic ingredient uptake. The phenotypic model focusing on AMPK, HIF-1, and MYC reveals metabolic states: OXPHOS (O), glycolysis (W), hybrid (W/O), and low/low, characterized by varying levels of AMPK and HIF-1, influencing pathway activities and anabolic processes. Parameter randomization analysis shows state robustness, especially in MYC overexpressing cancer cells. Analyzing TCGA data reveals differential expression of glutamine metabolism genes. The "W" state exhibits enhanced glutamine uptake, the "O" state heightened glutamine oxidation, and the "W/O" state displays both, aligning with the model's predictions. Bifurcation analyses of AMPK, HIF1, and MYC shed light on state stability and transitions, providing insights into regulatory mechanisms. The low/low phenotype, inactive in both OXPHOS and glycolysis, raises questions about significance and therapy resistance. The study explores this phenotype further, unraveling molecular underpinnings and therapy resistance implications. A deeper understanding could reveal novel therapeutic targets, enhancing comprehension of cancer cell behavior. This study introduces a minimal network model capturing essential features of cancer metabolism, replicating experimental observations of metabolic heterogeneity. The model predicts diverse cancer cell phenotypes based on MYC expression levels, emphasizing the importance of considering both catabolic and anabolic processes.

#2350 Comparison of normalization methods for RT-qPCR microRNA expression in cancer datasets.

H. Treleaven, L. Ludwig, A. Viloria-Petit, R. D. Wood, A. Ali, G. A. Wood;
University of Guelph, Guelph, ON, Canada

Real-time quantitative PCR (RT-qPCR) is a widely used method for quantifying microRNA (miRNA) expression, but its accuracy depends on appropriate normalization. RT-qPCR is susceptible to technical variation from several sources, including sample collection and storage, miRNA quantity/quality, and extraction and amplification efficiencies. Normalization corrects for these factors, theoretically leaving behind only biological variation. With growing interest in miRNAs as biomarkers for the diagnosis and prognosis of various cancers, analyses must be accurate and consistent. Primarily, the comparative Ct method is used, which compares the expression of miRNAs to a reference value. Unfortunately, there is a lack of consistency on what to use as a reference. A standard recommendation is the average of multiple, stable miRNAs referred to as endogenous controls (ECs). Currently, there are no known universally stable miRNAs. Therefore, ECs should be selected on a per-disease and per-sample type basis. Multiple algorithms exist to identify stable ECs, but few studies indicate what, if any, steps were taken to implement them correctly. Also, many studies have used non-ideal reference values such as small nuclear RNAs or a single miRNA. This lack of agreement on protocol often leads to difficulty comparing studies and may produce incorrect results. This work addresses these inconsistencies by making recommendations for the normalization of RT-qPCR miRNA expression. We compared 2 widely used methods for EC selection, NormFinder and GeNorm, and to show how normalization influences results we also used an unstable miRNA. Only miRNAs with expression in all samples were considered as potential ECs. GeNorm is sensitive to correlated genes. Therefore, for any pair or trio of correlated miRNAs 1 was kept. NormFinder performs optimally with 5-10 candidate genes; therefore, we tested the 10 miRNAs with the lowest coefficients of variation (CV). The top 3 stable miRNAs were selected from each algorithm to serve as ECs, and we used their average expression to normalize each sample. For the single miRNA, samples were scaled based on its value. We applied these methods to 3 independent datasets: First, plasma samples from a study on canine osteosarcoma (OSA), including pre-amputation (n=45), post-amputation (n=27), and healthy controls (n=21). Second, tissue samples from a study on canine OSA, including primary tumour (n=42) and lung metastases (n=12). Third, serum samples from a study on canine lymphoma included B-cell (n=24), T-cell (n=16), and healthy controls (n=14). For datasets 1 and 3, NormFinder provided a better reduction in gene-specific CV and a more favourable cumulative distribution of the CV. For dataset 2, there was less initial variability, but NormFinder still had slightly better results. Both algorithms had pros and cons, but NormFinder consistently provides a better reduction in sample variation across datasets.

#2351 Genomics annotation and interpretation in somatic oncology using structured data from a clinical knowledgebase.

Jian Li[1], Lili Niu[1], Shuba krishna[1], Fnu Kinshuk[2], Martin Jones[3], Carlos Hernandez[3], Michael Clark[4], Sandra Balladares[5]

[1]Computational Biology - Research and Early Development, Roche Diagnostics Solutions, Santa Clara, CA,[2]Computational Science & Informatics - SW Engineering, Roche Diagnostics Solutions, Santa Clara, CA,[3]Computational Science & Informatics - Product Management, Roche Diagnostics Solutions, Santa Clara, CA,[4]Clinical Development - Oncology & Genetic SC, Roche Diagnostics Solutions, Santa Clara, CA,[5]Disease Area Life Cycle - Oncology, Roche Diagnostics Solutions, Santa Clara, CA

Accurate and comprehensive interpretation of genomic variants has become a bottleneck in clinical sequencing applications due to the accelerating precision oncology and biomedical information explosion. This motivated us to build Ephesus, a framework enabling curation of predictive, prognostic and diagnostic evidence for clinical biomarkers in cancers. Currently Ephesus is the primary content source for Roche navify Mutation Profiler (nMP).

The Ephesus' data model ensures adherence to best practices in clinical genomic content curation. Variant classification follows the AMP guidelines for somatic variant interpretation. Variant interpretations are derived from international regulatory approvals and clinical practice guidelines (FDA, EMA, TGA, eVIQ, etc.) and recommendations (NCCN, ESMO). The data model is mapped to a set of relational tables. To enforce data integrity and validity, strategies such as data normalization based on standard nomenclatural ontologies, a submit-review-approval workflow, and biological constraints are adopted. Ephesus is deployed as a web application used by curators inside and outside Roche. The UI allows users to conduct edits, filtering, sorting and bulk operations on entities by attributes. In order to minimize manual effort and maximize content coverage, inference rules are applied before ingesting into nMP.

Currently Ephesus is developed for data collection, browsing and summarizing primary entities such as biomarkers, evidence items, genes, variants, variant groups, and drugs. The content from the 2023-Aug snapshot contains 11,596 directly curated biomarker profiles (including biomarker combinations), and 6M+ expanded profiles for 41 major cancer types. To evaluate the clinical reporting value of the curated knowledge, ~160k real cancer patient samples of the AACR GENIE project were queried on Ephesus. Compared with three other major knowledgebases, Ephesus/NMP is observed showing the highest performance.

Table1 Percentage of patients or biomarkers with at least one interpretation from each knowledgebase

	CGI (2022-10-17)	CIVIC(2023-09-01)	ClinVar(2023-09-09)	NMP(2023-08-11)	AACR-Genie-v14.0 Total
patient % with any interpretation	25% (40,545)	46% (73,835)	81% (130,882)	89% (142,905)	160,965
biomarker % (including combos) with any interpretation	0.03% (256)	0.06% (526)	13.26% (122,424)	73.79% (681,128)	923,093

#2352 Development of an AI-based algorithm to quantify eosinophils in H&E images from colorectal cancer (CRC) tissue sections guided by biomarker staining using multiplex immunofluorescence imaging.

A. Hanifi, E. Blain, J. Hargrove, J. Lock, N. Tran, V. Chizhevsky, Q. Au;
NeoGenomics, Aliso Viejo, CA

Background: Eosinophils are innate immune granulocytes that migrate to areas of inflammation to combat against infection and disease. Best known for their detrimental role in asthma and allergic disorders, there is growing interest in the involvement of eosinophils in cancer. Eosinophils are routinely observed in the tumor microenvironment (TME) and, depending on the cancer type, have been shown to drive other immune cells to either suppress or promote tumor growth - In colorectal cancer (CRC), eosinophil infiltration into the TME has been linked to a favorable prognosis. However, the behavior of eosinophils and their effect on associated immune mediators in the TME remains poorly understood. Currently, eosinophils are primarily identified from H&E stained tissue sections based on morphological features by a pathologist, but it can be challenging to reliably and efficiently identify all eosinophils based on morphology alone. Here, we present a novel image analysis workflow that established an AI-based cell classifier which can accurately quantify eosinophils in H&E stained CRC tissue sections by leveraging biomarker staining of eosinophils using multiplex immunofluorescence (mIF) imaging in conjunction with the morphological characteristics of eosinophils observed by H&E.

Methods: CRC tissue sections were labeled with a 5plex panel of eosinophil-specific markers and imaged by mIF using the PhenoImager HT platform (Akoya). Biomarker fluorescence was then quenched, sections stained by H&E, and reimaged using the PhenoImager. mIF and H&E images were then imported into the HALO® platform for algorithm development. Halo AI cell classification of eosinophils was trained on the morphological features of eosinophil staining in H&E images, guided by eosinophil-specific labeling in the 5plex mIF images. H&E staining was also performed on a serial section of each specimen. Morphological identification of eosinophils in H&E images was performed by a pathologist.

Results: Correlation analysis was performed to evaluate the relationship, per high power field (HPF), between manual eosinophil counts by a pathologist and AI algorithm derived eosinophils counts. The results showed the two methods are highly correlated, demonstrating reliable algorithm performance.

Conclusion: The AI-based eosinophil detection algorithm established here enables high-throughput analysis and quantification of eosinophils from H&E stained CRC tissue specimens and facilitates morphology diagnosis.

#2355 SGN-EGFRd2 binding and activity are agnostic to common EGFR extracellular resistance mutations acquired in response to anti-EGFR targeted antibody therapies.

L. Nguyen, C.-S. Wong, S. Wo, B. Grogan, D. Diolaiti, M. Palanca-Wessels, A. Clarke;
Seagen Inc., Bothell, WA

SGN-EGFRd2 is an investigational bispecific antibody comprised of two camelid-derived humanized variable heavy chain only (VHH) domains, one targeting Vγ9Vδ2 (gamma delta) T cells and the other targeting the epidermal growth factor receptor (EGFR). Selective antitumor activity occurs when two conditions are met: 1) the molecule engages both EGFR-expressing tumor cells and gamma delta T cells and 2) butyrophilins, in complex with phosphoantigens (pAgs), are expressed by EGFR-positive tumor cells, resulting in gamma delta T cell directed tumor cell killing by activation, degranulation and secretion of cytolytic molecules. The tumor specific proximity of gamma delta T cells and expression of the butyrophilins/pAgs complex results in the killing of EGFR-expressing tumor cells but not EGFR-expressing normal cells.

EGFR is an oncogenic receptor tyrosine kinase and target of several classes of therapeutic modalities, including antibodies. Two antibodies are currently approved for the treatment of EGFR-expressing, KRAS wild-type metastatic colorectal cancer (mCRC): cetuximab (CET) and panitumumab (PAN). Although these anti-EGFR therapies provide significant survival benefits to patients, the duration of response is transient, and most patients progress and develop secondary resistance [1]. One such escape mechanism is the acquisition of mutations in the extracellular domain (ECD) of EGFR, which prevent binding of therapeutic antibodies [2].

Because SGN-EGFRd2 will be tested on patients previously exposed to anti-EGFR therapeutic antibodies, it is paramount to assess its binding to EGFR ECD mutations identified in antibody resistant mCRC patients. EGFR-negative A2058 cells were transduced to express wild type EGFR and a panel of EGFR ECD resistance mutations (N=16). The binding specificity and kinetics of SGN-EGFRd2 were compared to CET and PAN by flow cytometry on engineered cell lines and biolayer interferometry, respectively. Results indicated SGN-EGFRd2 maintained the ability to bind to all tested EGFR ECD mutants, whereas CET and PAN were unable to bind several ECD mutants, as previously described [3,4]. SGN-EGFRd2 binding to EGFR ECD mutant cell lines induced the production of interferon gamma and expression of cell surface CD107a on gamma delta T cells, confirming functional engagement.

In contrast to current anti-EGFR therapeutic antibodies, SGN-EGFRd2 binding and activity was unaffected by commonly identified EGFR ECD mutations. These findings highlight SGN-EGFRd2 as a novel molecule targeting wild-type EGFR and common EGFR ECD mutations identified in the mCRC setting.

#2356 NAV-006: A next-generation rituximab targeting CD20 for the treatment of B-cell lymphomas immunosuppressed by MUC16/CA125.

L. Grasso, J. Kline, N. C. Nicolaides;
Navrogen, Cheyney, PA

Rituximab is a CD20-targeting antibody that is the standard-of-care for patients with Non-Hodgkin Lymphoma (NHL) cases. Rituximab's mechanism of action includes complement-dependent cytotoxicity (CDC) and antibody-dependent cellular cytotoxicity (ADCC), herein referred to as Humoral Immuno-Oncology (HIO) mechanisms. Recent clinical evidence suggest that high serum levels of the MUC16 (CA125) protein inversely correlate with the effectiveness of rituximab clinical activity in 40-50% of follicular lymphoma (FL) as well as diffuse large B-cell lymphoma patients with newly diagnosed or relapsed/refractory (R/R) disease. In this study we demonstrated that CA125 binds to and suppresses the activity of rituximab, tafasitamab as well as the bispecific mosunetuzumab and glofitamab antibodies, which are approved for treating cases with indolent disease. These therapies have an overall response rate around 50-60%, suggesting the presence of a mechanism that allows lymphoma cells to escape these agents' immune-mediated killing effects. CA125 may facilitate this immunosuppressive mechanism, and in fact, upon binding rituximab, CA125 reduces its affinity for the Fc receptor, CD16a, thus suppressing ADCC. Using a proprietary technology called Block-Removed Immunoglobulin Technology (BRITE) that employs randomized amino acid substitution and HIO effector function screening, we have identified a rituximab variant named NAV-006. NAV-006 is refractory to the immunosuppressive effects mediated by CA125 via its reduced CA125 interaction and increased HIO activity as compared to parent rituximab as well as the other antibodies used to treat R/R FL. In an *in vivo* model of human B-cell lymphoma, NAV-006 showed superior efficacy compared to parent rituximab. These data warrant further investigation of NAV-006 as a next generation anti-CD20 antibody that could improve upon the efficacy of antibody-mediated therapies used to treat NHL patients with high levels of CA125.

#2357 T cell receptor beta chain-directed Tri-specific antibody molecules retarget V-beta T cell subsets to tumors to promote potent and durable antitumor activity.

M. Katragadda, J. Moisan, G. Guntas, M. Sequeria, R. Servattalab, J. Lowry, R. Ruidera, K. Nybakken, E. Gerson, K. Liu, K. Chin, Z. Su, A. Bayliffe; Marengo Therapeutics, Cambridge, MA

Background We have previously shown that novel bifunctional “STAR” antibody-fusion molecules comprising germline β chain TCR-targeting antibodies fused to costimulatory cytokines co-engage the TCR and T cell cytokine receptors, thereby promoting activation and expansion of subsets of T cells expressing distinct germline variable β (Vβ) chain TCRs. Here we describe a new class of T cell engager (TriSTAR) that utilizes a tri-specific format comprising the STAR TCR β chain antibody-IL-2 fusion with an additional Fab arm targeting tumor-associated antigens (TAA). By design, TriSTAR molecules promote the activation and expansion of Vβ T cell subsets that adopt a novel memory phenotype and are subsequently re-targeted to tumors expressing specific TAAs. TriSTAR molecules induce potent and durable anti-tumor activity which in refractory murine solid tumor models appear to be superior to established anti-CD3 T cell engager (TCE) formats.

Methods Using the gp75 (Tryp1) melanoma antigen as a model TAA, gp75-targeting TriSTARs were tested in vivo in the B16F10 syngeneic mouse tumor model, compared with a conventional gp75-targeting CD3 bispecific TCE. Cured mice were re-challenged with tumors to assess the potential of TriSTARs to induce immunological memory responses. The pharmacodynamics and pharmacokinetics of gp75-targeting TriSTARs and anti-CD3 TCEs were assessed in blood and tumor using flow cytometry, NanoString and other immunoassays. This work was further extended to testing human TAA-targeting TriSTARs using in vitro human cytotoxicity assays and a transgenic MC38 model.

Results In the B16F10 murine melanoma model, gp75-targeting TriSTARs induced potent anti-tumor responses that were superior to control constructs and gp75-targeting CD3 TCEs. The superior anti-tumor activity of the gp75-targeting TriSTARs was attributed to a significant increase and accumulation of $CD8^{+}$, $CD25^{+}$ and Granzyme B^{+} T cells in tumors that was due to the expansion of the target Vβ T cell subset. Further immune profiling by flow cytometry and NanoString in tumors and blood isolated from treated B16F10 mice highlighted significant remodeling of tumor-infiltrating lymphocytes (TILs) and other immunological changes associated with immune activation. These observations with murine gp75-targeting TriSTAR molecules were broadly confirmed with TriSTARs targeting human TAAs in both human in vitro studies and human TAA transgenic mouse tumor models.

Conclusions Vβ TCR-targeting TriSTAR molecules represent a new class of T cell engager with the potential to deliver improved anti-tumor activity compared with existing anti-CD3 T cell engagers in immunologically “cold” solid tumors with low levels of T cell infiltration and antigen presentation and may therefore offer a new therapeutic approach for the treatment of patients with refractory solid tumors.

#2358 YH41723 (IMC-202), a Novel TIGITxPD-L1 bispecific antibody, leads to potent anti-tumor immunity through T cell engaging and T/NK cell activation.

Min Hyeok Jee[1], Young Bong Park[1], Byeong-Yun An[1], Hee Ra Jung[1], Eunjung Lee[1], Jun Hwan Kim[1], Ji Eun Park[2], Ji Young Yoon[2], Seung Mi Jeong[2], Yang Kyun Ryu[2], Sung Ho Kim[2], Heung Tae Kim[2], Se-Woong Oh[1], Yeol Hong Kim[1]

[1]Yuhan Corporation R&D Institute, Yongin, Korea, Republic of,[2]ImmuneOncia Therapeutics Inc., Seoul, Korea, Republic of

Immune checkpoint inhibitors (ICIs) have been making innovative advances in current cancer therapy. In particular, the PD-L1/PD-1 blockades changed the paradigm of anti-cancer treatment, showing high efficiency compared to conventional therapy. However, drug resistance has been observed in many patients receiving PD-1/PD-L1 monoclonal antibodies (mAbs), and there are still many limitations in restoring T cell. To overcome this, various ICI targets including T cell immunoreceptor with Ig and ITIM domain (TIGIT) are being studied. TIGIT is a T cell co-inhibitory receptor, highly expressed on regulatory T (Treg) cells and memory T cells and natural killer (NK) cells. In combination with PD-1/PD-L1 inhibition, the activation of CD226 through the blocking of TIGIT/PVR ligation is important for T cell activation. In this study, we demonstrated the synergistic effect that can be obtained by simultaneously blocking of PD-L1 and TIGIT and effect of T cell engager function using TIGITxPD-L1 bispecific antibody (BsAb). We generated an anti-TIGITxPD-L1 BsAb, YH41723 (IMC-202), with Fc-engineering to enhance the effector function. In order to confirm superior efficacy of YH41723 compared to combination of two monoclonal antibodies, PD-L1 mAb+TIGIT mAb, we verified the $CD8^{\pm}$ T cell-mediated tumor killing effect by T cell engager function of YH41723. We also observed strong antibody-dependent cell-mediated cytotoxicity (ADCC) effect of YH41723 against various cancer cell lines. In addition, YH41723 showed superior anti-tumor efficacy than combination treatment in NK cell-mediated tumor killing assay. We further confirmed the significant Treg cell depletion efficacy of YH41723 *in vitro* compared to combination. We tested *in vivo* anti-cancer efficacy of YH41723 in hPD-L1 KI CT26 with BALB/c-H/K-dKO mouse models (B cell-deficient mice). As a result, YH41723 showed superior tumor growth inhibition effect compared with anti-PD-L1 mAb and anti-TIGIT mAb combination. Even, 7 of 8 mice showed complete regression in 30 mg/kg dosing group. 60 days after the last administration, we further performed tumor re-challenge test. The tumor-free state of tumor re-challenged mice was sustained, indicating that the immune memory was generated by YH41723. Taken together, YH41723 showed strong efficacy in NK/T cell activation and Treg depletion *in vitro* and excellent anti-tumor efficacy *in vivo*, supporting that YH41723 as an effective anti-cancer immunotherapy and combination candidate with other ICIs.

#2359 New insights into targeting the CD200R1 pathway in T and NK cells using 23ME-00610 as a single agent or in combination.

M. R. Kumar, S. Duan, S. Yadav, A. Jarret, Z. Yan, J. Fenaux, M. Kinisu, Z. Yi, M. Poggio, P. Collins, A. Symons, L. Riol Blanco, M. Schmidt, S. Majeed, A. Diep, C. Lee;
23andMe, Inc., South San Francisco, CA

23ME-00610 is a monoclonal antibody that is being evaluated as a single agent in a Phase 1/2a clinical trial for advanced solid malignancies (NCT05199272). It binds with high affinity (K_D < 0.1 nM) to CD200R1, a promising immune-oncology (IO) target identified by surveying the 23andMe genetic and health survey database. CD200R1 is an inhibitory receptor that when bound to its ligand CD200, reduces pro-inflammatory cytokine production, and leads to an immunosuppressive tumor environment. To gain further insight into the mechanism of action of 23ME-00610 and its potential for combination therapy, we profiled CD200R1 and other immune inhibitory receptors in human dissociated solid tumor samples using spectral flow cytometry. CD200R1 was broadly expressed across tumor-infiltrating immune cells, including T cells and NK cells, cytotoxic cell types with known antitumor functions. Notably, CD200R1 expression pattern was differentiated from PD-1, which is mostly restricted to T cells, indicating differences in patient populations that could potentially benefit from anti-CD200R1 and anti-PD-1 treatments. The ligand, CD200 was broadly expressed, including on tumor cells and endothelial cells. The differential expression profiles of CD200R1 and PD-1 on immune cells, along with CD200 expression on endothelial cells, suggest that combining 23ME-00610 with other clinically validated immunomodulatory agents could enhance antitumor responses. Follow-up experiments were conducted to validate and extend these findings. In an *in vitro* assay with cancer patient-derived PBMCs, 23ME-00610 promoted higher production of IFNγ, a key functional antitumor cytokine, compared to anti-PD-1 in 9 of 10 donors. Subsequent attempts were made to pinpoint immune cells responsible for 23ME-00610's anti-tumor activity. 23ME-00610 reversed CD200-mediated suppression of chronically stimulated primary T cells and CD200-mediated inhibition of NK cell degranulation, suggesting that 23ME-00610 can mediate tumor cell killing through at least two different cell types. To test the potential of 23ME-00610 to combine with anti-PD-1 to enhance T cell function, an artificial antigen-presenting cell (aAPC) line overexpressing PD-L1 and CD200 was co-cultured with chronically stimulated primary human T cells. Anti-PD-1 and 23ME-00610 each independently enhanced IFNγ secretion levels compared to isotype control, yet their combination resulted in a more than additive effect. Taken together, these data demonstrate that 23ME-00610 can enhance both NK and T cell antitumor effector functions, and 23ME-00610 could synergize with anti-PD-1 to further increase the activity of T cells against cancer cells. The results of this study provide evidence that 23ME-00610 could expand IO treatment options for patients with advanced solid malignancies as a single agent or in combination with other anti-tumor therapeutics.

