RESULTS: Human $CD8^+$ T cells, stimulated in the presence of a Cbl inhibitor, demonstrated a concentration-dependent increase in activation hallmarks including cytokine secretion (IL-2, IFN-γ and granzyme B), proliferation, and the presence of highly polyfunctional cells. Furthermore, using serially stimulated $CD8^+$ T cells with reduced overall activity, Cbl inhibition showed a marked enhancement of IFN-γ production and cytotoxicity compared to controls upon re-stimulation. We then used an antigen-specific T cell assay where OT-I splenocytes were stimulated by peptides with optimal or reduced TCR affinities, Cbl inhibition produced significantly higher IFN-γ levels with all peptides relative to controls demonstrating that Cbl inhibition can increase the response of T cells to sub-optimal stimulation. Using mouse CT26 and MC38 tumor models, Cbl inhibition was able to significantly enhance tumor control in combination with α-PD-1 and as a monotherapy in CT26 tumors. Notably, a greater number of tumor antigen-specific cytotoxic T cells were found in Cbl inhibitor-treated tumors. Higher expression levels of the co-stimulatory molecule CD226 and the TCR in these anti-tumor cells were also observed, demonstrating the unique biology of Cbl inhibition in enhancing anti-tumor responses. Finally, Cbl inhibition had no effect on the growth or survival of cancer cells *in vitro* consistent with the notion that enhanced tumor control was driven by immune activity.

CONCLUSIONS: Altogether, these data demonstrate that pharmacologic Cbl inhibition robustly enhances T cell activity *in vitro* and *in vivo* and provide a mechanistic rationale for targeting Cbl-b/c-Cbl to amplify anti-tumor immune responses.

#4043 Nanoparticle-mediated combination therapy to synergistically harness Type I interferons and senescence in the pancreatic tumor microenvironment.

P. Atukorale[1], M. Ruscetti[2], L. Chibaya[2], C. Lusi[1], K. DeMarco[2], G. Kane[1], M. Brassil[1], C. Parikh[2], K. Murphy[2];
[1]University of Massachusetts - Amherst, Amherst, MA, [2]University of Massachusetts Chan Medical School, Worcester, MA

We seek to combine a unique innate immunomodulatory nanoparticle (NP) system with RAS inhibitors for a multi-faceted therapy that mitigates the formidable drug delivery challenges in pancreatic ductal adenocarcinoma (PDAC). PDAC has quickly risen to the third most deadly cancer largely due to its fibrotic, desmoplastic, and immunosuppressive tumor microenvironment (TME) that limits delivery and efficacy of chemo- and immunotherapeutics. We have engineered unique lipid-based NPs that co-encapsulate agonists of the Stimulator of Interferon Genes (STING) and Toll-like Receptor 4 (TLR4) pathways. NPs can be safely delivered in the systemic blood circulation to achieve TME deposition, uptake by innate antigen-presenting cells (APCs), and robust, synergistic production of Type I interferons by dual STING/TLR4 activation. Here, we hypothesize that combination therapy of proinflammatory NPs with tumor senescence-inducing RAS inhibitors, tremetinib and palbociclib, will not only augment $CD8^{\pm}$ T cell recruitment to the TME but enhance their sustained activation by mitigating local immunosuppression. In mice bearing orthotopic transplant *KPC* tumors or *KPC* GEMMs, combination NP/inhibitor treatment promoted significant NP delivery to tumors, APC and natural killer (NK) cell activation, and $CD8^{\pm}$ T cell-mediated clearance, compared to monotherapies and untreated controls. Unexpectedly and strikingly, these studies also showed that, besides innate immune cells, combination therapy also promoted Type I interferon and other proinflammatory cytokine production by PDAC tumor cells, which are otherwise notoriously unresponsive to current state-of-the-art treatments. Further, in *KPC* GEMMs, 25% of mice exhibited apparent complete responses following combination treatment, which, to our knowledge, is challenging to achieve in this model. Current studies include the mechanistic elucidation of immune- and tumor-intrinsic factors that govern efficacy of our combination therapy. In conclusion, these findings strongly corroborate the use of this NP-based system as a platform therapy for similar drugs and across other aggressive cancers. They also strongly make the case for the rational design of combination therapies to achieve synergistic therapeutic outcomes with minimal systemic toxicities.

#4044 Potentiated antitumor activity of poly-γ-glutamic acid combined with anti PD-L1 blockade on murine models of colorectal cancer.

Jae-Pyung Jang, Chan-Hee Yoo, Kyung-Soo Hahm, Do Young Lee, Young-Chul Park, **Jae Chul Choi**

BL Corporation, Yongin, Gyeonggi-do, Korea, Republic of

Objective: Immune checkpoint inhibitors(ICIs) have been shown to be key role in cancer therapy. Especially, antibodies targeting programmed cell death ligand1(PD-L1) promoted T cells to activate immune response against cancer cells. However, the current ICIs still have insignificant to motivate effective antitumor immunity by blocking PD-1/PD-L1 pathway and the regulatory network of PD-L1 by cytokines in the tumor microenvironment remains to be uncovered. Previously, we have reported the anti-cancer effects of combination treatment with a natural product, poly-γ-glutamic acid(γ-PGA), and PD-1 blockade. Now, we show that combination therapy with anti PD-L1 and γ-PGA can overcome the limits of ICIs and enhance anticancer effect in murine colorectal cancer.
Design: *In vivo* efficacy studies were performed by intraperitoneal injection of antibody targeting PD-L1 and oral administration of γ-PGA in C57BL/6 model transplanted with mouse tumor cell lines. Systemic changes in immunophenotype was measured by tumor volume size and body weight. The splenocyte was isolated from mice and the populations of myeloid-driven suppressor cells(MDSCs) and CD4/CD8 T cells were analyzed by FACS. Also, the significant cytokines activated by T- cell, IFN-γ and IL-2, were measured by ELISA.
Results and Conclusions: In murine model of colorectal cancer, γ-PGA and anti PD-L1 blockade combination therapy significantly improved anti-tumor activity compared with single agents. In addition, tumoral infiltration of $CD8^{\pm}$ T cells and IFN-γ productions were increased by γ-PGA, and its antitumoral activity was attenuated by antibody-mediated depletion of these cells, indicating that g-PGA suppressed tumor growth in a CD8 T cell-dependent manner. Therefore, our results suggest that γ-PGA promote ICI-mediated antitumor responses by the transformation of "cold tumors" into “hot tumors”

#4045 Dependence of human immune cell type, and impact of IL-7R or TLR1/2 agonism, upon trastuzumab-mediated ADCC.

M. Bryant, G. Tut, N. Harrison, E. Welsh, I. Morano, A. Kaur, A. Pegg, H. Chan, Z. Li, J. Cowley, C. Brady, J. Gordon, N. Barnes, O. Qureshi;
Celentyx Ltd, Birmingham, United Kingdom

Targeting of tumors over-expressing HER2 using trastuzumab provides clinical benefit for patients by inhibiting HER2 signalling and enhancing immune responses against the tumor by antibody-dependent cell-mediated cytotoxicity (ADCC). Cytokines such as IL-7 augment cytotoxic anti-viral responses through up-regulation of FasL, whereas TLR1/2 agonists enhance T cell cytotoxic responses but may also promote tumor cell survival. We therefore investigated the ability of IL-7R or TLR1/2 agonism to enhance trastuzumab-mediated ADCC.

We first determined the contribution of various human immune cell subsets (e.g. monocytes, T cells, NK cells) to deliver ADCC of human tumor cells using a live high-content imaging assay in both 2D and 3D formats. Our results demonstrate that trastuzumab evoked immune cell dependent, concentration-dependent killing of tumor cells that exhibited some differential sensitivity dependent upon the cell culture format. We then tested trastuzumab-mediated killing in the absence or presence of IL-7R or TLR1/2 agonism, and noted evident donor and immune cell dependent modulation of the cytotoxic response. Modulation of this cytotoxic response was associated with differential immune cell marker expression when analysed by flow cytometry.

Our findings provide mechanistic insight into trastuzumab-mediated ADCC and highlight how cytokine receptor and TLR pathways may modulate this response.

#4046 Orally active PD-L1 inhibitor MAX-10181 in combination with temozolomide effectively prolonged survival in GBM animal model study.

Y. Wang[1], Z. Feng[1], Q. Zhao[1], W. Zhang[2], Y. Jiang[2], Y. Huang[2], C. Qi[2], C. Zhang[2];
[1]Maxinovel Pharmaceutical, Inc., Shanghai, China, [2]Wenzhou Medical University, Wenzhou, China

Treatment of glioblastoma (GBM) with PD-1/PD-L1 immuno therapy is highly challenging due to the limited brain blood barrier (BBB) penetration of the marketed antibody drugs. During the past several years, we have successfully developed orally active, BBB penetrating, small molecule PD-L1 inhibitor MAX-10181 which is in the phase II clinical development. To demonstrate the utility of PD-1/L1 immuno therapy for the treatment of GBM, we completed the study of MAX-10181 in combination with Temozolomide (TMZ) in GL-261 animal model study. In this study, the combination of MAX-10181 with TMZ effectively prolonged the survival by 50% in comparison with TMZ single therapy. Details of this study will be reported in this meeting.

#4047 Unraveling synergistic therapeutic strategies involving FAK inhibition and immunotherapy using anti-PD1 antibody in KRAS and LKB1-driven lung cancer.

J. Koo, C. Tucker-Burden, M. Roy, C. Huang, W. Zhou, M. Gilbert-Ross, H. Fu, S. S. Ramalingam, A. I. Marcus;
Emory University, Atlanta, GA

Lung cancer presents a global health challenge demanding innovative preclinical models forresearch and therapeutic advancement. Genetically engineered mouse models (GEMMs) have seenremarkable growth in complexity and application over the past two decades. Our work leveragesthese models and is specifically designed to address the pressing need for effectiveimmunochemotherapies in the context of KRAS and LKB1 (KL) mutant lung adenocarcinoma,which shows resistance to most immunotherapies. Our study centers around a preclinicalsyngeneic orthotopic mouse model we developed using mouse lung and metastatic tumor cell linesderived from KL-GEMM. This model, optimized to mimic human lung cancer closely, providesan ideal platform for exploring the intricate interplay between the immune system and tumorprogression. Furthermore, we have previously shown the LKB1 mutant cell lines and tumormodels are uniquely sensitive to FAK inhibitors, and therefore we wanted to test whether thecombination of a FAK inhibitor with anti-PD1 therapy can improve sensitivity. The combinatoryadministration of FAK inhibitor (VS-6063) with anti-PD1 mAb synergistically increased anti-tumor response and survival outcome compared with single-agent therapy in the KL-mediatedsyngeneic orthotopic lung cancer model. By using GEMM-derived syngeneic cell lines, we haveevaluated the potential for creating innovative immunochemotherapies, customized for KL co-mutant lung adenocarcinomas with promising clinical potential. Furthermore, using this modelenables a deeper understanding of the KL mutant disease's pathogenesis, the impact of sex-biasedcancer development, and the assessment of novel immunochemotherapy treatment strategies in theKL genetic sub-type of lung adenocarcinoma.

#4048 Comparative effects of SOS1 inhibitor with IL-6 blockade and their combination on Kras mutant lung cancer.

Katherine E. Larsen, Maria J. Arredondo Sancristobal, Melody Zarghooni, Avantika Krishna, Maria T. Grimaldo, Nastaran Karimi, Arnav Gaitonde, Michael J. Clowers, Seyed Javad Moghaddam

UT MD Anderson Cancer Center, Houston, TX

Despite recent advances in treatment, lung adenocarcinoma (LUAD), particularly harboring *Kras* mutations, is still the leading cause of cancer mortality. We and others have previously shown that Kras mutant LUAD development and progression is associated with intrinsic inflammatory characteristics driven by epithelial NF-κB activation, increased levels of IL-6 (which is transcriptionally regulated by NF-κB), and activation of the IL-6-responsive transcription factor STAT3. We further demonstrated that IL-6 blockade suppresses lung tumorigenesis by reducing tumor-associated immunosuppressive myeloid populations and induction of a T cell-mediated anti-tumor response. The recent discovery of a novel SOS1-targeting compound (BI-3406) that selectively inhibits the KRAS-SOS1 interaction and leads to anti-proliferative activity has opened up the possibility to more efficiently inhibit Kras mutant lung cancer. Accordingly, in this study we used a mouse model of KRAS mutant LUAD (CC-LR) to compare the therapeutic effects of BI-3406, IL-6 blockade, and MEK inhibitor (trametinib). We also tested whether inhibiting IL-6 driven pro-tumor immune response would provide a synergistic/additive response and increase the tumor inhibitory effect of either BI-3406 or Trametinib. Eight cohorts of 14-week-old female mice were treated with either anti-IL-6 antibody, trametinib, or BI-3406, or their combinations for 4 weeks, and their tumor burden was compared at the end of study. We observed a significant reduction in tumor multiplicity and tumor area in response to all monotherapies, with the highest effect in the trametinib treated cohort. Neither combination therapy led to decreased tumor burden over either of the monotherapy regimens in our model. However, we observed an increase in T helper 1 and CD8 T expressing IFNγ cell populations in the cohort treated with Trametinib and anti-IL-6 Ab combination. In addition, using qPCR analysis of RNA extracted from the whole lung we found a higher expression of IFNγ along with a reduced expression of IL-10 in the cohort treated with BI-3406 and anti-IL-6 Ab combination. This suggests that these combinations may have the potential to improve the anti-tumor immune responses. Hence, we conclude that further adjustment of the treatment regimen (doses, interval, duration) may allow to obtain improved anti-tumor efficacy with these combinations. Overall, this study provides a new research perspective for the improvement of currently available treatment modalities for patients with Kras mutant lung cancer that could be further explored preclinically.

#4049 The beta-carboline Harmine sensitives microsatellite stable colorectal cancer mouse model to anti-PD-1 through upregulating MHC-I dependent antigen presentation machinery and improving the infiltration of CD8 T cells into the tumor microenvironment.

Ruize Gao[1], Kris Van Moer[1], Coralie Pulido[2], Anais Oudin[2], Diane Murera[1], Teresa L. Ramos[1], Margaux Poussard[1], Andreas Schlapfer[3], Annette Ives[3], Christian Auclair[3], **Bassam Janji**[1]

[1]Department of Cancer Research - Tumor Immunotherapy and Microenvironment (TIME) Group, Luxembourg Institute of Health, Luxembourg City, Luxembourg,[2]Department of Cancer Research - Animal Experimental Core facility, Luxembourg Institute of Health, Esch-sur-Alzette, Luxembourg,[3]AC Bioscience SA, Epalinges, Switzerland

Colorectal cancer (CRC) is the most common gastrointestinal cancer and the third leading cause of cancer-related death in both sexes. Mismatch repair deficient/microsatellite instability-high (MSI) colorectal cancer patients benefit from immune checkpoint blockades (ICBs)-based immunotherapy; however, this benefit has not been translated into microsatellite stable (MSS) colorectal cancer. It has been proposed that the loss of major histocompatibility complex class I (MHC-I) in tumor cells limits the use of ICB in colorectal cancer. Harmine displays a number of biological and pharmacological properties affecting the immune response and tumor phenotype. Here, we assessed the impact of combining harmine, also referred to as ACB1801 molecule, on improving the responsiveness of ICB in the mouse MSS CRC model. Our results showed that combining ACB1801 significantly improves the therapeutic benefit of anti-PD-1 in the CT26 CRC mouse model by decreasing tumor growth and improving the survival of tumor-bearing mice. The improvement of anti-PD-1-based therapy by combining ACB-1801 was associated with a modification of the immune landscape of tumors as evidenced by an increase in the CD8+ T cells and a decrease in the Treg infiltrations into the tumor microenvironment. By profiling the cytokine/chemokine network, we showed that ACB1801 induced the expression and the release of the proinflammatory chemokine CXCL10 by CRC tumor cells *in vitro*, which could be responsible for driving CD8+ T cells to the tumor microenvironment. Mechanistically, we showed that ACB1801 increased the expression of MHC-I genes, including TAP1 and TAPASIN, and improved the antigen loading on MHC-I in CRC cells *in vitro*. Overall, our study highlights the value of combining ACB1801 and anti-PD-1 as a therapeutic opportunity to convert MSS colorectal cancer into an “immune hot” cancer, which may define the future treatment paradigm of colorectal cancer for which there is a great unmet need.

#4051 Optimizing breast cancer therapy by modulating oxygen consumption.

A. Assouvie[1], S. Budhu[1], M. Mane[2], M. Bah[1], J. Zurita[2], I. Serganova[1], S. Min[2], J. Koutcher[2], V. Ponomarev[2], J. Wolchok[1], T. Merghoub[1];
[1]Weill Cornell Medicine, New York City, NY, [2]Memorial Sloan Kettering Cancer Center, New York City, NY

Immune checkpoint blockade (ICB) has achieved great clinical responses in multiple cancers. However, only a subset of patients with triple negative breast cancer (TNBC), a highly hypoxic tumor, respond to ICB. In TNBC, the immune checkpoints PD-1/PD-L1 and adenosine receptor (A2aR) are often activated to escape anti-tumor responses. These two immune checkpoints are sensitive to hypoxia. We propose that blocking tumor oxygen consumption using deferiprone (DFP), phenformin (Phen) and metformin (Met) will improve the efficacy of PD-1/PD-L1 and A2aR blockade. We generated two mouse breast cancer cell lines (4T1 and E0771) expressing green fluorescent protein (GFP) fused to Firefly luciferase under the control of the hypoxia reporter element (HRE). This construct, which we called HRE/TGL, serves as a hypoxia reporter, with GFP expression and luciferase activity increasing in hypoxic conditions. To induce hypoxia *in vitro*, we used two approaches: 1) we incubated cells in a hypoxia chamber (3% oxygen), and 2) treated cells with cobalt chloride, which chemically mimics hypoxia by inducing the expression of the hypoxia master regulator HIF1α. Both 4T1-HRE/TGL and E0771-HRE/TGL cells exhibited increased GFP expression and luciferase activity within hypoxia conditions. We orthotopically implanted these cells into mice. We measured luciferase activity *in vivo* using the IVIS spectrum imaging system overtime after tumor implantation. We observed high luciferase activity in 4T1-HRE/TGL tumors. Next, we examined the effects of DFP, Phen and Met on cell hypoxic responses by performing immunoblotting against HIF1α and phosphorylated AMPK (p-AMPK) on 4T1 and E0771 cells. We observed that, unlike Phen or Met, DFP increased HIF1α and p-AMPK expression. Binding of HIF1 proteins to HREs is known to activate the expression of the HRE promoter. To confirm our results, we treated 4T1-HRE/TGL and E0771-HRE/TGL cells with low (10μM) or high (100μM) doses of the drugs *in vitro*. We observed that, while DFP increased GFP expression and luciferase activity, Phen had no consistent measurable effect. We observed similar results *in vivo*. Finally, we examined the effect of DFP, Phen and Met either alone or in combination with anti-PD-1 on tumor progression and survival in mice bearing 4T1 or E0771 tumors. Contrary to what expected, we did not observe better tumor control and survival after treatment with these drugs. In addition, DFP, Phen and Met failed to improve the anti-tumor effect of anti-PD-1 treatment in both TNBC models. Future experiments will focus on charactering the adenosine pathway *in vivo* in 4T1 and E0771 tumors and examine how drugs targeting A2aR and oxygen consumption (DFP, Phen and Met) influence the activation of immune cells within the tumor microenvironment and potentially combinate these two strategies to improve their anti-tumor efficacy.

#4052 Neutrophil recruitment and activation promotes cutaneous adverse effects with T cell immunotherapies.

D. Hirschhorn[1], L. Kraehenbuehl[1], S. Budhu[1], V. Estrada Navarro[1], L. B Mangarin[1], Y. Marouf[1], J. Ricca[1], B. Gasmi[1], O. De Henau[1], Y. Li[1], C. Cortez[1], H. Linda[1], I. Schulze[1], C. Liu[1], K. Panageas[2], M. Lacuoture[3], G. A. Rizzuto[1], M. Egeblad[4], J. D. Wolchok[1], T. Merghoub[1];

[1]Weill Cornell Medicine, New York, NY, [2]Memorial Sloan Kettering, New York, NY, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Johns Hopkins University, Baltimore, MD

Immune-based therapies that induce tumor regression are often accompanied by immune-related adverse events (irAEs) which can occasionally present with severe and lethal symptoms. Currently, there are no well-defined preventative approaches to uncouple anti-tumor immunity from irAEs. Currently approved immunotherapies include agents that activate T cell responses, such as antibodies blocking immune checkpoints and infusion of tumor-derived, T cell receptor-transgenic or chimeric antigen receptor-modified T cells. While the beneficial and toxic effects of T cell-based therapies in the clinic are being extensively explored, the precise mechanisms underlying their activity remain the subject of investigation. In this study, we treated preclinical models of established melanomas with tumor-specific adoptive CD4+ T cell transfer in combination with T cell co-stimulation via OX40 agonism or CTLA-4 blockade. We found that, despite adequate T cell stimulation, acute local inflammation plays an important role in tumor elimination and the manifestation of irAEs. While stimulated T cells are necessary for initiating a therapeutic response, activation of endogenous neutrophils constitutes an important and necessary effector mechanism for both tumor destruction and the development of irAEs. Extensive neutrophil extracellular traps (NETs) were associated with irAEs. Furthermore, melanoma patients treated with immune checkpoint blockade with skin rashes equivalent to irAEs found in mice showed increased survival and NETs in biopsies from both rashes and tumors. Our results bring forward a novel paradigm where T cells prime an anti-tumor immune response that is followed by an inflammatory effector mechanism provided by the innate immune system, resulting in both curative and undesirable side effects in mice and patients.

#4053 Targeting oxygen consumption with metformin and phenformin have differential effects on immune cells in the tumor microenvironment.

S. Budhu[1], A. Assouvie[1], M. Bah[1], S. Verma[1], I. Serganova[2], M. Mane[3], J. Zurita[3], J. Koutcher[3], V. Ponomarev[3], J. D. Wolchok[1], T. Merghoub[1]; [1]Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Memorial Sloan Kettering Cancer Center, New York, NY

T cell immune checkpoint blockade (ICB) has shown remarkable promise in melanoma and other cancers. However, most patients do not show clinical benefit. This is because tumors can activate multiple checkpoints and immunosuppressive pathways to evade anti-tumor immune responses. Inhibition of these immune suppressive mechanisms and immune checkpoints or repolarizing the tumor microenvironment (TME) to become more accessible to the immune system may be necessary for maximal therapeutic efficacy of immunotherapies. There is increasing evidence that tumor hypoxia can attenuate the antitumor immune response by promoting immune suppression and inhibiting direct killing by cytotoxic immune cells. We propose that blocking tumor oxygen consumption using drugs that target the mitochondrial complex I (phenformin and metformin) will enhance the efficacy of immunotherapies such as ICB in preclinical models such as B16 melanoma. In this study, we examined how low oxygen levels (hypoxia) influence T cell effector function such as cytotoxic activity and cytokine production in vitro. We co-cultured B16 melanoma cells in the presence of tumor specific T cells (Pmels) and incubated at 37ºC in either normoxia (~21% O2) or hypoxia (3% O_2) and assessed killing and intracellular cytokine production 24 - 48 hours later. We show that the ability of tumor antigen-specific T cells to kill tumor cells or make effector cytokine such as IFNγ and TNFα is significantly reduced in hypoxia settings. We also examined the effects of hypoxia targeting drugs (metformin and phenformin) on T cell priming and activation. When T cells were activated in the presence of each drug in vitro, there was enhanced expression of T cell activation markers (CD25, Granzyme B) as well as an increase in their differentiation into central memory T cells. We next determined whether these drugs could alter the TME in vivo by treating C56BL/6J mice bearing established B16 tumors with phenformin and metformin and then examine the effects on the immune system in the tumor, tumor draining lymph nodes and spleen by flow cytometry. We found that these three drugs have differential effects on both the innate and adaptive the immune system in the tumors and periphery. Finally, we tested whether these drugs could delay B16 melanoma growth in vivo as a monotherapy or in combination with anti-PD1. We found that while both drugs can significantly delay tumor growth as monotherapies, only metformin showed improved anti-tumor efficacy when combined with anti-PD-1 in vivo. These studies show that while both drugs target tumor oxygen consumption (via inhibition of complex I), and can delay B16 tumor growth in vivo, they have differential effects on the TME and will need further considerations when combining with immune based therapies such as ICBs.

#4057 Beyond IL-2: The promise of anti PD-1-attenuated IL-2 fusion protein in cancer immunotherapy.

S. Amar[1], Y. Liubomirski[1], E. Yeini[1], M. Monsonego[1], T. Weiss[1], G. Tiram[1], A. Katyal[1], O. Avramoff[1], A. Krinsky[1], K. Reshef[1], S. Dulberg[1], A. Kaminitz[1], D. Bar On[2], I. Ben Eliezer[2], O. Iancu[2], T. Taura[2], D. Wilson[2], P. Ayton[2], R. Satchi-Fainaro[1], **A. Madi**[1];
[1]Tel Aviv University, Tel Aviv, Israel, [2]Teva Pharmaceutical Industries Ltd., Tel Aviv, Israel

PD1$^{\pm}$ CD8$^{\pm}$ tumor-infiltrating T-cells have been at the forefront of cancer immunotherapies due to their antigen-specificity, cytotoxicity, proliferative capacity, and stem-like/memory properties. IL-2 is essential for T cell growth and proliferation, however, its systemic administration at a high dose was associated with intolerable toxicities, while low-dose treatment contradicted the intended therapeutic effect by activating regulatory T cells.To overcome the limitations of IL-2, we fused modified IL-2 sequences with reduced affinity for the murine IL-2 receptor to a PD1 antibody designed to target the PD1$^{\pm}$ T cells found in tumors. The resulting murine PD1 antibody-attenuated-IL-2 (mAnti-PD1-IL2Att) demonstrated similar IL-2 potency on PD1$^{\pm}$ cells as native IL-2, but diminished potency by orders of magnitude on PD1^{-} cells. The agent was furthermore designed to bind PD1 non-competitively with known PD1-blocking antibodies, so that it could be used in combination with them to achieve effective anti-tumor response. We demonstrated that mAnti-PD1-IL2Att exhibits potent anti-tumor activity, resulting in complete tumor regression in a syngeneic MC38 colorectal cancer model, and significant anti-tumor activity in other models of different tumor types. The mechanism was evaluated by immunophenotyping and single-cell RNAseq. Shortly after the first administration of mAnti-PD1-IL2Att, CD8$^{\pm}$ T cells, rather than Tregs, emerged as the primary responding cells; these CD8$^{\pm}$ T cells exhibited increased proliferation and activation with reduced expression of exhaustion markers (PD1$^{\pm}$Tim3$^{\pm}$). Following subsequent doses, there was a notable increase in the number of effector cells, followed by a prolonged generation of effector and memory cells at a later stage. Myeloid cells exhibited increased transcriptional programs related to chemotaxis, co-stimulation, and co-inhibition, including the upregulation of the PD1-PDL1 pathway. By contrast, blockade of PD1 with a naked PD1 antibody led to distinct cellular responses and less pronounced anti-tumor activity, and a combination of the blocking antibody with PD1-attIL-2 was superior to either agent alone. Together, our findings suggest that mAnti-PD1-IL2Att potent anti-tumor activity was driven by its direct targeting of PD1$^{\pm}$ on tumor-infiltrating CD8$^{\pm}$ T-cells, shedding light on the specific changes in their dynamic differentiation trajectory and their impact on the tumor microenvironment.

#4058 Nanoparticle delivery of interleukin-2 induces anti-tumor immune response and therapeutic efficacy in mouse tumor models.

R. Wang[1], A. Wallstrum[2], N. White[2], P. Kumar[1], T. Watcharawittayakul[2], N. A. Crumrine[2], C. Baker[2], J. Saito[2], M. Reda[2], W. Ngamcherdtrakul[2], W. Yantasee[1]; [1]Oregon Health & Science University, Portland, OR, [2]PDX Pharmaceuticals, Inc., Portland, OR

Immune checkpoint inhibitors (ICIs) have demonstrated robust responses in some solid tumor types. However, the low response rate, which is associated with lack of pre-existing tumor-infiltrating lymphocytes (TILs), remains a significant challenge. Interleukin-2 (IL-2) can effectively expand TILs and has been FDA-approved for metastatic renal cancer and melanoma. However, IL-2 has several drawbacks—including short circulation half-life, dose-limiting toxicities, and counterproductive activation of regulatory T cells (Tregs)—resulting in less than 10% complete response rate. Numerous efforts have been made to enhance IL-2 formulations, but none have yet received FDA approval.

In this study, we utilized our proprietary nanoparticle platform (Pdx-NP™) to improve IL-2 formulation. Pdx-NP™ can load IL-2 with near-complete binding, resulting in a 160-nm nanoconstruct (IL2-NP), suitable for both local and intravenous administrations. To evaluate the efficacy, we utilized bilateral melanoma (B16F10) and colon (MC38) tumor models, in which the local tumor was treated intratumorally for 3 doses and the distal tumor was left untreated to assess the systemic anti-tumor immune response. In the B16F10 model, IL2-NP treatment demonstrated favorable immune profiles in local and distal tumors and the draining lymph nodes, such as increased CD8+ T cell proliferation, CD8+ T cells/Treg ratio, and recruitment of dendritic cells and macrophages, compared to saline or free IL-2 counterparts. These positive immune responses translated into significant growth reduction of IL2-NP treated tumors and improvement in survival of the mice compared to free IL-2. In the MC38 tumor model, the IL2-NP treatment resulted in complete regression of both local and distal tumors in 43% of the mice. When combined with ICIs (αPD-1 and αCTLA-4), the treatment achieved a cure rate of 100%, whereas ICIs alone yielded only a 29% cure rate.

In conclusion, IL2-NP induces robust proliferation and activation of TILs and is efficacious both as a monotherapy and in combination with ICIs. This is due to the ability of Pdx-NP™ to protect and retain therapeutics within tumors, with an 8-fold increase in tumor accumulation over the free drug counterpart. Our ongoing efforts are focused on the targeted delivery of IL-2 to tumors upon systemic administration, using αPD-L1 antibody-conjugated Pdx-NP™. This antibody-conjugated nanoparticle has an elimination half-life ($t_{1/2}$) of about 25 hrs in non-human primates. Paired with αPD-L1 for tumor homing, this nanoconstruct is hypothesized to enhance IL-2 accumulation in tumors compared to free IL-2, which has $t_{1/2}$ of only 1.5 hrs in human. The current clinical landscape of cancer immunotherapy focuses on combinational approaches, and our versatile Pdx-NP™ platform, which is capable of co-delivering different classes of therapeutics, is well suited for this endeavor.

#4059 Vitokine-2: A TIL-targeting tumor activable engineered IL-2 for cancer treatment.

S. V. Challa, Y.-T. Hsieh, K. Gelinas, A. Umana, W.-c. Weng, T. Berisha, C. Stephens, Y. Li, J. Xu;
Cugene, Waltham, MA

Background: Interleukin-2 is the first approved immune-oncology (IO) drug to treat multiple metastatic cancers with durable and curative antitumor effects. Yet, its application is restricted due to severe toxicity, short half-life, and a small fraction of response rate. To reduce toxicity and improve efficacy, we developed Vitokine-2, a tumor infiltrating lymphocyte (TIL)-targeting, tumor activable, and precision engineered IL-2 that remains inert systemically but activated in the tumor microenvironment (TME).

Methods: Through protein and structure-guided precision engineering, the biological activity of IL-2 was optimized, concealed, guided to exhausted TILs, and activated at TME. The biological activity was determined by measuring proliferation (Ki67) of CD8+ T and NK cells using human peripheral blood mononuclear cells (PBMCs). Pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor efficacy were evaluated in mice, encompassing healthy and multiple syngeneic tumor mouse models.

Results: Vitokine-2 was inactive in stimulating CD8+T and NK cell proliferation in vitro. Yet, its biological activity was fully restored following the cleavage and release of the concealing domain. Vitokine-2 displayed a significantly prolonged in vivo pharmacokinetic profile due to half-life extension, concealing and reduction of target sink. Administration of Vitokine-2 in mice resulted in minimal or no detectable activation, proliferation, and expansion of cytotoxic CD8+T and NK cells in the systemic circulation. However, marked CD8+ T cell proliferation and expansion with enhanced expression of granzyme B, a cytotoxic functional biomarker, was observed within the TME. The effect was specific to cytotoxic lymphocytes but not regulatory T cells. Corroborating with the expansion and enhanced functionality of CD8+ T cells in TME, robust antitumor efficacy was observed with Vitokine-2 but not with the non-activable IL-2 counterpart. Furthermore, dose-dependent tumor killing efficacy and complete eradication of tumors were demonstrated in multiple syngeneic tumor models. Vitokine-2 was found to be safe and well tolerated with minimal interferon gamma release and body weight loss even at much higher doses.

Conclusion: Vitokine-2 is a TIL-targeting, tumor activable and precision engineered IL-2. It demonstrated robust anti-tumor efficacy with minimal systemic toxicity. It is safe, well tolerated, and permits high dose administration, yielding a widened therapeutic window. Vitokine-2 presents a paradigm-shifting, potentially a first-in-class, highly safe and efficacious IO therapy with an immense potential to address both IO-responsive and unresponsive patient population.

#4060 Characterization of MDNA113, a tumor-targeting anti-PD1-IL-2^{SK} immunocytokine with conditional activation to increase tolerability and maximize efficacy.

A. Sharma, M. D. To, Q. Liu, F. Merchant;
Medicenna Therapeutics, Toronto, ON, Canada

Background-MDNA113 consists of an IL-13 decoy receptor-binding domain (MDNA213) fused to anti-PD1-IL-2^{SK} (MDNA223) immunocytokine using a matrix metalloprotease (MMP) sensitive linker (PSL). MDNA213 is an IL-13 superkine with high selectivity towards IL-13Rα2, a tumor associated antigen overexpressed in numerous aggressive solid tumors with limited expression in normal tissues. IL-13Rα2 overexpression is associated with MMPs abundancy in tumor microenvironment (TME) and poor clinical outcomes. MDNA223, a fusion of 'not-alpha, beta enhanced' IL-2 superkine with anti-PD1 is designed to facilitate cis-binding to PD1 and IL-2Rβγ on CD8^{+} T cells. MDNA223 is superior to co-administration of anti-PD1 and IL-2 agonist at inhibiting both immunologically 'hot' and 'cold' tumors in mice. MDNA113 is designed to target and accumulate in tumors via the MDNA213 domain, which also attenuates immune stimulation by hindering IL-2R activation to reduce peripheral activity. The dual targeting/masking MDNA213 domain is released within tumor microenvironment following MMP cleavage of PSL to fully restore IL-2R agonism while maintaining PD1/PDL-1 blockade.

Methods-*In vitro* signaling studies were performed in reporter cell assays and human PBMCs. Tolerability and pharmacodynamic studies were conducted in mice. Tumor growth inhibition was assessed in syngeneic mouse tumor models in monotherapy and combination settings.

Results-MDNA113 showed reduced IL-2R agonism (~38-fold) while maintaining PD1/PD-L1 blockade compared to MDNA223 (non-masked) in cell-based reporter assays. Capacity to stimulate human PBMC proliferation was reduced while potency in CD8+ T cell p-STAT5 signaling also decreased. MMP cleavage of MDNA113 to release MDNA213 domain fully restored IL-2R signaling. Systemic delivery of MDNA113 to mice showed reduction, but not complete blockade, of lymphocyte expansion compared to equimolar dose of MDNA223. A 3x increase in MDNA113 restored lymphocyte expansion to a similar level achieved with MDNA223, indicating a 'partial masking' effect of MDNA213 domain. Accordingly, MDNA113 was better tolerated than MDNA223 in viability studies in mice. In syngeneic tumor models, equimolar treatment with MDNA113 and MDNA223 (non-mask version) resulted in similar extent of tumor growth inhibition. In contrast, in vivo activity was partially compromised when mice were treated with a non-cleavable version of MDNA113, consistent with a role for MMP-cleavage to restore full anti-tumor effect within TME.

Conclusion-MDNA113 is a tumor-targeting and conditional-activatable anti-PD1/IL-2^{SK} fusion characterized with potent PD1/PDL1 blockade and 'not-alpha, beta enhanced' IL-2R agonism. MDNA113 is better tolerated than the non-mask version while achieving similar effect on tumor control, therefore offering a much broader therapeutic index.

#4061 Preclinical characterization of MBS309, a conditionally active PD-1-dependent IL-2 mutation with significantly superior anti-tumor efficacy with safety.

J. Li, **G. Lin**, L. Zhang, F. Li;
Beijing Mabworks Biotech Co Ltd, Beijing, China

Although PD-1/PD-L1 therapies have shown significant benefit among a range of tumor types, the majority of malignancy patients do not respond or develop resistance after initial tumor regression. Development of new modality to overcome primary and acquired resistance to anti-PD-1/PD-L1 therapy is a huge unmet medical need, and IL-2 is believed a potentially powerful approach for that. However, the current clinical application of IL-2 in cancer immunotherapy has been limited by its severe toxicity. Herein, we developed MBS309 (PD1/IL2m), a novel PD-1-targeted IL-2 mutation with significantly enhanced therapeutic window. MBS309 has the similar high affinity and blockade efficacy with monoclonal antibody to PD-1, and its IL-2 mutation has reduced binding to IL-2Rβγ and abolished binding to IL-2Rα. Our *in vitro* assays, including HEK-blue assay and $CD3^{+}$ T cell assay, both indicated that the IL-2 receptor agonist activity of MBS309 was conditionally induced only the antibody cis-binding to both PD-1 and IL-2 Rβγ. And the maximal agonist activities of MBS309 in HEK-blue assay and $CD3^{+}$ T cell assay were much lower than wild-type IL-2 and RG6279 analog enabling its high tolerated drug doses *in vivo*. In our *in vivo* tumor murine models, 1mg/kg MBS309 showed much better suppression effect in MC38/hPD-L1 tumor than 1mg/kg RG6279 analog and Pembrolizumab (1mg/kg) combination with wild type IL-2 (0.1mg/kg) ; And MBS309 at the dosage of 5mg/kg can significantly inhibit tumor growth in PD-1 resistant Pan-02 xenograft models without any side-effects observed, while RG6279 analog at the dosage of 5mg/kg induced severe body reduction of the mice and resulted in 80% (4/5) mice death after two dosages. MBS309 showed similar PK profile with anti-PD-1 monoclonal antibody and much better than RG6279 analog in mouse model. 20mg/kg of MBS309 was well tolerated in mouse, while 10mg/kg of RG6279 analog or PF-07209960 analog show severe toxicity and resulted in death of all the mice. Pharmacodynamic studies in murine models showed that MBS309 prioritized active tumor infiltrated $PD\text{-}1^{+}$ CD8 T cells rather than other organs. Taken together, MBS309 effectively expands tumor infiltrated T-cells, and avoids system immune cytokine side effects compared to other PD-1-targeted 2nd generation IL-2Rβγ agonist modalities currently in clinical development. And it shows much higher anti-tumor effect compared to anti-PD-1/-L1 antibodies alone in both PD-1 sensitive and resistant tumor models. MBS309 has demonstrated a favorable safety profile and highly anti-tumor activities *in vivo*, which has the potential to supporting its clinical development for the treatment of cancer.

#4062 A novel method for generating regulated cytokine therapeutics: Safety and activity of a conditionally active cLAG3-IL2 capable of delivering IL2 to LAG3+ cells while remaining inert on LAG3- cells.

J. Killebrew, S. Okada, L. Amon, D. Bienvenue, L. Carlucci, D. Colby, W. Curtis, K. Daniels, A. Etheridge, Z. Kraft, J. Nguyen, S. Notonier, J. Pham, M. Sprague, K. Thomas, D. Hollenbaugh, J. Mulligan;
Bonum Therapeutics, Inc., Seattle, WA

IL-2 is a powerful cytokine central to the generation of an effective immune response. However, its use in cancer immunotherapy has been limited by toxicities arising from its broad activity as well as the narrow patient population in which efficacy is seen. To address these limitations, many strategies have been pursued including IL-2 attenuation and targeting of IL-2 activity. These approaches, however, retain unacceptable toxicity and/or are not targeted to the appropriate cell populations. Using a novel approach that takes advantage of the ability of an antibody to bind specifically and competitively to two distinct antigens, we have generated a conditionally active cLAG3-IL2 therapeutic that targets IL-2 to $LAG3^{\pm}$ cells while remaining inert on IL-2Rβγ+ cells lacking LAG3 expression, even at high treatment doses. As a marker of antigen-activated and tumor-specific T cells, LAG3 is an ideal target toward which to direct IL-2 activity. In vitro, using both reporter cell lines and receptor binding assays, the regulated cLAG3-IL2 demonstrates >100 fold difference in activity in the presence or absence of LAG3. In primary immune cells, regulated cLAG3-IL2 preferentially induces IL-2 cis-signaling in activated human $LAG3^{\pm}$ CD8 T cells compared to $LAG3^{-}$ T cells. In mouse syngeneic tumor models, cLAG3-IL2 inhibits tumor growth while avoiding clinical signs of IL-2-mediated toxicity at doses well above the level where the non-regulated IL2 is toxic. Additionally, cLAG3-IL2 does not induce expansion of circulating $LAG3^{-}$ IL-2Rβγ+ cell populations, including NK cells and $LAG3^{-}$ T cells. In the TME, cLAG3-IL2 drives the expansion and activation of tumor-specific CD8+ T cells. Furthermore, cLAG3-IL2 demonstrates robust combinatorial activity with anti-PD1. These results demonstrate the strength of the Bonum platform, currently applied to multiple target/effector pairs including PD1, PDL1, ATP, LRRC15 and effectors IFNα, IL12 and TGFβ inhibition, and support the clinical development of our conditionally active cLAG3-IL2.

#4063 SAR445877, an anti-PD-1 antibody-IL-15 mutein fusion protein restores function to exhausted T cells.