#2360 ADV101, a first-in-class IL-1RAP ADC demonstrates significant anti-tumor activity in solid tumor models.

R. C. Sainson, L. Demolis, E. De Dreuzy, O. Favre-Bulle, A. Collette, L. Bourhis, S. Reda El Sayed, D. Genin, C. Primus, L. Bouquet, K. Pavletic, C. Ferrand, M. Deschamps, S. Lameynardie, E. Rutjens, J. Hasskarl;
Advesya, Paris, France

Chronic inflammation is intricately linked to cancer development, and the IL-1 cytokine family stands out as pivotal regulators of inflammation. All the pro-inflammatory cytokines within the IL-1 family rely on a single co-receptor called IL-1RAP which therefore emerges as a crucial and central node for modulating these pathways. While healthy tissues, except for the placenta, showed minimal plasma membrane IL-1RAP expression, tumor tissues exhibited high IL-1RAP expression, particularly in Acute myeloid leukaemia, Ewing sarcoma, ovarian cancer, head and neck, and squamous gastric and oesophageal cancers. In addition, elevated IL-1RAP expression in haematological and solid malignancies has also been associated with poor overall survival, making it an attractive target for therapeutic intervention. In this study, we present the development and characterization of an antibody-drug-conjugate (ADC) targeting IL-1RAP for potential anti-tumor applications. Following on from this, an anti-IL-1RAP antibody, ADV58, was generated and confirmed to have the anticipated biophysical, specificity, and functional properties, including low nanomolar affinity (SPR and ELISA), selectivity/specificity to human IL-1RAP, and internalization potential into IL-1RAP-positive tumor cells. In addition, ADV58 bind similarly well to human, cynomolgus and rhesus monkey IL-1RAP antigens but not to rat and mouse. Altogether these properties made ADV58 an ideal candidate for an ADC program. Concurrently, solid tumor cell lines from indications of interest with elevated IL-1RAP expression were identified, laying the groundwork for disease relevant pre-clinical tumor models. Using these models, the anti-tumor potential of ADV101 (ADV58-derived ADC) was assessed in vitro and in vivo in successful proof-of-concept studies by conjugating ADV58 with monomethyl auristatin E (MMAE, DAR of 4) or Deruxtecan (DXd, DAR of 8). Humanisation and conjugation did not compromise binding of the naked antibody, the ADV58-MMAE or the ADV58-DXd ADCs to human and non-human primate IL-1RAP. In vitro, the ADCs selectively killed IL-1RAP-positive tumor cells. In vivo efficacy studies in IL-1RAP-positive subcutaneous xenograft tumor models also demonstrated a significant dose-dependent and IL-1RAP antigen-dependent anti-tumor response for both anti-IL-1RAP ADCs. Altogether the robust preclinical data package supports the continued development of ADV101 as a novel targeted ADC therapeutic strategy for a broad spectrum of cancers.

#2361 A PD1-antibody-attenuated IL-2 fusion protein activates immune cells leading to the inhibition of tumor growth in ex vivo human 3D tumor models.

R. Satchi-Fainaro[1], O. Avramoff[1], A. Katyal[1], E. Yeini[1], A. Krinsky[1], Y. Liubomirski[1], S. Dulberg[1], G. Tiram[1], A. Kaminitz[1], J. Gill[2], J. Pedersen[2], D. Bar-On[2], A. Tamir[2], P. Ayton[2], T. Taura[2], D. Wilson[2], A. Madi[1];

[1]Tel Aviv University, Tel Aviv, Israel, [2]Teva Pharmaceutical Industries Ltd., Tel Aviv, Israel

IL-2 has been prescribed to effectively treat malignancies, mainly melanoma, for decades. Its use has waned in recent years due to significant toxicity and a narrow therapeutic index. To overcome the limitations of systemic administration of IL-2, we have generated a modified IL-2 (IL2Att) with specific substitutions to reduce the binding affinity with the IL-2R. The attenuated cytokine was fused to a high-affinity anti-PD1 antibody that does not block PD-1 binding with its ligands (PD-L1 and PD-L2). The resulting antibody-cytokine fusion, anti-PD1-IL2Att, allows selective delivery of IL-2 to tumor-reactive $PD1^{+}$ T cells, with limited potential to activate $PD1^{-}$ cells. To evaluate the effect of anti-PD1-IL2Att in a human tumor microenvironment (TME), we established a unique human 3D multi-cellular cancer system. This model system includes neoplastic and somatic cells that make up the TME, further supplemented with peripheral blood mononuclear cells (PBMC). We found that the anti-PD1-IL2Att reduced tumor cell survival more effectively in several types of these 3D cancer models (melanoma, glioblastoma, ovarian and colon cancer) than standard immune checkpoint inhibitors pembrolizumab or nivolumab. Combination treatments of anti-PD1-IL2Att with either of these agents resulted in improved immune activation and tumor cell killing. Our findings suggest that tumor-targeted attenuated cytokines such as IL-2 can promote robust tumor killing while minimizing systemic toxicity.

#2362 Preclinical efficacy and safety of M9140, a novel antibody-drug conjugate (ADC) with topoisomerase 1 (TOP1) inhibitor payload targeting carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5)-expressing colorectal tumors.

S. Raab-Westphal, F. Hart, W. Sloot, M. Shan, N. Rasche, C. Amendt, J. Anderl;
The Healthcare Business of Merck KGaA, Darmstadt, Germany

Background: M9140 is the first clinical-stage TOP1 inhibitor payload ADC directed against CEACAM5, which is expressed in colorectal cancer (CRC) and other cancer indications. M9140 is composed of a CEACAM5-specific antibody conjugated to eight, highly stable and hydrophilic ß-glucuronide-exatecan linker-payloads. After linker cleavage, the highly potent and membrane permeable TOP1 inhibitor exatecan is released.
Methods: M9140 potency was tested in viability assays using cancer cell lines with different levels of CEACAM5 expression. Potency shift viability assays were conducted using two CRC cell lines, with zosuquidar used as multidrug resistance-1 (MDR-1) inhibitor. The M9140 bystander effect was assessed in co-culture experiments with CEACAM5-negative and -positive cancer cells. Antitumor efficacy and safety were evaluated in patient-derived xenograft (PDX) mouse models and in cynomolgus monkeys, respectively.
Results: M9140 demonstrated specific binding to CEACAM5 and selective killing of target-positive cancer cells with potencies between 0.09 nM and 0.62 nM. A potent bystander effect of M9140 was demonstrated in co-culture experiments indicating the potential to treat tumors with heterogeneous target expression. Unlike other ADC payloads such as monomethyl auristatin E (MMAE) and the maytansine derivative DM4, exatecan potency was not affected by MDR-1 inhibition, indicating that this drug efflux resistance mechanism may not be relevant for exatecan. A single treatment with 10 mg/kg M9140 caused strong antitumor effects in all 14 CRC PDX models tested, with tumor stasis in 10 models and tumor regression in four models as the best response. The TOP1 inhibitor-based ADC M9140 caused strong antitumor efficacy with a tumor volume reduction of 74% and 88% as best response in two CRC PDX models where a maytansine-based CEACAM5 ADC was not effective. In cynomolgus monkeys, M9140 showed dose-dependent hematolymphoid and intestinal effects, consistent with exatecan payload, with no indication of any other toxicities such as interstitial lung disease (ILD) or ocular toxicity.
Conclusions: M9140 demonstrated high potency, strong antitumor activity, and bystander effect in preclinical models. The side effect profile in monkeys was favorable and in line with the expected toxicity of exatecan. Notably, ILD and ocular toxicity, which are known adverse effects of deruxtecan and maytansine-based ADCs respectively, were absent. A first-in-human study to evaluate the safety, tolerability, pharmacokinetics, and preliminary clinical activity of M9140 in advanced solid tumors is ongoing (NCT05464030).

#2363 Enhanced T cell activation and cytotoxicity against AML via targeted anti-CD99-A192 ScFv-ELP nanoparticle treatment.

S. Kadam, A. Ali, M. Pospiech, S. Onyemaechi, Y. Meng, K. Dhuri, A. Mackay, H. Alachkar;
USC - University of Southern California, Los Angeles, CA

CD99 is a transmembrane protein overexpressed in acute myeloid leukemia (AML), presenting a potential novel therapeutic target. Our previously developed anti-CD99-A192, comprising scFv and elastin-like polypeptides (ELPs), showed promising anti-leukemic activity by inducing apoptosis in AML cell lines and prolonging survival in AML xenograft models. Considering CD99's expression and role in T cell activation, we proposed that anti-CD99-A192 could have a dual function: targeting leukemic cells while activating T cells.

Blood samples were obtained from 20 healthy donors, and peripheral blood mononuclear cells (PBMCs) were isolated and stimulated with PHA and IL-2 cytokines to expand T cells for 72-96 hours. Post-expansion, T cells were treated with either anti-CD99-A192 or control anti-A192. Proliferation was evaluated via cell count and cell trace assays. The percentages of $CD4^{\pm}$, $CD8^{\pm}$, and $CD25^{\pm}$ T cells, and the levels of T cell activation markers CD69 and CD38, were quantified by flow cytometry. Cytokine release profiles were assessed by the Proteome Profiler Human Cytokine Array Kit. The cytotoxic impact of the anti-CD99-A192-activated T cells on MV4-11Luc+ AML cells was measured in co-culture apoptosis and luciferase assays. Statistical comparisons utilized paired and unpaired T-tests with Holm-Sidak correction for multiple comparisons, and P value <0.05 was considered significant.

T cells treated with anti-CD99-A192 displayed significant increased proliferation compared with untreated and anti-A192-treated groups at Day 5 (163.3% vs. 97% and 92.4%, p=0.042 and p=0.03, respectively). The percentage of $CD4^{\pm}$, $CD8^{\pm}$, and $CD25^{\pm}$ cells remained unchanged across treated and control groups. Activation marker analysis revealed increase in % $CD38^{\pm}$ cells in the anti-CD99-A192 group compared with the control (58.15% vs. 49.15%, p=0.0028). Among the cytokine panel, significant increases in IL-1β/IL-1F2 (11-fold change, p<0.001, adjusted p=0.006) and TNF-α (12-fold change, p=0.002, adjusted p=0.03) were observed, along with a marked decrease in IL-8 (70% reduction, p<0.001, adjusted p=0.001). GM-CSF (20-fold change, p=0.005, adjusted p=0.071) and IL-16 (2-fold change, p=0.003, adjusted p=0.051) levels also increased, though not significantly after adjustment. Co-culture assays showed greater apoptosis in MV4-11 cells at 18 hours (33.6% vs. 41.13%, p=0.015) and a reduction in viable leukemic cells at 18 hours (10.89% vs. 8.05%, p=0.034) and 48 hours (9.69% vs. 6.54%, p=0.065) in the anti-CD99-A192 compared with the control group, results were also validated by the luciferase assay (~32% reduction, p<0.001).

Anti-CD99-A192 scFv-ELP nanoparticle stimulates T cell proliferation, elevates activation markers, and increases the release of pro-inflammatory cytokines. Anti-CD99-A192 culminates in heightened cytotoxicity against leukemic cells.

#2364 Anti-CADM1 chimeric antigen receptor (CAR) is a novel therapeutic strategy against small cell lung cancer.

S. Katkam, S. Zolov, D. Shield, S. Chuikov, V. Keshamouni;
University of Michigan, Ann arbor, MI

Small cell lung cancer (SCLC) is a highly aggressive form accounting for 15% of all lung cancers. SCLC is characterized by high proliferative rates, early metastasis, and poor prognosis. The median survival is less than 2 years even in patients with early-stage disease and less than a year in patients with metastatic disease which highlights the need for new therapeutic strategies. Cell Adhesion Molecule (CADM) 1 encodes a glycoprotein which belongs to an immunoglobulin superfamily of cell adhesion molecules responsible for epithelial cell adhesion through its homophilic trans-interaction between the adjacent cells. CADM1 is highly expressed on the cell surface of 80% of the SCLC cells, associated with its neuroendocrine features, along with the expression of Neural Cell Adhesion Molecule (NCAM). CADM1 is known to act as tumor promoter through its interactions with actin binding proteins. Consistently, we observed CADM1 expression in H69, H82, and H510 SCLC cell lines as assessed by western immuno blot. More importantly they were all susceptible to NK mediated cytotoxicity when assessed against NK cell line, NK92. We previously demonstrated that CADM1 mediates NK-mediated immune surveillance in non-small cell lung cancer, suggesting that CADM1 could be a potential immunotherapeutic target for SCLC. Here we report the development of an anti-CADM1 chimeric antigen receptor (CAR) specific for T and NK cells engineered with T and NK cell specific adaptor domains. Assessed the specificity of CARs by expressing them in NK92 cells and testing them against CADM1 expressing and CADM1-null A549 cells as targets. Finally, we evaluated the efficacy of anti-CADM1 CAR-T and CAR-NK cells against SCLC targets and observed a robust killing, largely proportionate to the levels of CADM1 expression in them. We are further assessing the efficacy of anti-CADM1 CAR-T and CAR-NK products in inhibiting tumor growth in NSG mice against SCLC xenografts. Together, these observations demonstrate that targeting CADM1 with CAR-T and CAR-NK cells is a potential new therapeutic strategy for SCLC.

#2365 Disrupting IL-11/IL-11R signaling by an efficacious anti-IL-11 antibody 9MW3811 enhances T cell tumor infiltration and synergizes with anti-PD-1 therapies *in vivo*.

S. Wang, Sr.[1], C. Zhang[1], S. Jiao[1], D. Zeng[1], R. Wang[1], M. Wang[2], W. Lu[1], B. Zheng[2], X. Gui, Sr.[2], J. Zhang[2];
[1]Beijing Kohnoor Science and Technology Co.Ltd, Beijing, China, [2]Mabwell (Shanghai) Bioscience Co., Ltd, Shanghai, China

Background: IL-11 is known as an inflammation-related factor, and it has been proved to be a key driver in fibrotic diseases. Besides, the roles of IL-11 in tumor immunopathology were recognized more in-depth and comprehensively in recent years. IL-11 expression is highly and positively correlated with overall survival in various cancer types, including colorectal cancer, hepatocellular carcinoma and lung cancer. It was reported that IL-11 promoted tumor cell growth and metastasis, mediated partly through its direct effects on macrophages, T cells and cancer-associated fibroblasts. All these studies indicated that blocking IL-11 signaling may be a promising therapeutic approach for the treatment of solid tumors. In this report, 9MW3811, a high-affinity IL-11 blocking antibody was developed to test its anti-tumor activity and synergistic effects with anti-PD-1 antibody in mouse tumor models.
Methods: 9MW3811 was generated by mouse hybridoma technology followed by antibody humanization and affinity maturation. Affinity of 9MW3811 was measured by Octet system. Its blocking activity of IL-11/IL11Ra/gp130 protein interaction was detected by ELISA, and the inhibiting effect of IL-11-mediated signaling was assessed with a luciferase reporter cell-based assay. *In vivo* efficacy of 9MW3811 was tested on A549 xenograft and LUSC PDX models. ScRNA-seq data collection and computational analysis were used to investigate immune cell tumor infiltration and differentiation. The synergistic tumor-suppressing effect of 9MW3811 with anti-PD-1 antibody was evaluated in MC38, CT26 and Hepa1-6 syngeneic models.
Results: 9MW3811 showed sub-nanomolar binding affinity to recombinant and membrane bound IL-11 derived from human, mouse, rat and dog. 9MW3811 effectively blocked the formation of IL-11/IL-11R/gp130 protein complex, and inhibited the downstream cell signaling transduction. In the NSCLC A549 xenograft model, as compared with isotype control hIgG, 9MW3811 (2mpk) showed significant tumor growth inhibition (TGI 62%). In two LUSC PDX models, the TGIs for 9MW3811 (10 mpk) were 50% and 28%, respectively. Further, in MC38 and Hepa1-6 syngeneic models, 9MW3811 addition increased the TGI of anti-PD-1 antibody from 45% to 83%, and 34% to 75%, respectively. Interestingly, in an anti-PD-1 non-responsive CT26 model, the combo of 9MW3811/anti-PD-1 antibody exhibited an impressive antitumor activity (TGI 67%). Mechanistic study showed that treatment with 9MW3811 could significantly ameliorate T cell exhaustion, increase CD8+ T cells tumor infiltration and enhance the cytotoxic function of these infiltrated T cells by modulating the expression of a variety of cytokines/chemokines
Conclusion: Our results demonstrated profound antitumor activity of 9MW3811 in different tumor models. 9MW3811 is currently in phase I clinical trials in AU, CN and US.

#2366 Balancing efficacy and toxicity of a fibroblast activation protein dependent tetravalent CD40 agonist antibody for cancer therapy.

s. chen, Y. Lin, X. Zhou, X. Sun, C. Yang, C. Liao;
Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

Background: CD40 agonist antibodies have been found to augment tumor antigen presentation and have shown potential as anti-tumor treatments in human clinical trials. The clinical success of CD40 agonist antibodies has been restricted due to their limited efficacy and on-target, off-tumor toxicity. We hypothesized that toxicity associated with CD40 agonist antibodies could be overcome by activating CD40 specifically through tumor-specific antigens. Additionally, limited efficacy can be improved by rational design of CD40 bispecific antibodies (BsAbs). Herein, we present FAPxCD40, a trivalent CD40 agonist BsAb targeting fibroblast activation protein (FAP) possessing an optimized therapeutic window.
Method: We generated a series of FAPxCD40 bispecific antibodies with 2, 4, and 6 CD40 valences by using a high-affinity anti-FAP antibody and a crosslink-dependent CD40 agonist VHH antibody. These BsAbs were evaluated using multiple immune cell functional assays, including assays for dendritic cell (DC) maturation, B cell maturation, and CMV-reactive T cell recall. The in vivo therapeutic window of the FAPxCD40 bispecifics was compared in CD40 humanized mice with subcutaneously transplanted FAP-positive MC38 tumor xenografts.
Results: We developed FAPxCD40 BsAbs with varying valences, including bivalent FAPxCD40-2, tetravalent FAPxCD40-4, and hexavalent FAPxCD40-6. FAPxCD40-2 showed strict FAP-dependent CD40 agonist activity in both DC and B cell maturation assays, while its CD40 agonist activity upon FAP-crosslinking was modest. FAPxCD40-4 exhibited efficient CD40 agonist activity upon FAP-crosslinking, but however, it also exhibited some undesired FAP-independent CD40 agonist activity. FAPxCD40-6 efficiently clustered CD40 but marginally benefited from FAP binding, making it unsuitable as a choice. In the humanized CD40 mice model, FAPxCD40-2 effectively eliminated systemic toxicity at all tested doses. Its antitumor activity, however, is modest with TGI (tumor growth inhibition) rate of 32.8 % at a dose of 6.96 mpk. Further escalation of the FAPxCD40-2 dosage to 13.92 mpk did not result in enhanced antitumor activity with TGI rate of 46.9 %, indicating that its CD40 agonist activity may have reached a plateau. In contrast, FAPxCD40-4 broke this plateau and induce a promising antitumor response at a dose of 1.3 mpk, resulting in a 92% TGI rate. Furthermore, no liver enzyme upregulation or platelet count decrease was observed under these conditions, indicating an ideal therapeutic window. In addition, during nonclinical toxicology studies conducted on cynomolgus monkeys, it was found that doses of FAPxCD40-4 up to 99 mg/kg administered weekly for a total of four doses were well-tolerated.
Conclusion: Our study demonstrates that FAPxCD40-4, a tetravalent FAPxCD40 BsAb, exhibits efficient CD40 agonist activity with an optimized therapeutic window.

#2367 STING agonist ADU-S100 improves the antitumor response of CLDN18.2/CD3 BiTEs by enhancing stem-like tumor-reactive CD8$^{\pm}$ T cells in pancreatic adenocarcinoma.

T. Zhou, J. Yan, B. Wang, Y. Xie, C. Yang, J. Yu, J. Hao;
National Clinical Research Center for Cancer; Key Laboratory of Cancer Prevention and Therapy, Tianjin Clinical Research Center for Cancer; Tianjin Key Laboratory of Digestive Cancer; Pancreas Center, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Immunotherapy with CLDN18.2/CD3 BiTEs (bispecific T-cell engagers) has shown clinical activity in pancreatic adenocarcinoma. However, only few patients benefit from the treatment, and most responders develop acquired resistance. STING agonists may promote the development of stem-like central memory CD8$^{\pm}$ T cells and enhance antitumor responses. This study aimed to investigate the synergistic effect and related mechanism of STING agonist plus CLDN18.2/CD3 BiTEs regimen.

Methods: Single-cell RNA sequencing and flow cytometry were used to examine the tumor immune landscape in humanized PDX mouse models. By qPCR, western blot and flow cytometry, an orthotopic transplantation mouse model of pancreatic cancer and an *in vitro* tumor-PBMC coculture system were established to reveal the potential molecular mechanism of STING agonist ADU-S100 in optimizing the effects of CLDN18.2/CD3 BiTEs (IBI389).