I. Pratumchai[1], M. Bernardo[2], K. L. Marquardt[1], C. Zhu[2], F. Menas[3], R. Carrio[4], T. Byers[4], D. Shaffer[2], X. Li[2], J. R. Teijaro[1];
[1]The Scripps Research Institute, San Diego, CA, [2]Sanofi, Boston, MA, [3]Sanofi, Madrid, Spain, [4]Sanofi, Orlando, FL

During persistent viral infections and cancer, antigen-specific T cells become exhausted, express elevated levels of inhibitory receptors and gradually lose their functional potential. Immune checkpoint blockade can restore function of exhausted T cells to result in tumor clearance, however, only a minority of cancer patients see durable tumor control. Immune-stimulatory cytokines can augment the antitumor efficacy of checkpoint blockade, but their clinical use is marred by substantial toxicity. SAR445877 (SAR'877, formerly KD050), is a novel antibody-cytokine fusion protein consisting of Fc silenced human anti-PD-1 IgG1 fused to a mutated interleukin-15 (IL-15)/IL-15 receptor alpha sushi domain fusion, which can cis-activate direct cytokine stimulation to effector T cells and alleviate off target binding and the resultant toxicity. Here, we leveraged existing models of chronic antigen exposure to characterize the potential of SAR'877 to restore activity of exhausted T cells.C57BL/6 mice exposed to lymphocytic choriomeningitis virus (LCMV) Clone 13 develop persistent viral infection that results in development of dysfunctional, exhausted T cells. We tested the SAR'877 murine surrogate molecule (mKD050) using the LCMV Clone-13 (CL13) infection model for its ability to promote T cell function *in vitro*, *in vivo,* and to control viral infection. Treatment of exhausted T cells with mKD050 *in vitro* was able to increase expansion and cytokine production of antigen-specific CD8 T cells which was superior to anti-PD-1 antibody or non-targeting antibody-IL15/IL-15Ra fusion protein (mntKD050). Moreover, *in vivo* treatment of CL13 infected mice with mKD050 increased the numbers and functional output of antigen-specific CD4 and CD8 T cells compared to anti-PD-1 or mntKD050 treatments. Further, mKD050 increased the frequency of antigen-specific $TCF1^{+}TIM\text{-}3^{-}$ stem-like CD8 T cells, which are critical to maintaining the T cell pool during chronic viral infection and cancer. The enhanced T cell function observed following treatment with mKD050 translated to hastened clearance of CL13. Finally, the hastened CL13 clearance observed following mKD050 treatment required an intact CD4 T cell compartment. Given the robust activity of mKD050 in reinvigorating dysfunctional T cells in a mouse model of chronic viral infection, we utilized the MIMIC CD8 T cell exhaustion model to explore whether SAR'877 could rescue the function of exhausted human T cells. SAR'877 stimulated proliferation and functional activity of exhausted human CD8 T cells *in vitro*. SAR'877 more potently induced proliferation and IFNγ and granzyme B production compared to anti-PD-1 and non-targeted IL15 mutein alone. Together, these results demonstrate that the PD-1 targeted IL15 mutein SAR'877 rescues the functional activity of chronically stimulated, exhausted T cells.

#4064 hetIL-15 and Fenofibrate combination alters the metabolic fitness of tumor-infiltrating CD8$^{\pm}$T cells leading to TNBC tumor eradication in mice.

D. Stellas[1], S. Karaliota[2], V. Stravokefalou[1], K. C. Goldfarbmuren[3], B. Myers[2], G. N. Pavlakis[1], B. K. Felber[1];
[1]National Cancer Institute at Frederick, Frederick, MD, [2]Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD, [3]Advanced Biomedical Computational Science, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD

Introduction: Tumor-infiltrating cytotoxic CD8$^{\pm}$T cells frequently undergo an altered state of differentiation referred to as "exhaustion" and, as a result, they fail to control tumor growth. IL-15 is a cytokine which stimulates the generation, proliferation and cytotoxic function of tumor CD8$^{\pm}$T and NK cells. We have produced the native heterodimeric form of IL-15 (hetIL-15) which has advanced in clinical trials. The aim of this study was to overcome the exhaustion of the tumor-infiltrating CD8$^{\pm}$T cells and to increase their cytotoxicity, using Fenofibrate (FF), a PPAR-α agonist, in combination with hetIL-15.
Experimental Procedures: We have evaluated the therapeutic efficacy of hetIL-15 immunotherapy as a monotherapy and in combination with FF in the murine EO771 orthotopic breast cancer model. The effects of hetIL-15 and/or FF on immune cells and on tumor microenvironment were analyzed by flow cytometry, transcriptomics, metabolomics and proteomics. The metabolic profile of tumor-infiltrating T cells was performed with Seahorse analysis.
Results and Conclusions: hetIL-15 monotherapy resulted in tumor eradication in 40% of treated mice and increased survival. Seahorse analysis of tumor-infiltrating CD8$^{\pm}$T cells confirmed a rise in oxygen consumption rate (OCR) with substantial increase of spare respiratory capacity. Upon hetIL-15 treatment, tumor-infiltrating CD8$^{\pm}$T cells showed elevated extracellular acidification rate (ECAR), resulting in a pronounced shift in the OCR/ECAR ratio in comparison to control, confirming their increased proliferating status. These tumor-infiltrating CD8$^{\pm}$T cells also showed increased mitochondrial potential and/or mass and fatty acid (FA) uptake, as evidenced by increased MitoTracker and Bodipy staining, respectively. Transcriptomic analysis revealed increased expression of genes involved in several metabolic pathways such as oxidative phosphorylation, FA oxidation and glycolysis. Monotherapy with FF had no effect on tumor growth delay, whereas the FF- hetIL-15 combination resulted in complete eradication of the tumors in 85%. Combination therapy reshaped the tumor microenvironment, resulting in higher IFN-γ and in differentially expressed metabolites as shown by tumor proteomics and metabolomics, respectively. The combination treatment increased the mitochondrial function, FA uptake and OCR, revealing a more metabolically active phenotype. We conclude that hetIL-15 supports a favorable metabolic profile of intratumoral effector lymphocytes, important for their function. Our data suggest that metabolic reprogramming of tumor specific CD8$^{\pm}$T cells using FF is a promising strategy to overcome T cell exhaustion and to promote survival in a metabolically hostile tumor microenvironment.

#4065 Entinostat synergizes with the IL-15 superagonist N-803 and anti-PD-1 to engage cDC1 and stem-like TCF-1^{+} CD8^{+} T and NK cells to overcome colorectal tumors refractory to anti-PD-1 therapy.

C. M. Minnar, M. Miyamoto, A. S. Khelifa, G. Lui, K. L. Lothstein, P. L. Chariou, T. J. Meyer, A. Lobanov, M. Cam, J. Schlom, S. R. Gameiro;
National Cancer Institute, Bethesda, MD

Background: Immune checkpoint blockade (ICB) has limited efficacy in colorectal carcinoma (CRC), where ~85% of patients harbor microsatellite stability (MSS). A minor subset of CRC patients (~15%) harbor microsatellite instability (MSI) and demonstrate improved responses to ICB ranging from 30-50%. Combination therapy has the potential to increase the response rate. Entinostat, a class I HDAC inhibitor, has demonstrated potential to enhance ICB efficacy, such as αPD-1 and immunostimulatory cytokines. N-803, a heterodimeric IL-15 superagonist that enhances proliferation and activation of CD8^{+} and NK cells has demonstrated to enhance the clinical benefit of Nivolumab in non-small cell lung cancer patients that were relapsed or refractory to αPD-1 monotherapy. Here, we investigated the antitumor efficacy and mode of action of combination therapy comprising αPD1, Entinostat, and N-803 in αPD1-refractory CT26 and Jak1-deleted MC38 CRC tumor models.

Methods: Entinostat, N-803, and αPD1 alone or in combination were administered to mice bearing established CT26 or Jak1-deleted MC38 tumors. Antitumor efficacy, survival, and protective memory upon tumor rechallenge were monitored. Comprehensive flow cytometric profiling of the tumor microenvironment (TME), tumor-draining lymph node (tdLN), and spleen cell populations was conducted. CT26 tumor and tdLN immunomes were examined by single-cell transcriptomics. Cytokines and chemokines were examined in the TME and sera. Antigen-specific IFNg T cell responses were evaluated by ELISpot.

Results: We demonstrated that combination therapy with Entinostat, N-803 and αPD1 elicits potent suppression of CT26 and Jak1-deleted MC38 tumors, with median overall survival increasing 33% to not reached. These effects were associated with increased activation, infiltration, cytokine production, and cytolytic function of tumor CD8^{+} T and NK cells, and increased sera IFNg and TNFα. Tumor resolution and protective memory were associated with development of p15e-specific T cell responses. Increased migration of CD8^{+} T cells and cross-presenting dendritic cells (cDC1) to the tdLN, as well as significant enrichment of cross-presentation genes in tumor cDC1s was observed. Transcriptomic and phenotypic analyses demonstrated increased stem-like TCF-1^{+} CD8^{+} T cell accumulation in the tdLNs and TME of mice treated with triple combination.

Conclusions: Combination therapy with Entinostat plus N-803 and αPD1 synergized to promote a sustained antitumor response and prolonged survival. We hypothesize the antitumor effects were due to collaborative efforts of CD8^{+} T and NK cells, and cDC1 cells in tdLN and TME. These results provide a rationale for the clinical testing of αPD1, Entinostat and N-803 combination for patients with CRC, including those with acquired resistance to ICB.

#4066 Generation of tumor targeted self-assembling split IL-12 subunits for the treatment of cancer.

J. Heiber, P. Gurel, R. G. Newman, K. Dreaden, Y. Zhao, C. Wang, S.-P. Pearson, J. Chamoun;
Mural Oncology, Waltham, MA

A major milestone in immuno-oncology was the development of immune checkpoint inhibitors, resulting in significant benefits for numerous patients. However, many patients are not responsive, become refractory, or cannot tolerate the treatment due to toxicity or side effects, demonstrating the need for additional immunotherapies. Cytokines are a class of promising immunomodulatory proteins being explored as therapeutics, but their success has been limited due to their rapid clearance or pleiotropic properties. Classically known as 'signal 3' of an endogenous immune response, IL-12p70 is a heterodimeric cytokine comprising p35 and p40 subunits. When administered exogenously, IL-12 is a potent stimulator of the immune system and can have profound anti-tumor activity; however, the clinical use of IL-12 has been limited due to poor systemic tolerability. Therefore, developing an immunotherapy that can be systemically administered and improve the therapeutic index could capitalize on the potential clinical benefit of IL-12. Mural Oncology has developed an innovative approach to mitigate the toxicity of IL-12 by splitting the heterodimer into inactive p35 and p40 monomers. The individual subunits are separately fused to two non-competitive antibody fragments targeting a highly expressed tumor-associated antigen. The goal of this approach is to conditionally activate IL-12 preferentially in the tumor microenvironment (TME). This is achieved by sequential administration of the targeted subunits, which will drive assembly and activity of the IL-12 heterodimer primarily at the tumor site, reducing systemic exposure and thereby potentially reducing associated toxicities. To engineer the split IL-12 subunits, a structure-based rational design approach was used to remove the natural intra-molecular disulfide bond and generate variants that maintained affinity between the p35 and p40 monomers. The engineered subunits were characterized using analytical methods and screened for the pair with the strongest affinity. Additionally, the candidate pair was assessed for receptor binding and functional activity on human T cells through phosphorylation of STAT4 and secretion of IFN-γ. Pharmacokinetics and pharmacodynamics were evaluated in mouse models with and without tumors demonstrating that dual targeting led to an increase in tumor retention, rapid clearance from circulation, and dose dependent release of IFN-γ. The results thus far demonstrate that the innovative approach of tumor targeted self-assembling split IL-12 has the potential to enhance the overall therapeutic potential of this cytokine. A development candidate will be identified and moved into clinical testing in cancer patients to enable us to fully understand if this design approach holds true in the clinical setting.

#4067 Development of tumor-restricted IL-12 with antigen-dependent expression and localized IL-12 activity.

S.-H. Huang[1], T. M. Davenport[2], H. F. Moffett[2], B. D. Weitzner[2], L. Cassereau[1], L. E. Baker[2], B. Hammerson[2], S. Zhuang[1], C. Saechao[1], L. Song[2], J. Mimms[2], D. Chian[1], C. Sims[1], H. Hiraragi[1], M. J. Lajoie[2], S. E. Boyken[2], **B. Boldajipour**[1];

[1]Lyell Immunopharma, South San Francisco, CA, [2]Outpace Bio, Seattle, WA

IL-12 is an immune-stimulatory cytokine that can modulate the tumor microenvironmnent (TME) to enhance the cytotoxic activity of T and NK cells; however, IL-12 expression by T cells caused severe toxicity in a previous clinical trial. Using Outpace's OutSmart™ technology, we designed a tumor-restricted IL-12 (trIL-12) that is under control of an activation-inducible promoter and auto-inactivates within minutes after secretion.

T cells were engineered via lentiviral vectors (LVV) to express wild-type single-chain IL-12 (WT scIL-12) or trIL-12 under the control of an activation-inducible promoter; a second LVV introduces an NY-ESO-1 TCR. Kinetics of IL-12 expression was measured by qPCR and MSD technology; kinetics of IL-12p70 heterodimer half-life was measured using Octet bio-layer interferometry (BLI). T-cell cytotoxicity and cytokine production was evaluated in vitro after repeated stimulation with NY-ESO-1 expressing target cells using Incucyte and MSD. IL-12 activity in bystander cells was measured by detection of IFN-γ using flow cytometry. In vivo T-cell function of trIL-12-engineered NY-ESO-1 TCR T cells was measured in NSG MHCI/II KO mice bearing A375 xenografts. trIL-12 activity in a fully immune-competent mouse model was measured in B6 mice implanted with B16F10 tumor cells engineered to express murine surrogates of trIL-12.

Expression of WT scIL-12 under the control of an activation-inducible promoter peaks within 6 hours after activation and produces sufficient IL-12 to improve T-cell function in vitro and in vivo. trIL-12 was created by inclusion of a cleavable linker and elimination of the covalent disulfide bond between the p35 and p40 subunits of IL-12p70, resulting in dissociation of the functional cytokine within 10 minutes post-cleavage. Additional mutations further reduce the IL-12p70 half-life. trIL-12 activates the IL-12-producing T cells, as well as proximal bystander T-cells in direct co-culture, but it does not have the ability to activate distal bystander T-cells separated by Transwell membranes. In xenograft mouse models, trIL-12-expressing T cells have improved proliferation upon antigen recognition and display potent anti-tumor activity and cytokine production without showing systemic IL-12 accumulation. Furthermore, in fully immune competent mice, expression of a murine trIL-12 surrogate by tumor cells led to generation of potent anti-tumor responses without systemic trIL-12 accumulation and reduced systemic IFN-γ.

trIL-12-engineered T cells generate potent anti-tumor activity in vitro and in vivo. Unlike WT scIL-12, trIL-12 activity is localized to the region around the producing T cell and systemic IL-12 exposure is not observed in vivo. Collectively, these preclinical data suggest that trIL-12 may enable the development of potent T-cell therapeutics while maintaining an acceptable safety profile.

#4068 *In vitro* masked effect, *in vivo* anti-tumor activity and toxicology study of KGX101, an interleukin-12 prodrug, in monotherapy or in combination with anti-PD-L1 antibody.

Shumin Yang, Nuo Li, Jing Wang, Li Ma, Yi Zhao, Hui Chen, Haixiang Wu, **Weidong Jiang**

Shanghai KangaBio Co., Limited, Shanghai, China

Interleukin-12 (IL-12) has long been limited in its clinical use due to its short half-life ($t_{1/2}$) and dose-related toxicity, despite its remarkable ability to activate effector functions in T cells and natural killer (NK) cells. To address these challenges, we engineered an IL-12 prodrug called KGX101. In KGX101, the C-terminus of IL-12 is fused with ADCC-impaired IgG1 Fc to extend its half-life. Meanwhile, the N-terminus is concealed with its corresponding receptor soluble domains, IL-12Rβ1 and IL-12Rβ2, using tumor-specific protease cleavable linkers. This innovative design prevents systemic immune system overactivation. Once the linker is cleaved by tumor microenvironment (TME)-specific proteases, KGX101 functions like IL-12, effectively stimulating T cells and NK cells, reshaping the TME, and displaying significant potential in cancer therapy. To confirm KGX101's masking effect, we conducted IFNγ induction efficacy tests using peripheral blood mononuclear cells (PBMCs) from three donors. KGX101 demonstrated a 300 to 2500-fold reduction in activity compared to unmasked IL-12-Fc. Importantly, the masking effect of KGX101 was nearly abolished after protease digestion, affirming its mechanism of action. To further establish KGX101's effectiveness, we conducted *in vivo* antitumor studies in hPBMC xenograft mouse models using human colorectal cancer HCT116 and PD-L1-overexpressed human malignant melanoma A375. Mice were subcutaneously implanted with a specific mixture of cancer cells and hPBMCs, and then intravenously injected with PBS or KGX101 at various dose levels twice a week for 4-5 cycles. Compared to the PBS control group, KGX101 demonstrated up to a 42% tumor growth inhibition (TGI) in the HCT116 model at 0.18 mg/kg and a 76% TGI in the hPD-L1-A375 model at 0.06 mg/kg. Analysis of tumor-infiltrating lymphocytes (TILs) revealed that KGX101 increased the percentage of T cells in the tumor environment in a dose-dependent manner. We also evaluated the combination of KGX101 with an anti-PD-L1 antibody in an HCT116/hPBMC xenograft mouse model, which showed limited response to anti-PD-L1 monotherapy. The TGI% for KGX101 at 0.06 mg/kg, anti-PD-L1 antibody at 1 mg/kg, and their combination were 36.56%, 6.93%, and 66.22%, respectively, demonstrating a promising antitumor synergy. In terms of pharmacokinetics, a single dose of KGX101 at 0.06 mg/kg and 0.18 mg/kg in the HCT116/hPBMC xenograft mouse model resulted in a serum half-life ranging from 52.75 to 64.87 hours, while the $t_{1/2}$ in *Cynomolgus* monkeys was approximately 3 days. In a 4-week repeat dose toxicity study in *Cynomolgus* monkeys, the highest non-severely toxic dose (HNSTD) of KGX101 was determined to be 0.1 mg/kg. The results from nonclinical toxicology studies support the potential of KGX101 as a well-tolerated therapy for the First-in-Human (FIH) clinical trial.

#4069 IL12-expressing genetically engineered myeloid cells remodel the stromal dense and T cell poor tumor microenvironment and premetastatic niche of F42010 murine osteosarcoma.

K. Jackett, A. Browne, S. Kaczanowska, M. Clements, R. Kaplan, K. Wessel, B. Ball, J. Cronk;
National Institutes of Health (NIH), Bethesda, MD

Treatment options for patients with metastatic and recurrent osteosarcoma are poor. The development of immunotherapies for osteosarcoma has been hindered by the lack of immunocompetent preclinical models that recapitulate the stromal dense, myeloid-rich, T cell poor, and overall immunosuppressive microenvironment of human osteosarcoma. We hypothesized that the syngeneic murine osteosarcoma model F42010 may serve as a useful immunocompetent preclinical model of osteosarcoma suitable for developing novel immunotherapies for osteosarcoma. To test this, we used flow cytommetry, bulk RNA sequencing, and immunohistochemistry to characterize the stromal and immune compartments of this model. We found that the F42010 osteosarcoma model recapitulates the ECM-rich and immunosuppressive nature of human osteosarcoma primary tumor and pre-metastatic microenvironments, characterized by increased myeloid infiltrate expressing suppressive markers and lymphocyte exhaustion. Finally, we used this model to test the utility of a myeloid immunotherapy for osteosarcoma, IL-12 secreting genetically engineered myeloid cells (IL12-GEMys) that can reverse immune suppression in the pre-metastatic niche and tumor microenvironment. IL12-GEMy treatment augmented immune activation and significantly extended survival by delaying tumor growth. Our findings highlight that the F42010 osteosarcoma model effectively replicates key features of the osteosarcoma tumor microenvironment and is a valuable model for developing novel tumor microenvironment and pre-metastatic niche modulating immunotherapies for osteosarcoma.

#4070 CIS-demasking cytokine linker technology allows a selective cytokine delivery to activated immune cells while sparing others and peripheral toxicity.

A. Morello, C. Mary, v. Thepenier, M. Seite, J. Durand, C. Batty, K. Biteau, J. Taurelle, G. Teppaz, A. Georges, N. Poirier;
OSE Immunotherapeutics, Nantes, France

Immunocytokines are promising new therapeutic approaches to enhance T-cell response by delivering interleukins into the tumoral site. Fusion of wild-type or attenuated interleukins to anti-PD-1 antibody has shown some efficacy to preferentially cis-activate PD1-expressing T-cells but on-target/off-tumor activity on PD-1-negative cells is still observed due to the high affinity of the cytokine to its receptor leading a broad systemic effect, toxicity, high clearance and low tumor biodistribution limiting the potential of some immunocytokines (e.g. anti-PD-1/IL-2/IL-15/IL-21). Various strategies have emerged to achieve localized cytokine activation using conditional strategies (*e.g.* allosteric modulators, MMP-cleavable linkers or pH-dependent binding) that remain challenging due to high dependency to specific TME composition (MMP, acidosis...). We developed the OSE-Cytomask® Platform, a universal and innovative linker technology allowing exclusive cytokine CIS-demasking upon binding of the fused antibody to its target without TRANS-activation associated with undesired effects (*e.g.* Toxicity). A series of different linkers were screened for optimal cis-activation of cytokine on PD1-expressing vs PD1-negative T-cells using different cytokines fused to a high-affinity anti-PD1. OSE-Cytomask® linker technology decreases IL-2 or IL-15 cytokine activity (pSTAT5 signaling) on PD1-negative cells while maintaining high activation of PD1-transduced T-cells even in co-culture. We confirmed activity of OSE-Cytomask® Immunocytokine on (PD1+) human T-cells while very low activation has been observed in naïve T-cells. Importantly, Cytomask® linker technology does not induce TRANS-activation on PD1-negative T-cells illustrating an innovative and strict CIS-demasking mechanism of action. *In vivo*, Anti-PD-1/IL-15 and/or anti-PD1/IL-2 OSE-Cytomask® molecules illustrated reduced toxicity after single or multiple injections (2mg/kg). High T-cell proliferation has been observed in tumor-micro-environment where PD1-expressing T cells are located. Low T-cell proliferation in periphery was seen, illustrating the potential of CIS-demasking technology to target the right T-cells at the right place. Altogether, OSE-Cytomask® linker technology illustrates specific intrinsic property to mask cytokine on naïve peripheral immune cells not expressing the target of the antibody while allowing selective CIS-demasking of the cytokine and CIS-activation of activated immune cells expressing (*e.g.* PD-1). This linker technology could be used with a broad range of cytokine to abrogate OFF-tumor cytokine activity associated with toxicity while selectively CIS-activating activated immune cells in the TME.