Results: In PDAC organoids, IBI389 induced potent, specific cytotoxicity, the CLDN18.2 BiTEs significantly engaged human CD3$^{\pm}$ T cells with tumor cells in an organoid-PBMC coculture system *in vitro*, resulting in the formation of the immunological synapse (IS). IBI389 monotherapy significantly suppressed tumor growth and improved survival *in vivo* in hCD3e C57BL/6 and humanized hCD34$^{\pm}$ PDX mouse models. Further, single-cell RNA sequencing and flow cytometry analysis revealed that the intertumoral TCF1$^{\pm}$PD-1$^{\pm}$ stem-like T cells and STING signaling activity of T cells were enriched in the early stage of tumor development and sharply decreased in the late stage during CLDN18.2 BiTEs administration. Furthermore, we discovered that the STING agonist ADU-S100 could significantly induce the enrichment of TCF1$^{\pm}$PD-1$^{\pm}$ stem-like CD8$^{\pm}$ T cells *in vitro* and *in vivo*, increasing IBI389's therapeutic effects. Furthermore, humanized PDX mice that were given the combination of IBI389 and ADU-S100 and survived after complete tumor rejection were rechallenged with PDX tumors. Humanized PDX tumors and hCD3e KPC orthotopic tumors from mice treated with the combination contained increased numbers of TCF1$^{\pm}$PD-1$^{\pm}$ stem-like CD8$^{\pm}$ T cells, CD4$^{\pm}$CD127$^{\pm}$ memory T cells, CD8$^{\pm}$CD127$^{\pm}$ memory T cells, and fewer numbers of CD4$^{\pm}$PD-1$^{\pm}$Tim-3$^{\pm}$ exhausted T cells, CD8$^{\pm}$PD-1$^{\pm}$Tim-3$^{\pm}$ exhausted T cells and CD4$^{\pm}$CD25$^{\pm}$ Treg cells.

Conclusions: Pancreatic tumors appear to evade immune response by inducing immune-suppressive tumor microenvironment development. In mice, the combination of STING agonist ADU-S100 and CLDN18.2 BiTEs increased the proportion of memory and stem-like CD4$^{\pm}$ and CD8$^{\pm}$ T cells while decreasing the proportion of regulatory and exhausted T cells in pancreatic tumors, eradicating all detectable tumors. This data may be utilized to formulate immune-based combination therapies for PDAC.

#2368 Intratumoral delivery of HER-2-CD3hFc mRNA-LNP inhibits ovarian tumor growth..

V. M. Golubovskaya[1], J. Sienkiewicz[1], J. Sun[1], S. Zhang[1], Y. Huang[1], L. Hu[1], H. Zhou[1], H. Harto[1], S. Xu[1], R. Berahovich[1], L. Wu[2];
[1]ProMab Biotechnologies, Inc., Richmond, CA, [2]ProMab Biotechnologies/Forevetek Biotechnology, Richmond, CA

Her-2 is a well-known driver of carcinogenesis that is overexpressed in breast, ovarian and other tumors. Immunotherapy with bispecific antibodies is a promising cancer therapy approach. Her-2 (Herceptin) antibody was used to test bispecific antibody against ovarian cancer cells. First, Her-2-CAR-T cells with Her-2 (4D5) ScFv and 4-1BB costimulatory domain were generated and tested using *in vitro* killing and IFN-gamma assays, and *in vivo* efficacy SKOV-3 xenograft NSG mouse model. Her-2-CAR-T cells killed SKBR-3 breast and SKOV-3 ovarian cancer cells and stopped SKOV-3 xenograft tumor growth. This Her-2-ScFv was used to generate bispecific Her-2 ScFv-CD3-ScFv human Fc antibody using *in vitro* transcribed mRNA. The 5'capped Her-2-CD3-hFc mRNA with 5'UTR, 3'UTR and poly A tail was generated by *in vitro* transcription using DNA template. The mRNA was embedded into lipid nanoparticles (LNP) using microfluidic PreciGenome Flex S NanoGenerator. Western blotting detected >160 kDa bispecific antibody secreted from A1847 and 293 cells transfected with mRNA-LNPs. The bispecific antibody was binding Her-2-positive A1847 ovarian cancer cell lines and T cells by FACS analysis. The Her-2-CD3-hFc bispecific antibody with T cells effectively killed Her-2-positive target cells in a dose-dependent manner in RTCA assay and produced high level of IFN-gamma. Moreover, intratumoral delivery of Her-2-CD3-hFc mRNA-LNP with intravenous injection of T cells completely blocked A1847 xenograft tumor growth. In conclusion, intratumoral delivery of Her-2-CD3 mRNA-LNP blocks ovarian xenograft tumor growth and provides a solid basis for future pre-clinical and clinical studies.

#2369 EVOLVE-105, a differentiated CD20-targeted CD2 co-stimulatory T cell engager engineered for the treatment of B cell malignancies.

X. An, M. Sarkar, S. Martomo, M. Hackett, G. Jin, T. Liang, D. Klaskin, T. Lichter, N. Pels, A. Abulizi, E. Teran, A. Sabrin, O. A. Sergeeva, A. Fearnley, H. Karp, J. Rodriguez, Jr., E. M. Tam, L. Matis, J. S. Fine, J. S. Myers;
EvolveImmune Therapeutics, Inc., Branford, CT

Despite the recent approvals of CD20-targeted CD3 bispecific molecules in follicular lymphoma (Lunsumio™, mosunetuzumab) and diffuse large B cell lymphoma (Columvi™, glofitamab; and Epkinly™, epcoritamab), significant opportunities to improve patient outcomes in these indications remain. Targeted induction of T cell costimulatory receptors (signal 2) as a complement to T cell activation mediated by T cell receptor signal 1 is an attractive strategy to sustain and optimize the redirected T cell effector response to these tumors. Drug combinations of CD3-bispecifics and tumor-targeted costimulatory biologics such as CD19-41BBL and CD19-CD28 costimulatory agonists are promising approaches that have shown preclinical efficacy and are being investigated in the clinic. EVOLVE-105 is a CD20-targeted trispecific T cell engager biotherapeutic with an integrated, affinity-tuned CD3 and a CD2 co-stimulatory agonist. The advantages of physical integration include an increased probability of simultaneous T cell receptor and CD2 receptor engagement on each T cell and a simplified patient management strategy, compared to drug combinations of molecules individually targeting each receptor. EVOLVE-105 displays improved human T cell activation, increased T cell expansion, and tumor cell killing activity without a substantial increase in cytokine release compared to CD20xCD3 bispecifics with matching CD3 affinity which does not supply CD2 costimulation. EVOLVE-105 also displays superior potency compared to the CD20xCD3 clinical benchmarks mosunetuzumab, epcoritamab, and odronextamab. Importantly, the tumor-killing potency of EVOLVE-105 was within two-fold of the activity of glofitamab, while inducing less cytokine release, suggesting its potential to establish an improved therapeutic index. In cynomolgus monkeys, EVOLVE-105 demonstrated favorable tolerability and pharmacokinetics consistent with an attractive clinical developability profile. Sustained, dose-dependent B cell depletion in peripheral blood, lymph nodes, and spleen was observed. Circulating cytokine excursions, including IL-6, IFNγ, and TNFα at efficacious doses were markedly reduced by EVOLVE-105 treatment, in contrast to the circulating levels of cytokines reported for epcoritamab and glofitamab at their efficacious doses. EVOLVE-105 demonstrates favorable biophysical properties conducive to its development as intravenous and subcutaneous formulations. The emerging profile of EVOLVE-105 suggests its potential as a differentiated CD20-targeted immunotherapy capable of providing superior, more durable tumor control with a preferred cytokine release profile, compared to current CD20-targeted T cell engager therapies.

#2370 Revitalizing anti-tumor immunity through PLT012 monoclonal antibody, targeting CD36 for metabolic rewiring in the tumor microenvironment.

Y.-R. Yu[1], S.-F. Tzeng[2], H.-W. Hsiao[3], J. Park[4], L. Kandalaft[5], Y.-H. Lin[1], C.-H. Tsai[2], P.-C. Ho[4];

[1]Pilatus Biosciences SA, Epalinges, Switzerland, [2]Institute of Life Science, National Defense Medical Center, Taipei, Taiwan, [3]Elixiron Immunotherapeutics, Taipei, Taiwan, [4]University of Lausanne, Epalinges, Switzerland, [5]Center for Experimental Therapeutics, Lausanne University Hospital (CHUV), Lausanne, Switzerland

The accumulation of lipid metabolic products in the TME has been extensively documented to exacerbate cancer malignancy by suppressing anti-tumor immunity. This phenomenon is characterized by the induction of immunosuppressive features in various immune cells and the development of exhausted phenotypes in T cells, creating formidable obstacles for effective immunotherapies. Notably, CD36, a fatty acid transporter, has been identified as up-regulated in both malignant cells and various tumor-associated immune cells, including regulatory T cells, tumor-associated macrophages, and CD8+ T cells. This upregulation serves to adjust the metabolic preferences of these cells, enabling adaptation to the lipid-enriched TME. CD36-mediated adaptation not only instigates alterations in metabolic regulations but also significantly influences immune cell properties, contributing to the establishment of an immunosuppressive TME. Consequently, it has been proposed that inhibiting CD36-mediated fatty acid uptake could strategically reshape the host's anti-tumor immunity within the TME, resulting in the reduction of tumor-infiltrating regulatory T cells and the restoration of both survival and functionality in CD8 T cells. These findings underscore the therapeutic potential of anti-CD36 antibodies as a targeted approach to mitigate the immunosuppressive milieu within the TME. Hence, PLT012, a humanized anti-CD36 antibody, was developed via phage display, followed by affinity maturation and developability optimization, and possesses cross-reactivity among species, including murine, non-human primates, and human. Through CryoEM-based structural analysis, we found that PLT012 recognizes the lipid binding domain of CD36 without interfering with the TSP-1 binding site. Moreover, administration of PLT012 significantly reduced oxLDL-mediated M2 macrophage polarization and fatty acid uptake in CD8+ TILs. Notably, HCC-bearing mice treated with PLT012 exhibited a significant reduction in tumor growth with an increased CD8/Treg ratio and CD8 effector functions, consistent with the ex vivo observations of PLT012 treatments in human HCC samples. In addition to murine studies, PLT012 also demonstrated excellent tolerability in NHP studies without any adverse effects. Ongoing studies in translational medicine will further bridge our findings and proposed mechanism of action with clinical observations, highlighting the potential therapeutic outcome in HCC patients particularly. Taken together, these results reveal that blocking CD36-mediated metabolic alterations in Treg and CD8+ TILs with PLT012 treatment can elicit robust tumor growth inhibition and shift the immunosuppressive nature within the TME toward an immunosupportive one. This study further provides the pillar for harnessing immunometabolic targeting in cancer immunotherapy.

#2371 BGB-B167, a first-in-class 4-1BB (CD137)/ CEACAM5 bispecific antibody, exhibits potent in vitro and in vivo anti-tumor activity and superior safety profile in preclinical models.

Z. Li[1], L. Qu[2], X. Chen[2], L. Xue[2], J. Li[1], Q. Liu[2], J. Sun[2], H. Sun[2], Y. Chen[1], Y. Xie[2], W. Wang[2], L. Zhu[2], P. Wang[2], X. Zhou[2], H. Hou[2], J. Chen[2], X. Liu[2], Y. Zhang[2], N. Liu[2], X. Liang[2], S. Zhang[2], X. Tang[2], J. Song[2], T. Zhang[2], X. Song[2], X. Liu[2], K. Li[2], C. Huang[2];

[1]BeiGene (Shanghai) Research & Development Co., Ltd., Shanghai, China, [2]BeiGene Co., Ltd., Beijing, China

4-1BB (CD137) is a key costimulatory immunoreceptor and a promising therapeutic target in cancer. CEACAM5 (CEA) is a well-established tumor associated antigen overexpressed in many cancers, including colorectal, gastric, lung, pancreatic cancer, liver, breast and thyroid cancers. BGB-B167 is a novel immunoglobulin G (IgG)-based bispecific antibody targeting 4-1BB and CEA and is under clinical development for the treatment of advanced or metastatic solid tumors in humans. BGB-B167 binds to its target proteins with high specificity and affinity. Potent and CEA-dependent functional activities were demonstrated using peripheral blood mononuclear cell (PBMC)-based immune cell activation and cytotoxicity assays. In humanized 4-1BB knock-in mice bearing human CEA-expressing tumors, BGB-B167 exhibited potent, dose-associated single-agent efficacy as well as synergistic antitumor activity in combination with anti-PD-1 antibody. BGB-B167 was well tolerated in 1-month repeat-dose toxicology study in cynomolgus monkeys. Here, we describe the characterization of BGB-B167 with regard to preclinical proof-of-concept and basic drug-like properties. The combined dataset provides an overview on the design, mode of action, preclinical pharmacology and safety profile of BGB-B167.

#2372 ATG-102, a novel LILRB4 x CD3 T cell engager, targeting two nonoverlapping epitopes of LILRB4, for the treatment of monocytic AML.

A. Sun[1], M. Gao[2], R. Guo[1], H. Liu[2], Z. Hu[2], E. Zheng[1], H. Yuwen[1], P. Chen[1], J. Mei[3], B. Shan[3], **B. Hou**[3];
[1]Antengene Corporation Co., Ltd., Shanghai, China, [2]Antengene Biologics, Hangzhou, China, [3]Antengene Corporation Co., Ltd., Shaoxing, China

Background: Acute myeloid leukemia (AML) is the most common acute leukemia in adults, and the treatment of AML, especially monocytic AML subtypes still has a poor outcome. T cell engagers (TCE) have been well used for the treatment of hematological malignancies, such as B cell leukemia and multiple myeloma. However, lack of ideal target antigens that only express on AML and leukemic stem cells (LSCs) but not on normal hematopoietic stem cells (HSCs) hampers the development of TCE therapy for AML. Leukocyte immunoglobulin-like receptor B4 (LILRB4), an inhibitory receptor belonging to the LILR family, is highly and restrictedly expressed on monocytic M4/M5 AML subtypes and LSCs, but not on normal HSCs which makes it an ideal target for TCE. Here we report a novel LILRB4 x CD3 bispecific T cell engager based on *AnTenGager*™ platform, ATG-102. It targets two distinct epitopes of LILRB4, inducing potent T cell-dependent cellular cytotoxicity (TDCC) with low CRS, resulting in a potent anti-tumor efficacy *in vitro* and *in vivo*.

Method: ATG-102 was constructed by introducing a high affinity anti-CD3 single chain fragment variable (scFv) to the hinge region of one of the heavy chains of a LILRB4 monoclonal antibody. A scFv targeting another epitope of LILRB4 was connected to the C terminal of the same heavy chain by GSSS linker, enabling a trivalent, dual epitope recognition of LILRB4. ATG-102 was evaluated in a series of preclinical studies for binding epitope and affinity, T cell activation, T cell dependent cytotoxicity (TDCC), and cytokine release. The *in vivo* antitumor efficacy of ATG-102 was evaluated in a humanized PBMCs and THP-1-luciferase cells engrafted NCG mice model.

Results: ATG-102 binds to LILRB4 positive cells with a single-digit nM affinity. It binds to two distinct and nonoverlapping epitopes of LILRB4. ATG-102 showed limited binding capability to CD3+ cells before LILRB4 crosslinking. However, with the presence of LILRB4 positive THP-1 cell, ATG-102 strongly activated primary T cells, upregulating early and later markers of T cell activation, CD69 and CD25, respectively. ATG-102 induced strong TDCC against LILRB4-high expressing THP-1 cells, and it induced more potent TDCC against LILRB4-low expressing MOLM-13 cells than a benchmark antibody. While compared with benchmark, ATG-102 induced significantly lower release of IL-6, which is one of the major cytokines involved in cytokine release syndrome (CRS). In addition, ATG-102 demonstrated more potent *in vivo* anti-tumor efficacy compared with the benchmark antibody at 1 mg/kg and 0.1 mg/kg dose level in PBMC-humanized NCG mice bearing THP-1-luciferase cells.

Conclusion: ATG-102 demonstrates trivalent, dual epitope recognition of LILRB4, conditionally redirects and activates T cells to recognize and kill monocytic AML cells. It demonstrates potent *in vitro* and *in vivo* anti-tumor efficacy with low risk of CRS.

#2373 Functional and specific T-cell engagers against a peptide-MHC tumor target.

Davide Tortora, Peter Bergqvist, Allison Goodman, Ryan Blackler, Nathalie Blamey, Stefania Carrara, Lauren Chong, Gabrielle Conaghan, Cindy-Lee Crichlow, Valentine de Puyraimond, Harveer Dhupar, Patrick Farber, Jessica Fernandes Scortecci, Kate Gibson, Rodrigo Goya, Ahn Lee, Franco Li, Tova Pinsky, Craig Robb, Patrick Rowe, Antonios Samiotakis, Eduardo Solano Salgado, **Raffi Tonikian**, Ping Xiang, Irene Yu, Kelly Bullock, Tara Fernandez, Stephanie K. Masterman, Kush Dalal, Tim Jacobs, Bryan C. Barnhart

AbCellera, Vancouver, BC, Canada

Accessing peptides from intracellular tumor antigens displayed on MHC class I (pMHC) can expand the T-cell engager (TCE) target pool for solid tumor applications. A challenge limiting TCE development for pMHC targets is the identification of rare, high-affinity, and high-specificity pMHC-binders. In this work, we describe TCEs in a 1x1 format with potent tumor-cell killing activity and high specificity for MAGE-A4, a pMHC tumor antigen expressed in multiple cancer types. We identified functional MAGE-A4 x CD3 TCEs with high specificity and affinity to a human MAGE-A4 peptide sequence of 10 amino acids presented on MHC-I (HLA-A:02*01). We strategically selected MAGE-A4-binders with high binding specificity for pMAGE-A4$_{230\text{-}239}$, but not MHC-I or many closely related MHC-restricted peptides. We then paired them with diverse and developable CD3-binders with a range of binding affinities, subunit specificities, and binding kinetic profiles. High-throughput *in vitro* functional characterization of hundreds of these TCEs enabled identification of molecules with optimal T-cell dependent cellular cytotoxicity in MAGE-A4-expressing tumor cell lines, with comparable tumor-killing activity and cytokine release to a clinical-stage TCE in a 2x1 format. Previous studies have highlighted unique challenges associated with pMHC targets, including their potential for cross-reactive binding to pMHCs on healthy tissues, and the absence of pharmacologically relevant species for preclinical toxicity testing. To address these challenges, we have designed and implemented an *in vitro* and *in silico* workflow to identify antibody binding to potential off-target peptides. Using this approach, we selected TCEs with several pMHC binding orientations and high specificity and affinity. These TCEs killed tumor cell lines endogenously expressing MAGE-A4 pMHCs and not isogenic cells with MAGE-A4 knocked out. Results demonstrate that our high-resolution, multiparametric antibody discovery capabilities can identify pMHC-binding antibodies with desired functional and specificity attributes. This approach unlocks the discovery and development of optimal TCEs against complex pMHC antigens.

#2374 Bispecific and trispecific GPRC5D antibodies with potent cell-killing activity against multiple myeloma.

H. Roth, D. Rogers, **I. Sanchez**, B. Tyrell, T. Barnes, A. Snyder, N. Nowgu, K. Doolan, B. J. Doranz, R. Chambers, J. B. Rucker;
Integral Molecular, Philadelphia, PA

Background: GPRC5D is a G protein-coupled receptor that is expressed on multiple myeloma cells but absent from most healthy tissues except for hair follicles. It is an attractive target for anti-tumor modalities including T cell-engaging bispecific antibodies. Recent clinical data demonstrate that combination therapy of T cell-engaging molecules individually targeting GPRC5D and BCMA on tumor cells offers unprecedented therapeutic benefits in relapsed/refractory multiple myeloma patients. A trispecific antibody that simultaneously engages these molecules while activating T cells is expected to provide comparable and additional benefits as a monotherapy.

Methods: Multipass membrane proteins are valuable therapeutic targets but are largely inaccessible for antibody discovery due to structural complexity and high conservation. We developed an antibody discovery platform (MPS) tailored for membrane proteins that utilizes advanced immunization techniques including DNA, mRNA, and Lipoparticles (virus-like particles) and evolutionarily divergent host species.

From the parental antibodies isolated, we engineered panels of GPRC5DxCD3 bispecific and GPRC5DxBCMAxCD3 trispecific antibodies using multiple formats and CD3 arms that encompass different geometries and binding stoichiometries. GPRC5D multispecific antibodies were tested for target specificity using Integral Molecular's Membrane Proteome Array (MPA), and epitope residues were defined using alanine scanning mutagenesis. Both bispecific and trispecific antibodies were tested for in vitro potency and cytokine release using MM.1R and RPMI 8226 multiple myeloma cell lines. In vivo efficacy for a subset of antibodies was determined using xenograft models in PBMC-engrafted mice.

Results: We immunized chickens with GPRC5D to obtain high-titer immune responses and configured resulting antibodies as T cell-engaging bispecific molecules with a CD3 binding arm. A subset of GPRC5DxCD3 bispecific antibodies displayed potent T cell-mediated cytotoxicity with picomolar potency on multiple myeloma cell lines. Antibody specificity profiling showed high specificity binding, and epitope mapping helped to explain why only some GPRC5D antibodies were active as multispecific antibodies.

Bispecific molecules were then re-engineered as trispecific antibodies with additional binding to BCMA, a well-validated multiple myeloma target. GPRC5DxBCMAxCD3 trispecifics showed improved cytotoxic activity against multiple myeloma cells. Both bispecific and trispecific antibodies demonstrated a large window between cell killing and cytokine release. We will present in vivo efficacy data for a panel of bi- and trispecific molecules against MM.1R xenografts in PBMC-engrafted mice.

#2375 23ME-01473, a novel anti-ULBP6/2/5 monoclonal antibody, reinvigorates anti-tumor NK cell function through NKG2D and FcγRIIIa activation.