#4071 The first-in-class PD1-IL18 conjugate BPT567 induces potent anti-tumor immunity by preferentially activating PD1$^{\pm}$IL18R$^{\pm}$ intratumoral effector T cells in *cis*.

K. Martin[1], T. Luu[2], J.-P. Carralot[1], L. Gremlich[1], P. Herzig[2], C. Herr[1], R. Meoded[1], P. Moosmann[1], A. Goepfert[1], A. Zippelius[3], V. Pattabiraman[1], B. Kreft[1]; [1]Brightpeak Therapeutics AG, Basel, Switzerland, [2]Department of Biomedicine, Cancer Immunology, University of Basel and University Hospital Basel, Basel, Switzerland, [3]Department of Biomedicine, Cancer Immunology & Medical Oncology, University Hospital Basel, University Hospital Basel, Basel, Switzerland

Antibody-cytokine conjugates leverage orthogonal mechanisms of action (MoA) in one molecule to induce potent antitumor immune responses. PD-1-targeting conjugates are of particular interest since they preferentially target antigen-experienced PD-1$^{\pm}$ CD8$^{\pm}$ T cells enriched in the tumor microenvironment (TME) while simultaneously blocking the PD-(L)1 pathway and inducing potent cytokine receptor stimulation in the same CD8$^{\pm}$ T cell *in cis (cis*-signaling*)*. Interleukin 18 (IL-18) is a proinflammatory cytokine able to integrate both innate and adaptive immunity resulting in profound anti-tumor immune responses mediated by T effector and NK cells. BPT567 has been generated via chemical conjugation of the anti-PD-1 Ab Lipustobart^{TM} to an enhanced human IL-18 variant of increased potency and reduced sensitivity to IL-18 binding protein (IL-18BP). BPT567 is designed to specifically target and activate a subset of tumor-infiltrating PD-1$^{\pm}$ IL18R$^{\pm}$ CD8$^{\pm}$ T effector cells recently described to exhibit superior cytotoxic and proliferative activity (Codarri Deak et al., Nature 2022). Due to its ability to signal *in cis*, BPT567 shows enhanced potency as well as increased resistance to IL-18BP when analyzing IFNγ release *in vitro* in PD-1$^{\pm}$ cells. Subsequent PD-1 receptor occupancy analyses showed that it is fully sufficient for BPT567 to engage a low number of PD-1 receptors to induce maximum IFNγ release in NK92 cells expressing human PD-1. Strikingly, despite addressing overlapping epitopes in PD-1, even a 200-fold excess of pembrolizumab has no impact on the *in vitro* potency of BPT567. *In vivo*, BPT567 exhibits strong anti-tumor efficacy at significantly lower IL-18 doses compared to the combination of an untargeted antibody-IL-18 conjugate and an anti-PD1 Ab further corroborating the importance of *cis*-signaling as a unique MoA of this PD1-IL18 conjugate. Detailed analyses of tumor-infiltrating immune leukocytes (TIL) revealed that BPT567 triggers a preferential expansion of CD8$^{\pm}$ T effector memory cells within the TME. In line with this finding, activity in the MC38 tumor model is dependent on the presence of CD8$^{\pm}$ T cells while depletion of other immune cell subsets (e.g. NK cells, CD4$^{\pm}$ T cells, macrophages) had no impact on efficacy. Although not required for anti-tumor efficacy, CD4$^{\pm}$ T cells are essential for proficient formation of an immunological memory. In an effort to confirm findings generated in murine models in relevant human *ex vivo* systems, we analyzed the release of cytokines and chemokines in dissociated cells isolated from primary human tumor explants. Also in this human model, BPT567 is able to induce significantly stronger IFNγ release compared to either single agents or the combination of untargeted IL-18 and an anti-PD1 Ab, thus confirming the unique MoA of the PD1-IL18 conjugate triggering superior TIL activation in *cis*.

#4072 Unleashing natural IL-18 activity using an anti-IL-18BP blocker antibody induces potent immune stimulation and anti-tumor effects.

A. Menachem[1], Z. Alteber[1], G. Cojocaru[1], T. Kfir[1], D. Blat[1], O. Leiderman[1], M. Galperin[1], L. Sever[1], N. Cohen[1], K. Cohen[1], R. Granit[1], S. Vols[1], M. Frenkel[1], L. Faigenbloom[1], L. Soffer[1], K. Meyer[1], K. Menachem[1], H. Tilleman[1], D. Morein[1], I. Borukhov[1], A. Toporik[1], M. Perpinial Shahor[1], E. Tatirovsky[1], P. Ferre[2], **E. Ophir**[1];

[1]Compugen Ltd., Holon, Israel, [2]Compugen Ltd., Toulouse, France

IL-18 is an inflammasome induced proinflammatory cytokine that augments T and NK cell activity and stimulates IFNγ production. The activity of IL-18 is naturally blocked by a high affinity endogenous binding protein (IL-18BP). IL-18BP is induced in the tumor microenvironment (TME) in response to IFNγ upregulation in a negative feedback mechanism. By evaluating 88 human tumor specimens and serum samples we were able to show that IL-18 is upregulated in the TME (median 11.2ng/gr) compared to serum samples (median 0.3ng/ml). Moreover, we showed that most of the IL-18 is bound by IL-18BP. IL-18BP-bound IL-18 levels were largely above the amount required for T cell activation *in vitro* (1.2ng/gr), implying that blocking IL-18BP has the potential to release IL-18 in tumors above the minimum range required for immune system stimulation. Next, to assess whether tumor endogenous IL-18 levels released by IL-18BP blockade are sufficient to provoke anti-tumor responses, COM503, a high affinity (<1pM) anti-IL-18BP Ab, was generated and examined in T and NK cell-based assays. In a co-culture assay of tumor cells with ex-vivo stimulated human tumor infiltrating $CD8^{\pm}$ lymphocytes, COM503 was able to displace IL-18 from a pre-formed complex and enhance IFNγ (197%, p<0.01) and TNFα (84% p<0.01) secretion. Additionally, COM503 induced human NK cell activation as reflected by increased IFNγ secretion (26-fold, p<0.001). Finally, in human ex vivo dissociated tumor cells assay, COM503 mediated an increase in Granzyme B (25%), IFNγ (38%), TNFα (58%) and IL-12 (50%) production. *In vivo*, administration of an anti-mouse IL-18BP Ab resulted in potent anti-tumor responses and increased survival across multiple mouse tumor models. In orthotopic E0771 tumor model, anti-IL-18BP Ab induced significant tumor growth inhibition (91% TGI, p<0.0001), as well as pronounced TME-localized immune modulation. This modulation included an increase in $CD8^{\pm}$ T cells expansion (108.5%, p=0.015) and activation, specifically in polyfunctional effector $IFN\gamma^{\pm}GrB^{\pm}CD8^{\pm}$ T cells (259%, p=0.02) and $IFN\gamma^{\pm}TNF\alpha^{\pm}$NK cells (77%, p=0.001). Similarly, anti-tumor effects were shown in $MC38OVA^{dim}$ model (58% TGI, p<0.001), accompanied by a robust TME-localized immune modulation including increased $CD8^{\pm}$ T cells expansion (85%, p=0.009) and IFNγ secretion (76%, p=0.052). In contrast to immune modulation in the TME, no increase in inflammatory cytokines and lymphocyte numbers or activation state was observed in serum and spleen. Taken together, our data suggest that IL-18 is upregulated in the TME, mostly bound by IL-18BP, and could be exploited to induce pronounced TME-localized immune modulation. Anti-IL-18BP Ab approach has a leading edge in inhibiting tumor growth while avoiding peripheral toxicity associated with administration of a cytokine. COM503 is currently undergoing IND-enabling studies.

#4073 Decoy-resistant IL-18 enhances checkpoint inhibitor combinations beyond anti-PD-1 *in vitro* and *in vivo*.

J. N. Lindquist[1], K. Qin[2], A. M. Ring[2], H. Uppal[1];

[1]Simcha Therapeutics, Inc., San Francisco, CA, [2]Fred Hutchinson Cancer Center, Seattle, WA

Background: Interleukin-18 (IL18) is a proinflammatory cytokine that modulates both innate and adaptive immune responses. Historically, wild-type recombinant IL-18 has shown limited anti-tumor efficacy in preclinical models and clinical trials, likely due to upregulation of IL-18 binding protein (IL-18BP), a negative regulator of the IL-18 signaling axis. Accordingly, an engineered IL-18 cytokine capable of interacting with the IL-18 receptor, but resistant to IL-18BP interactions (i.e., “Decoy-Resistant IL-18”, DR-18), has demonstrated enhanced therapeutic potential in mouse tumor models, both as a single agent and in combination with anti-PD-1 [1, 2]. Here we evaluated murine DR-18 in combination with additional checkpoint inhibitors beyond anti-PD-1 in a set of mouse tumor models, and tested human DR-18 activity *in vitro*/*ex vivo* for activation of human immune cells and anti-tumor activity.

Results: Treatment with mDR-18 elicited strong efficacy as a single agent and combination activity with immune checkpoint inhibitors (ICIs) across diverse syngeneic mouse models of solid tumors. As a single agent, mDR-18 demonstrated robust single agent activity in tumor growth inhibition for MC38 (>80%), CT26 (>60%) and B16-F10 (>55%). Combination treatment of mDR-18 with anti-PD-1, anti-CTLA-4, or anti-LAG-3 increased the efficacy for the MC38 (>85-95%), CT26 models (>80-85%), while the B16-F10 (>60%) showed smaller efficacy enhancement with the combinations. *In vitro* assays revealed human DR-18 (ST-067) activated immune cells and enhanced A549 tumor cell killing over 72hrs. Furthermore, *ex vivo* studies of 3D patient-derived tumor spheroids demonstrated that ST-067 impaired growth and increased immune cell infiltration, highlighting the potential of hDR-18 to enhance immune activity within the human tumor microenvironment.

Conclusion: These studies expand the breadth of IL-18/checkpoint synergism beyond anti-PD-1 and confirm enhanced human immune response *in vitro* with the clinical candidate ST-067. Taken together, these findings strengthen the rationale for clinical combination of ST-067 with ICI agents in patients with solid tumors.

#4074 Discovery of WTX-518, an IL-18 pro-drug that is conditionally activated within the tumor microenvironment and induces regressions in mouse tumor models.

K. R. Morris, H. Brodkin, K. Economides, D. J. Hicklin, J. LePrevost, C. Nagy-Domonkos, C. Nirschl, A. Salmeron, C. Seidel-Dugan, C. Spencer, Z. Steuert, W. M. Winston;
Werewolf Therapeutics, Watertown, MA

Systemic administration of proinflammatory cytokines is a promising approach to treat cancer. IL-18 has been shown to promote activation of both innate and adaptive anti-tumor responses in pre-clinical models. Specifically, IL-18 has been shown to impact macrophage suppressive function as well as drive CD4+ T cells towards a TH1 phenotype. However, IL-18 therapies have been hampered by a lack of efficacy due to the suppressive activity of IL-18 binding protein (IL-18BP), which binds to IL-18 and prevents its interaction with its receptor. Several groups have taken the approach of modifying IL-18 to render it resistant to IL-18BP as a potential strategy to enhance anti-tumor activity. To explore the therapeutic benefit of delivering a conditionally-activated IL-18 to the tumor microenvironment, we have developed inducible polypeptides (INDUKINE™ molecules) consisting of mouse IL-18 or IL-18BP resistant IL-18 (BPR IL-18) tethered via protease-sensitive linkers to a high affinity antibody blockade domain, and a half-life extension (HLE) domain which improves exposure in the tumor. IL-18 INDUKINE™ molecules are inactive until reaching the tumor microenvironment, where the linkers are cleaved by intra-tumoral proteases, releasing active IL-18. Intraperitoneal (i.p.) administration of an IL-18BP resistant IL-18 (BPR IL-18) INDUKINE™ molecule led to complete tumor regression in the MC38 tumor model. In contrast, equimolar doses of wild-type IL-18 INDUKINE™ protein were not as efficacious. Moreover, BPR IL-18 INDUKINE treatment led to increased activation and frequencies of NK cells and tumor specific CD8 T cells in MC38 tumors. WTX-518 is a novel INDUKINE™ molecule that is designed to selectively deliver active human BPR IL-18 to the tumor microenvironment. WTX-518 is inducible in vitro, either when tested using a reporter assay or primary immune cells. Importantly, the active BPR IL-18 payload is resistant to IL-18BP in reporter or primary immune cell assays. WTX-518 is also selectively inducible, as incubation *ex vivo* with various primary human tumors led to the release of active BPR IL-18, while WTX-518 was stable in human serum and after exposure to primary cells from healthy tissues. Pharmacological and efficacy data support continued preclinical development of this innovative and differentiated engineered IL-18 therapy.

#4075 Targeting attenuated IL-18 to PD-1: A next generation checkpoint inhibitor with enhanced anti-tumor activity.

X. Zhou, J. Takimoto, S. Yoon, N. Khanna, **B. Rabinovich**;
Fuse Biotherapeutics Inc., Boston, MA

PD-1 antagonists have shown strong clinical proof of concept, but the development of next-generation versions that can target tumors that weakly respond and/or acquire drug resistance is a critical medical need. Lymphocytes, including T cells and NK cells, upregulate PD-1 and other immunoregulatory receptors in response to neoantigens. Such immunoregulation is important for maintaining the persistence of immune responses in a controllable manner so that immune pathology does not overwhelm the host. In addition to microbial proteins, neoantigens are often expressed by tumor cells. These 'tumor antigens' are derived from mutated genes or proteins not presented during T cell education. As such, many established tumors contain areas of chronic inflammation, including a subset of PD-1+ T cells that can be 'de-immuno-regulated' by anti-PD-1 antagonist antibodies, thus enhancing anti-tumor activity. IL-18 is a cytokine that delivers a 'danger' signal to NK cells and T cell subsets that express the IL-18 receptor complex (RC) and increases their capacity to kill, induces proliferation, diminishes terminal exhaustion, and sustains survival. Importantly, IL-18RC is expressed on progenitor exhausted T cells, the population of T cells in solid tumors that is most active and responds to anti-PD-1, but not terminal exhausted T cells. The latter have been shown to be non-responsive to PD-1 antagonism. Thus, we engineered an anti-PD-1-IL-18 antibody to enhance anti-tumor immune responses. Such a therapeutic requires two key characteristics: resistance to inhibition by IL-18BP, IL-18's natural antagonist, and PD-1-dependent cis-restricted binding to the IL18RC on PD-1+ cells to reduce trans-based systemic toxicity. We have engineered an IL-18BP-resistant mutant of IL-18 and generated variants with different degrees of attenuation for PD-1-dependent cis targeting. Attenuation was achieved by sterically hindering the capacity of IL-18 to bind the IL-18RC while maintaining cis activity without a requirement for proteolytic activation. We identified a variant of IL-18 that is 10,000-fold attenuated and, when fused to an anti-PD-1 antibody, mediated (1) PD-1-dependent cis activity in vitro equivalent to ~5x that of anti-PD-1 alone and (2) tumor shrinkage in mouse tumor models, including an ~80% frequency of complete responses. Due to the high degree of IL-18 attenuation, we were able to dose mice without toxicity to levels at which full PD-1 antagonism is maintained. To our knowledge, this anti-PD-1-IL-18 variant is the first PD-1 targeted cytokine capable of activating PD-1+ T cells via the cytokine's receptor and fully antagonizing PD-1 as a single agent. Thus, targeting a highly attenuated variant of IL-18 that retains strong cis activity to PD-1 holds promise as a clinical candidate for the treatment of cancer indications that respond weakly to anti-PD-1 and/or are associated with acquired resistance.

#4076 Interleukin-18 engineered for resistance to IL-18 binding protein (IL-18BP) and half-life extension to enhance its therapeutic potential.

J. Chamoun, C. DiLea, K. Dreaden, P. Gurel, J. Heiber, R. G. Newman, S.-P. Pearson, C. Wang, Y. Zhao, **M. Whitmore**;
Mural Oncology, Waltham, MA

Interleukin-18 (IL-18) possesses a unique combination of innate and acquired immune functions with high potential to be transformative in cancer immunotherapy of solid tumors. In clinical studies, recombinant wild-type IL-18 was limited by rapid upregulation of IL-18 binding protein (IL-18BP), which serves as a negative feedback checkpoint of the IL-18 pathway. As its name implies, IL-18BP tightly binds to IL-18, thereby blocking its ability to activate the IL-18 receptor. We have focused our protein engineering efforts to obtain variants of IL-18 that are resistant to IL-18BP suppression while retaining IL-18 biological activity. To further capitalize on the immunological effects of IL-18, the IL-18BP resistant variants were fused to half-life extension protein scaffolds for enhanced in vivo exposure. Rational protein design and combinatorial approaches were used to generate a pool of IL-18 variants that were screened for potency and resistance to IL-18BP. Several IL-18 variants showed undetectable binding to IL-18BP (up to 1 mM IL-18BP) and displayed a spectrum of potencies relative to recombinant wild-type IL-18. Importantly, these variants retained their full biological activity in the presence of super-physiological levels of IL-18BP, as tested with in vitro cell-based IFN-γ release assays. In vivo pharmacokinetic studies in mice compared several IL-18BP resistant variants fused to a half-life extension scaffold with a non-half-life enhanced IL-18BP resistant variant. The half-lives for the fusion proteins ranged from 15 - 30h, while the non-fused variant showed a half-live of 0.6h. Furthermore, the IL-18 variants displayed a more durable, Th1 immune response compared to a non-half-life enhanced variant. Thus, IL-18 variants with strong resistance to IL-18BP that are fused to a half-life extension protein scaffold displayed enhanced pharmacokinetic and pharmacodynamic properties in preclinical mouse models. These protein engineering modifications will enable us to select an appropriate development candidate with enhanced pharmaceutical properties to achieve the full therapeutic potential of IL-18 to assess in patients with cancer.

#4077 T cell targeting with PD-1-selective immune cell engagers based on GlycoConnect™ (GC™-ICEs) show excellent efficacy and tolerability.

R. van Geel, M. Verhagen, E. Post, W. Vugs, S. Popal, S. van Berkel, F. van Delft;
Synaffix - A Lonza Company, Oss, Netherlands

Engagement of T cell cells to harness a patient's immune system is a promising approach in immuno-oncology. An immunocytokine, *i.e.* a tumor-targeting antibody (fragment) genetically fused to an immunostimulatory cytokine, is specifically designed for this purpose. Fusion antibody-immunocytokines, based on molecular architectures generated by a variant of DNA recombinant technologies, have recently entered the clinic. Earlier we have demonstrated how GlycoConnect™, a site-specific conjugation technology anchoring on the native antibody glycan[1], can be applied for attachment of various cytokines, including RLI or IL-15, without prior antibody engineering. The immunostimulatory activity of these GlycoConnect™ immune cell engagers (GC™-ICEs) can be modulated by tailoring linker design and payload stoichiometry. In this presentation, we demonstrate the GC™-ICE with either IL-15 or RLI can be applied to selective targeting of T cells, based on PD-1-selective binding and activation, using either protease-sensitive or non-cleavable linkers. We will show how such T cell targeting can be achieved leading to significant tumor volume reductions in syngeneic mouse models. Moreover, we have found that the GC-ICE™ can be applied without inducing systemic immune activation, thereby displaying a promising therapeutic index. In vitro and in vivo studies will be presented to showcase the biological activity of these GC™-ICEs in comparison to conventional immunocytokines obtained via genetic engineering.

[1]Wijdeven et al., Enzymatic glycan remodeling-metal free click (GlycoConnect™) provides homogenous antibody-drug conjugates with improved stability and therapeutic index without sequence engineering. *mAbs* 2022, 14, DOI: 10.1080/19420862.2022.2078466.

#4078 WTX-712, a conditionally active IL-21 INDUKINE™ molecule, induces a strong anti-tumor phenotype through a differentiated mechanism.

J. M. Sullivan, P. A. Aderhold, H. R. Brodkin, C. Nagy-Domonkos, K. Economides, D. J. Hicklin, N. Ismail, Y. Lewis, C. Seidel-Dugan, W. M. Winston, A. Salmeron;
Werewolf Therapeutics, Watertown, MA

Despite great strides seen recently in the development of immunotherapies such as immune checkpoint inhibitors (ICI), many patients do not respond or acquire resistance, highlighting a need for alternative immunotherapies. As potent immunomodulators, cytokines have been explored as treatments for cancer, but their use has been limited due to toxicity and poor pharmacokinetics (PK). One of these key cytokines, interleukin 21 (IL-21), is a pluripotent cytokine that activates anti-tumor T cell responses, induces B cell activation, and promotes generation and maintenance of germinal centers and tertiary lymphoid structures. IL-21 acts on a broader range of cells and does not induce vascular leak syndrome compared to IL-2, another common-gamma chain family member. Half-life extended IL-21 (IL-21-HLE) drives robust anti-tumor activity in several syngeneic tumor mouse models. Of particular interest, IL-21-HLE showed superior anti-tumor activity compared to IL-2-HLE in the EMT-6 and Renca models, both of which are highly resistant to anti-PD-1/PD-L1 treatment. Although IL-21-HLE and IL-2-HLE induced a similar frequency of tumor infiltrating CD8+ T cells, IL-21-HLE treatment led to higher polyfunctionality in CD8+ T cells than IL-2-HLE treatment. Of note, IL-21-HLE induced greater amounts of effector cytokines, Granzyme B and perforin, than IL-2-HLE. Transcriptomic analysis revealed that IL-21 drives upregulation of a type I IFN signature in the tumor promoting an anti-tumorigenic microenvironment. Clinical activity of IL-21 has been hampered by poor PK and adverse events at dose levels associated with signs of efficacy. To overcome these limitations Werewolf Therapeutics has developed WTX-712, an IL-21 INDUKINE™ molecule, which contains wild-type human IL-21, an inactivation domain, and a half-life extension domain tethered together by protease sensitive linkers. In preclinical studies with mouse syngeneic tumor models, WTX-712 is inactive in the periphery, and wild-type IL-21 is selectively released within the tumor, resulting in anti-tumor efficacy with an expanded therapeutic window compared to IL-21-HLE. Anti-tumor efficacy was linked to expansion and activation of tumor infiltrating CD8 T cells with increased polyfunctionality. We will show additional mechanistic data evaluating the effect of WTX-712 dosing on immune populations, including tumor spatial profiling using different models.