J. Benjamin, A. Jarret, S. Bharill, S. Yadav, D. Ayupova, C. Hom, Z. Bahrami Dizicheh, I.-L. Chen, A. Diep, S. Shi, C. Bonnans, D. Kellar, G. Fuh, M. Schmidt, **K. Gerrick**, P. Koenig, M. Poggio;
23andme, Inc., South San Francisco, CA

Using genome-wide association studies (GWAS) of the 23andMe genetic and healthy survey database across all phenotypes as part of our unique target discovery platform, we identified immuno-oncology (I/O)-related genetic variants as those with opposing directionality of effects on cancer and immunological phenotypes, which comprise the I/O signature. This I/O signature identified ULBP6 as a potential cancer therapeutic target. ULBP6 is a stress-induced cell surface ligand found on cancer cells, that binds to the activating receptor, NKG2D, on NK and T cells to induce tumor cell killing. However, as a mechanism of immune escape, tumors shed ULBP6 to produce a soluble form that attenuates NKG2D activation and is elevated in cancers. Given that the 2 allelic variants of ULBP6 have the highest binding affinity to NKG2D of all human NKG2D ligands, ULBP6 may be the most immunosuppressive soluble NKG2D ligand and a critical regulator of anti-tumor response. Accordingly, soluble ULBP6 exhibited significant suppression of IFNγ release and detectable cell surface NKG2D expression on healthy donor PBMCs using in vitro cell-based assays. Moreover, the overexpression of human ULBP6 in a genetically modified MC38 murine model resulted in decreased infiltration of NK, NKT, and CD8 T cells in vivo. As such, we developed a novel humanized monoclonal antibody, 23ME-01473, that binds with high affinity to ULBP6, and due to the high sequence homology, to ULBP2 and ULBP5, to block their interaction with NKG2D. By preventing the binding of soluble ULBP6 to NKG2D on PBMCs in vitro, 23ME-01473 restored NKG2D activation as measured by increased detectable cell surface NKG2D expression, IFNγ and granzyme B release, and tumor cell killing by PBMCs. To further leverage the binding of 23ME-01473 to ULBP6/2/5, 23ME-01473 was designed to have an afucosylated Fc domain that enhances its binding affinity to the activating Fc receptor, FcγRIIIa, on NK cells to induce ADCC against tumor cells. The combination of NKG2D and FcγRIIIa activation resulted in synergistic PBMC-mediated IFNγ secretion and enhanced tumor cell killing, compared to activation of either NKG2D or FcγRIIIa. Taken together, these results reveal ULBP6 as a novel cancer therapeutic target, and given the dual activation of NKG2D and FcγRIIIa, suggest the potential of 23ME-01473 to activate NK cells and elicit anti-tumor immunity.

#2376 Mitazalimab, a potent CD40 agonist in combination with FOLFIRINOX demonstrates changes consistent with increased immune activation in TME and peripheral blood in a preclinical pancreatic cancer tumor model.

K. Enell Smith, **D. Gomez Jimenez**, M. Thagesson, A. Nilsson, Y. Pico de Coana, S. Ambarkhane, P. Ellmark;
Alligator Bioscience, Lund, Sweden

Mitazalimab is a human CD40 FcγR-conditional agonistic IgG1 antibody developed for cancer immunotherapy. Immune-excluded tumors, such as pancreatic ductal adenocarcinoma (PDAC), are defined by low infiltration of immune cells. In PDAC, effector $CD8^{\pm}$ T cells are excluded from the tumor by its desmoplastic stroma which surrounds cancer cell islets and hosts immunosuppressive macrophages. CD40 is expressed on key myeloid cell populations and targeting this receptor has a two-fold mode of action. First, mitazalimab activates macrophages, skewing them towards a tumoricidal phenotype that can potentially reverse the suppressive tumor microenvironment found in PDAC and sensitizes the tumor for chemotherapy by stromal degradation. Second, mitazalimab activates antigen-presenting cells, resulting in priming and expansion of tumor-specific T cells with the potential to generate an effective immune response that could provide immunological memory resulting in long term benefits to patients.

Mitazalimab is currently being investigated in a phase 2 study in patients with metastatic PDAC (OPTIMIZE-1) in combination with modified FOLFIRINOX (NCT04888312). The treatment starts with a dose of mitazalimab administered one week prior to chemotherapy in the first cycle to leverage the mode of action and increase the efficacy of the combination therapy. Interim results of the study demonstrated encouraging anti-tumor activity with good durability of responses.

To study the changes induced by mitazalimab and FOLFIRINOX in the tumor microenvironment, we evaluated the combination in human CD40 transgenic mice using the KPCY pancreatic tumor model. Tumor, tumor draining lymph nodes, blood and spleen were analyzed for changes in the immune compartment using multiplex assays at different time points.

The results showed distinct immunophenotypical changes induced by mitazalimab, FOLFIRINOX and the combination. The combination of mitazalimab and FOLFIRINOX resulted in an increased tumoricidal immune profile, including a marked increase in effector $CD8^{\pm}$ T cells compared to the individual therapies.

Overall, these preclinical data support the chosen dosing regimen of mitazalimab and modified FOLFIRINOX in the OPTIMIZE-1study and underline the synergistic potential of this combination for an improved antitumor response.

#2377 HER2-ADC efficacy is rooted in its induction of immunogenic cell death with FcGR activation and a systemic bystander effect.

L.-C. Tsao, X. Ma, J. S. Wang, T. N. Trotter, T. Wang, J.-P. Wei, G.-j. Lei, J. McBane, P. Fan, I. Spasojevic, **Z. C. Hartman**;
Duke University Medical Center, Durham, NC

Background: T-DXd is an antibody-drug conjugate (ADC) targeting HER2 that has demonstrated superior clinical efficacy over previous HER2-targeting agent Trastuzumab emtansine (T-DM1). Notably, T-Dxd is clinically effective in breast cancers (BC) with a range of HER2 expression. While its purported mechanism of action (MOA) involves its cleavable linker leading to bystander killing, it remains unclear how this potential MOA accounts for efficacy in HER2-low cancers or the role FCGR-mediated signaling and immune induction plays in its clinical efficacy.
Method: In vitro studies utilized co-culture, internalization, FCGR activation, ADCP, flow cytometry, and gene expression by QRT-PCR and ELISA assays. Assessments of tumor antigen-specific T cell stimulation involved JEDI T cells. In vivo studies were conducted using in vivo implantation of HER2+ and HER2- cells, PK assessments of T-Dxd/DM1 and therapeutic effects determined using an endogenous HER2 transgenic mouse model that measured HER2-specific adaptive immune responses, in combination with immune checkpoint blockade anti-CD47.
Results: T-Dxd elicited a systemic bystander effect that was only partially dependent on HER2 expression, mediated by specific cathepsins in the extracellular TME. Notably, T-Dxd cytotoxicity induced immunogenic cell death (ICD), while also retaining the ability to engage FCGRs to promote ADCP and innate immune activation. ICD was mediated by secretion of specific Dxd driven DAMPs (HMGB1 and eATP), resulting in TLR4/STING activation. ICD and FCGR activation along with antigen ADCP together elicited myeloid cell activation (CD80, CD40) and antigen presentation, resulting in effective expansion of tumor antigen-specific T cells responses, demonstrated by co-culture assays using EGFP/HER2+ BC cells and CD8+ JEDI T cells. T cell activation required TLR4 and STING pathways while in vivo, T-Dxd anti-tumor responses associated with augmented HER2-specific T and B cell responses. However, T-Dxd also induced CD47 to limit phagocytosis. But, the use of CD47/SIRPa blocking antibodies dramatically enhanced CD8+ T cell expansion in vitro and anti-tumor efficacy in vivo upon T-Dxd treatment.
Conclusion: Our study demonstrates that T-Dxd is cleavable in HER2 negative BC in vivo, which permits more widespread Dxd activity against HER2 low BC. Critically, Dxd elicits ICD, resulting in innate immune stimulation of myeloid cells, which when combined with FCGR activation and ADCP, leads to a striking induction of tumor-specific adaptive immunity. This combination was unique to T-Dxd, which may underlie its clinical superior efficacy. However, T-Dxd activity also elicits suppressive CD47 expression which could be negated using CD47/SIRPA blockade. We found that this combination dramatically enhanced T-Dxd resulted therapeutic efficacy, thus supporting clinical exploration of these combinations.

#2378 The triple-specific antibody KA-3003, targeting PSMA, CD28, and 4-1BB, is developed for the treatment of prostate cancer by enhancing T cell activity within the tumor.

G. Wu, Z. Guo, H. Peng, F. Hao, T. Liu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Immunotherapy, revolutionizing the treatment of advanced solid tumors by blocking PD1 signaling, has encountered a challenge in prostate cancer, exhibiting a low response ratio to anti-PD-1 therapy. Furthermore, cancer immunotherapy using 4-1BB agonists faces limited clinical development due to dose-limiting toxicity. Here, we developed a tri-specific antibody, KA-3003, targeting PSMA, CD28, and 4-1BB, with the goal of enhancing T cell activation in the tumor microenvironment. This antibody was created using our common light chain bispecific antibody discovery platform and nanobody antibody discovery platform with knob-into-hole technology. KA-3003, in IgG1 format, features mutations in the Fc domain to eliminate ADCC, ADCP, and CDC activity. It contains two identical nanobodies at the C-terminal against 4-1BB, while binding to PSMA and CD28 with two Fabs at the N-terminal, sharing an identical light chain. KA-3003 exhibits high affinity for PSMA and relatively lower affinity for CD28 and CD137. In the presence of a low concentration of CD3 antibody to stimulate T cell activation, co-culture of tumor cells expressing PSMA with primary T cells isolated from human PBMC enhances T cell activation and proliferation. In PBMC humanized immunodeficient mouse tumor models, KA-3003 effectively suppresses the growth of 22Rv1 tumors with or without a PD1 antagonist antibody. Additionally, KA-3003 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this antibody with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature. KA-3003 shows neither aggregation nor degradation. In conclusion, the tri-specific antibody KA-3003, developed with our common light chain antibody discovery platform, stands out as a promising pre-clinical candidate drug for the treatment of prostate cancer.

#2379 The bispecific antibody KA-3007 against B7H3 and CD28 enhances T cell activation in solid tumors.

G. Wu, Z. Guo, H. Peng, F. Hao, F. He, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Immunotherapy, revolutionizing the treatment of advanced solid tumors by blocking PD1 signaling, faces challenges as most cancers remain unresponsive to anti-PD-1 therapy. CD28, a key immune co-stimulatory receptor on T cells, often lacks ligands expressed on tumor cells. B7H3 is highly expressed in various solid tumors. In this study, we developed a bispecific antibody (BsAb) named KA-3007, targeting B7H3 and human CD28 to activate T cells in the tumor microenvironment. KA-3007, featuring an identical light chain, was developed using our common light chain bispecific antibody discovery platform with knob-into-hole technology. This BsAb is in regular IgG1 format with mutations in the Fc domain to eliminate ADCC, ADCP, and CDC activity. Its two Fabs bind to B7H3 with high affinity and CD28 with relatively low affinity. Co-culturing T cells with tumor cells expressing B7H3 enhances T cell activation. In PBMC humanized immunodeficient mouse tumor models, KA-3007 effectively suppresses the growth of NCI-H292 tumors, with or without a PD1 antagonist antibody. Furthermore, this antibody exhibits a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of KA-3007 with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and it shows neither aggregation nor degradation. In conclusion, the BsAb KA-3007, developed with our common light chain antibody discovery platform, emerges as a promising pre-clinical candidate drug for the treatment of solid cancers.

#2380 The bispecific antibody KA-3004, targeting PD-L1 and 4-1BB, is designed to enhance anti-tumor activity.

J. Liang, Z. Guo, H. Peng, F. Hao, T. Liu, J. Ning, **G. Wu**;
Kyinno Biotechnology Co., Ltd, Beijing, China

Checkpoint inhibitors (CPI) have transformed the treatment landscape for advanced solid tumors; however, a majority of cancers still do not respond to immune checkpoint therapy. In this study, we developed a bispecific antibody (BsAb) named KA-3004, targeting PD-L1 and human 4-1BB, with the aim of enhancing the functionality and survival of stimulated CD8+ T cells in the tumor microenvironment. This antibody was designed using our nanobody antibody discovery platform. KA-3004, in IgG1 format, incorporates mutations in the Fc domain to eliminate ADCC, ADCP, and CDC activity. It features two identical nanobodies at the C-terminal against 4-1BB to stimulate 4-1BB signaling in T cells and binds to PD-L1 with two Fabs at the N-terminal. KA-3004 binds to PD-L1 with high affinity, blocking the interaction of PD-1 and PD-L1. It also binds to 4-1BB expressed on 293T cells and activated human T cells. In the presence of a low concentration of CD3 antibody to stimulate T cell activation, co-culture of tumor cells expressing PD-L1 with primary T cells isolated from human PBMC enhances T cell activation and proliferation. In PBMC humanized immunodeficient mouse tumor models, KA-3004 effectively suppresses the growth of NCI-H292 tumors expressing PD-L1. Additionally, KA-3004 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this antibody with different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, and KA-3004 shows neither aggregation nor degradation. In conclusion, the BsAb KA-3004, developed with our nanobody antibody discovery platform, stands out as a promising pre-clinical candidate drug for the treatment of solid cancers.

#2381 The bispecific antibody KA-3001, targeting PSMA and CD28, specifically enhances T cell activation within prostate tumors.

J. Liang, C. Su, H. Peng, F. Hao, T. Liu, J. Ning, **G. Wu**;
Kyinno Biotechnology Co., Ltd, Beijing, China

Immunotherapy, which involves blocking PD-1 signaling, has revolutionized the treatment paradigm for advanced solid tumors. However, prostate cancer exhibits a low response ratio to anti-PD-1 therapy. In this study, we have developed a bispecific antibody (BsAb), KA-3001, targeting PSMA and human CD28, aiming to enhance T cell activation in the tumor microenvironment. KA-3001, in a regular IgG1 format, features an identical light chain and was designed using our common light chain bispecific antibody discovery platform with knob-into-hole technology. Mutations in the Fc domain were introduced to eliminate ADCC, ADCP, and CDC activity. KA-3001's two Fabs demonstrate high affinity for PSMA and relatively low affinity for CD28. In comparison to REGN5678, KA-3001 exhibits significantly stronger binding to PSMA-expressing prostate tumor cells, along with relatively lower CD28 activation, minimizing toxicity while maintaining anti-tumor efficacy. In PBMC humanized immunodeficient mouse tumor models, KA-3001 effectively suppresses the growth of 22Rv1 tumors with or without PD-1 antagonist antibody. Furthermore, KA-3001 has a half-life of more than five days in the blood of Balb/c mice. Finally, we assessed the developability of this antibody through various treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature. The BsAb demonstrates neither aggregation nor degradation. In conclusion, the BsAb KA-3001, developed using our common light chain antibody discovery platform, stands out as a promising pre-clinical candidate drug for the treatment of prostate cancer.

#2382 KY-CLC-mouse: a common light chain bispecific antibody discovery platform.

H. Peng, **G. Wu**, F. Hao, F. He, Y. Gu, J. Ning;
Kyinno Biotechnology Co., Ltd, Beijing, China

Bispecific antibodies (BsAbs) have emerged as a potent therapeutic tool in cancer treatment, gaining increasing centrality in therapeutic applications. However, the development of bispecific antibodies is hindered by the mispairing of light and heavy chains. In response to this challenge, our company developed the KY-CLC-mouse, featuring an identical κ light chain without the expression of the λ light chain. This mouse shows great promise in bispecific antibody development, as the identical κ light chain, modified from a frequently occurring light chain in mice, pairs with multiple heavy chains. The advantages of such a light chain include good solubility and stability, as well as ease of humanization without post-translational modifications in the complementary-determining regions (CDRs). Furthermore, the CDRs were modified to reduce immunogenicity. This KY-CLC-mouse platform has facilitated the identification of antibodies that specifically target over a dozen antigens, such as PD-1, LAG33, MET, PSMA, and CD28, with KD ranging from 0.1 nM to 10 nM. We apply the knob-in-hole technology to assemble bispecific antibodies, targeting two antigens or different epitopes of the same antigen, following their humanization. Prime examples include fully humanized BsAbs PD1xLAG-3, PDL1xEGFR, PSMAxCD28, and EGFRxB7H3. These bispecific antibodies have an identical light chain and were developed with knob-into-hole technology. With different treatments such as high concentration, low pH, repeated freezing and thawing, and high temperature, the BsAbs show neither aggregation nor degradation, suggesting good developability of these antibodies. Additionally, these BsAbs have a half-life of more than five days in the blood of both mice and monkeys. In conclusion, our common light chain KY-CLC-mouse is a powerful bispecific antibody discovery platform.

CLINICAL RESEARCH: Biostatistics in Clinical Trials / Surgical Oncology

#2386 Meta-analysis of efficacy and safety in early-phase clinical trials for refractory colorectal cancer.

Maarten A. Huismans, Lidwien P. Smabers, Niels N. van Nieuwenhuijzen, Monique C. Minnema, Miriam Koopman, Hugo J. G. Snippert, Anne M. May, Jeanine M. L. Roodhart

UMC Utrecht, Utrecht, Netherlands

Introduction: Despite a decade of metastatic colorectal cancer (mCRC) therapeutic innovations, a comprehensive synthesis of patient outcome and risk-benefit assessment of phase 1/2 trials, extending beyond single-center studies, is missing. The aim of this meta-analysis is to assess efficacy, safety, and trends over time for phase 1 and 2 mCRC trials by examining clinical benefit rate (CBR), overall response rate (ORR), grade 3 or higher adverse events (AE), and discontinuation due to AE.
Methods: The protocol and search were preregistered on PROSPERO. We searched PubMed and Embase for publications of phase 1/2 trials between 2010-2022. Reports were screened for inclusion criteria, followed by data-extraction by two researchers. Trials reporting on non-standard therapies for treatment-refractory mCRC or trials reporting specific mCRC efficacy data were included. CBR was defined as the proportion of patients with complete/partial response or stable disease ≥14 weeks. We used logit transformations for pooled effect analysis via a random-effects model, assigning study weights by the inverse variance method. Subgroup analyses were performed for publication year, preselection on molecular traits, and drug class: antiangiogenics, chemotherapy, immunomodulator, targeted therapy, or vaccine. Data are presented with 95% confidence intervals (CI); reported differences had non-overlapping CIs.
Results: The search strategy yielded 4175 unique reports, from which we extracted data for 279 trials. Most trials were phase 1 (63%). ORR was limited to 6% [6-7] in both phase 1 and 2, CBR was higher in phase 2 than in phase 1 trials (36% vs 27%). Trials testing antiangiogenic drugs had the highest CBR (47%) and immunomodulators the highest ORR (8%). Trials with patients preselected on molecular traits had higher CBR compared to other trials (38% vs 28%). We observed an increase in efficacy, especially in phase 2 trials, with a CBR rising from 22% to 42% between trials published in 2010-2012 and 2019-2021. Compared with 2010-2012, trials in 2019-2021 were more often testing immunomodulators (23% vs 4%), performed on molecular preselected populations (38% vs 4%), and including younger patients (median age <60 in 66% vs 44%). The occurrence of grade 3+ AE was 33% [28-38] in both phase 1 and 2. AE led to discontinuation in 12% of phase 1 trial patients, and 7% of phase 2 patients. Grade 3+ AE occurred in 4% of vaccine trial patients, in contrast to 41% in trials on targeted therapies. Occurrence of grade 3+ AE did not change over time.
Conclusion: We found limited ORR and CBR in early phase trials conducted in 2010-2021 for mCRC patients, while noting severe AEs in many patients. However, during this period, clinical benefit rate increased for phase 2 trials, possibly due to evolving study strategies that entail testing new treatment types in a younger, fitter, and stricter preselected study population based on molecular traits.

#2387 Drivers of precision in oncology trials: A landscape analysis of biomarkers and treatments.

M. Schuessler[1], E. Skarga[2], P. Geldsetzer[1], Y. Lu[1], M. Hohberg[3];

[1]Stanford University, Stanford, CA, [2]Heidelberg University, Heidelberg, Germany, [3]University Medical Center Goettingen, Goettingen, Germany

Background: Molecular profiling is powerful to match patients' tumor profile with targeted therapies in oncology. While our understanding of treatments and biomarkers that enhance overall response rates is growing, the level of consistency at which treatment response is assured in biomarker-enriched (BE) cohorts (e.g. immune-checkpoint inhibitors in PD-L1-positive tumors) remains poorly understood. In essence, an optimal biomarker would not only result in high mean survival but also precise, closely clustered response of all patients around this mean. **Objectives**: The primary objective of this study is to develop a method to measure the variability of survival outcomes from published Kaplan-Meier (KM) curves in trials. The secondary objective is to assess whether novel treatments, when given in the presence of predictive biomarkers, improve not only mean survival, but also its precision. This is clinically relevant as higher precision guarantees patients a treatment outcome closer to the mean, thereby providing safeguards against non-response. **Methods**: We conducted a criteria-based search in PubMed and EMBASE to identify all phase-II and -III drug trials on breast cancer and non-small cell lung cancer (NSCLC) published between 2018-2022. We developed an algorithm to derive pseudo-individual patient data (p-IPD) from KM curves. We measured variability of survival outcomes in treatment and control groups using ratios of coefficients of variation (CVRs) derived from log-normal models and restricted mean survival time. This novel computational approach enables comparing the consistency of treatment responses in BE subgroups versus total, i.e. intention-to-treat (ITT), populations in each trial. **Results**: From screening 780 publication records (NSCLC: n = 405; breast cancer: n = 375), we identified 67 biomarker-stratified drug trials (NSCLC: n = 41; breast cancer: n = 26). We successfully constructed p-IPD using KM curves from ITT and BE cohorts for the first 18 trials (NSCLC: n = 10; breast cancer: n = 8) from a total of 11,373 patients (NSCLC: n = 7,547; breast cancer: n = 3,826). The preliminary meta-analysis for overall survival on these first 18 trials shows that BE treatment groups respond more precisely, with a variability reduction from 0.93 [95%-CI: 0.91, 0.96] in the ITT group to 0.86 [0.83, 0.91] in the BE subgroup. This variability reduction varies across treatment, biomarker, and tumor types. Finally, we observe different variability estimates in trials (n = 6) that are stratified by subgroups of different PD-L1 expression. **Conclusion**: This is the first study that presents a viable approach to analyze the variability of biomarker-treatment pairs in oncology at large scale. We find a reduction of treatment variability in breast and lung cancer trials in BE populations. Our work offers an orthogonal approach to measure biomarker utility with the potential to inform biomarker discovery and trial design.

#2388 Artificial neural network based ensemble models for single-arm glioblastoma trials: A new historical control adjustment method.

Wonsuk Yoo[1], Tortsen Ullrich[2], Nader Sanai[1]

[1]Barrow Neurological Institute, Phoenix, AZ,[2]Brown University, Providence, RI

Background: Despite a long history of poor decision making leading to repeated failed phase 3 trials, phase 2 single-arm studies continue to be common in glioblastoma (GBM). With the drawback of inflated false positive rate in current adjustment method for historical control data as concurrent controls, the new statistical methods and validation approach will be needed for adequate covariate adjustment in the GBM single-arm trial data.
Methods: The systematic review was performed to extract the summary-level external data of survival outcomes (mean progression-free survival, mPFS, and PFS at 6 months, PFS6) and prognostic factors (age, gender, extent of resection, KPS, methylation status, and treatment history) from published randomized clinical trials for the standard of care (SOC) treatment in GBM. Four models of the standard, bootstrap aggregating, random subspaces, and random patches models were developed to construct a powerful predictive tool by comprising a series of connections producing survival outputs as a function of prognostic inputs using (1) artificial neural network (ANN) method and (2) linear method (Fig1). The root mean square errors (RMSEs) were calculated to evaluate the model performance using the five-fold cross-validation approach with the effects of ensemble size. The predictive survival outcomes among prognostic factors were calculated to evaluate the relative importance of factors.
Results: We identified 19 Phase 2 and 3 clinical trials in glioblastoma and two survival outcomes and seven prognostic factors (Table1). ANN models have less prediction error and therefore better performance on the test set than linear models. Presumably, the relationships in the data are highly nonlinear, and thus linear models cannot capture these relationships (Table2). Bagging models typically outperform their standard counterparts for both ANNs and linear models. Ensemble methods can capture many trends within the data by manipulation of the training set and are therefore less prone to biases of individual models exacerbated by the small sample size. The previous treatment history and methylation status were the top two influential prognostic factors for both mPFS and PFS6, followed by the extent of resection and mean age (Fig2). With the examination of the ANN parameters of sample size, learning rate, training hyperparameters, it could be observed that there is no clear change in error when increasing sample size beyond 10 (Fig3).
Conclusions: High failure rate of phase 3 glioblastoma trials emphasizes the need for greater reliability of earlier studies in phase 2 single-arm trials. The proposed statistical and epidemiologic approach based on the ensemble-based ANN models will be an effective tool to lead to better decision with phase 2 single-arm trials, which may give better chance to appropriately advance to phase 3 trials with higher predictive power.

#2389 Empowering early drug development in neoadjuvant non-small cell lung cancer studies using an innovative proof-of-concept platform trial design.

Z. Chen, P. A. Dennis, J. Lin;
Sanofi US Services Inc., Cambridge, MA

Several platform trial designs have recently been proposed in oncology. However, developing an efficient one in the neoadjuvant non-small cell lung cancer (NSCLC) is not easy due to the difficulties in patient recruitment and limited relevant data. These obstacles hinder the inclusion of a control arm, thereby losing the ability to make an informed Go/No-Go decision, and to assess prognostic and predictive biomarkers. To overcome these challenges, we have developed an innovative and efficient proof-of-concept platform trial design that aims to empower drug development in early stage of neoadjuvant NSCLC. The proposed platform trial incorporates available experimental agents, allowing for new agents to be added when available. Within the master protocol structure, a small control arm is included, only about 20% of experimental arm size, and is shared by all experimental arms for the analysis purpose. Consequently, the resulting direct comparison with the control arm enables an informed Go/No-Go decision-making, while the total sample size and budget impacts are minimized. The flexibility of Go/No-Go decision-making is further enhanced in a 3-outcome decision-making framework where a consider zone is introduced for physicians to examine the totality of data. Two innovative statistical techniques are incorporated: Bayesian dynamic borrowing for current control, and response-adaptive randomization (RAR). The former helps reduce the sample size, and the latter aims to optimize patient allocation and improve the ability to identify promising agents. Simulation results demonstrate that the direct comparison sharply reduces the false positive rate below 10%, compared to a single-arm design setting. The effective sample size of the control arm is statistically augmented through Bayesian dynamic borrowing. The patient allocation is guided based on the agent's efficacy data with a well-calibrated RAR. The promising agent receives meaningfully more patients than if a fixed-randomization is used, while the variability in patient allocation is decreased. Compared to a traditional design, our innovative design boosts the probability of identifying promising agent by up to 2-fold. To conclude, this research develops an innovative platform trial design to improve the success of drug development in early stage NSCLC. The master protocol structure, inclusion of a small control arm, and dynamic borrowing, increase the plausibility of conducting a trial in the neoadjuvant population. Advanced statistical features optimize the patient allocation and enhance the ability to identify promising drugs. Lastly, the proposed design can be easily applied to other oncology indications with appropriate modifications.

#2390 Longitudinal assessment of circulating tumor DNA in patients with advanced colorectal cancer: A proposed general statistical framework and visualization tool.

C. R. Pretz, J. Liao, L. Drusbosky, A. Das;
Guardant Health, Palo Alto, CA

Background: Understanding how ctDNA levels change over time can act as a surrogate marker for disease progression. Since ctDNA evolution is complicated—exhibiting variability within and between patients—we propose a rigorous and flexible statistical framework that comprehensively represents these types of time-varying biomarkers. We propose employing a hierarchal random effects cubic spline model due to its advantages over traditional longitudinal modeling approaches such as the former's ability to incorporate patient characteristics and create patient-specific results. Visualization of individual patient trajectories may provide clinical utility in precision oncology settings.

Methods: 167 patients with CRC were selected from GuardantINFORM, a real-world database linking genomic and claims data. All patients received chemotherapy and had at least three serial liquid biopsy tests completed via Guardant360. To meet model assumptions, ctDNA levels, measured by maximum variant allele frequency on each test, were transformed into logits. Due to the model's hierarchal structure, an unconditional cubic spline model was fit first, producing an estimated response pattern for the cohort. Next, as patient-level results are of interest, the unconditional model was built upon by fitting a conditional model that incorporated covariates consisting of demographic, health status, and mortality information, which provided numerous patient-level response patterns. The best fitting conditional model was guided by Akaike's information criteria.

Results: Since model parameter estimates are uninterpretable, and because numerous patient-level projections are generated (each covariate value combination produces a unique projection), an R-Shiny application was developed to visually present and compare results in an intuitive interactive fashion. Additionally, to enhance the understanding of patient response patterns, velocity plots, which provides the instantaneous rate of change in ctDNA levels at different time points, are also provided.

Conclusions: We demonstrate that the proposed method can successfully be applied to genomic data to describe and explore complex patient-level temporal ctDNA patterns while accounting for the impact of covariate values have on these patterns. We implemented the proposed methodology as a visualization tool that can be used in a wide variety of settings, ranging from hypothesis testing in clinical trials to patient monitoring. Results from the model can further our basic conceptualization of ctDNA dynamics and enhance our ability to integrate these results into targeted, patient centric, clinical decision-making.

#2391 Towards better prediction of treatment resistance: Directly modeling progression from multiple lesions.

S. Protich[1], M. Stoddard[2], **L. Yuan**[2], D. White[3], D. Bottino[4], A. Chakravarty[2];
[1]PHP Agency Inc, Brentwood, CA, [2]Fractal Therapeutics, Inc., Lexington, MA, [3]Independent Researcher, Atlanta, GA, [4]Takeda Pharmaceuticals, Inc., Cambridge, MA

Late-stage cancers in the clinic present as a set of dispersed tumors, each with distinct growth kinetics. As most patients enrolled in trials of experimental anticancer therapeutics have late-stage malignancies, it is important to understand the impact of data analysis methodologies on the ability to detect treatment effect. In particular, we are interested in the potential risk posed by aggregating individual tumor measurements from multiple-lesion clinical data into a single tumor burden measurement, as this may cause a loss of information. In this work, we use quantitative modeling to assess how analyzing multiple lesions separately versus using an aggregated readout affects tumor response and detection of progression free survival and relapse. To assess the impact of data aggregation, we built a two-population clonal dynamics model consisting of sensitive and resistant tumor cells undergoing growth in the presence or absence of treatment. We performed parameter sweeps to assess the impact of individual model parameters on progression free survival and relapse. We then extended these sweeps to the multi-lesion situation, using nonlinear regression to compare parameter values of aggregated models and the parameter values of the individual models that comprised it. From our simulations, the most influential parameters in determining rebound are the growth rate of the resistant cells and the fraction of these cells, while growth rate of sensitive cells and growth rate inhibition affect effectiveness of treatment. In analyzing the multiple lesion model in different situations, we found that estimates for progression free survival were significantly more sensitive when the lesions were analyzed separately, rather than being aggregated. Our work suggests that aggregating the lesions into a single readout loses impact of individual lesion growth rate inhibitions, impairing early detection as the ability to detect fast growing, small, resistant lesions (despite overall tumor burden decreasing) is lost. Taken together, our findings suggest that data aggregation causes a loss of information. Relapse can be predicted at earlier times when using the multiple lesion model compared to an aggregated model.

#2392 Use of early dynamics of clinical and laboratory parameters to predict resistance in patients with metastatic urothelial carcinoma receiving post-platinum atezolizumab.

Christopher Graser[1], Thomas O. McDonald[1], Guru Sonpavde[2], Franziska Michor[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]AdventHealth Cancer Institute, Orlando, FL

Background: Substantial variability exists in outcomes of patients with metastatic urothelial carcinoma (mUC) receiving PD1/PD-L1 inhibitors. Unfortunately, there is an absence of optimal predictive biomarkers of refractory disease. We hypothesized that with a combination of baseline and early-on-treatment (EOT) parameters we can distinguish patients who will respond from those who will have refractory disease. We investigated readily available baseline and EOT variables from the phase 3 clinical trial IMvigor211, which compared atezolizumab, a PD-L1 inhibitor, with chemotherapy (taxane or vinflunine), in patients with mUC who have progressed on platinum-based chemotherapy.

Methods: Of 931 patients in IMvigor211, 902 were evaluable for our analysis. We built logistic regression models for both atezolizumab and chemotherapy to predict the clinical endpoint of risk of treatment failure defined as progressive disease as best response. We used LASSO to select covariates from an array of clinical (e.g. metastatic site, performance status, prior therapy) and laboratory variables (e.g. albumin, hemoglobin, PD-L1 expression) measured before treatment, and EOT 3-6 weeks after starting therapy. Moreover, we used our models to identify clinical features that are differentially associated with outcomes in response to either therapy.

Results: Based on pre-treatment information, our baseline model achieves a predictive accuracy for treatment failure of AUC = 0.69 for both therapies. The strongest baseline predictors are PD-L1 expression, prior treatment with both cisplatin and carboplatin, and the presence of liver metastases. Moreover, higher TNM-stage of the primary tumor is strongly predictive of worse treatment outcomes for atezolizumab but not for chemotherapy. After the first treatment cycle (3 weeks), the predictive accuracy of the model increases to AUC = 0.83 with differences in importance of variables between the atezolizumab- and chemotherapy-treated patients. No variable stood out as a dominant predictor in the EOT model, with 14 variables significant at p=0.05. We found that 66% of patients have a lower predicted risk of treatment failure for atezolizumab than for chemotherapy at baseline. Our EOT model suggests that 36% of patients treated with atezolizumab would benefit from switching to chemotherapy after the first cycle.

Conclusions: Our prediction models employing readily available and affordable EOT clinical and laboratory variables robustly (AUC 0.83) identified patients with early resistance and may inform patient-specific therapeutic decisions. Further validation is required.

#2393 Development of a novel implantable drug-eluting product for the local treatment of pancreatic adenocarcinoma.

M. Lashof-Sullivan[1], L. S. Sloan[1], M. P. Kim[2], **L. Indolfi**[1], C.-W. D. Tzeng[2];
[1]PanTher Therapeutics, Austin, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Background Local control of non-metastatic pancreatic ductal adenocarcinoma (PDAC) remains a major challenge. Therapies with reduced systemic toxicity are needed as intravenous (IV) infusions are limited by patient tolerance with only small amounts reaching the tumor. PanTher created PTM-101, a novel absorbable drug formulation containing paclitaxel, designed to be locally applied via minimally invasive surgery to provide chemotherapy precisely to the peritumoral area in PDAC.

Methods A study was conducted using 3 cadaveric abdomens to evaluate surgical feasibility of delivering PTM-101 via laparoscopy. Prior to insertion of PTM-101 into the peritoneum, the surgeons prepared each product by suturing a 3-0 Vicryl SH (Ethicon) at four evenly spaced locations around the edge of the flat circular product. A periumbilical 10mm Hasson port was placed to insufflate the abdomen, followed by placement of 3 additional working ports (5mm). The liver capsule was carefully surveyed to exclude metastatic disease. The surgeons opened a window into the lesser sac through the greater omentum, lifting the stomach up from the transverse colon to expose the pancreas. PTM-101 (a 1mm thick and 6cm diameter film) was rolled into a tubular shape, inserted through the cannula, and affixed to the peri-pancreatic fat with existing vicryl stitches.

Results The estimated total operative time from placement of the first trocar to removal of all equipment was 45 minutes, for the 3 procedures. The operations included 25 minutes for entry, port placement, exposure of the simulated pancreatic tumor location and 20 minutes to place and suture PTM-101. PTM-101 was easy to fit through the cannula and was sutured without difficulty to the peri-pancreatic fat that surrounds the capsule of the pancreas. To simulate a tumor with hepatic artery involvement, the implant was sutured towards the hepatoduodenal ligament in one specimen, near the area of the gastroduodenal artery takeoff, proper hepatic artery, and proximal portal vein. PTM-101 covered the entire head/neck area of the simulated tumor locations without requiring disruption of the tumor area or dissection of the tunnel under the pancreatic neck.

Conclusion PTM-101 is flexible and conforms easily to the underlying topography, both in a concave (i.e., with the tumor intact) and convex (i.e., after resection) scenario. Although human anatomy does not allow for PTM-101 to completely wrap around the pancreas, the size and flexibility of the product enables it to “drape” over the edges covering areas near the superior mesenteric vein and artery (SMV/SMA). This placement could hypothetically increase the amount of drug reaching the area behind the pancreas to target tumors which abut or encase the mesoportal vasculature. A decrease in the tumor-vessel interface could downsize pancreatic tumors, with the goal of increasing resection rates and post-resection local control.

#2394 Significance of regional lymph node dissection in patients with clear cell sarcoma and epithelioid sarcoma.

T. Takemori, E. Kobayashi, S. Iwata, K. Ogura, S. Osaki, S. Fukushima, A. Kawai;
Department of Musculoskeletal Oncology and Rehabilitation, National Cancer Center Hospital, Tokyo, Japan

Objective Clear cell sarcoma (CCS) and epithelioid sarcoma (ES) are common as soft-tissue sarcoma subtypes causing lymph node metastasis (LNM), but the role of regional lymph node dissection is still unclear especially in these patients without imaging evidence of LNM. Here we retrospectively investigated the significance of lymph node dissection for patients with CCS and ES. Methods Forty-one patients (CCS: 13, ES: 28) with no distant metastasis other than in the regional lymph nodes were enrolled in this study. Of these 41 patients, those without LNM on imaging findings were categorized into two groups: "with dissection (WD)" group and "no dissection (ND)" group, respectively. Overall survival (OS), lymph node metastatic-free survival (LNMFS), progression-free survival (PFS), and post-operative LNM rate were compared between two groups. Results There were 26 patients who had undergone regional lymph node dissection and 15 patients who had not undergone regional lymph node dissection (ND group). Histopathological examination revealed metastasis to the lymph nodes in 9 of the 26 patients (38.5%). 9 patients were suspected of having LNM based on preoperative imaging findings such as CT or FDG PET/CT. Among the remaining 17 patients (WD group) in whom LNM was not suspected based on preoperative imaging findings, 6 patients (35.3%) had LNM. OS ($p=0.03$), LNMFS ($p<0.01$), and PFS ($p<0.01$) were all significantly better in the WD group. The postoperative LNM rate was significantly lower in the WD group than in the ND group ($p=0.03$), and there were no significant differences in OS, LNMFS, or PFS between the CCS and ES groups in terms of histological type. Discussion Even in cases where LNM was not suspected on preoperative imaging, LNM was present in more than 30% of cases. The possibility of regional LNM should be borne in mind in soft-tissue sarcomas, which frequently present with LNM, regardless of imaging findings. We also suggested that simultaneous dissection of the regional lymph nodes at the time of resection of the primary tumor improves the prognosis. Although ES and CCS are ultra-rare sarcomas, further validation with the accumulation of case series is desirable.

#2395 Camrelizumab combined with apatinib and hepatic artery infusion chemotherapy (HAIC) as conversion therapy for patients with unresectable hepatocellular carcinoma(HCC): A single-arm exploratory clinical study.

L. Zhao, B. Zhang, X. Shi, K. Cui, J. Zhang, J. Zhong, Z. Li, P. Sun, C. Zhang, L. Li;
Shandong Cancer Hospital, Jinan, China

Background: There is still no standard treatment recommendation for hepatocellular carcinoma transformation therapy, and researches are still under exploration.
Methods: This study was a single-arm phase II trial, eligible patients had histologically or cytologically confirmed unresectable HCC, without extrahepatic metastases and multiple diffuse liver lesions. Patients received camrelizumab and apatinib combined with HAIC for 2-8 cycles followed by surgery after evaluation. Primary endpoints were radiographic assessment of conversion rate and radical (R0) resection rate. Secondary endpoints were pathologic complete response rate (pCR) , objective response rate (ORR) by modified RECIST (mRECIST) and RECIST version 1.1(RECIST v1.1) and safety.
Results: Between March 17, 2021 and July 28, 2023, 22 patients were enrolled, including 9 (40.9%) patients with BCLC stage A, 2 (9.1%) patient with B, and 11 (50%) patients with C, 9 (40.9%) patients had tumor thrombus. Patients received treatment of a median of 2 cycles (range: 1-6 cycles). All 22 patients were included in thte safety set, before the first scheduled post-baseline tumor assessment, one patient changed treatment plan because of live function damage, three patients were failed to return to hospital for treatment because of civid-19. At the data cut off on 23 November, All other 18 patients conducted at least one efficacy evaluation, 8(44.4%) of 18 patients had an objective response and 16(88.9%) had disease control according to RECISIT v1.1, 3(16.7%) had a complete response, 9(40.9%) had a partial response and 18(88.9%) had disease control according to m RECIST. 15(68.2%) of 22 patients could undergo surgical resection based on imaging evaluation. 7 patients failed to undergo surgery due to CR (3patients), abnormal liver function(1 patient), immune myocarditis(1 patient), patient rejection(1 patient) waiting for surgery(1 patient). Resection was completed in 8 (44.4%) patients, and the R0 resection rate was 100%. The pCR rate in the surgery population was 25%, and the MPR rate is 37.5%. The most common grade 3 adverse events were increased alanine aminotransferase (36.3%) and decreased lymphocyte count (36.3%). A case of grade 4 immune-associated myocarditis occurred. No grade 5 treatment-related toxicity occurred.
Conclusion: Camrelizumab combined with apatinib and HAIC showed promising activity and manageable toxicity, and might be a potential conversion treatment option for patients with unresectable HCC.

#2396 Tumor treating fields (TTFields) for spinal metastasis: Clinical trial concept for use of conductive implants as waveguides to enhance TTFields strength.

C. E. Tatsui[1], K. W. Carlson[2], C. B. Patel[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Carlson Research LLC, Concord, MA

Tumor treating fields (TTFields) is a FDA-approved electric fields-based therapy for glioblastoma (GBM) and malignant pleural mesothelioma. We describe a novel approach to increase the strength and therapeutic effect of TTFields at vertebral tumor targets, using spinal implants as electrically-conductive waveguides. In vivo anti-cancer efficacy is achieved with TTFields strength >1 V/cm. If the tumor is surrounded by tissues of lower conductivity (e.g., the skull in the case of GBM), then the TTFields strength reaching the tumor is decreased. Surgical treatment of radiation-refractory spinal metastases is difficult and provides a short-term benefit at the expense of a lengthy recovery. Such resections require bone removal that disrupts the spinal stability, necessitating reconstruction with titanium (Ti) pedicle screw constructs that are electrically conductive. We theorize that astute placement of Ti hardware in the proximate spinal levels post-resection would have a waveguiding effect of electrical current from the surrounding muscle towards the tumor. This would in turn boost TTFields strength achieved around the resection cavity, decreasing the chances of tumor recurrence. Bomzon et al. described a computational model of the distribution of TTFields in a realistic human torso. The simulation demonstrated that a TTFields strength of 3 V/cm can be achieved, which is approximately 3-fold greater than what is achieved in the brain parenchyma in the context of TTFields for GBM. In a more generic simulation using a 0.5 × 100 mm waveguide targeting a tumor deeper in the torso (480 mA), we found 21.8 vs. 61.2 cm^3 volumes achieving ≥ the 1.0 V/cm efficacy floor, without and with the waveguide, respectively, a 2.8-fold increase. At a higher amplitude (550 mA) and stronger TTFields strength threshold of ≥1.5 V/cm, a negligible volume was attained with no waveguide (0.1 cm^3), whereas a volume of 17.6 cm^3 was attained around the tip of the waveguide when present. Based on compelling pre-clinical data, a prospective clinical trial is being designed in which patients with radiation-refractory spinal metastasis from any number of primary sites will undergo resection. Next, primary cultures of their tumor cells will be made and evaluated for the TTFields frequency that maximizes cell death on a per-patient basis. Patients will then undergo postoperative local TTFields therapy ± systemic therapy. The primary endpoint will be safety and efficacy of such an approach, with future aims focusing on local control rates. The application of TTFields as an adjunct to surgery may offer a new therapeutic option for patients with spinal metastasis who would otherwise not be considered surgical candidates. Similarly, waveguides may be used throughout the head and body to increase TTFields efficacy.