#4079 EGL-001 is a novel immunocytokine designed to specifically target and disarm T regulatory cells in the tumor microenvironment.

[1]Egle Therapeutics, Paris, France, [2]Institut Curie, Paris, France, [3]Institut Pasteur, Paris, France

Introduction Immune checkpoint blockade (ICB) therapies targeting PD-1/PD-L1 or CTLA-4 have greatly improved clinical outcome in many cancers. However, multiple mechanisms of resistance to ICB severely limit the number of patients experiencing long-term survival benefits. Overcoming resistance to ICB represents a significant challenge for drug development. Regulatory T cells (Tregs) in the tumor microenvironment (TME) prevent effector T cells (Teffs) from mounting a productive immune response and have been implicated in ICB resistance. Novel therapeutic strategies aimed at disarming Tregs in the TME could restore anti-tumor responses and sensitize patients to ICB therapy. Treg survival is dependent on interleukin-2 (IL-2), which signals in Tregs via the high affinity IL-2 receptor (IL-2R). Tumor-associated Tregs differentiate from tumor-associated Teffs and from peripheral Tregs by higher expression of CD25, the IL-2R alpha chain. Tregs in the TME also express higher surface levels of CTLA-4 as compared to peripheral Tregs. Thus, CD25 and CTLA-4 overexpression could allow preferential targeting of tumor-associated Tregs.

Methods and Results We used single-cell RNA sequencing data from cancer patients and flow cytometry analysis of human tumor samples to verify that CD25 and CTLA-4 are selectively overexpressed in tumor-associated Tregs as compared with peripheral Tregs or other T cells. Based on these findings, we developed EGL-001, a novel immunocytokine (ICK) comprising a humanized IgG1 directed against CTLA-4 fused to a Treg-specific IL-2R antagonist IL-2 mutein, to selectively target tumor infiltrating Tregs. EGL-001 IgG1 moiety binds membrane CTLA-4, as demonstrated by flow cytometry, and competes with CTLA-4-CD80/86 interaction, as evaluated by ELISA. EGL-001 IL-2 mutein moiety binds to CD25, as demonstrated by bio-layer interferometry, and specifically blocks high-affinity IL-2R signaling in Tregs. Signaling blockade is further potentiated by a CTLA-4 dependent CD25 downmodulation process evidenced by confocal microscopy and flow cytometry. We demonstrate that EGL-001 unique tumor-associated Treg-targeted dual mechanism of action results in increased Treg apoptosis and decreased Treg frequencies in multiple in vitro, ex vivo and in vivo systems. Importantly, EGL-001 only minimally affects IL-2 signaling and survival of Teffs, which are then expected to be unleashed from Treg cell-mediated suppression. Accordingly, EGL-001 induces anti-tumor responses in mice in combination with anti-PD1 therapy.

Conclusions EGL-001 is an ICK with a novel and unique mechanism of action combining ICB and Treg selective IL-2 starvation, designed to specifically disarm and deplete tumor-associated Tregs. Based on our preclinical data, EGL-001 is being developed as a cancer immunotherapeutic to improve patients' response to ICB and counteract ICB resistance.

#4080 IBB0979, A novel B7H3/IL-10 immunocytokine of monovalent anti-B7H3 antibody fused with IL-10 homodimer.

X. Jiang, C. Wu, Z. Chen, **L. Yin**;
SUNHO (China) BioPharmaceutical Co.,Ltd., Nanjing, China

Background: This study demonstrates the preclinical evaluation of a novel B7H3/IL-10 immunocytokine IBB0979. IBB0979 was designed to solve the problems of immune cell exhaustion and drug resistance in current immunotherapy. As the tumors progress, the domination of progenitor exhausted T cells (which are the major target cells of current PD-1/L1 based immunotherapy) will be replaced by terminally exhausted T cells (which are the major target cells of IL-10) causing resistance of current PD-1/L1 based therapies. Thus, IL-10 is a potent activator of antigen-specific CD8+ T cells in the tumor microenvironment and can restore the tumor-killing activity of tumor-infiltrating lymphocytes by restoring the oxidative phosphorylation metabolism of terminally exhausted T cells. B7H3 is highly expressed on various tumors but expressed at lower levels in normal tissues and blood vessels, which makes it an ideal target for developing cancer treatment. Also, B7H3 antibody extended the half-life and performed tumor-targeted delivery of IL-10, which improves the safety and efficacy of IL-10.
Methods: We designed several structures of B7H3 antibody and IL-10 bifunctional fusion protein. Binding activity to B7H3 and IL-10 receptor was evaluated by both ELISA and FACS. C57BL/6J mice bearing MC38-hB7H3 cell line were used to evaluate the anti-tumor efficacy of IBB0979. Preclinical PK and toxicity study was also performed in cynomolgus monkeys to describe the safety profile of IBB0979.
Results: Preclinical study showed that IBB0979 has high affinity to both targets and exhibited potent TGI in C57BL/6J mice bearing MC38-hB7H3 cell line, with TGI of 100% at 0.3mg/kg, 1mg/kg and 3mg/kg. An *in vivo* study in cynomolgus monkeys showed that after intravenously administered with 1 mg/kg, 2 mg/kg and 6 mg/kg of IBB0979 once a week for 29 days (5 times in total, given on days 1, 8, 15, 22 and 29), MTD was not reached up to 6 mg/kg which is significantly higher than the 10-20 μg/kg tolerated by IL-10 cytokines alone.
Conclusion: IBB0979 is the world's first B7H3/IL-10 immunocytokine receiving IND approvals from both the FDA and the NMPA, showing excellent preclinical efficacy and safety profile. The Phase I clinical trial is currently on-going, with the first patient dosed in July 2023 and achieved SD at first efficacy evaluation after 2 cycles of administration. Since B7H3 is overexpressed in a wide range of cancers including lung, prostate, glioma, thyroid, head and neck, rectal, breast, skin, renal cell, and ovarian cancers, IBB0979 has the potential to become a next-generation therapy for resolving T cell exhaustion in cancer patients.

#4081 rhIL-7-hyFc (efineptakin-alfa, NT-I7) increases tumor-specific CD8+ T cells despite FOLFOX cytotoxicity effect.

Soung-Min Lee[1], Miyoung Kim[1], **Taekyung Yu**[2], Sara Ferrando-Martinez[3], Sun-Kyoung Im[1], Mankyu Ji[1], Donghoon Choi[1]

[1]NeoImmuneTech, Inc., Gyeongsangbuk-do, Korea, Republic of,[2]Research Institute of NeoImmuneTech, Co., Ltd., Pohang, Korea, Republic of,[3]NeoImmuneTech, Inc., Rockville, MD

rhIL-7-hyFc (efineptakin-alfa; NT-I7) is a potent T cell amplifier, comprised of two molecules of interleukin-7 (IL-7) fused to the hybrid Fc domain of IgD/IgG4 immunoglobulin. NT-I7 safely, significantly, and persistently increases the absolute lymphocyte counts (ALC) in humans in a dose-proportional manner. Importantly, this increase is primarily due to an increase in T cells (1). Previous studies have shown that NT-I7 not only significantly increases the number of CD8+ T cells in peripheral blood but also dramatically boosts the presence of tumor-infiltrating CD8+ T cells, including both tumor-specific (p15E+PD-1+) and tumor non-specific (PD-1-) CD8+ T cells in mice (2). FOLFOX is a chemotherapy regimen composed of 5-fluorouracil, leucovorin, and oxaliplatin that inhibits DNA duplication and eradicates rapidly dividing cells (3). Although the mechanism of FOLFOX results in direct tumor killing, it also has the potential to kill newly dividing lymphocytes during NT-I7 treatment (4-6). Therefore, in this study, we aimed to evaluate the feasibility of combining FOLFOX with NT-I7 in a syngeneic MC38 mouse tumor model. Our results show that NT-I7 improves the efficacy of FOLFOX, irrespective of the timing of NT-I7 administration: simultaneous administration or delayed 3 hours, or 2 days after FOLFOX administration. This improvement persists despite a significant decrease in ALC for the first 6 days, which was significantly lower than the ALC observed with FOLFOX alone. FOLFOX decreases the absolute numbers of tumor non-specific CD8+ T cells. However, adding FOLFOX does not affect the NT-I7-driven increase of tumor-specific CD8+ T cells within the tumor. Taken together, our data demonstrate that FOLFOX does not compromise NT-I7's ability to increase tumor-specific T cells within the tumor and the combination enhances the anti-tumor response irrespective of the timing of NT-I7 administration.

#4082 Anchored IL-12 synergizes with an epigenetic modulator to promote immune remodeling and overcome anti-PD1-refractory murine tumors.

A. S. Khelifa[1], K. L. Lothstein[1], M. Miyamoto[1], R. Tighe[2], S. Battula[2], H. L. Kaufman[2], J. Schlom[1], S. R. Gameiro[1];
[1]National Cancer Institute, Bethesda, MD, [2]Ankyra Therapeutics, Cambridge, MA

Background Most patients with solid malignancies harbor innate or acquired resistance to immune checkpoint blockade (ICB), prompting the need for novel therapeutic strategies. Interleukin-12 (IL-12) is a promising cytokine for cancer therapy due to its ability to bridge innate and adaptive immunity. However, a narrow therapeutic index limits the use of systemic IL-12 therapy. Here, we investigated the tumor-suppressive effects and mode of action of intra-tumorally delivered murine Interleukin-12 anchored to aluminum hydroxide (referred as mANK-101) in combination with the class I HDAC inhibitor entinostat, in various ICB-refractory murine tumor models, including CT26 (colorectal) and MOC-1 ($HPV16^{neg}$). We hypothesized that combining Entinostat with an anchored form of IL-12 could overcome systemic toxicity while maintaining anti-tumor activity.
Methods Entinostat and intra-tumoral mANK-101 were administered to mice bearing well-established αPD-1-refractory CT26 (colorectal) and MOC-1 ($HPV16^{neg}$) tumors. Antitumor activity, survival, and protective memory upon tumor rechallenge were evaluated. Comprehensive proteomic and immune cell analysis was performed in MOC-1 tumors, tumor-draining lymph node (tdLN), and periphery. Tumor-specific T cell responses were examined.
Results We demonstrate that intra-tumoral mANK-101 synergizes with entinostat to suppress multiple αPD1-refractory tumors, resulting in significant tumor eradication (62-88%), survival benefit ($P < 0.0001$), and protective memory, including CT26 (colon, Kras $G12D^{mut}$) and MOC-1 (oral, $HPV16^{neg}$). Analysis of MOC-1 tumor-bearing mice demonstrated these effects to be associated with peripheric activation of $CD8^{\pm}$ and NK lymphocytes, augmented polyfunctional $IFNγ^{\pm}/TNFα^{\pm}$-producing $CD8^{\pm}$ T cells, $CD8^{\pm}$ T cell effector memory, and tumor-specific T cell responses. Significant decrease in $CD4^{\pm}$ Tregs and increased CD8/Treg ratio were also observed. Ongoing functional studies, proteomic and immune cell analysis at the tumor site, tdLN, and periphery, including single cell transcriptomics and epigenetic studies, will allow for a deeper understanding of the synergistic effect of mANK-101 with the epigenetic modulator Entinostat.
Conclusions Collectively, these findings form a rationale for the clinical combination of intralesional delivery of ANK-101 with entinostat for patients with ICB-refractory malignancies, including colorectal and $HPV16^{neg}$ head and neck cancers.

#4083 Pre-clinical development of IAMA-005, a long-acting cytokine fusion of modified IL-2 and IFN-α.

L. Liu, Z. Han, Y. Fan, Q. Pan;
Nanjing JSIAMA Biopharmaceuticals, Ltd., Nanjing, China

In 1990s, both IL-2 and IFN-α were approved as the first two immunotherapies for metastatic melanoma and renal cell carcinoma; IFN-α was also approved for hairy cell leukemia. Although the response rates are relatively low, along ~25%, those who responded have long term survival benefits. However, the severe toxicity especially in high dose prohibited their broad use in oncology. Recently, there have been tremendous interests in modifying these two cytokines in the efforts to reduce the toxicity and enhance the activity. One such effort is to enhance the binding of IL-2 to the intermediate affinity β/γ receptors, which are expressed and function on CD8 T cells and NK cells. Another effort is to reduce the binding of IL-2 to high affinity α/β/γ receptors which mostly expressed on Treg and stimulate the growth of Treg cells, which suppress immune responses. Recently, whether it's better to target intermediate affinity or high affinity for cancer therapy has become controversial with some studies showing that high affinity receptor engagements are required for robust anti-tumor activity while others favoring intermediate affinity receptor engagement for better efficacy; However, the clinical comparison is still lacking to be sure which approach is better. Here we have developed a long-acting novel IL-2-Fc-IFN-α fusion molecule termed IAMA-005 that has mutations to reduce the toxicity effects of IL-2 and IFN-α. We have characterized this molecule preclinically both *in vitro* and *in vivo*. IAMA-005 has demonstrated a potent tumor cell killing activities in numerous cancer cell lines including BT-474, SK-OV-3, NCI-N87, OE19, HCC-1954, MDA-MB-231, MDA-MB-468. When combined with IAMA-004 (a Her2-CD47-CD16 tri-specific antibody) *in vitro*, the tumor cell killing activities were dramatically increased. In addition, IAMA-005 was also tested in patient-derived *Ex-Vivo* fluids (one malignant pleural effusion and one malignant asities) and demonstrated excellent tumor cell killing efficacies. In addition, the killing activities of IAMA-005 could be attributed to the specific part of the fusion molecule because of the TME immune cell compositions. The *in vivo* assays to demonstrate efficacy and safety are ongoing and will be presented in the poster. These results suggest that this fusion cytokine molecule may be used in monotherapy in certain indications and an excellent complementary therapeutic to antibody targeted therapies or immunotherapies when used in combination.

#4084 Potent anti-tumor activity of ABN202 (anti-EGFR antibody-interferon-beta mutein) through direct cytotoxicity and indirect immune activation against non-small cell lung cancer, regardless of EGFR mutation status.

H. Park[1], S. Cho[1], H. Park[1], M. Jo[1], J. Park[2], M. Seo[2], J. Kim[2], S. Hong[3], K. Song[4], C. Lee[5], H. Jeong[5], S. Lee[1], N. Kim[1], J. Choi[1], Y. Shin[2];
[1]ABION Inc., Seoul, Korea, Republic of, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of, [3]Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of, [4]College of Pharmacy, Duksung Women's University, Seoul, Korea, Republic of, [5]Genopharm Inc., Seoul, Korea, Republic of

Epidermal growth factor receptor (EGFR) is overexpressed or mutated in many patients with non-small cell lung cancer (NSCLC). Targeting EGFR mutation by tyrosine kinase inhibitors (TKIs) has significantly improved overall survival (OS) in patients with EGFR mutations. However, many patients experience tumor recurrence due to various resistance mechanisms. Therefore, there is an unmet medical need for new treatment strategies for patients with EGFR-positive NSCLC, regardless of EGFR mutation status. ABN202 is an antibody-cytokine fusion protein (ACFP) that serves as a platform technology compromising the IFN-β mutein (ABN102) fused to various antibodies for specific tumor targeting. In a previous study, we designed ABN202 (αEGFR) to comprise an EGFR targeting antibody (Cetuximab) and IFN-β mutein (ABN102) and we confirmed anti-cancer activities of ABN202 against EGFR-positive NSCLC. In this study, the direct cytotoxicity of ABN202 (αEGFR) was evaluated in human NSCLC cell lines with various driving mutations and EGFR expression levels. The indirect immune activation was tested in human peripheral blood mononuclear cells (PBMCs) and human IFNAR1/2 knock-in (KI) mice. The *in vivo* efficacy was evaluated in human NSCLC xenograft mouse models and human IFNAR1/2 KI mouse models. ABN202 (αEGFR) demonstrates potent anti-tumor activity through direct cytotoxicity and indirect immune activation in NSCLC, regardless of EGFR mutation status. Taken together, we suggest that ABN202 (αEGFR) is a promising drug candidate against NSCLC, regardless of EGFR mutation status.

#4085 The anti-VISTA x MSLN bispecific antibody-interferon beta mutein fusion protein: A trispecific immunocytokine with potent therapeutic efficacy against malignant pleural mesothelioma.

H. Park[1], H. Kim[2], M. Seo[2], J. Park[2], T. Kim[2], J. Choi[2], J. Park[2], K. Song[3], C. Lee[4], H. Jeong[4], J. Choi[1], Y. Jeon[5], Y. Choi[6], S. Hong[7], Y. Shin[2];
[1]ABION Inc., Seoul, Korea, Republic of, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of, [3]College of Pharmacy, Duksung Women's University, Seoul, Korea, Republic of, [4]Genopharm Inc., Seoul, Korea, Republic of, [5]Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [6]Department of Pathology and Translational Genomics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [7]BitD Inc., Siheung, Korea, Republic of

Background Malignant pleural mesothelioma (MPM) is a rare and highly fatal cancer primarily induced by asbestos exposure. The 5-year overall survival rate for MPM patients is less than 20%. Before the FDA approval of the combination of immune checkpoint inhibitors (Nivolumab + Ipilimumab, CHECKMATE-743), chemotherapy was the only systemic therapy for MPM. However, the predominant histological type of MPM, epithelioid MPM, comprising approximately 70% of cases, showed limited clinical benefits from immune checkpoint inhibitors when compared to non-epithelioid histology. Consequently, there is an unmet medical need to develop a new anti-cancer drug specifically for the treatment of epithelioid MPM. In this study, we discovered that V-domain Ig suppressor of T cell activation (VISTA), an immune checkpoint protein, and Mesothelin (MSLN), a tumor differentiation antigen, are co-expressed in epithelioid MPM. Subsequently, we developed a biomarker-based anti-VISTA x MSLN bispecific antibody (BsAb) and anti-VISTA x MSLN BsAb-IFN-β mutein fusion protein (trispecific immunocytokine) for the treatment of epithelioid MPM.

Method We designed and screened various structures of the anti-VISTA x MSLN BsAb. To produce the trispecific immunocytokine, we fused IFN-β mutein (R27T/C17S), which exhibits improved stability, productivity, and pharmacokinetic properties compare to recombinant IFN-β. The *in vitro* efficacy of the trispecific immunocytokine was tested in human MPM cell lines, and its *in vivo* efficacy was evaluated in a human MPM xenograft mouse model and a human IFNAR1/2 Knock-in (KI) mouse model.

Results We demonstrated a strong positive correlation between the expression levels of VISTA and MSLN in epithelioid MPM. The Anti-VISTA x MSLN BsAb showed improved binding affinity and antibody-dependent cell cytotoxicity (ADCC) activity. The trispecific immunocytokine displays analogous biological activities to both Anti-VISTA x MSLN BsAb and IFN-β mutein. The trispecific immunocytokine exhibited potent *in vivo* and *in vitro* anti-cancer activities against epithelioid MPM preclinical models, operating through both direct cytotoxicity and indirect activation of immune cells.

Conclusion The trispecific immunocytokine demonstrated robust *in vitro* and *in vivo* anti-cancer efficacy in the epithelioid MPM model. Our findings suggest that the trispecific immunocytoine is a promising drug candidate for epithelioid MPM.

#4086 ABN202 (anti-Trop-2-interferon-beta mutein): A potent antibody-cytokine fusion protein for the treatment of Trop-2 positive solid tumors.

H. Park[1], H. Lee[1], M. Seo[2], D. Kim[2], S. Bang[2], J. Lee[2], S. Hong[3], K. Song[4], C. Lee[5], H. Jeong[5], S. Lee[1], N. Kim[1], J. Choi[1], Y. Shin[2];
[1]ABION Inc., Seoul, Korea, Republic of, [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Republic of Korea., Seoul, Korea, Republic of, [3]Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Republic of Korea., Seoul, Korea, Republic of, [4]College of Pharmacy, Duksung Women's University, Seoul, Republic of Korea., Seoul, Korea, Republic of, [5]Genopharm Inc., Seoul, Republic of Korea., Seoul, Korea, Republic of

Trop-2, trophoblast cell-surface antigen 2, is a type 1 transmembrane glycoprotein overexpressed in many solid cancers, including breast, lung, pancreatic, bile duct and bladder cancer. Overexpression of Trop-2 in cancer patients is associated with disease progression and poor prognosis. The antibody-drug conjugate (ADC) targeting Trop-2, Sacituzumab-govitecan (Trodelvy®), is approved for patients with triple-negative breast cancer (TNBC) and bladder cancer. However, Trop-2 targeting ADCs exhibit a high frequency of grade 3/4 adverse events and a short duration of response. Therefore, there is an unmet medical need for new treatment strategies beyond ADCs. In a previous study, we designed ABN202 (αTrop-2) to comprise a Trop-2 targeting antibody (Sacituzumab) and IFN-β mutein (ABN102) for the Trop2-positive tumor-specific delivery of ABN102. We confirmed anti-cancer activities of ABN202 against Trop-2 positive bladder cancer. In this study, we evaluated *in vitro* and *in vivo* anti-cancer efficacy of ABN202 (αTrop-2) in Trop-2 positive TNBC, bile duct cancer and bladder cancer cell lines. To identify response biomarkers for ABN202 (αTrop-2), we analyzed cell lines exhibiting both response and non-response to ABN202 (αTrop-2). In conclusion, ABN202 (αTrop-2) demonstrated potent anti-cancer efficacy compared to Trodelvy®. Our results support ABN202 (αTrop-2) as a promising drug candidate against Trop2-positive solid tumors.