#2397 Double lung transplantation (DLT) in patients with stage IVA lung-limited non-small cell lung carcinoma (NSCLC): A case series.

Y. Chae, T. Demir, L.-Y. Chung, C. Moloney, R. Tomic, A. Bharat;
Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction: Despite technological advances and expanded indications in lung transplantation, lung cancer constituted less than 0.1% of the lung transplantation over the past two decades. DLT may offer curative treatment for stage IVA NSCLC patients without extrapulmonary disease. We present a case series of consecutive NSCLC patients who underwent DLT.

Methods: Patients treated with DLT were identified between 09/2021 and 09/2023 at Canning Thoracic Institute of Northwestern University. All patients had enrolled in the DLT registry aimed for lung-limited malignancies (DREAM) study (NCT05671887). Exclusion criteria include: presence of extrapulmonary disease and medical ineligibility for lung transplantation. All patients were followed up with computed tomography and tumor-informed ctDNA assay every 12 weeks.

Results: Five patients with stage IVA NSCLC who underwent DLT were included. Three (60%) patients had invasive mucinous, and two (40%) had invasive non-mucinous adenocarcinoma histology. One of the two invasive non-mucinous patients had acinar, and the other had mixed lepidic, papillary, and acinar histology. Patients were aged 56-70; one (20%) was Asian, four (80%) were White, three (60%) were male, and two (40%) had a history of smoking. No patient had a past medical history of interstitial lung disease (ILD) or chronic obstructive pulmonary disease (COPD). All patients had high oxygen requirements before DLT due to cancer progression. Pre-transplant endobronchial ultrasound and evaluation of bilateral pneumonectomy lungs found no lymph node involvement (pN0). One patient had an epidermal growth factor receptor (EGFR) mutated cancer and but had failed relevant targeted therapy prior to transplant. All patients had disease progression on standard of care treatments with/without clinical trials. The indication for DLT was respiratory failure or refractory cancer for all patients. After DLT, one patient had a recurrence of the disease at 18 months with a 1cm solid nodule and was treated with stereotactic body radiotherapy (SBRT). Both original and recurrent tumors had invasive mucinous adenocarcinoma histology, negative PD-L1 expression, and the same JAK3 c.2174C>T, P725L mutated clone. It suggests that the recurrence likely arose from the original cancer. Transplant rejection did not occur in any of the cases. Following the transplant, there was no requirement for oxygen therapy for any patient. All patients are alive with 25, 15, 6, 3, and 1-month posttransplant follow-up.

Conclusion: Five patients underwent DLT successfully without significant complications. Notably, one patient (25 months post-transplant) experienced cancer recurrence 18 months post-transplant and was effectively treated with SBRT. Ongoing DREAM study will continue to investigate the role of DLT in stage IVA NSCLC patients (especially in pN0).

#2399 Stage-matched prognosis comparison between ypTNM and pTNM stage in pancreatic cancer.

H. Kim, H. Chae, S. Lim, H. Jeong, S. Yoon, S. Shin, I. Han, J. Heo, H. Kim;
Samsung Medical Center, Seoul, Korea, Republic of

Introduction: The prognostic significance of pathological stage in pancreatic cancer is well-established. The 8th American Joint Commission on Cancer (AJCC) TNM staging introduced the ypTNM stage for neoadjuvant treatment (NAT) patients responding to the increased use of NAT. Despite this, there has been no comparative assessment of the prognosis between ypTNM and pTNM stages in pancreatic cancer. This study aimed to evaluate and compare the prognoses between ypTNM and pTNM stages in surgically resected pancreatic cancer.

Method: A cohort of 586 patients who underwent pancreatic cancer surgery at a tertiary center from January 2018 to March 2022 was analyzed. Exclusions comprised those with prior pancreatectomy, suspicious liver metastasis or peritoneal seeding before NAT, those with open biopsy, R2 resection, and distant metastasis during operation, and postoperative mortalities or immediate follow-up losses. Clinicopathologic demographics underwent analysis, and a propensity score-matched (PSM) analysis (1:3) was conducted based on factors influencing overall survival (OS) in multivariate analysis. Subgroup analyses, categorized by stage, compared survival between ypTNM and pTNM stages.

Results: The analysis included 541 patients, with 100 undergoing NAT (ypTNM) and 441 opting for upfront surgery (pTNM). Comparable OS was observed between ypTNM and pTNM patients (median 51.0 vs. 46.0 months, 3-year survival rate (YSR) 68.7% vs 56.3%, $p = 0.094$). Subgroup analysis by stages I (3YSR 76.8% vs 67.5%, $p = 0.577$), II (56.2% vs 53.0%, $p = 0.715$), and III (26.5% vs 28.7%, $p = 0.596$) revealed similar survival between ypTNM and pTNM. Multivariate analysis identified factors such as age >65 (HR 1.651, $p = 0.002$), CA19-9 >150 (HR 1.476, $p = 0.010$), preoperative biliary drainage (HR 1.372, $p = 0.048$), pathologic T2 stage (HR 2.188, $p = 0.002$) and T3, 4 stage (HR 3.178, $p < 0.001$) compared to T0, 1 stage, lymphovascular invasion (HR 2.087, $p < 0.001$), and adjuvant treatment (HR 0.243, $p < 0.001$) associated with OS. After PSM analysis, stages I (3YSR 76.8% vs 71.7%, $p = 0.923$), II (56.2% vs 46.6%, $p = 0.886$), and III (26.5% vs 31.4%, $p = 0.856$) exhibited no significant difference in OS between ypTNM and pTNM stages.

Conclusions: Our study underscores comparable survival outcomes between ypTNM and pTNM stages in surgically resected pancreatic cancer, affirming the applicability of the TNM staging system after NAT. Consistent survival results, even following PSM analysis, highlight the reliability of TNM staging for guiding therapeutic decisions even in patients with NAT.

#2400 Determinants of early recurrence in surgically-resected colon cancer: A multi-omics analysis.

S. Al-Aomar[1], H. Abushukair[1], A. Zaitoun[1], S. Zytoon[2], S. Illeyyan[1], H. Almomani[2], G. Al-Majali[1], A. Hammad[1], K. Obeidat[1], F. Turfah[3], A. Shahait[4], F. Ali[5]; [1]Jordan University of Science & Technology, Irbid, Jordan, [2]Yarmouk University, Irbid, Jordan, [3]Corewell Health, Dearborn, MI, [4]Southern Illinois University, Carbondale, IL, [5]University of Texas Southwestern, Dallas, TX

Introduction: Colon cancer is the third most common cancer worldwide. The mainstay treatment for localized disease is surgical resection, often followed by adjuvant chemotherapy in stage III patients, and stage II patients with high-risk features. Unfortunately, some patients experience early local and/or distant recurrence. Besides classic anatomical/pathological tumor features, insight into the genomic determinants of early recurrence in colon cancer is lacking. Herein, we utilize a multi-omics approach to identify early-recurrence-specific features that could aid in more accurate risk stratification.

Methods: We utilized the Cancer Genomic Atlas Colon Adenocarcinoma (TCGA-COAD) Database. Clinical, histopathological and genomic data were retrieved through the cBioPortal database. Our analysis was limited to patients with stage 2 or 3 (n = 390) disease based on the American Joint Committee on Cancer Code. Early recurrence (ER) was defined as disease relapse/recurrence within 12 months of sample acquisition post-surgery. Accordingly, patients were categorized into the ER and non-early recurrence (NER) groups based on a cut-off point of 12 months of disease-free survival.

Results: The colon cancer ER and NER group included 45 and 345 patients, respectively. Comparable age, sex and race percentages were found between both groups. The ER group had significantly worse overall, progression-free, and disease-specific survival (HR: 0.083 95% CI: 0.031-0.220, HR: 0.035 95% CI: 0.011-0.0109, HR: 0.021 95% CI: 0.006-0.076, respectively). ER patients had a significantly higher proportion of patients with T4 and N2 disease based on the TNM staging system. ER patients had significant (P< 0.05) expression of TRIM46, TRPC4, ELOVL7, CSMD1, BCLAF1, and CD70 mutations, while tumor mutational burden was comparable between both groups (median TMB in ER vs NER: 4.2 vs 3.62, p = 0.28). Differential gene expression analysis revealed 68 genes to be upregulated in the ER group which were found to be enriched in hypoxia and interleukin-11 pathway genes. Genes upregulated in the NER group (n = 49) were enriched in interferon-alpha response and glycolysis/gluconeogenesis pathway genes. Proteomics analysis revealed significantly higher levels of EIF4E, CCNE1, SRSF1, SCD, and PECAM1 proteins in NER patients

.Conclusion: Our results highlight insights into molecular and genomic features unique to colon cancer patients with early recurrence. Understanding such predictors for early recurrence will aid in risk stratification and help in determining patients who would derive the most benefit from adjuvant treatment considerations.

#2401 Changes in skeletal muscle mass after gastrointestinal cancer surgery by body composition.

Y. Maeda, Y. Miyamoto, M. Ohuchi, Y. Hiyoshi, N. Yoshida, H. Baba;
Kumamoto University, Kumamoto, Japan

Background: Previous studies have extensively explored the correlation between preoperative skeletal muscle mass and long-term survival in gastrointestinal cancers. However, investigations into postoperative skeletal muscle mass alterations are limited. In gastrointestinal cancers, factors such as the tumor and surgical interventions can significantly impact dietary intake, nutritional status, and skeletal muscle mass, affecting postoperative body composition. This study aimed to examine these postoperative changes in skeletal muscle mass across different gastrointestinal cancers, including esophageal, gastric, and colorectum.
Methods: This study encompassed 969 patients with Stage I-III esophageal (307 cases), gastric (278 cases), and colorectal (384 cases) cancers who underwent radical resection between 2005 and 2019. Skeletal muscle mass was quantified as the total psoas volume (TPV), measured using Ziostation2® imaging software from preoperative and postoperative CT scans at 1, 2, and 3 years. The study compared postoperative TPV trends across the different cancer types.
Results: The study cohort comprised patients with esophageal (median age 66 years, 85% male), gastric (65 years, 60%), and colorectal cancers (67 years, 55%). Median BMIs were 21.5, 19.4, and 22.6 kg/m^2, and median TPVs were 352.0, 305.8, and 309.5 cm^3 for esophageal, gastric, and colorectal cancers, respectively. Esophageal cancer patients had significantly higher TPV and male predominance, while gastric cancer patients had notably lower BMI. Relative to preoperative TPV, the postoperative TPV at three years was 0.92, 0.91, and 0.96 for esophageal, gastric, and colorectal cancers, respectively. A year-by-year decrease in TPV was observed for each cancer type, with colorectal cancer demonstrating a less pronounced decrease compared to esophageal and gastric cancers ($p<0.01$). Stage-wise analysis revealed no significant differences among the cancer types. Regarding gender, no significant differences were noted between gastric and colorectal cancers, but esophageal cancer showed a more marked decrease in TPV in males compared to females. In recurrent cases, no significant TPV differences were observed in esophageal cancer, while recurrent gastric and colorectal cancers exhibited significant TPV decreases.
Conclusions: The study indicates a general decline in TPV following gastrointestinal cancer surgery, with the extent of reduction varying according to the type of tumor and treatment.

#2405 Harnessing liquid biopsy and genetic barcoding in evaluating diversity within triple-negative breast cancer.

D. Ceresa[1], **B. Cardinali**[1], A. Daga[1], R. Tasso[2], A. Sciutto[1], I. Appolloni[2], D. Marubbi[2], F. Carli[1], P. Fregatti[1], P. Malatesta[2], L. Del Mastro[1];
[1]IRCCS Ospedale Policlinico San Martino, Genova, Italy, [2]Universita di Genova, Genova, Italy

Introduction: While liquid biopsy shows promise as a non-invasive precision medicine tool, its ability to comprehensively represent the complexity of a tumor or only a subset of its clones remains uncertain. This issue is particularly crucial in the context of triple-negative breast cancer (TNBC), a type of cancer known for its significant heterogeneity. The goal of this study is to examine the clonal diversity within Circulating Biomaterials (CBMs): namely circulating tumor cells (CTCs), extracellular vesicles RNA (evRNA), and circulating tumor DNA (ctDNA), employing genetic barcoding and patient-derived TNBC xenografts.
Methodology: Cells from TNBC patients' resected tumors were tagged with a unique barcode sequence through vector transduction. These barcoded cells were subsequently introduced into immunodeficient mice to form xenografts. When these xenografts grew to a certain size (15mm in diameter), the mice were humanely euthanized, and the tumor tissues as well as CBMs from their blood and plasma were collected. CTCs were isolated through negative enrichment and DEPArray technology; evRNA was extracted using ultracentrifugation and TRIzol™ Plus RNA Purification method; ctDNA was retrieved using the QIAamp DNA Micro Kit. Tumor tissues were processed for RNA and DNA using RNeasy micro kit and Qiamp DNA micro kit, respectively. RNA sequencing of the tumor tissues was carried out using the Lexogen - CORALL Total RNA-Seq Kit and Illumina NextSeq high output reagents.
Results: Analysis of xenografts from four patients showed that ctDNA was the predominant genetic material detected through liquid biopsy. Crucially, clonal analysis using Next Generation Sequencing (NGS) demonstrated that ctDNA provides an accurate reflection of the primary tumor's clonal heterogeneity. The method efficiently identified both main tumor clones and subclones, even those constituting as little as 1% of the tumor, with a 50% detection probability. Transcriptomic analysis of the tumor tissues uncovered a distinct mesenchymal and pro-metastatic signature, more pronounced in tumors with higher ctDNA release. Clonal analysis of CTCs and evRNA is still ongoing.
Conclusions: This investigation affirms the effectiveness of ctDNA analysis in liquid biopsy for identifying subclonal diversity in TNBC. Our results suggest that liquid biopsy via ctDNA is capable of managing TNBC's extensive intra-tumoral heterogeneity, including the identification of smaller subclones. Furthermore, a link was identified between the release of ctDNA and a mesenchymal, prometastatic gene expression pattern in the tumors.

#2406 Circulating tumor DNA as a potential indicator of treatment response in patients with surgically unresectable PDAC.

F. Pittella Silva[1], Y. Kimura[2], M. Motoya[2], T. Nakamura[3], T. Murakami[2], K. Watanabe[3], S.-K. Low[4], Y. Nakamura[4];
[1]University of Brasilia, Brasilia, Brazil, [2]Sapporo Medical University School of Medicine, Sapporo, Japan, [3]Hokkaido University, Sapporo, Japan, [4]Japanese Foundation for Cancer Research, Tokyo, Japan

Pancreatic ductal adenocarcinoma (PDAC) is a highly heterogeneous and extremely aggressive neoplasm. Most patients with PDAC present with symptomatic, surgically unresectable disease at initial diagnosis. Systemic chemotherapy is the standard care for patients diagnosed with unresectable PDAC, despite the dismal survival rate due to disease recurrence. In this context, liquid biopsy based ctDNA monitoring may aid to improve detection accuracy and allow real time disease prognosis. Here we aimed to investigate the utility of ctDNA in longitudinal tumor monitoring to assess treatment response and to predict disease recurrence. We performed targeted NGS sequencing to investigate over 900 mutations (SNVs) and 12 copy number variations (CNVs) in 53 genes, using the Ion S5 Oncomine PanCancer gene panel in 40 PDAC patients with unresectable disease. Serial plasma samples were obtained from patients in the course of 24 months, including samples collected before the first intervention (baseline) as well as within 2 months after initiation of chemotherapy. Patients were followed for a period of up to 2-years from diagnosis through treatment, to death or final follow-up. Genomic DNA from paired plasma-buffy coat samples were sequenced to exclude clonal hematopoiesis. Overall detection of ctDNA alterations in baseline samples was 55% (22/40) with increasingly higher detection rates and mutation loads in advanced disease (88% in stage IV patients). Alterations including SNVs and CNVs were preferentially distributed among 9 genes; mutations in *TP53* (45%), *KRAS* (38%) and *SMAD4* (5%) were most commonly identified. To asses response to chemotherapy, the presence of residual ctDNA after clinical intervention was evaluated by comparing total ctDNA MAF (mutant allele frequency) detected in plasma at diagnosis and within 2 months of chemotherapy. 71% (17/24) of patients who reached progressive disease (PD) had detectable baseline mutations and 79% (19/24) had persistent residual mutations at 2 months of treatment. Conversely, 94% (15/16) of non-PD patients had no detectable ctDNA or had a significant reduction in total MAF after 2 months of chemotherapy. Absence of residual ctDNA after 2 months of chemotherapy was associated with a better OS (p=0.031; HR = 3.48). On the other hand, residual ctDNA after 2 months of chemotherapy was associated with a shorter PFS (p=0.042; HR = 3.28). Our study demonstrates that monitoring ctDNA levels derived from plasma provides valuable insights into the therapeutic response in patients with unresectable PDAC, even in the absence of matched tumor genotyping. We found a significant correlation between increased ctDNA levels following the initiation of treatment and poorer survival outcomes.

#2407 Detection of hotspot *PIK3CA* mutations in primary tumors and plasma-cfDNA of breast cancer patients using a novel highly sensitive CE-IVD kit.

S. Smilkou[1], D. Stergiopoulou[2], E. Tzanikou[2], L. Kaklamanis[3], I. Balgkouranidou[4], H. Linardou[5], F. Zagouri[6], E. Razi[7], S. Kakolyris[4], A. Psyrri[8], C. Papadimitriou[9], I. Koukli[2], **A. Markou**[1], E. Lianidou[1];

[1]National & Kapodistrian University of Athens, Athens, Greece, [2]Pharmassist Ltd, Athens, Greece, [3]Onassis Cardiac Surgery Center, Athens, Greece, [4]University General Hospital of Alexandroupolis, Alexandroupolis, Greece, [5]Metropolitan Hospital, Athens, Greece, [6]Alexandra Hospital, Athens, Greece, [7]Hygeia Hospital, Athens, Greece, [8]Attikon University Hospital, Athens, Greece, [9]Aretaieio University Hospital, Athens, Greece

Introduction: Detection of *PIK3CA* mutations in primary tumors (FFPEs) and liquid biopsy samples is of increasing importance for treatment decisions in breast cancer. Oncolipsy PIK3CA kit (Pharmassist Ltd, Greece) is based on the combination of allele-specific priming, asymmetric PCR, and melting curve analysis. The CE-IVD kit can detect the presence of four PIK3CA hotspot mutations (E542K, E545K, E545Q, H1047R). The aim of the present study was to: a) evaluate the performance of this novel CE-IVD kit both in FFPEs and plasma-cfDNA samples from patients with metastatic breast cancer (MBC) and b) directly compare the derived results using the Oncolipsy *PIK3CA* kit with the cobas® *PIK3CA* mutation test (CE-IVD, Roche Diagnostics, Germany) in identical gDNAs isolated from FFPEs samples.

Patients and methods: We analyzed 42 primary tumors (FFPEs) and 29 plasma-cfDNA samples from patients with estrogen receptor (ER) positive metastatic breast cancer. Genomic DNA was isolated from FFPEs using the QIAamp DNA FFPE Tissue Kit (Qiagen, Hilden, Germany), while cfDNA was extracted from 2.00 mL of plasma using the QIAamp DSP cNA Kit (Qiagen, Hilden, Germany). *PIK3CA* hotspot mutations were detected in the LightCycler® 2.0 (IVD instrument, Roche Diagnostics, Germany) using the highly sensitive Oncolipsy *PIK3CA* kit (analytical sensitivity 0.05%). A direct comparison study was performed using the cobas® *PIK3CA* Mutation Test on the cobas z 480 analyzer (IVD instrument, Roche Diagnostics, Germany).

Results: In primary tumors the E545K mutation was detected in 22/42 (52.4%), the E542K and H1047R mutations were detected in 11/42 (26.2%) and 4/42 (9.5%) of primary tumor samples, respectively, while the E545Q mutation was not detected in any FFPE sample tested. At least one *PIK3CA* mutation was detected in 14/29 (48.3%) plasma-cfDNA samples. More specifically the E545K mutation was detected in 11/29 (38%), the H1047R mutation in 3/29 (10.4%) and the E542K mutation in 2/29 (6.9%) while the E545Q mutation was not detected in any plasma-cfDNA sample tested. In FFPEs, as expected, *PIK3CA* mutation frequency was higher compared to plasma-cfDNA. Direct comparison of the results derived using these two commercially available kits, the Oncolipsy CE-IVD kit and the cobas *PIK3CA* mutation test, using the same gDNA isolated from 42 FFPEs revealed a concordance of 34/42 (81%).

Conclusions: The commercially available Oncolipsy *PIK3CA* CE-IVD kit is highly sensitive and specific for the detection of four *PIK3CA* hotspot mutations in primary tumors and plasma-cfDNA.

#2408 Comprehensive genomic profiling of ctDNA reveals distinct genomic signatures and therapeutic implications for immunotherapy response in advanced head and neck cancer.