The crosstalk between gut microbiome and anti-tumor immunity has recently gained attention in clinical settings. The administration of antibiotics during immune checkpoint blockade (ICB) therapies has been correlated with poorer outcomes in cancer patients, suggesting that microbiome alterations affect overall responses to ICB. The establishment of microbiota-specific T cell clones with tumor cross-reactivity potential was proposed as one of the mechanisms linking the microbiome to anti-tumor responses. Vaccine-based strategies aimed at reactivating these dormant pools of T cells to help eliminate tumors have been proposed as an alternate approach, but the parameters required for successful responses remain poorly understood. Here, we performed in silico selection of bacterial peptides derived from healthy mice based on their mimicry of either tumor-associated antigens (TAAs) or neoantigens expressed by murine melanoma cells and not healthy tissue. We show that in silico predicted peptide binding affinity to MHC I correlates with experimental MHC I binding, a key factor associated with strong immune responses. Moreover, we confirmed that a significant proportion of selected peptide candidates can provoke an immune reaction in a vaccination setting. From this group of peptides, we selected candidates which triggered cross-reactive immune responses against TAAs or neoantigens. Data from preliminary tumor challenge experiments with prophylactic peptide vaccination and ICB allowed us to define key parameters such as target gene expression levels which can predict the cross-reactive potential of bacterial peptides that mimic tumor antigens. These findings provide novel insights into the design of gut microbiome peptide-based tumor vaccines and pave the way for establishing combinatorial therapies with immunomodulatory drugs.

#4091 A novel cancer vaccine based on hyaluronic acid nanogel combined with adoptive T cell therapy induces complete regression of established tumors and long-lasting memory CD8$^{\pm}$ T cells.

F. Momose[1], T. Nakai[2], K. Yabuuchi[2], M. Yamane[1], T. Hayashi[1], L. Wang[1], Y. Nakagawa[2], S. Aso[2], T. Katsumata[2], T. Shimoboji[2], Y. Miyahara[1];
[1]Mie University Graduate School of Medicine, Mie, Japan, [2]Asahi Kasei Corporation, Tokyo, Japan

Background: We have developed nanosized hydrogel particles (nanogels) to create new nanomaterials for biomedical applications. In particular, Hyaluronic Acid, partially hydrophobized by chemical modification with cholesteryl groups, has a distinguished characteristic to form physically cross-linked NanoGel particles. HANG efficiently forms a stable complex with an antigenic polypeptide (HANG-Vaccine) through hydrophobic interactions. In this study, we investigated the efficacy of HANG-V against tumors resistant to immune checkpoint inhibitors (ICIs) and adoptive TCR-T therapy.
Methods: C57BL/6-derived B16F10 melanoma and BALB/c-derived CMS5a sarcoma are both known to be resistant to ICIs and adoptive TCR-T therapy. The efficacy of HANG-V was tested by using each tumor-bearing mice treatment model. HANG-V was prepared by mixing gp100 or CMS5a neoantigen (Ag) with HANG, respectively.
Results: HANG-V was subcutaneously injected into B16F10-bearing C57BL/6 on days 7, 11, and 15, and CD8$^{\pm}$ T cells from Pmel-1 mice were intravenously administered on days 8 and 12. Surprisingly, complete regression of established B16F10 tumors with more than 100 mm^2 were observed. Vaccinated mice survived with changing hair color of mice into white, while non-vaccinated mice were all dead by day 25. Moreover, gp100-specific CTLs was observed abundantly in systemic including tumor site. Even two months after the treatment, transferred T cells with memory phenotype were persistently detected in peripheral bloods. Furthermore, booster vaccination elicited robust expansion of these memory T cells persisting for more than one year. In similar experimental settings, we treated CMS5a tumor-bearing mice by HANG-V combined with adoptive transfer of CD8$^{\pm}$ T cells from DUC18 mice, whose T cells are specific for mutated ERK2 neoAg. All mice survived as well with complete reduction of established CMS5a tumors, rejected a rechallenge with CMS5a and induced an Ag-specific CTL responses on more than 2 years. Notably, by using neoantigen-knockout CMS5a, we obtained results suggesting that HANG-V with TCR-T therapy potently induced the so-called “antigen spreading”. Furthermore, induction of Ag-specific CTLs was associated with CD44 hyaluronic acid receptor which expressed in APCs crucial for cross-presentation to CD8$^{\pm}$ T cells.
Conclusions: HANG-V strongly enhanced the efficacy of adoptive TCR-T cell therapy against ICI refractory tumors leading to total tumor suppression. Furthermore, HANG-V induced potent and persistent Ag-specific CTLs systemically through interaction with CD44 hyaluronic receptor, allowing long-term protection of tumor recurrence with memory CD8$^{\pm}$ T cells. Our studies may propose crucial insights for clinical application of HANG vaccine with adoptive T cell therapy in patient with ICI-resistant tumors with poor prognosis.

#4092 Characterizing the endogenous retroviral envelope protein ERVMER34-1 as a target for a therapeutic cancer vaccine.

M. Maldonado, M. Iida, M. Gracia Hernandez, L. Le, R. N. Donahue, C. Palena, J. Schlom, D. H. Hamilton;
NIH-NCI, Bethesda, MD

Endogenous retroviruses (ERVs) are remnants of retroviral germline infections which occurred over the course of evolution and constitute between 5-8% of the human genome. Although ERV protein expression is typically silenced epigenetically in normal adult human tissues, previous studies have shown that some ERVSs, can be aberrantly expressed in multiple cancer types. This atypical expression of ERVs in tumors may represent a class of immunologically relevant tumor-associated antigens that can potentially be targeted clinically using therapeutic cancer vaccines. For the first time, this study evaluates the ERV envelope protein ERVMER34-1 as a potential target for a therapeutic cancer vaccine. We first assessed the expression of ERVMER34-1 in multiple tissues and found that ERVMER34-1 protein is absent in most healthy adult tissues and over expressed in multiple types of human carcinomas. ERVMER34-1 specific T-cells were detected in PBMCs of cancer patients but not healthy donors following an overnight stimulation. However, reactive T-cells are readily expanded from both healthy donor and cancer patient PBMCs following a 7-day in-vitro stimulation. Importantly, reactive CD8+ T cells selectively killed human carcinoma cells expressing the target antigen. Based on these findings, we rationally designed a ERVMER34-1 therapeutic cancer vaccine and assessed its immunogenicity and anti-tumor efficacy in established syngeneic murine tumors expressing the full-length ERVMER34-1 protein. Our rationally designed ERVMER34-1 cancer vaccine significantly mediated tumor regression and extended survival as a monotherapy and in combination with checkpoint blockade. Altogether, our work supports the clinical development of a therapeutic cancer vaccine targeting the retroviral envelope protein ERVMER34-1 as a potential first-in-class immunotherapeutic target for the therapy of several carcinoma types.

#4093 Modeling tumor immunoediting under immune selective pressure to inform neoantigen landscape dynamics for effective cancer vaccines.

M. M. George[1], J. Lihm[2], H. Choi[1], Y. Elhanati[2], S. Martis[2], M. Luksza[3], B. Greenbaum[2], J. D. Wolchok[1], T. Merghoub[1];
[1]Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Mount Sinai School of Medicine, New York, NY

Tumor specific neoantigens, encoded by somatic mutations, are recognized by T cells, inducing anti-tumor immune responses. This renders neoantigens viable targets for personalized cancer vaccines. However, the identification of immunogenic neoantigens remains suboptimal. Understanding how immune selective pressure-mediated tumor evolution and neoantigen editing contribute to emergence of immunogenic neoantigens may improve prediction accuracy. In this study, we aimed to model tumor evolution and heterogeneity under immune pressure using three preclinical models of lung cancer with common driver mutations, Kras G12D/+ and p53 -/-, namely KPA, KPC, and HKP1, subcutaneously implanted in immunocompetent C57BL/6 (B6) and immune-deficient Rag1-/- mice. Our data suggest that despite shared driver mutations identified by whole exome and RNA-seq, tumor growth in vivo varied between tumor models. KPA tumors were immunogenic, as they were controlled in B6 mice but rapidly progressed in Rag1-/- mice, suggesting immunoediting of KPA-specific neoantigens. In contrast, HKP1 was non-immunogenic, with tumors progressing regardless of immune competency. KPC showed moderate tumor control in B6 mice, which was lost in Rag1-/- mice. We then estimated the cancer cell fraction on every mutation based on phylogenetic reconstruction. Immunogenic KPA tumors had significantly lower mutation burden in B6 than in Rag1-/- mice and the fraction of cell line mutations edited in vivo was significantly higher, suggesting active immunoediting in the former. Non-immunogenic HKP1 tumors did not show significant differences in mutation burden nor fraction of mutations edited between B6 and Rag1-/- mice. The immunogenicity was reflected in the immune infiltrate levels within tumors, with KPA being highly infiltrated by activated CD4 and CD8 T cells compared to KPC. HKP1 tumors showed increased infiltration of suppressive regulatory T cells. T cell receptor (TCR) sequencing on lung tumors showed that clonal expansion is strongly associated with immunogenicity. KPA tumors showed significantly higher TCR clustering with less diversity compared to KPC and more than HKP1. Following a simple approach to study the immunogenicity of shared neoantigens to elicit cross-protective anti-tumor responses, mice were immunized with whole irradiated (IR) tumor cell lines and implanted with live tumor cells (matched and unmatched). While immunization with IR-KPA protected against corresponding tumor implant and moderately against KPC, it did not protect against HKP1, indicating lack of immunogenicity of mutations shared between KPA and HKP1. Further studies testing the anti-tumor responses and characteristics of neoantigens shared between these three related tumor cell lines will inform the conditions under which tumors may escape or regress and help improve neoantigen identifying algorithms.

#4094 Immune modulatory cancer vaccines against IDO1 and PD-L1 trigger distinct pathways and cooperatively reduce tumor growth in preclinical models.

M. Chapellier[1], E. Martinenaite[1], P. Patel[1], L. Svendsen[1], S. Munir Ahmad[2], H. Jorinde Glockner[2], M. Carretta[1], E. Sutanto-Ward[3], J. DuHadaway[3], S. Dey[3], S.-C. Shen[3], D. Ghaban[3], M. Iglesias[1], M. Biller[1], I. Lecoq[1], A. J. Muller[3], M. Hald Andersen[2], A. Wakatsuki Pedersen[1];
[1]IO Biotech, Copenhagen, Denmark, [2]Center for Cancer Immune Therapy, Copenhagen, Denmark, [3]Lankenau Institute for Medical Research, Wynnewood, PA

While immune checkpoint inhibitors have shown clinical efficacy in many cancers, drug and immune resistance remain challenging. Indoleamine 2,3-dehydrogenase (IDO1) and Programmed Death Ligand 1 (PD-L1) both contribute to immunosuppression, leading to immune escape and cancer progression. In this context, vaccination to promote T-cell immunity against IDO1^{+} and PD-L1^{+} cells is an attractive strategy that demonstrated encouraging clinical results in melanoma (Kjeldsen et al. Nat Med 2021). Our study aims to further evaluate the efficacy and mode of action of combined IDO1 and PD-L1 peptide vaccines.
Mice injected with tumor cells and treated with IDO1 or PD-L1 peptides were monitored for tumor growth. Vaccine activity was determined by IFNγ Elispot assay. Gene expression analysis was performed on tumors using Nanostring nCounter PanCancer IO360 Panel. IDO1 and PD-L1 expression were also examined via multiplex immunofluorescence in a human tumor tissue microarray (TMA) panel. Human IDO1 and PD-L1 specific CD4^{+} T cell clones were isolated and expanded from melanoma patients treated with IDO1/IO102 or PD-L1/IO103 peptide vaccines in combination with aPD1 therapy.
Immunofluorescence analysis of murine tumor sections showed expression of IDO1 and PD-L1 by different cell populations. Vaccination against each target led to expansion of specific T cells in splenocytes and reduced tumor growth in MC38 and CT26 models. Combining IDO1 and PD-L1 treatments further enhanced the anti-tumor response. Gene expression analysis of tumors revealed distinct signatures following monotherapy and combination treatments. While PD-L1 vaccination predominantly enhanced the cytotoxic effector T cell function in the tumor microenvironment (TME) and concomitantly increased gene signatures associated with enhanced activation of T effector cells, IDO1 vaccine primarily exerted its effect via reduction in the immune suppression loop. TMA analysis of IDO1^{+} and PD-L1^{+} cells in human tumors also revealed that they represent largely distinct cell populations. Lastly, IDO1 and PDL1-specific CD4^{+} T cell clones from melanoma patients treated with IO102-IO103 vaccine could selectively target cells differentially expressing IDO1 or PDL1.
Our data collectively show that cells expressing IDO1 and PD-L1 represent distinct populations in the TME thus targetable by the IDO1-PD-L1 vaccination approach. The vaccines targeting IDO1 and PD-L1 cooperatively reduce tumor outgrowth, and each contributes to the anti-tumor effect through distinct molecular programs regulating immunosuppression in the TME and T cell activation respectively. These data are supported by ex vivo functional assays using target specific T cells from vaccinated patients. Altogether, our data support the use of a dual antigen approach to reduce the immunosuppression and enhance anti-tumor effect.

#4095 Targeting alternative classes of tumor antigens to improve immunotherapy for microsatellite stable, mismatch repair-proficient colorectal cancer.

R. Dolcetti[1], B. Zeng[1], J. Ye[2], T. Shamekhi[2], M. Harpur[1], D. Moi[1], S. Roth[1], R. Ramsay[1], D. Duscharla[2], A. W. Purcell[2], P. Faridi[2], R. Mazzieri[1];
[1]University of Melbourne, Melbourne, Australia, [2]Monash University, Clayton, Australia

Background: The clinical outcomes of immunotherapy for microsatellite stable (MSS) colorectal cancer (CRC) remains unsatisfactory. The development of more effective immunotherapies is hampered by limited knowledge of the appropriate target antigens, also considering the low burden of mutations generating neoantigens of these tumors. Alternative classes of MSS CRC antigens may provide actionable epitopes.
Methods: We have characterized the immunopeptidome of 2 MSS CRC cell lines derived from the primary tumor (SW480) and a metastatic lymph node (SW620) of the same patient. Given the low mutational burden of MSS, we focused on peptides belonging to alternative sources of HLA-A*02 epitopes, such as proteasomal cis-spliced peptides derived from cancer testis antigens and linear epitopes derived from Human Endogenous Retroviruses (HERVs), which are frequently reactivated in CRC. Peptide immunogenicity was functionally validated based on their ability to expand HLA-A*02$^{\pm}$ donor T cells (>3) specifically killing targets cells presenting the relevant peptides or HLA-matched CRC cell lines. *In vivo* epitope immunogenicity was verified by analyzing polyfunctional responses of human CD8$^{\pm}$ T cells obtained from NSG-A2 mice humanized with A*02$^{\pm}$ donor PBMCs and immunized with epitope-loaded nano-emulsions selectively targeting human Clec9A$^{\pm}$ dendritic cells. Therapeutic exploitation of the novel epitopes was investigated by adoptive transfer of epitope-specific T cells in NSG-A2 mice injected with SW620 cells. Epitope-specific T cell responses were investigated in PBMCs from 10 MSS CRC patients and 7 donors.
Results: Among >50,000 HLA-bound peptides identified by in depth immunopeptidomics analysis, 11 cis-spliced peptides and 5 HERV peptides were functionally validated as immunogenic. Epitope-specific T cells showed specific cytotoxic activity against SW480 and SW620 CRC cells. Globally, cis-spliced peptides were more immunogenic *in vitro* than HERV-derived peptides. The immunogenicity of both groups of peptides was confirmed *in vivo* in humanized mice. Adoptively transferred HERV or cis-spliced epitope specific T cells significantly inhibited the growth of SW620 cells *in vivo*, with cis-spliced epitope-specific T cells being more effective. Therapeutic efficacy of Clec9A-targeting vaccines exploiting these epitopes is currently under investigation. T cell responses specific for cis-spliced and HERV epitopes were detected in PBMCs from 3/4 MSS CRC HLA-A*02$^{\pm}$ patients but in none of 4 HLA-A*02^{-} MSS CRC patients or 7 healthy donors (4 HLA-A*02$^{\pm}$ and 3 HLA-A*02^{-}).
Conclusions: We have identified and validated a new class of immunogenic HLA-A*02 epitopes derived from alternative classes of MSS CRC antigens. We also provide the proof of principle supporting their therapeutic exploitation to improve the management of these poorly immunogenic tumors.

#4096 Comparative molecular profiling of sporadic and Lynch syndrome MSI tumors: Unraveling insights for vaccine design.

Hagay Ladany[1], Mark Grossman[2], Julian Hess[3], Nicole Lu[3], Derin Keskin[4], Catherine J. Wu[4], Nir Hacohen[5], Erika Hissong[2], Richard Gallon[6], John Burn[6], Wendy Frankel[7], Rachel Pearlman[7], Heather Hampel[8], Zsofia Stadler[9], Gad Getz[3], Yosef E. Maruvka[1], Steven Lipkin[2]

[1]Technion, Haifa, Israel,[2]Weill Cornell Medical College, New York, NY,[3]Broad Institute, Cambridge, MA,[4]Dana-Farber Cancer Institute, Boston, MA,[5]Massachetest General hospital, Boston, MA,[6]Newcastle University, Newcastle, United Kingdom,[7]The Ohio State University Wexner Medical Center, Comprehensive Cancer Center, Columbus, OH,[8]Ohio State University, Columbus, OH,[9]Memorial Sloan Kettering Cancer Center, New York, NY

Lynch Syndrome (LS) is a hereditary syndrome that predisposes carriers to colorectal cancer (CRC). The hallmark of LS is microsatellite instability (MSI), resulting from a defective DNA mismatch repair (MMR) system. MSI cases have hyper-elevated frameshift mutation rates including “shared” hotspot mutations recurrently across patients. Frameshift mutations can generate neopeptides that activate the immune system. These open the door for preventive vaccines. However, preventive vaccines work best with neopeptides that happen early during tumorigenesis.Here we present 83 newly sequenced adenomas and carcinomas from Lynch syndrome carriers and combine them with previously published 68 Lynch cases and 133 Sporadic cases, thus generating the largest currently available colorectal neoplasiaMSI cohort. We leveraged this large cohort to analyze the molecular landscape of adenomas vs carcinoma tumors and Lynch vs sporadic tumors. Employing our recently developed MSIDetect tool on our WGS samples, we identified microsatellite instability in 75% of adenomas, which is higher than previously reported. We found that about 30% of normal adjacent tissues showed MSI, suggesting early mismatch repair defects. This early MSI occurrence supports the potential effectiveness of preventive vaccines.We observed comparable levels of SNVs, microsatellite Indels, and single base signature activity among Lynch adenomas and carcinomas, as well as sporadic carcinomas while adjusting for variations in coverage across different datasets. Moreover, using RNA sequencing data and PCA analysis we found that adenoma and carcinoma cluster together. This large cohort enabled us to identify (as fast as we know for the first time) MS-indels that tend to have a second MS-indel in the same locus. The high similarities observed between Lynch and sporadic tumors allow for their combination in one vaccine.Using the combined MSI cohort we generated a set of about 300 neopeptides that emerged from frequent mutations (>5% in our cohort) with a strong binding affinity for at least one HLA type. We evaluated that a set of about 60 neopeptides per person from that list is predicted likely to initiate an immune response in ~99.5% of the carriers.These findings hold promise for the development of a preventive vaccine capable of targeting early tumorigenic stages. This work is approved under Weill Cornell IRB exemption 1810019672

#4097 LNP-mRNA neoantigen vaccines to intercept progression of pre-invasive to invasive lung adenocarcinoma.

Y. He[1], S. Zhong[2], B. Bhinder[1], G. Markowitz[1], A. Singh[1], E. Gardner[1], M. Ko[1], N. K. Altorki[1], S. Jiang[2], V. Mittal[1];
[1]Weill Cornell Medicine, New York, NY, [2]Cornell University, Ithaca, NY

The widespread use of chest computed tomography in lung cancer screening has led to the detection of ground-glass opacity (GGO) nodules, which typically harbor pre-invasive or minimally invasive adenocarcinoma and 20-40% of GGO nodules progress to invasive lung adenocarcinoma within 4 years. Lack of approved treatments to intercept disease progression has imposed challenges in the clinical management of patients with GGOs. Previous studies showed that GGO nodules have substantially lower rates of HLA deletions than invasive/metastatic lung cancer, suggesting that GGO nodules constitute a critical window of vulnerability for immune interception. We therefore sought to identify the most immunogenic and cytotoxic neoantigens in patients with GGO nodules and to develop LNP-mRNA cancer vaccines to intercept the disease progression from pre-invasive to invasive adenocarcinoma. Whole exome and RNA sequencing of a large cohort (>300) patients identified potential neoantigen candidates, with KRAS-G12C, KRAS-G12D and EGFR-L858R as the most frequently predicted shared neoantigens consistent with >40% GGO patient population harboring either mutant KRAS or EGFR driver oncogenes. LNP-mRNA vaccines targeting KRAS-G12C and EGFR-L858R showed marked immunogenicity as determined by ELISPOT assays. Moreover, KRAS-G12C vaccination induced CD4+ T cell responses whereas EGFR-L858R vaccination triggered CD8+ T cell responses. Both these vaccines are being tested in GGO immunoprevention studies. Our data suggest the potential of KRAS and EGFR vaccines in the treatment of early disease, particularly in EGFR mutant patients who fail to respond to immunotherapy.