A. Bharde[1], V. Noronha[2], M. Ratnaparkhi[1], V. Patil[3], B. Jadhav[1], S. Prajapati[1], A. Choughule[2], P. Chandrani[2], S. Haldar[4], F. Moubeen[4], N. Menon[2], K. Hariramani[4], M. Basavalingegowda[1], A. Ramesh[1], J. Khandare[1], P. Chaturvedi[2], G. Shafi[5], K. Prabhash[2];
[1]OneCellDx, Pune, India, [2]Tata Memorial Hospital, Homi Bhabha National Institute, Mumbai, India, [3]Tata Memorial Hospital, Mumbai, India, [4]Indxtechnology, Pune, India, [5]OneCellDx, Cupertino, CA

Background: Head and Neck Cancer (HNC) is highly prevalent malignancy in Southeast Asia. We investigated comprehensive genomic profiling (CGP) of ctDNA, aimed to compare genomic landscapes between responders (R) and non-responders (NR) to immunotherapy among advanced HNC patients.
Methods: An observational study, ctDNA was evaluated in 69 advanced HNC patients both at the baseline (BL) and during follow up (FL). OncoIndx® CGP was used to identify patient-specific genomic alterations in the ctDNA cohort. Raw sequence alignment and variant calling were performed using iCare® software. Progression-free survival (PFS) and overall survival (OS) were assessed using Kaplan-Meier statistics.
Results: Total 250 mutations, encompassing pathogenic (P), likely pathogenic (LP), and variants of unknown significance (VUS), were identified at BL. In FL samples a slight decrease in the overall number of mutations was observed. Loss-of-function (LOF) KMT2C, MSH6 mutations, and activating HNF1α mutations were consistently present at comparable frequencies in BL and FL samples, exhibiting ubiquity across immunotherapy R and NR populations (F test, P 0.00063, OR 13). The variants did not demonstrate statistically significant association with PFS and OS. Most prevalent variants at follow-up emerged from tumor suppressor genes TP53, BRIP1, STAT5B, NF1, suggesting their potential role as therapy-resistant variants. PFS and OS were notably lower for patients with TP53 + BRCA pathway variants compared to their wild-type counterparts (median PFS TP53 + BRCA pathway mutated 2.7 months vs wt 9.1 months, HR = 4.1; median OS TP53 + BRCA pathway mutated 4.7 months vs 12.8 months for wt, HR 7.7). Similarly STAT5B carriers compared to the wild-type STAT5B-bearing population. Multivariate analysis further confirmed the independent role of TP53 + BRCA pathway and STAT5B variants as determinants for worst outcome (P 0.006, HR2.5). Population with prevalent TP53 and STAT5B LOF variants exhibited a strong negative correlation with the PD-L1 score compared to the population with their wild-type counterparts (P 0.03). Average scores for genome-wide homologous recombination deficiency (HRD), bTMB, and loss of LOH were low at BL and FL and did not correlate with the PD-L1 score. Interestingly, bTMB was low for the cohort, Tumor fraction (TF) emerged as an independent prognosticator for OS and PFS.
Conclusions: ctDNA revealed distinct genomic signatures in R and NR populations at BL and FL. Significant prevalence of TP53, BRIP1, STAT5B, and NF1 in the NR population suggest a potential role in conferring immunotherapy resistance. Genomic signatures, TMB and TF impacted survival of immunotherapy responders. Integrating CGP into SOC protocol may help in identifying therapy resistance in advanced HNC patients who did not respond to initial treatment.

#2409 Circulating differential methylation allele fraction (DMAF) strongly correlates with circulating tumor DNA (ctDNA) variant allele fraction (VAF).

P. Srinivasan[1], T.-C. Chen[1], E. Haghshenas[1], M. Kordi[1], I. Tunc[1], W. Chan[1], O. S. Solari[1], J. Babiarz[1], Y. Nakamura[2], T. Yoshino[2], A. Aleshin[1], T. Kawli[1], J. G. Reiter[1];

[1]Natera, Inc., Austin, TX, [2]National Cancer Center Hospital East, Kashiwa, Japan

Measurement of ctDNA has been established as a prognostic biomarker of cancer disease burden. Emerging evidence has demonstrated that differential methylation patterns can serve as an accurate biomarker both for cancer detection and for predicting the tissue of origin. While it is important to distinguish cancer-positive from cancer-negative patients, clinical decision making increasingly depends on the exact level of the measured biomarker. To that end, we report on the correlation between ctDNA VAF and DMAF across patients with colorectal cancer (CRC). Pre-surgical plasma samples from patients with CRC (N=70) were sourced from the prospective GALAXY, observational arm of ongoing CIRCULATE-Japan study trial (UMIN000039205). Samples classified as ctDNA-positive by a tumor-informed ctDNA assay (Signatera™) were included in this analysis and ctDNA VAF (%) was calculated. We performed deep methylation sequencing (Illumina Novaseq) across multiple target regions using two independent target sets. DMAF was calculated computationally, which estimates the fraction of differential methylation alleles for circulating cell-free DNA across target regions. Among 70 CRC patients, 68 had positive ctDNA results. Median age at testing was 64.0 years and male individuals represented 55.9% (n=38) of the cohort. Among them, 9 (13.2%) were stage I, 24 (35.3%) were stage II, 22 (32.3%) were stage III, 8 (11.7%) were stage IV, and 5 (7.3%) had unknown staging. The correlation of DMAF with ctDNA VAF was 0.894 (Spearman's Rank Correlation Coefficient) and was independent of disease stage, histology, age, and sex. Among MSS (micro-satellite stable; n=58) and MSI-H (micro-satellite unstable n=10) patients, the DMAF correlation was 0.9 and 0.915, respectively. The correlation between two target sets evaluating DMAF with differing numbers of targeted regions was high (0.89). These data demonstrate that abundance of differential methylation in CRC patients correlates with VAF regardless of clinicopathologic features of patients with CRC. Methylation-based assays are a promising tool for cancer detection and quantifying the disease burden.

#2410 Comparative genomic profiling of unresectable NSCLC patients in the U.S. and China using a globally harmonized liquid biopsy assay platform.

H. Tang[1], C. Jia[1], F. Xie[1], Y. Zhang[1], X. Dong[2], Y. Huang[2], S. Jia[2];
[1]Huidu (Shanghai) Medical Sciences, Ltd., Fengxian District, Shanghai, China, [2]Predicine, Inc., Hayward, CA

Background: Non-Small Cell Lung Cancer (NSCLC), accounting for over 80% of all lung cancers, benefits from targeted therapies based on genetic tests like EGFR, KRAS, ALK, and ERBB2. While prior studies focused on molecular characteristics through tissue biopsies, limited research has explored NSCLC molecular profiles via liquid biopsy, especially across different human races. This study presents a comprehensive genomic profiling analysis of unresectable NSCLC patients in the U.S. and China, using a globally harmonized liquid biopsy assay.
Methods: As part of Predicine's Phoenix Program, a global molecular biomarkers screening initiative, 61 patients in the U.S. and 352 patients in China with unresectable advanced NSCLC were enrolled. All were treatment-naïve or recurred after 1st-line targeted therapies. Blood samples (10ml) were tested using PredicineCARE, an NGS-based liquid biopsy assay, to profile somatic mutations, copy number variations, and gene fusions.
Results: The assay, validated in both regions using the same reference materials, achieved a Limit of Detection (LOD) of 0.25% mutation allele frequency, with a positive predictive value exceeding 99%. Profiling NSCLC patients in the U.S. and China revealed common genes like TP53, CDKN2A, EGFR, KRAS, RB1, and PIK3CA. TP53 and PIK3CA variations showed equivalent prevalence. However, EGFR variations were significantly higher in China ($p<0.05$), while CDKN2A ($p<0.001$), KRAS ($p<0.01$), and RB1 ($p<0.01$) variations were notably higher in the U.S.
Conclusions: This study unveils the mutational landscape of advanced NSCLC through liquid biopsy. Unique prevalence patterns between U.S. and China cohorts suggest novel biomarkers for clinical diagnosis and provide insights for targeted therapy mechanism studies.

#2411 A deep learning-based multimodal ensemble algorithm for lung cancer early detection with cross-ethnic generalizability.

T.-R. Lee[1], J. Ahn[1], J. Lee[1], D. Kim[1], B.-H. Jeong[2], D. Oh[3], M. Wang[4], M. Salmans[4], A. Carson[4], B. Leatham[4], K. Fathe[4], B. Lee[4], C.-S. Ki[1], Y. Park[5], **E.-H. Cho**[1];

[1]GC Genome, Yongin, Korea, Republic of, [2]Division of Pulmonary and Critical Care Medicine, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [3]Department of Radiation Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [4]GENECE Health, San Diego, CA, [5]Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Background: Lung cancer is the leading cause of cancer-related mortality worldwide, and early detection is crucial for improving patient outcomes. Cell-free DNA (cfDNA) whole genome sequencing (WGS) is a non-invasive technique that has the potential to detect lung cancer early, but it is challenging to develop accurate and generalizable detection algorithms due to the low abundance of tumor-derived cfDNA in early-stage cancer.
Methods: We developed a novel deep learning-based multimodal ensemble algorithm that combined two independent models: FEMS (fragment end motif frequency and size) and COV (coverage of genome positions). To assess the performance and ethnic generalizability of our algorithm, we evaluated it on three distinct cohorts: a Korean development cohort, a Korean external cohort, and a Caucasian external cohort. The Korean development cohort for model development comprised 236 lung cancer samples (stage I: 30%, stage II: 12%, stage III: 24%, stage IV: 20%, unknown: 14%) and 2205 normal samples. The Korean external cohort for performance evaluation of the model comprised 288 lung cancer samples (stage I: 31%, stage II: 13%, stage III: 26%, stage IV: 19%, unknown: 12%) and 1463 normal samples. And the Caucasian external cohort for confirm the ethnic generalizability consisted of 126 lung cancer samples (stage I: 17%, stage II: 12%, stage III: 37%, stage IV: 32%, unknown: 3%) and 93 normal samples. All data were generated using Novaseq6000 with a minimum of 40 million reads.
Results: Our multimodal ensemble algorithm achieved high sensitivity and specificity in all three cohorts. The Korean development cohort had an overall sensitivity of 94.1% (95% CI: 90.7% to 97%) and specificity of 85%. The Korean external cohort had an overall sensitivity of 90.4% (95% CI: 82.7% to 98.1%) and specificity of 82%. The Caucasian external cohort had an overall sensitivity of 92.1% (95% CI: 87.3% to 96%) and specificity of 82.8%. The Caucasian cohort also had a sensitivity of 80% for early-stage lung cancer.
Conclusion: Our deep learning-based multimodal ensemble algorithm is a promising tool for early lung cancer detection using low-coverage cell-free whole genome sequencing (LC-cfWGS). It performed well on three distinct cohorts, including a Caucasian cohort, suggesting that it is robust and generalizable to different populations. This makes it a potential candidate for clinical implementation.

#2412 Circulating HPV DNA as a potential biomarker to monitor response to the pembrolizumab and vorinostat combination in patients with squamous cell carcinoma of different locations.

E. Jeannot[1], D. Filippini[1], C. Dupain[1], M. Halladjian[1], G. Marret[1], C. Coutzac[2], E. Coquan[3], M. Saint-Ghislain[1], O. Le Saux[2], L. Mazzarella[4], G. Frige[4], E. Guerini-Rocco[5], M. Francisco[6], N. Servant[6], M. Tonini[7], L. Chanas[1], F. Legrand[8], S. Bernhart[9], G. Balogh[9], M. Jimenez[8], I. Bieche[1], T. Filleron[10], B. Cabarrou[10], **C. Le Tourneau**[1], M. Kamal[1];

[1]Institut Curie, Paris, France, [2]Centre Leon Berard, Lyon, France, [3]Centre Francois Baclesse, Caen, France, [4]IEO - Istituto Europeo di Oncologia, Milan, Italy, [5]IEO - Istituto Europeo di Oncologia IRCCS, Milan, Italy, [6]INSERM U900, Paris, France, [7]Luxembourg Institute of Health, Luxembourg, Luxembourg, [8]Unicancer, Paris, France, [9]Universitat Leipzig, Leipzig, Germany, [10]Institut Claudius Regaud, IUCT-Oncopole, Toulouse, France

Background: The PEVOsq basket trial (NCT04357873) evaluated the efficacy of pembrolizumab and vorinostat (P+V) in patients (pts) with advanced squamous cell carcinoma (SCC) of different locationsAmong 112 pts included, 66 were HPV-positive (HPV+). Here we report HPV ctDNA monitoring in these pts.
Methods: ctDNA before treatment (T0) and at first imaging (T1) from HPV+ SCC pts enrolled in the PEVOsq trial were analyzed using digital droplet PCR. Changes in HPV ctDNA levels between T0 and T1 were correlated to tumoral response (RECIST1.1). Landmark survival analyses were performed to study the association with progression free survival (PFS) and overall survival (OS).
Results: Among the 66 HPV+ pts, 47 (71%) had plasma at T0 and T1. Most pts had anal (n=24, 51%) or cervix cancers (n=11, 23%), followed by vulva/vagina (n=8, 17%), penis (n=3, 6%) and head and neck (n=1, 2%) cancers. HPV ctDNA was detected in all 47 pts at baseline. Increasing HPV ctDNA copies at T1 correlated with progressive disease in 8 pts (67%), whereas decreasing HPV ctDNA occured in 6 (100%) and 8 (80%) pts with complete (CR) and partial response (PR), respectively (Table).Increase in HPV ctDNA copies were more frequent in non-responders pts versus responder pts (p=0.03) and was associated with shorter OS (12.1 months vs not reached, p=0.02) and a trend towards shorter PFS (4.3 versus 8.2 months, p=0.06). Taken as a continuous variable, 10% increase in HPV ctDNA between T0 and T1 was associated with higher risk of progression (HR=1.05; 95%CI, 1.02-1.08, p=0.0007) and shorter OS (HR=1.02; 95%CI, 1.01-1.03, p<0.0001) in univariate analysis.
Conclusions: HPV ctDNA was detected at baseline in all pts reliably reflecting HPV detected on tissue. Dynamic changes in HPV ctDNA levels might help monitoring response to treatment in pts with advanced HPV+ cancers.
Table:

Variation in HPV-ctDNA (N=47)	Best response			
	CR N=6	PR N=10	SD N=19	PD N=12
Increase	0	2 (20%)	6 (32%)	8 (67%)
Decrease	6 (100%)	8 (80%)	13 (68%)	4 (33%)

#2413 Mutated *TP53* prevalence in *EGFR*-mutated advanced non-small cell lung cancer patients with brain metastases.

S. Stensgaard[1], I. Z. Eide[2], E. Stensland[2], A. Helland[3], S. Ekman[4], K. H. Hansen[5], S. Cicenas[6], B. Gronberg[7], P. Meldgaard[1], B. S. Sorensen[1], O. Brustugun[2]; [1]Aarhus University Hospital, Aarhus, Denmark, [2]Vestre Viken Hospital Trust, Drammen, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]Karolinska University Hospital, Stockholm, Sweden, [5]Odense University Hospital, Odense, Denmark, [6]Vilnius University Faculty of Medicine, Vilnius, Lithuania, [7]Trondheim University Hospital, Trondheim, Norway

Introduction: Approximately 50% of patients with *EGFR*-mutated advanced non-small cell lung cancer (NSCLC) develops brain metastases (BM), which is associated with a poor prognosis. Mutations in *TP53* are associated with earlier development of resistance to *EGFR* tyrosine kinase inhibitors, but it is unclear whether patients who develops BM have a higher prevalence of *TP53* mutations. Analyses of circulating tumor DNA (ctDNA) in blood have been established as a good alternative to tissue biopsies to assess the genomic landscape of NSCLC. In this study, we aim to analyze ctDNA from patients with advanced *EGFR*-mutated NSCLC to investigate the prevalence of *TP53* mutations in patients with BM, and to explore whether patients with BM exhibit a distinct ctDNA profile compared to patients without.

Materials and Methods: Plasma samples collected before treatment commenced from 97 of the 100 patients with *EGFR*-mutated advanced NSCLC enrolled in the First-line Treatment With Osimertinib in *EGFR*-mutated Non-small Cell Lung Cancer study (The FIOL study: NCT03804580) were analyzed. Patients were split into cohorts with (n=44) and without BM (n=53) at baseline. The cell-free DNA was isolated and sequenced with targeted next-generation sequencing with the AVENIO ctDNA Surveillance Panel (Roche) containing 197 lung cancer-related genes.

Results: Mutations in ctDNA were found in 83 patients (85.6%), with 6 patients with BM having no ctDNA mutations and 8 patients without BM having no ctDNA mutations. Besides *EGFR* mutations, *TP53* was the most frequently mutated gene, with 42 patients (43.3%) harboring *TP53* mutations. There was no significant difference in the prevalence of *TP53* mutations between the cohort with BM (n=23) and the cohort without (n=19), (p=0.15). There was no difference in the number of identified mutations in the two cohorts (BM: median: 2 (range: 0-6), without BM: median: 2 (range: 0-11), p=0.71). Patients with BM had a numerically lower ctDNA level (median: 45.5 mutant molecules/mL), than patients without BM (median: 75.9 mutant molecules/mL), though the difference was not statistically significant (p=0.68).

Conclusion: Prevalence of *TP53* mutations in plasma collected before osimertinib treatment initiation in advanced *EGFR*-mutated NSCLC was similar between patients with and without BM at baseline. Furthermore, there was no difference in the ctDNA profile between these two cohorts. Future experiments will clarify the impact of *TP53* mutations in patients with or without BM.

#2414 Feasibility and clinical utility of blood based NGS in head and neck carcinomas : A single center experience from precision medicine program..

Filippo Gustavo Dall'Olio[1], Damien Vasseur[2], Lea Loriguet[1], Francois Regis Ferrand[1], Antoine Moya-Plana[1], Yungan Tao[3], Mariana Iacob[1], Karim Benihoud[4], Odile CASIRAGHI[5], Catherine Brenner[4], Pierre Busson[4], Philippe Gorphe[1], Santiago Ponce[6], Pierre Blanchard[3], Etienne Rouleau[2], Yohann Loriot[6], Ludovic Lacroix[2], Antoine Italiano[6], Ingrid Breuskin[1], Caroline Even[1]

[1]Head and Neck Oncology, Gustave Roussy, Villejuif, France,[2]Medical Biology and Pathology Department, Gustave Roussy, Villejuif, France,[3]Radiation Oncology, Gustave Roussy, Villejuif, France,[4]Metabolic and Systemic Aspects of Oncogenesis for New Therapeutic Approaches, Gustave Roussy, Villejuif, France,[5]Anatomopathology, Gustave Roussy, Villejuif, France,[6]Drug development, Gustave Roussy, Villejuif, France

Background: While blood-based next-generation sequencing is increasingly integral to clinical practice across various malignancies, the routine assessment of circulating tumor DNA (ctDNA) in head and neck cancer remains underexplored, with limited supportive data.
Methods: This study focused on head and neck cancer patients enrolled in the Gustave Roussy precision medicine program (STING, NCT04932525), undergoing liquid biopsy (LB) with the FoundationOne Liquid CDX panel. The Molecular Tumor Board discussed cases, calculating Tumor Fraction (TF) based on aneuploidy, categorizing it as high or low with a 10% cutoff.
Results: The analysis encompassed 239 LBs from 214 patients with relapsed or metastatic head and neck cancers. Of these, 59 LBs were from 57 patients showing stability or positive response (SD/R), while 180 were from 167 patients at diagnosis or disease progression (BL/PD). Notably, 156 (73%) were male, with a median age of 61 years. Within the cohort, 65% of LBs were from patients with squamous cell carcinomas (SCC), 15% adenoid cystic carcinomas (ACC), and 20% other histologies mainly adenocarcinomas. The anatomical distribution included 59 LBs from salivary gland (SG) cancers, 49 oropharynx (OP), 48 oral cavity (OC), and others including larynx, hypopharynx, sinus and nasopharynx. Among LBs performed at BL/PD, 72% were informative, while only 36% were so at SD/R. The proportion of informative biopsies varied across anatomical sites. For SCC, TP53 mutations were most prevalent (71%), followed by TERT and PIK3CA variants, and FGF19 and FGF3 amplifications. ACCs showed NOTCH1 mutations (6/19, 32%) as the most common, followed by TP53 and various other variants. In the entire cohort, clonal hematopoiesis-related variants were identified, with 40% showing at least one of DNMT3A, CHEK2, or ASXL1. Patients with low TF at BL/PD exhibited significantly improved overall survival (21.6 vs. 7.6 months, HR 0.35, 95% CI 0.23 - 0.53, $p < 0.0001$), consistent across subgroups except for OP.Conclusion: This study demonstrates the feasibility of liquid biopsy in HNSCC and rare head and neck tumors, providing valuable therapeutic and prognostic insights. The findings underscore the potential of liquid biopsy as a valuable tool in clinical decision-making for head and neck cancer patients.

#2415 Resistance to immune checkpoint inhibitor (ICI) therapy in metastatic melanoma is revealed by deep circulating tumor DNA tracking in concert with tumor immune profiling.

C. W. Abbott[1], L. Keller[2], I. Heidrich[3], J. Kott[3], G. Geidel[3], D. J. Smit[3], R. Simon[3], S. Schneider[3], J. Pugh[1], S. M. Boyle[1], R. O. Chen[1], K. Pantel[3], C. Gebhardt[3];

[1]Personalis, Inc., Fremont, CA, [2]IUCT Oncopole, Toulouse, France, [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Monitoring clinically actionable and emerging mutations in circulating tumor DNA (ctDNA) may be crucial for guiding treatment, but adoption has been slow due to the narrow scope and reproducibility of current approaches. Here, we investigate melanoma patients receiving ICI over several years, beginning with extensive tumor mutational and immune profiling followed by deep, whole-exome ctDNA monitoring.Here, 66 plasma samples from 23 advanced stage melanoma patients that were collected throughout ICI treatment (up to 40 months) were profiled using the NeXT Liquid Biopsy® platform (NeXT LB) . NeXT LB monitors exome-wide ctDNA by leveraging a patient's tumor, PBMCs and plasma samples, detecting both tumor-derived and emerging mutations. In addition to ctDNA tracking, we also used the ImmunoID NeXT Platform® to immunologically profile tumor tissue; including gene expression quantification, HLA profiling (typing, mutation, and loss of heterozygosity), T-cell receptor and tumor microenvironment profiling, and neoantigen prediction. ctDNA dynamics and tumor immunity were correlated with clinical outcome. Patients who progressed had lower tumor mutational burden (TMB, Mann-Whitney (MW); p=0.03), and lower neoantigen burden (MW; p=0.04). Responding tumors were enriched for interferon gamma and inflammatory signaling (Wald; adjusted p<0.01) and myeloid dendritic cells (MW; p=0.01), as measured by baseline RNA expression profiling. With an average coverage of 2260X SD +/-157, plasma samples yielded from 4 to 4081 variants. The number of on-treatment tumor variants detected in plasma predicted increased OS hazard (HR=2.95, Wald p=0.03; Kaplan-Meier (KM) p=0.0003) and progression hazard (HR=1.74, Wald p=0.04; KM p=0.0003). Overall, 10% (4277) of all variants were novel mutations observed only in the plasma. Novel variants were less likely to emerge in genes conferring sensitivity to ICI therapy (mixed-model; p<0.001). Dynamic shifts in allelic fraction between baseline and the first available on-treatment timepoint predicted increased OS hazard (HR=3.02, Wald p=0.05) and progression hazard (HR=2.90, Wald p=0.02). In ctDNA clonal phylogenies, 100% of BRAF and NRAS mutations belonged to the dominant clone. By combining immune and ctDNA features, a multivariable model predicted resistance to ICI treatment (log-likelihood p=0.002; c-index=0.89). Using a single liquid biopsy platform, we profiled tumor immunity and tracked existing and emerging ctDNA variants over the course of ICI treatment. We demonstrate that, even though counts of on-treatment ctDNA variants were sufficient for significant survival models, deep profiling of both tumor immunity and ctDNA dynamics provided deeper understanding of ICI resistance. Subsequent studies will determine if ctDNA-guided intervention can improve clinical outcomes.