#4098 A citrullinated-ENO1 peptide vaccine delayed tumor growth and markedly improved overall survival in a mouse model of triple-negative breast cancer.

R. A. Leon Letelier, H. Katayama, Y. Chen, Y. Cai, F. Hsiao, B. Arun, S. Hanash;
The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: To evaluate the impact of a novel citrullinated-enolase 1 (cit-ENO1) peptide-based vaccine on the immune response, tumor growth and overall survival in a mouse model of triple-negative breast cancer (TNBC).
Background: Cancer vaccines have consisted primarily of mutated or overexpressed proteins in cancer. We have uncovered dysregulated protein citrullination by peptidyl arginine deiminases (PADI) as a feature of triple negative breast cancer inducing immunogenicity to citrullinated proteins. On the basis of these findings, we investigated a novel vaccine based on cancer-selective cit-ENO1 peptides that we identified from mass spectrometry analysis of the surfaceome and immunopeptidome in TNBC. We assessed the extent to which the vaccine elicited an immune response and delayed tumor growth and improved overall survival in a syngeneic mouse model of TNBC.
Experimental Design: We immunized female B6129SF1/J mice with cit-ENO1 peptides or corresponding unmodified ENO1 (unm-ENO1) peptides as antigens, together with the TLR3 agonist poly I:C as an adjuvant, once a week, for three weeks. PBS or poly I:C alone were used as controls. One week post the last round of immunization, draining lymph nodes (LN) and immunized skin were harvested, and T cell phenotypes evaluated using flow cytometry. To assess anti-cancer efficacy, mice were immunized with cit-ENO1 or unm-ENO1 peptides, followed by orthotopic implantation with murine BRCA1$^{co/co}$; MMTV-Cre; p53$^{+/-}$ TNBC cells. Tumor growth and overall survival were assessed.
Results: Cit-ENO1 peptide vaccination induced a statistically significantly greater percentage of activated CD8+ PD-1+ effector T cells as well as CD8+ CD44+ CD62L- effector memory T cells in the LNs compared with either the control groups or the unm-ENO1 peptide. CD8+ PD-1+ T-cells were also significantly elevated in immunized skin of cit-ENO1 vaccinated mice. Both cit-ENO1 and unm-ENO1 vaccine increased CD4+ PD-1+ T cells from the LNs and immunized skin. Remarkably, the cit-ENO1 vaccine but not the um-ENO1 vaccine significantly delayed tumor growth and markedly improved overall survival compared to respective controls.
Conclusion: Cancer-selective cit-ENO1 peptides induced a potent anti-cancer immune response and significantly delayed tumor initiation and progression in a preclinical, immune competent mouse model of TNBC.

#4099 AMP-peptide vaccination against multiple p53 mutant epitopes promotes lymph node delivery to generate potent, functional T cell immunity.

M. P. Steinbuck, X. Cabana-Puig, E. Palmer, M. M. Jung, T. Williams, K. Osaer, J. Zhang, C. M. Haqq, P. C. DeMuth;
Elicio Therapeutics, Boston, MA

Background p53 is the most commonly mutated gene in human cancer, prevalent in nearly all tumor types. Despite its significant medical relevance and the knowledge that human T cells recognize these mutations[1,2], immunotherapies designed to promote responses against mutated p53 (mp53) have not had the hoped-for clinical impact[3]. The Amphiphile (AMP) platform improves the potency of vaccine immunotherapy by programming the delivery of vaccine components to the lymph nodes where efficient uptake by immune cells initiates tumor-targeted immune responses. AMP-modification of vaccine components (peptide antigens, molecular adjuvants) results in covalent conjugation to albumin-binding lipids. Upon injection, AMP-vaccines associate with tissue-resident albumin which efficiently distributes to draining lymph nodes. This approach was shown to promote activation of polyfunctional, cytotoxic T cells with promising safety and improved clinical outcomes in a Phase 1 trial of ELI-002, an mKRAS AMP therapeutic vaccine (AMPLIFY-201 NCT05726864). Application of this strategy to p53 mutations with ELI-008 offers the potential for improved immunotherapeutic activity in a setting of significant unmet need.

Methods Following immunization of C57BL/6J mice with AMP-modified or soluble comparator vaccines consisting of mp53 peptides and CpG adjuvant, analyses were performed 7 days after the third bi-weekly dose. To assess antigen-specific T cell responses, ELISpot (IFNγ, GzmB), multiplexed proteomic, and flowcytometric analysis of effector cytokines (IFNγ, TNFα, IL-2) were performed following antigenic stimulation. Responses were determined in secondary lymphoid tissues and lung. Cytolytic capabilities of antigen-specific T cells were evaluated by monitoring specific killing of IV-transferred antigen-pulsed target cells.

Results AMP-immunization generated robust immune responses yielding strong T cell activation against common p53 hot spot mutations (R248W, R248Q, R175H, G245S, R273H, Y220C, C135Y, R158H, H214R). Responses to AMP-vaccination were characterized by the generation of increased frequency of polyfunctional T cells (IFNγ, TNFα, IL2) specific to mp53 epitopes. Induced T cells demonstrated significant levels of cytolytic activity including GzmB production and elimination of target cells *in vivo*. Non-lymph targeted vaccines using soluble comparators were inactive.

Conclusions AMP-conjugation permits efficient delivery directly to the lymph nodes and thus improves the immunogenicity of peptide vaccination. These substantially improved immune responses induced by ELI-008 represent a promising therapeutic opportunity for targeting cancer in a large fraction of human tumors. The AMP-platform technology is simple, rapid and scalable, promising broad clinical, off-the-shelf application for treating p53 mutated tumors.

#4100 AMP-peptide vaccination against mutant BRAF epitopes promotes lymph node delivery to generate potent, functional T cell immunity.

M. P. Steinbuck, X. Cabana-Puig, E. Palmer, M. M. Jung, T. Williams, K. Osaer, J. Zhang, C. M. Haqq, P. C. DeMuth;
Elicio Therapeutics, Boston, MA

Background Mutations in BRAF cause ~8% of human cancers[1]. Nonetheless, therapies designed to promote immune responses against mutated BRAF (mBRAF) have led to limited clinical success[2], despite evidence confirming T cell recognition of these mutations[3,4]. The Amphiphile (AMP) platform improves the potency of vaccine immunotherapy by programming the delivery of vaccine components to the lymph nodes where efficient uptake by resident immune cells initiates tumor-targeted immune responses. AMP-modification of vaccine components including peptide antigens and molecular adjuvants results in covalent conjugation to albumin-binding lipids. Upon injection, AMP-vaccines associate with tissue resident albumin which efficiently distributes to draining lymph nodes. This approach was shown to promote activation of polyfunctional, cytotoxic T cells with promising safety, and improved clinical outcomes in a Phase 1 trial of ELI-002, an mKRAS AMP therapeutic vaccine (AMPLIFY-201 NCT04853017). Application of this strategy to prevalent BRAF mutations with ELI-007 offers the potential for improved therapeutic activity in a setting of significant unmet need, as BRAF inhibitors benefit only a fraction of patients, with near universal progression.

Methods Following multi-dose immunization of C57BL/6J mice with AMP-modified or soluble comparator vaccines consisting of mBRAF V600E/K peptides and CpG adjuvant, immunological readouts were performed 7 days after dosing. Antigen-specific T cell responses were assessed after *ex vivo* re-stimulation of cells with mBRAF overlapping peptides. Assays included analysis of antigen-specific T cell frequencies, multiplexed proteomics determining polyfunctionality, and effector function and cytotoxic potential evaluation. Responses were determined in secondary lymphoid tissues (spleen), as well as lung, to which many BRAF driven cancers metastasize.

Results AMP-immunization generated robust *in vivo* immune responses yielding strong T cell activation against mBRAF epitopes. Non-lymph node targeted vaccination using soluble comparators were inactive with no response above mock treated mice. Responses to AMP-vaccination were characterized by the generation of significantly increased frequency of Th1-skewed, polyfunctional T cells (IFNγ, TNFα, IL2) specific to mBRAF V600E and V600K. Induced T cells further exhibited mBRAF-specific cytotoxic function.

Conclusions AMP-conjugation enhances efficient delivery directly to the lymph nodes and thus improves the immunogenicity of peptide vaccination. These enhanced immune responses provide an encouraging therapeutic opportunity to treat >90% of BRAF-mutated cancers[5] with the AMP-mBRAF vaccine, ELI-007. Moreover, the AMP-platform technology is simple, rapidly executable, and scalable, promising broad clinical off-the-shelf application for BRAF.

#4101 Immune inhibition of murine colorectal cancer by a p53 peptide mucosal vaccine.

S. Wang, Z. Cao, K. W. Janczak, Y. Feng, M. Green, E. R. Fearon, J. R. Baker Jr.;
University of Michigan, Ann Arbor, MI

Colorectal cancer (CRC) is among the most common cancers with high morbidity and mortality for patients despite multi-modality treatment options. Immune checkpoint inhibitors often have impact in the 15% of CRC patients with microsatellite instability-high status CRCs but have limited utility in the remaining 85% of CRC patients. Given the presence of p53 mutations in CRC, we pursued a vaccine approach against tumor cells expressing murine CRC Trp53 codon 270 missense alleles (codon 273 mutation in human cancer) using a combination of R270H p53 peptide, wild type p53 recombinant protein and used a mucosal adjuvant (MA) to drive epithelial immune responses. The vaccine (p53/MA) was studied in a CDX2-CreERT2 (tamoxifen-induced Cre-Lox) transgenic mouse CRC model where tumors arise in the cecum and proximal colon epithelium following combined $Apc^{\Delta 580}$, $Kras^{G12D}$, and $Trp53^{R270H}$ mutations (AKP model). The p53/MA vaccine treatment was administered intranasally to the mice at defined time points after tamoxifen tumor induction. p53/MA vaccinated animals had increased anti-p53 IgG ($p<0.01$), IgG2a ($p<0.01$), and IgG2b ($p<0.001$) in sera compared to control mice. The treatment enhanced antigen-specific Th1 and Th17 cellular immune responses, as shown by increasing of IFN-γ ($p<0.05$), IL-17a ($p<0.01$) and IL-2 ($p<0.01$) both in splenocytes and draining lymph nodes measured by Luminex assay. Vaccinated mice also showed significant more cells producing IFN-γ ($p<0.001$) and IL-17a ($p<0.001$) as analyzed by ELISpot. Importantly, the immunized animals had decreased tumor size/volume ($p<0.001$) and prolonged survival ($p<0.05$) compared to control animals that received only saline or MA respectively. Tumors from vaccinated mice also showed more mononuclear cell infiltrates than tumors from the control animals. In conclusion, novel p53/MA vaccinations can induce significant p53-specific immune responses and anti-tumor effects in the mouse AKP CRC model.

#4102 Treatment with androgen receptor targeting vaccines provides an overall survival benefit in AR-V7 expressing tumor models.

R. D. Marek, J. Wei, T. Wang, X.-Y. Yang, G. Lei, Z. C. Hartman;
Duke University, Durham, NC

Background: Androgen receptor (AR) signaling inhibition is part of the mechanism behind many effective prostate cancer therapies, including androgen deprivation and next generation anti-androgens. However in castration resistant prostate cancer up to 50% of treatment resistance has been linked to AR amplification or expression of the constitutively active RNA splice variant, AR-V7. Although the use of immune checkpoint blockade has failed to demonstrate clinical success, immunotherapeutic interventions remain attractive as prostate cancer's relatively slow progression provides time for anti-tumor immune responses to develop. Cancer specific vaccines have the potential to enable and enhance tumor specific immune responses by stimulating and directing T cell immunity to important oncologic targets. We hypothesized that a cancer vaccine designed to induce a T cell response against cells expressing high levels of AR would result in an anti-tumor effect and potentially prevent or delay the development of therapeutic resistance.

Methods: Adenoviral vaccines against AR (Ad-AR) or AR splice variant 7 (Ad-AR-V7) were used to evaluate the potential of AR targeting vaccination in mouse models. We evaluated AR and AR variant specific adaptive responses produced by our vaccines with naïve and tumor-bearing mice by ex vivo peptide restimulation. We challenged vaccinated mice with multiple syngeneic subcutaneous tumor models that we engineered to express AR-V7, including a $PTEN^{-/-}$ $p53^{-/-}$ prostate tumor cell line. Finally we tested our vaccines in a therapeutic regimen, vaccinating mice after implanting our subcutaneous AR-V7 expressing models.

Results: Across multiple strains of mice, AR or AR-V7 targeting adenoviral vaccination induced robust adaptive immune responses against the N-terminal domain of AR. Vaccination with either Ad-AR or Ad-AR-V7 resulted in significant anti-tumor responses, providing a significant overall survival benefit and complete tumor rejection by the majority of mice vaccinated against AR or AR-V7. Similarly tumor bearing mice treated with Ad-AR or Ad-AR-V7 vaccination displayed tumor growth inhibition or complete tumor regression resulting in an overall survival benefit. Additionally, we found that vaccine responses were unaffected by the use of the approved antiandrogen drug enzalutamide, suggesting that vaccinations could be deployed in tandem with standard-of-care therapies.

Conclusions: Vaccination against AR and AR splice variants can induce AR specific adaptive immune responses capable of inhibiting the growth of AR-V7 expressing tumor models, illustrating the potential of AR and its splice variants as immunologic targets in prostate cancer.

#4103 Novel mRNA-encoded HPV vaccine with APC maturation signal and endolysosomal trafficking domain demonstrates superior T cell-mediated immunogenicity and efficacious tumor clearance *in vivo*.

Liang Du, Hongya Han, Jingshu Ma, Zhenxing Yang, Jinjuan Mao, **Jijun Yuan**, Bo Ying

Abogen Bioscience, Suzhou, China

Human Papillomavirus (HPV), particularly HPV16, is a known causative agent of cancers in various anatomical sites, notably the anogenital and oropharyngeal regions. Despite the availability of prophylactic HPV vaccines for almost two decades, vaccination rates among young females, who are at a heightened risk for cervical intraepithelial neoplasia (CIN) and subsequent invasive cancer, remain suboptimal. The current standard of care for cervical cancer, involving invasive surgery and chemotherapy-based treatments, underscores the pressing need for safer and more effective therapeutics to enhance patient survival and quality of life.

In this context, while several HPV16-E6/E7 targeted therapeutic vaccines are in development and clinical trials, their clinical efficacy has been limited due to inadequate antigen presentation and suboptimal immunogenicity. Addressing this, our team has developed a novel, highly immunogenic mRNA therapeutic cancer vaccine, engineered to activate a robust T cell-mediated adaptive immune response and exhibit strong anti-tumor potential.

Our innovative approach includes the design of an HPV16-E6/E7 mRNA vaccine (ABO2101) that incorporates a unique antigen-expressing cassette. This cassette features endolysosomal trafficking domains and antigen presenting cell (APC) activation stimulators, enhancing both Class I and Class II antigen presentation and APC maturation, thereby amplifying antigen-specific T cell responses.

In both murine and human-derived experimental models, ABO2101 has demonstrated a significantly more potent adaptive T cell response against HPV16 antigens compared to other HPV16 mRNA therapeutic vaccines.

In antitumor efficacy evaluations using TC-1 tumor-bearing mice, ABO2101 single-dose administration successfully eradicated both early-stage (50 mm^3) and advanced (500 mm^3) tumors. This was accompanied by a marked increase in HPV16-specific CD8+ cytotoxic T lymphocytes within the tumor microenvironment.

Moreover, in prophylactic and adjuvant therapy models, ABO2101 prevented tumor growth across various dosages, indicating its robust preventative capabilities.

Further, the combination of ABO2101 with immune checkpoint inhibitors, including PD-1 and CTLA-4 antibodies, displayed a synergistic effect in both immune-oncology sensitive and resistant animal models, suggesting a potential for combinational clinical therapy.

In conclusion, our development of ABO2101, a mRNA-based HPV16-E6/E7 therapeutic cancer vaccine inclusive of APC maturation signals, represents a groundbreaking advancement in HPV-associated cancer treatment, as supported by our compelling preclinical data.

#4104 Randomized phase II trial of imiquimod with or without 9vHPV vs observation in patients with CIN 2 and 3.

S. S. Sheth[1], J. Oh[2], S. Bellone[1], E. R. Siegel[3], N. Buza[1], A. Iwasaki[1], **A. D. Santin**[1],

[1]Yale University, New Haven, CT, [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, [3]University of Arkansas for Medical Sciences, Little Rock, AR

Introduction: We report the results of a randomized phase II trial of imiquimod, a topical immune-response modulator, vs imiquimod plus a 9-valent human papillomavirus vaccine (9vHPV) vs surveillance in cervical intraepithelial neoplasia (CIN) 2 and 3 patients.

Methods: We randomly allocated 133 patients with untreated CIN 2/3 in equal proportions to a 4-month treatment with self-applied vaginal suppositories containing imiquimod (arm B) or imiquimod plus 9vHPV (arm C) vs clinical surveillance (arm A). The main outcome was efficacy, defined as histologic regression to CIN 1 or less. Secondary outcomes were HPV clearance and treatment tolerability. Exploratory objectives included the comparison of cervical CD4/CD8 T-cell infiltration at baseline, mid-study, and post-treatment by flow-cytometry.

Results: Of the 114 evaluable patients 77% and 23% had CIN2 and CIN3, respectively. Histologic regression to CIN1 or less was observed in 95% of patients in the Arm B: imiquimod group and 84% in the Arm C: imiquimod+9vHPV compared with 79% in Arm A: surveillance ($p=0.043$ and 0.384, respectively). The difference between either treatment arm compared with control did not reach the prespecified $\alpha=0.025$. No significant differences were noted in HPV clearance. The number of tissue-resident memory CD4/CD8 T-cells in cytobrush samples demonstrated a >5-fold increase in Arm-B: imiquimod when compared to Arm-A: surveillance ($p<0.01$). Imiquimod treatment was well tolerated. In contrast, there was no significant difference in T-cell responses among participants in Arm-C compared to Arm-A. Imiquimod treatment was well-tolerated.

Conclusions: Although imiquimod induced a higher percentage of regression to CIN1 or less and significant increases in CD4/CD8 T-cells infiltrating the cervix, it did not meet its prespecified statistical outcome for efficacy. A higher regression rate than expected was observed in the surveillance arm of this prospective trial. Future clinical trial with imiquimod targeting CIN3 patients are warranted.

#4105 Immune-modulating vaccines targeting CD73.

Y. Luo, T. Shi, H. Wang, B. Liu, J. Wei;
Department of Oncology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China

Background: To realize the generalizable regulation of the tumor microenvironment (TME), immune-modulating vaccines are developed to target shared antigens expressed by immunosuppressive cells and cancer cells. CD73, also known as ecto-5'-nucleotidase, is a pivotal enzyme in the adenosine metabolic pathway and is expressed on the surface of multiple cancer cells and immunosuppressive cells in the TME. In this study, we aim to develop a CD73-targeting immune modulatory peptide vaccine by predicting antigen sequences, screening immunogenic antigen peptides, and assessing their anti-tumor efficacy and capacity to improve the TME.

Methods: The expression level of CD73 on various cancer cell lines were evaluated by flow cytometry. Several online software were used to predict CD73-derived peptides that bind to the mouse MHC-I (major histocompatibility complex class I) molecules. Cells from the draining lymph nodes of healthy mice and peptide-immunized mice were harvested and stimulated by the synthetic peptides *in vitro*. T cell activation level, IFN-γrelease degree and their cytolytic capability towards cancer cells was measured. CD73-derived peptides were mixed with CpG to treat 4T1 tumor-bearing mice and the changes in the TME were investigated by flow cytometry. The online website (www.camoip.net) was used to analyze the correlation between CD73 expression and patient survival in the TCGA Breast invasive carcinoma (BRCA) cohort.Results: 4T1 exhibited a strikingly elevated surface expression of CD73 compared to other mouse cancer cell lines. Three CD73-derived peptides (EP1, EP2, EP3) consisting of 8-10 amino acids were synthesized. *In vitro* stimulation experiments indicated that EP1 and EP3 significantly elicited T-cell responses in draining lymph nodes. After stimulation, the proportions of $CD25^{+}$, $CD69^{+}$, $CD107a^{+}$, and $CD137^{+}$ cells markedly increased in $CD8^{+}$ T cell populations. These cells also displayed enhanced cytotoxicity against 4T1 tumor cells. *In vivo* experiments demonstrated that EP3 induced a pronounced anti-tumor response in an established 4T1 tumor model without evident toxicity. Moreover, subcutaneous injection of EP3 improves the TME by promoting antigen-specific $CD8^{+}$ T-cell responses, reducing M2 macrophages, and inducing neutrophil maturation. High tumor CD73 expression was also found to be associated with poor outcomes among BRCA patients, which further indicated clinical relevance.

Conclusions: In this study, we successfully identified an immunogenic vaccine targeting CD73. It expressed dual functionality by effectively triggering cytotoxic T-cell responses that directly killing CD73-highexpressing tumor cells and regulating the tumor microenvironment through eliminating immunosuppressive cells with elevated CD73 expression. These findings hold promise for a novel immune-modulating vaccine and suggest a potential therapeutic avenue for the treatment of breast cancer and other types of cancer.

#4106 A novel synthetic long peptide vaccine composition targeting multiple PD-L1 T-cell epitopes exhibits anti-tumor efficacy in a syngeneic mouse colorectal cancer model.