#2416 Personalized minimal residual disease detection using tumor-derived structural variants in cell-free DNA.

B. R. McDonald[1], **K. L. Dennison**[1], A. L. Schussman[1], S. M. McGregor[1], B. A. Pockaj[2], M. Murtaza[1];
[1]University of Wisconsin-Madison, Madison, WI, [2]Mayo Clinic Arizona, Phoenix, AZ

We demonstrate development and technical validation of a novel approach for analysis of plasma circulating-tumor DNA (ctDNA) for residual disease detection and monitoring that offers improvements over existing technologies. ctDNA in blood can be leveraged to monitor treatment response, detect cancer recurrence, and inform treatment decisions for cancer patients. However, accurate detection and quantification of ctDNA is technically challenging due to low concentration of plasma DNA, especially in the adjuvant setting. Most current assays rely on interrogating multiple patient-specific point mutations to achieve exquisite limits of detection but struggle with polymerase errors, sequencing artifacts and limited conversion of input DNA. To overcome these challenges, we developed an approach called Structural Variant Enrichment and Normalization (SVEN) that targets patient-specific genomic rearrangements to achieve sensitive detection and quantification of plasma ctDNA. This method leverages intrinsic features of tumor-derived structural variants (SVs) to improve enrichment and confidence of detection at low tumor fraction through multiplexed PCR and amplicon-based next generation sequencing. To evaluate the assay, we performed whole genome sequencing of DNA from two breast cancer cell lines, as well as matched FFPE tumor and buffy coat samples from 21 early-stage breast cancer patients. We identified consensus SVs, and designed multiplexed SV-specific primers for each subject. We then conducted PCR amplification of cell-free DNA followed by sequencing, amplicon identification, and quantification. Analytical validation was conducted using 284 replicates of cell line dilutions from 1% to 0.003%, and 5 to 40 ng of input. We developed multiplexed assays targeting 25 and 32 SVs across two cell lines, and 3 - 43 SVs across breast cancer patients (median 23 per patient). 91% and 42% of PCR targets were successfully validated for cell lines and FFPE samples respectively. Cell line dilutions demonstrated a sensitivity of 89% at 0.003% tumor fraction with 10 ng input or more. Tumor fractions measured using SVEN agreed with known values (R^2 = 0.989). Application of validated panels to patient plasma samples and tumor/germline dilutions is ongoing. SVEN is a novel approach for tumor-guided ctDNA detection and quantification with potential relevance for residual disease detection. On-going studies are investigating the performance of this approach for ctDNA detection in patients with early and locally advanced breast cancer treated with neoadjuvant therapy.

#2417 Detection and quantification of site-specific DNA methylation from liquid biopsies as a pharmacodynamic biomarker of OTX-2002, a novel MYC-targeting epigenomic mRNA therapeutic.

J. Chen, W. Senapedis, S. Siecinski, E. Figueroa, A. Katz, S. Mildrum, Y. E. Wang, H. Belaghzal, K. Gallagher, G. Hodgson, C. W. O'Donnell, T. G. McCauley; Omega Therapeutics, Cambridge, MA

Omega Therapeutics has developed a novel platform of programmable epigenomic mRNA medicines capable of modifying chromatin state to specifically tune gene expression at the pre-transcriptional level. Epigenomic controllers (ECs) unlock targets that have been historically considered "undruggable," with one of the most elusive being the *MYC* oncogene. A direct MYC-targeting anti-cancer agent has previously remained intangible, largely due to the absence of a drug binding pocket and tight autoregulation. A clinical trial is underway (MYCHELANGELO, NCT05497453) to investigate pre-transcriptional inhibition of *MYC* with OTX-2002 in patients with hepatocellular carcinoma (HCC). OTX-2002, a first-in-class mRNA therapeutic delivered via lipid nanoparticles (LNP), encodes two proteins that durably modify chromatin, in part, through CpG DNA methylation at the *MYC* locus. Using both liquid and solid biopsy sampling from *in vivo* studies, we investigated whether target engagement for OTX-2002 could be assessed by *MYC* methylation.

Detection of DNA methylation has long held promise as an oncology biomarker given its functional roles in various cancer types and the potential signal afforded by methylated CpGs. Indeed, DNA methylation has been shown to serve as a robust analyte in liquid biopsy-derived multi-cancer early detection (MCED) and minimal residual disease (MRD) tests that have recently been utilized in the clinic. Many of these platforms are founded on complex models that leverage methylation signals across >1 million CpGs that can span tens of megabases of genomic space. We faced a distinct challenge when compared to these MCED/MRD tests in developing a pharmacodynamic methylation assay for OTX-2002 as the target region consists of just a few kilobases. With a tissue specific LNP delivery system, ultra-high sensitivity was required to identify rare ctDNA events from the larger cfDNA population.

To this end, we designed a minimal hybridization/capture panel that targeted ~50 kb of genomic space, effectively allowing for ultra-deep methylation sequencing of *MYC*. When this technique was paired with enzymatic (EM) conversion for methylation detection and supported by an analysis pipeline focused on epiallele identification, this assay was able to detect methylation down to the theoretical limit in a dilution series of control genomic DNA, 1 in 10^4 copies of *MYC*. This degree of sensitivity translated to successful preclinical detection of on-target methylation by OTX-2002 from DNA extracted from plasma samples collected from mice-bearing human HCC xenografts. Overall, we present a non-invasive and exquisitely sensitive method of assessing target engagement and site-specific pharmacodynamic activity of a novel epigenomic medicine that can be directly translated to the clinical setting.

#2418 Copy number variation status of DNA in extracellular vesicles as novel biomarkers of high-grade serous ovarian carcinoma.

R. Uekusa[1], A. Yokoi[1], K. Yoshida[1], J. Matsuazki[2], Y. Yamamoto[3], H. Kajiyama[1];

[1]Nagoya Univ. Graduate School of Medicine, Nagoya, Japan, [2]Keio University Faculty of Pharmacy, Tokyo, Japan, [3]National Cancer Center Research Institute, Tokyo, Japan

Objective: Ovarian cancer is a gynecologic malignancy with a dismal prognosis due to the lack of accurate methods for early diagnosis methods and effective therapies. High-grade serous ovarian carcinoma (HGSOC) is the most common subtype and copy number variations (CNVs) are the dominant genomic events in HGSOC. Extracellular vesicles (EVs) circulate in body fluids and carry pathological genomic information positively. In this study, we evaluated the significance of EV-DNA as novel biomarkers for HGSOC patients.

Methods: A total of 124 samples from HGSOC patients and cell lines were analyzed. EVs were isolated using the ultracentrifuge method. Comprehensive CNV statuses were analyzed by whole genome sequencing (WGS) and SNP array. In reference to the Ovarian Cancer Moon Shot database, 30 dominant CNVs in HGSOC were selected as dominant targets for analysis by droplet digital PCR (ddPCR). For predicting the response to PARP inhibitors, HGSOC patients who were treated with olaparib were collected, and DNA was extracted from FFPE tissue at the time of surgery.

Results: NTA assays and cryo-electron microscopic analyses showed that the EVs were successfully isolated from all samples. Both WGS and SNP arrays detected correlating CNVs in cell-DNA and EV-DNA for cell lines, and in tissue-DNA and EV-DNA in ascites for patients. The CNV status was also accurately measured by ddPCR. Copy numbers of *RAD51*, *BRCA1*, *AKT2*, *CCNE1*, and *MSH6* were significantly higher in malignant tissue than in benign tissue ($p<0.0001$, $p<0.0001$, $p=0.0012$, $p=0.002$. $p=0.0328$, respectively), and were detectable in EV-DNA from ascites. Additionally, the amount of DNA in malignant ascites was significantly higher than in benign ascites ($p=0.016$), and increased DNA in ascites itself suggested the presence of malignancy. Furthermore, EV-DNA more accurately reflected the CNV status of tumor DNA than cell-free DNA in ascites. Regarding the prediction of PARP inhibitor response, the CNV status in EV-DNA from patients who were treated with olaparib, a PARP inhibitor, demonstrated a marked difference between responders and non-responders. The equation calculated based on the combination of six genes (*RB1*, *GABRA6*, *CTNNB1*, *MYC*, *RAD51*, *BARD1*) could predict the response to olaparib (AUC: 1.0). The selected genes were validated in vitro using EV-DNA, and responders could be identified using the prediction equation calculated from CNV status of the selected genes in EV-DNA from ascites.

Conclusion: CNV status of EV-DNA was correctly evaluated and can serve as novel diagnostic and prognostic biomarkers for HGSOC.

#2419 Personalized longitudinal ctDNA monitoring is useful for biomarker in head and neck squamous cell carcinoma.

R. Kogo, T. Manako, T. Nakagawa;
Kyushu University, Fukuoka, Japan

Introduction: There is no established and useful tumor biomarker to evaluate treatment response and predict early locoregional and distant metastatic relapse in head and neck squamous cell carcinoma (HNSCC). Circulating tumor DNA (ctDNA) has a potential for detecting minimal residual diseases (MRDs). However, the absence of specific hotspot mutations in most HNSCCs makes ctDNA-based studies difficult in HNSCC. As a novel biomarker, we investigated whether individualized ctDNA analysis could help monitor and predict treatment response and relapse in HNSCC.
Methods: Thirty-two HNSCC patients were enrolled in this study. Twenty-two patients received radical resection and 10 patients were received radical irradiation as initial curative treatment. We collected tumor tissues and paired PBMCs (peripheral blood mononuclear cells) before treatment. Furthermore, we collected serial plasma samples for ctDNA analysis. To identify tumor specific individualized mutation, we isolated DNA from tumor tissue and PBMC and performed mutation analysis using custom SCC panel with frequent altered 31 genes (all exon coverage). We defined tumor-specific mutated genes per patient with variant allele frequency (VAF) >10 % and total coverage >100 as ctDNA candidate genes and performed ctDNA analysis using dPCR. We generated mutation specific primer-probe for droplet digital PCR (ddPCR), quantified the amount of ctDNA in plasma and compared ctDNA level with clinical data.
Results: For mutation analysis, most frequent mutated gene was *TP53* (21/32, 65.6%). Longitudinal ctDNA was monitored in a total of 24 cases. In 13 cases, ctDNA tested positive again or did not test negative, and all 13 cases had a residual tumor or relapsed after initial treatment. In 11 cases, after initial treatment, ctDNA remained negative and patients were alive without recurrence. Our cohort included 6 patients in whom it was possible to monitor ctDNA during chemotherapy in recurrent metastatic HNSCC cases. ctDNA alterations correlated well with clinical treatment response in four cases, but not in two cases. Patients who remained negative for ctDNA during follow-up after initial treatment (n=11) had a significantly better prognosis than those who reverted to ctDNA positivity (n=13, $P < 0.0001$).
Conclusion: Custom SCC panel is useful to detect more tumor specific mutation in HNSCC patients. Detection of ctDNA using next generation sequencing and digital PCR is promising strategy capable of monitoring in HNSCC patients. However, this method is not useful in all HNSCC, and there is room for improvement in the selection of ctDNA candidate genes.

#2420 Evaluating circulating tumor DNA (ctDNA) as a prognostic biomarker utilizing a tissue-free epigenomic assay in early-stage triple negative breast cancer (TNBC).

F. O. Ademuyiwa[1], C. X. Ma[1], K. Weilbaecher[1], R. Suresh[1], L. Peterson[1], R. Bose[1], N. Bagegni[1], C. E. Rigden[1], A. Frith[1], K. Clifton[1], A. Davis[1], D. Dustin[2], M. Cai[2];

[1]Washington University School of Medicine in St. Louis, Saint Louis, MO, [2]Guardant Health, Palo Alto, CA

Background: ctDNA has shown promise as a prognostic biomarker in early-stage solid tumors. Current breast cancer clinical guidelines do not recommend routine screening for metastatic disease outside of clinical features suggestive of disease recurrence. The detection of ctDNA may be a useful biomarker for the management of early-stage cancer patients to identify patients who are at high risk of recurrence.

Methods: Patients with stage II or III TNBC undergoing neoadjuvant docetaxel and carboplatin chemotherapy on a clinical trial (NCT02124902) followed by surgery were included in this study. Blood samples were prospectively collected prior to, during, and after completion of neoadjuvant chemotherapy, post-surgery, and throughout pre-specified surveillance time points (every 6 months for 5 years). Plasma samples were analyzed using Guardant Reveal powered by Infinity, a tissue-free, multiomic assay that interrogates differentially methylated regions of DNA using an applied bioinformatics filter optimized to detect breast cancer DNA from non-cancerous cell-free DNA and estimate quantitative tumor fraction. Samples were sequenced and resulted blinded to the patients' clinical data.

Results: A total of 120 patients with evaluable plasma samples were included in this study. At baseline prior to chemotherapy, ctDNA was detected in 75% (54/72) of patients. Baseline ctDNA detection was higher in node-positive cancers (100%; 29/29) versus node-negative cancers (58%; 25/43; p<0.0001). ctDNA quantity was higher in node-positive cancers (p<0.0001), and in stage III versus stage II disease (p=0.0179). During surveillance follow-up, the sensitivity for detecting any distant metastatic recurrence was 71% (5/7). Among patients with samples drawn within one year of recurrence, the sensitivity for detecting distant recurrence was 83% (5/6) with a sample-level specificity of 98% (186/190) and a patient-level specificity of 94% (63/67). ctDNA detection prior to recurrence had a median lead time of 5.0 months (range, 4.6-5.6). Notably, the detection of ctDNA during follow-up was associated with worse recurrence-free (HR 23.3, 95% CI 2.70-201, p<0.0001) and distant-recurrence free survival (HR 29.3, 95% CI 1.86-461, p<0.0001).

Conclusions: ctDNA is detected with a tissue-free MRD assay with high sensitivity and specificity for distant recurrence in early-stage TNBC. Furthermore, the presence of ctDNA during follow-up is a prognostic indicator. Additional prospective studies are needed to assess the clinical utility of ctDNA monitoring in early-stage TNBC.

#2421 Targeted and low-pass whole genome sequencing of cerebrospinal fluid circulating tumor DNA for the diagnosis and monitoring of pediatric, adolescent and young adult CNS tumors.

I. Burns[1], L. Nobre[2], Y. Nakano[1], M. Ku[3], M. Johnson[3], J. Sheth[4], L. Negm[4], C. Cacciotti[5], M. Rana[3], R. Yuditskiy[3], A. Bondoc[3], R. Siddaway[3], U. Tabori[1], C. Hawkins[1];

[1]The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]The Hospital for Sick Children, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada, [5]University of Western Ontario, London, ON, Canada

Molecular analysis of CNS tumors is essential to their diagnosis and guides individualized treatment for patients, but tissue biopsy of primary and/or relapsed lesions to allow for this characterization often carries intolerable risk. The analysis of genetic material in cerebrospinal fluid (CSF), known as liquid biopsy, can allow for minimally invasive tumor identification and diagnosis. Furthermore, liquid biopsy can serve as a more sensitive test for residual disease than imaging or cytologic analyses. We aimed to implement CSF liquid biopsy at Canada's largest pediatric hospital. >150 CSF samples were collected from CNS tumor patients with a median age of 9. The most common tumor types were low-grade gliomas (40%), high-grade gliomas (21%) and medulloblastomas (MB) (17%). The majority were collected via lumbar puncture (46%), external ventricular drain (24%) and intraoperatively (22%). The most frequent collection times were diagnosis (53%) and progression/relapse (28%). Cell-free DNA was extracted, and circulating tumor DNA was analyzed using low-pass whole genome sequencing and a targeted hybridization capture glioma gene panel for select cases. Pathogenic mutations and copy number alterations (CNA) were called using an in-house bioinformatics pipeline. Somatic alterations were detected in 57% of samples from patients with pathologically confirmed CNS tumors. CNAs were identified in 5/7 MB patients at the time of pre-treatment staging lumbar puncture. We also detected CNAs in several MB patients during treatment and at progression/relapse, including a patient with disseminated MB who was mid-induction chemotherapy with 1 suspicious cell in their CSF, highlighting our ability to detect minimal residual disease. Among samples with no previous biopsy, we identified tumor DNA in 29%, often providing diagnostic clarity and guiding management. For example, we identified a targetable FGFR1 N546D missense mutation in a patient with an unbiopsied suprasellar lesion. We also diagnosed recurrent MB in a patient 6 years off treatment with a new ambiguous nodule in their tumor bed by detecting an isochromosome 17q CNA. Overall, our liquid biopsy platform is feasible and can yield clinically impactful results. Next steps include refining our assays to increase their sensitivity and systematically evaluating our platform's efficacy for monitoring response to treatment and tumor surveillance.

#2422 Liquid biopsy approaches for monitoring metastatic pancreatic cancer in immunotherapy treated patients.

C. A. Hruban[1], I. Chen[2], D. C. Bruhm[1], S. Koul[1], J. Yao[1], S. Theile[2], K. Boyapati[1], N. A. Vulpescu[1], A. Annapragada[1], L. Ferreira[1], S. Cristiano[1], Z. H. Foda[1], V. Adleff[1], J. Johansen[2], J. Phallen[1], R. B. Scharpf[1], V. E. Velculescu[1];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark

Introduction: Pancreatic cancer has a poor prognosis especially when identified at advanced stages. Globally in 2020, >450,000 people died from the disease. For those with locally advanced or metastatic cancer, the standard of care treatment is chemotherapy. Preliminary studies show that some patients with advanced-stage disease respond to immune checkpoint blockade treatment. Determining response to therapy using imaging techniques can be challenging. There is a clinical unmet need for noninvasive approaches that can provide a real-time assessment of response to therapy in these patients. We evaluated two methods for assessing response to therapy using circulating cell-free DNA (cfDNA) in patients with metastatic pancreatic cancer treated with immune checkpoint inhibition and radiation as part of the CheckPAC study (NCT02866383).

Methods: For all patients with available samples (n=40), we evaluated one pre-treatment blood draw and one on-treatment blood draw (26-65 days after treatment start). We extracted cfDNA from each sample and performed low-coverage 1-2x whole genome sequencing (WGS). We evaluated tumor and matched buffy coat for the 34 patients who had > 10% tumor purity using WGS with at least 60x and 30x coverage, respectively. We compiled the mutated bases in the tumor genome and examined these positions in the cfDNA. We counted the number of mutant observations from cfDNA WGS and divided them by the total number of observations at these bases to calculate whole-genome mutant allele frequency (MAF). We categorized responders based on >30% drop in MAF from baseline. In a tissue independent approach, we detected changes in genome-wide cfDNA fragmentation patterns using the DNA evaluation of fragments for early interception (DELFI) approach. We evaluated survival using DELFI scores of on-treatment samples. Samples were designated DELFI high (above median) or DELFI low (below median.) Log-Rank tests were used to compare survival curves.

Results: For the mutation based approach, molecular responders (n=7) had a median progression free survival (PFS) of 485 days compared to 57 days for non-responders (n=9) (p=0.02). Molecular responders had a median overall survival (OS) of 694 days compared to 200 days for non-responders (p=0.062). Patients with DELFI low scores after therapy (n=14) had a longer median PFS than those with DELFI high scores (n=14) (307 days versus 70 days, respectively) (p=0.013). DELFI low patients also had a longer median OS than DELFI high patients (627 vs 158 days, respectively) (p<0.0001).

Conclusions: These analyses suggest that WGS mutation-based and fragmentation cfDNA approaches can identify individuals with metastatic pancreatic cancer who respond to immune checkpoint inhibition. Incorporation of these molecular methods for evaluation of tumor burden may provide information for patient-physician decision making to improve patient quality of life.

#2423 Linking liquids: cfDNA in urine and plasma as informative allies in metastasized prostate cancer.

T. Moser, A. Eberhard, M. J. Moser, L. Glawitsch, S. Hammer, G. Vlachos, I. Lazzeri, L. Ziegler, E. Bauernhofer, N. Monsberger, J. B. Geigl, T. Bauernhofer, E. Heitzer;
Medical University of Graz, Graz, Austria

Background: Liquid biopsy has become a cornerstone of non-invasive cancer diagnostics. While the major analyte for detecting and monitoring tumors has been blood, examining other body fluids, such as urine or saliva, is increasingly shifting into focus. Urine is a particularly valuable specimen due to its easy accessibility. Particularly in urologic cancers, the sensitivity of liquid biopsy could be improved by proximal sampling. While there is already evidence that cell-free DNA from urine (ucfDNA) can add to the diagnostic sensitivity in renal and bladder cancer, less is known about ucfDNA in prostate cancer patients. In this study, we aimed to determine the presence, levels, and potential clinical applications of ucfDNA in patients with metastatic prostate cancer. Moreover, we compared the findings with information obtained from plasma cell-free DNA (cfDNA).