K. Lin, M. Toh;
CK Life Sciences Development Limited, Hong Kong, Hong Kong

Background Cancer immunotherapy targeting immune checkpoints has shown promising clinical anti-tumor efficacy over the past decades. Monoclonal antibodies against PD-1 or PD-L1 have demonstrated clinical efficacy in a wide spectrum of cancer types. Despite the clinical success of therapies using immune checkpoint inhibitors (ICI), only a subset of patients shows long-lasting tumor remission, while resistance and toxicities to these agents remain to be addressed. This supports the need to explore alternative immunotherapeutic approaches or additional therapies for synergistic combinations to augment the anti-tumor efficacy for cancer patients receiving ICI therapies.
Methods As an active immunotherapy approach, we developed a blend of four novel synthetic peptide vaccines each containing one PD-L1 T-cell epitope with individual covalent conjugation of the carrier protein, keyhole limpet haemocyanin (KLH), which is to break immune tolerance towards self-molecules. The four PD-L1 epitopes range from 30 to 40 amino acids in length, which target different domains of mouse PD-L1 protein. The PD-L1 peptides were synthesized using the technique of solid-phase peptide synthesis and purified by high performance liquid chromatography. All naked peptides were conjugated to KLH protein by thiol-maleimide reaction, followed by dialysis for purification. The peptide vaccines were formulated with a Toll-like receptor 9 agonist CpG ODN 1826 and aluminum hydroxide gel for animal immunization.
Results These synthetic long PD-L1 peptide vaccines are highly immunogenic in a syngeneic BALB/c mouse model for a cell-mediated immune response when admixed and formulated with adjuvants. The vaccine composition is well tolerated by the mice with no evidence of toxicity and autoimmunity. *In vivo* administration of the vaccine formulation can elicit a positive PD-L1-specific T cell response in splenocytes with an IFN-γ ELISPOT assay. Moreover, *in vivo* vaccination of these PD-L1 peptide vaccines in a CT26 syngeneic mouse preventive colorectal cancer model exhibits a potent anti-tumor activity, with a 54% tumor growth inhibition ($p<0.001$) in tumor volume compared to that of the adjuvant-control group at the end of the study.
Conclusions Taken together, our data demonstrate a proof-of-concept that T cell-based PD-L1 peptide vaccines are a promising therapeutic strategy for inducing anti-tumor immunity to combat cancers.

#4107 Evaluating the efficacy of personalized neoantigen cancer vaccine in preclinical model: A promising step towards precision immunotherapy.

T. Ghosh Halder[1], K. Gutowsky[1], S. Ng[1], T. Thode[1], A. Weston[1], E. Kelley[1], J. Soria-Bustos[2], J. A. Giron[2], T. Bargenquast[3], M. Kaadige[1], S. Tripuraneni[1], B. Durbin[1], S. Rheinschmidt[1], S. Adamson[1], M. Gordon[3], J. Moser[3], J. Altin[2], R. Soldi[1], S. Sharma[1];

[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]TGen (The Translational Genomics Research Institute), Flagstaff, AZ, [3]HonorHealth Research Institute, Scottsdale, AZ

Background: In the past decade, immunotherapy has transformed cancer treatment, with the development of immune-checkpoint inhibitors and adoptive cell therapies. A novel frontier is personalized vaccines targeting neoantigens unique to tumor cells. Vaccines based on neoantigens have several advantages. First, neoantigens are exclusively expressed by tumor cells and can, therefore, elicit truly tumor-specific T cell responses, thereby preventing 'off-target' damage to nonmalignant tissues. Second, neoantigens are de novo epitopes derived from somatic mutations, which presents the possibility to circumvent T cell central tolerance of self-epitopes and thus induce immune responses to tumors. One of the major challenges is the optimal neoantigen discovery/selection. Our study combines in silico HLA binding models with the 'MHC-PepSeq' platform to enhance neoantigen prediction, creating a personalized neoantigen peptide vaccine. We aim to demonstrate its efficacy in a mouse CT26 colon cancer model.

Methods: Our method involved whole exome sequencing of tumor and normal DNA to identify neoantigens expressed in CT26 tumors, generating a peptide library. The peptides were further filtered using an in-silico prediction algorithm and our proprietary peptide-MHC binding assay (PepSeq assay), to determine those exhibiting the highest binding affinity with mice HLAs. Vaccines were prepared by dissolving these peptides in sterile PBS. Mice (BALB/C) were subcutaneously implanted with CT26 tumors, then immunized with the vaccine via IV injection in combination with a TLR7/8 agonist. Mice received a second vaccine dose on Day 14, and some groups were treated with an anti-PD-1 agent. Tumors and spleens from the mice were collected, processed into single-cell suspensions, and analyzed by single-cell sequencing, TCR analysis, IHC, and flow cytometry assays. Peripheral blood mononuclear cells (PBMCs) were collected and utilized in MHC tetramer assays.

Results: Preliminary in vivo studies demonstrated significant tumor growth restrictions (TGI around 70%) and prolonged tumor-free survival in some mice. Our data showed the generation of neoantigen-specific T cells in vaccinated mice. Remarkably, vaccinated, tumor-free mice, when re-challenged with the same tumor cells, maintained their tumor-free status, suggesting the vaccine induced post-treatment immunological memory. Combining the vaccine with checkpoint inhibition resulted in better tumor growth restriction in mice (TGI around 93%).

Conclusion: Overall, our data suggests that our personalized neoantigen vaccine platform has the potential to evoke robust and durable immune responses and, when paired with suitable complementary therapies and immune adjuvants, may serve as an effective cancer treatment.

#4108 Safety and feasibility of personalized neoantigen DC vaccines in postoperative esophagus squamous cell carcinoma: A Phase 1b trial.

Yueyun Chen, Hua-Shan Shi, Yang Hu, Yong Yuan, Yu-Shang Yang, Heng Xu, Li Yang, Zhen-Yu Ding

West China Hospital, Sichuan University, Chengdu, China

Background: Immunotherapy, currently stands at the forefront of esophagus squamous cell carcinoma (ESCC) research. Yet, the landscape of post-surgical adjuvant therapy, particularly for patients resistant or unresponsive to initial immunotherapy, remains unexplored. Addressing this, our prospective study evaluates the efficacy of a personalized neoantigen-loaded dendritic cell vaccine (Neo-DCVac) as a novel adjuvant in ESCC patients after neoadjuvant immunochemotherapy (nICT).
Methods: Neo-DCVac, designed for 12 ESCC patients post-radical mastectomy following nICT. The vaccine regimen included five doses at weeks 1, 2, 4, 6, and 8, followed by bi-monthly boosts for a year. The primary endpoints were safety and immune response post-vaccination, with 1- and 2-year overall survival (OS) and progression-free survival as secondary endpoints. The T-cell response to neoantigen peptides was evaluated using ELISPOT, flow cytometry, ELISA, and single-cell sequencing to investigate the vaccine's mechanism of action.
Results: From April 2021 to October 2023, a total of 12 ESCC patients were enrolled. The occurrence of all-grade AEs was 38.5% (5/12), all of grade 1-2, with no dose-limiting toxicities. No treatment interruptions or treatment-related deaths were observed. Till October 27 2023, the median follow-up was 31.2 months. Survival analysis revealed 1-year and 2-year disease-free survival (DFS) and overall survival(OS) rates of 88.3%, 66.7%, and 100.0%, 91.7%, respectively. Patients with diver genes had a longer median DFS (not reached) compared with patients without diver genes (10.8 months, P = 0.001). Post-vaccine immunization, all patients showed a marked increase in peripheral blood T cell subtypes (CD3, CD4, CD8), with significant neoantigen peptide response in 75% (9/12) as evidenced by ELISPOT and ELISA tests. Single-cell sequencing coupled with CoNGA analysis revealed a distinct MAIT cell population, displaying 65 clonotypes and 146 cells with consistent GEX profiles and TCR sequences. GLIPH2 analysis on Neo-Vac immunotherapy patients identified shared peptide-MHC specificities, notably in patient ES0-01, and similar patterns in patients ES0-04 and ES0-07, suggesting T cell expansion and neoantigen-specific responses post-vaccination.
Conclusions: The neoantigen DC vaccine demonstrated favorable safety and exhibited notable efficacy in ESCC.
Clinical trial information: NCT05023928. Research Sponsor: No.

#4109 Discovery of a novel cancer-specific antigen for therapeutic targeting using the Oncotope platform.

J. S. Manavalan[1], D. Mor[2], J. Davis[1], S. Saini[2], I. Pal[3], D. Feith[3], Y. Hikichi[4], E. Davis[1];
[1]Cancer Antibodies Inc, Longwood, FL, [2]Augusta University, Augusta, GA, [3]University of Virginia, Charlottesville, VA, [4]Tuning Fork Bio, Cambridge, MA

Identification of druggable cancer-specific surface antigens is hindered by the complexity of cancer's molecular diversity and the risk of normal cell cross-reactivity. We developed the Oncotope Platform that rapidly identifies multiple cancer-specific cell surface targets not expressed on normal cells (JCO 2022). In this study, we generated polyclonal antibodies to human Triple Negative Breast Cancer (TNBC; Hs578T, ATCC). Following this, we used the Oncotope Platform to filter the anti-TNBC antibody-enriched serum, to yield cancer specific polyclonal antibodies. Using a Protein Microarray, we assessed the binding affinity of both the Total Anti-TNBC Serum (before filtration) and the Oncotope Filtered Anti-TNBC Serum towards approximately 25,000 human proteins. Our results identified antigens that exhibited significantly higher affinity binding to the Oncotope Filtered Anti-TNBC Serum than the Total Anti-TNBC Serum. One of these antigens ZIP7, a zinc transporter situated in the ER and Golgi, has been shown to activate cell proliferation related signaling pathways in TNBC. Our findings revealed the aberrant cell surface expression of ZIP7 on TNBC cells and its potential as a therapeutic target. Flow cytometry analysis using rabbit polyclonal antibodies against ZIP7 revealed substantial binding to TNBC cells, while no significant binding was observed with normal breast epithelial (NBE) cells from the same patient (Hs578BsT, ATCC). Additionally, cytotoxicity assays, employing the same antibodies and a secondary anti-rabbit ADC, showed the preferential killing of TNBC cells over NBE cells (Table 1). In summary, our study marks a breakthrough in identifying cancer-specific antigens with therapeutic potential. The Oncotope Platform, in combination with protein microarrays, enables rapid identification of unique cancer-specific antigens absent in normal cells. Specifically targeting ZIP7 on TNBC cell surfaces highlights its promise for precision cancer therapy.

Table 1

Cell Line	Incubated with:	%Binding Flow Cytometry (1:400 Ab dilution)	%Cytotoxicity (4ug/ml Ab conc.)
TNBC (Hs578T)	Total Anti-TNBC Serum	96.65	94.5 +/- 2.5
	Oncotope Filtered Anti-TNBC Serum	97.46	79.2 +/- 2.1
	ZIP7 Polyclonal antibody ((Proteintech 11200-1-AP)	46.2	73.2 +/- 0.5
Normal Breast Epithelial cells (Hs578Bst)	Total Anti-TNBC Serum	92.95	92.3 +/- 3.0
	Oncotope Filtered Anti-TNBC Serum	20.39	17.9 +/- 4.5
	ZIP7 Polyclonal antibody ((Proteintech 11200-1-AP)	6.37	14.1 +/- 1.6

#4110 Identification of tumor peptides for therapeutic mRNA vaccination in a mouse multiple myeloma model.

A. Van der Vreken[1], F. Thery[2], S. Meulewaeter[3], K. Vanderkerken[1], E. De Bruyne[1], K. De Veirman[1], L. Franceschini[1], R. Verbeke[3], F. Impens[2], J. Lentacker[3], K. Breckpot[1], E. Menu[1];

[1]Vrije Universiteit Brussel, Brussels, Belgium, [2]VIB, Ghent, Belgium, [3]Ghent University, Ghent, Belgium

Background: Multiple myeloma (MM) is a plasma cell cancer for which immunotherapy holds the promise of durable control. To date, cancer vaccines mainly focused on tumor-associated antigens with survivin eliciting protective T-cell responses in both preclinical and clinical studies. Given the success of mRNA vaccines in medicine, we developed Galsomes, lipid nanoparticles containing mRNA and α-galactosyl ceramide to activate both $CD8^+$ T cells and invariant natural killer (iNK) T cells, both potential anti-MM effectors.

Materials and Methods: Mouse 5T33MM cells were studied by PCR and flow cytometry (FCM) for expression of survivin and CD1d, respectively. Intravenous (IV) prime-boost Galsome vaccination was performed with a 7-day interval in C57BL6/KalwRij mice that received an IV injection of 5^x10^6 5T33MM cells 3 days earlier. As a control, mice were injected with saline. After 2 weeks, MM burden was studied by serum electrophoresis and FCM, incl. expression of CD1d and PD-L1 on MM cells. Activation of iNKT cells and survivin-specific T cells was studied by measuring IFN-γ secretion in ELISA and dextramer staining. Immunopeptidomics was used to identify new vaccine candidates for which Galsome vaccination is ongoing.

Result: The 5T33MM cells showed expression of survivin and CD1d, making it a suitable model for Galsome vaccination. Two weeks following prime-boost vaccination, the serum M-protein was reduced, though not significantly. In contrast, MM cells were significantly reduced in bone marrow and spleen. Expression of CD1d and PD-L1 on MM cells was high but unchanged by Galsome vaccination. Activation of iNKT cells and survivin-specific T cells following prime vaccination was shown. However, following boost vaccination these cell populations reduced significantly compared to control. We repeated prime-boost vaccination in healthy mice, observing a similar outcome. This suggests that the negative effect of the boost Galsome vaccination was not related to immune dysfunctionality due to MM progression. So, we studied the impact of survivin mRNA in the vaccine, as survivin is also expressed in activated T cells, making them a potential target. We observed that iNKT cells and ovalbumin-specific T cells were more reduced when ovalbumin mRNA was paired with survivin mRNA in the Galsomes. To identify other vaccine candidates, we studied peptides eluted from MHC-I/peptide complexes on 5T33MM cells. We selected 4 vaccine candidates including the MM idiotype based on immunogenicity, pathway classification and abundance. mRNA and Galsomes were prepared, and the efficacy of these Galsomes in 5T33MM mice is currently under evaluation.

Conclusion: These data show that Galsome vaccination has the potential to reduce MM cell levels. To reach higher efficacy, careful selection of the vaccine antigen is required. Moreover, combination with other immunotherapies might be needed to reach durable disease control.

#4111 Multi-peptide cancer vaccines targeting KRAS induce significant anti-tumor efficacy.

C. Li, M. Toh;
CK Life Sciences Development Limited, Hong Kong, Hong Kong

Background and objective: *Kirsten rat sarcoma viral oncogene homologue (*KRAS) is frequently mutated in human cancers. KRAS mutants offer the potential for the development of cancer-specific immunotherapy, as epitopes harbouring mutations are strong neoantigens to which the immune system generates cancer-specific anti-tumor effects. However, previous clinical trials of KRAS-targeted vaccines failed to generate satisfactory anti-cancer efficacy. Evidence suggested that CD4 T cell activity plays a critical role in augmenting the cytotoxic effect of CD8 T cells. Here, we design long peptides based on the MHC II hotspots on the entire KRAS protein that activate both CD4 and CD8 T cells to kill KRAS-driven cancer cells. Long peptides also cover a wider range of HLA alleles to increase their utility in a broader spectrum of patients. Our objective is to create a multi-peptide vaccine simultaneously targeting the mutant and wild-type (WT) regions of human KRAS protein.

Methods: By selecting MHC II hotspots via multiple epitope prediction algorithms, we designed and synthesized 8 long peptides with lengths between 25 to 30mers. One of them harboured a G12D mutation, while the others covered the WT regions of KRAS. In addition, the corresponding *keyhole limpet hemocyanin (*KLH) conjugated peptides were also generated. We first demonstrated their immunogenicity in mouse *in vivo* models. Different combinations of peptides adjuvanted with either CpG oligodeoxynucleotide + aluminum (CpG+alum) or complete/incomplete Freud's adjuvant (CFA/IFA) were immunized into Balb/c mice before determining the immune response by mouse interferon γ (mIFNγ) ELISPOT assay. Subsequently, an *in vivo* prophylactic anti-tumor study was conducted by immunizing this multi-peptide vaccine in Balb/c mice and observing the growth inhibition of the CT26-derived tumors.

Results: T cell responses were observed in two peptide mixes with or without G12D mutation, suggesting that both mutant-harbouring peptide and WT peptides were immunogenic. We showed that KLH-conjugated peptides and CpG+alum elicited stronger immune responses than the naked peptides and CFA/IFA respectively. Furthermore, peptide mapping showed that the G12D mutant-harbouring peptide and two other WT peptides may contribute to the overall T cell response in the Balb/c mouse. In the prophylactic anti-tumor study (n = 10), immunization of KRAS naked peptide and KLH-conjugated peptide vaccines significantly inhibited tumor growth by 51.2% (****$p < 0.0001$) and 44.7% (***$p < 0.001$) respectively, compared to control. Subsequent mIFNγ ELISPOT assay showed that the tumor inhibitory effect was attributed to the activation of antigen-specific T cell response of the vaccines.

Conclusion: Our multi-peptide vaccines targeting both the mutant and WT regions of KRAS could generate KRAS-specific T cell responses and elicit significant anti-tumor effect in mouse models.

#4112 Identification of Th1-specific epitopes from non-mutated KRAS lesions for off-the-shelf cancer vaccines.

Y. Choi, J. Lim, H.-H. Park, J. Kang, H. Jung;
Aston Sci., Seoul, Korea, Republic of

Background KRAS is crucial for cell growth, differentiation, and signaling. Mutations in the KRAS gene (i.e., codon 12 or 13) are frequently associated with the development and progression of cancer, particularly lung, colorectal, and pancreatic cancers. Recently, it has been captured that KRAS targeting cancer vaccine research and clinical trials have been conducted in certain tumor types and vaccine approaches are encouraged to move forward. It has been well known that the tumor-eradicating efficacy of cancer vaccines arises from Th1 epitope selection. While tumor growth may persist after immunization with non-selected epitopes (including full-length), immunization with a highly selected Th1-specific epitope vaccine can lead to tumor regression by suppressing the activation of immune inhibitory cells. The Th-Vac® discovery platform uses a combination of in-silico, in-vitro, and in-vivo studies to precisely identify Th1-specific epitopes. It consists of two modules: module 1 (in-silico) and module 2 (in-vitro and efficacy evaluation). The aim is to identify MHC class II epitopes that are specific to antigens for CD4+ T cells, displaying the most favorable binding affinity across diverse alleles. Th1-specific epitope vaccines aim to boost and sustain T cell immunity against tumor antigens, overcoming the lack of a precise T cell response or pre-existing tolerance in the immunosuppressive TME. This study aimed to explore Th1-specific epitopes for KRAS vaccine to be potentially effective in numerous KRAS mutation-driven cancers.

Methods Peptide sequence candidates that have highly potential of MHC class II binding affinity were comprehensively predicted via a module 1 (ASEP program). All of peptides selected in ASEP were synthesized as 15 mers. Each peptide was evaluated for immunogenicity using ELISpot and/or FACS analysis in module 2 (2a for in vitro and 2b for in vivo immunologic evaluation) of the Th-Vac® discovery platform. Specifically, in Module 2b, immunogenicity was evaluated using a 38-mer peptide formed by combining five overlapping peptides selected in 2a. These kinds of immunogenicity evaluations were conducted using type 1 and/or type 2 cytokine(s) produced by CD4+ T cells.

Results In ASEP prediction, twelve peptides were selected as potential candidates demonstrating a high affinity to MHC class II, which were in different lesions of common mutation of KRAS. In module 2 using ELISpot and FACS analysis, two epitopes (non-mutated sequences) were finally selected as Th1-specific epitopes based on the type 1 T cell response.

Conclusion Unlike previous vaccines using mutant lesions, in this study, two non-mutated Th1-specific epitopes are under the in-vivo efficacy studies as mono and combining regimen(s) in certain tumor types. Additionally, the Th-Vac® platform was fully validated in terms of the performance and its application would be expanded beyond a cancer vaccine.

#4113 AST-301,a pDNA-based cancer vaccine encoding HER2-ICD, enhances anti-tumor effect of HER2-ADC in a HER2-expressed gastric cancer xenograft model.

J. Kang[1], H.-H. Park[1], J. Choi[1], J. Lim[1], S.-Y. Jang[2], M.-A. Kim[2], M.-K. Park[2], Y.-H. Park[3], S. Lim[3], C.-W. Chung[3], J. Choi[4], E. Joung[1], A. Y. Kim[5], H. Jung[1]; [1]Aston sci., Seoul, Korea, Republic of, [2]Korea testing & Research institute, Hwasun, Korea, Republic of, [3]LegoChem Biosciences, Inc., Daejeon, Korea, Republic of, [4]Jeonbuk National University Medical School, Jeonju, Korea, Republic of, [5]Aston sci. USA, Inc., Seoul, Korea, Republic of

Background: In gastric cancer, the HER2 overexpression (6% to 29.5% of gastric cancers) is considered to increase proliferation activity and suppress apoptosis of the cancer cells. However, HER2-targeting therapy in gastric cancer has not been fully evaluated. Currently, new approaches with HER2-tageted antibody-drug conjugates (ADCs) have led to promising results in HER2-related solid tumors. ADCs may have immune-modulating properties and that the payloads delivered by ADCs may induce immunogenic cell death. Based on this rationale, ADC and cancer vaccine combination would be potentially synergistic to improve clinical outcomes. This study was conducted to evaluate an synergistic effect and immune response of the combination of AST-301 and HER2-ADC in HER2-expressed gastric cancer xenograft model. AST-301 phase 1 study (PN109) was completed and phase 2 randomized-control trials (CornerStone-001, CornerStone-003) have been conducted in breast cancer and gastric cancer.

Methods: NCI-N87 cells were mixed with the same amount of matrigel at $1x10^7$ cells to formation tumors in the flanks of athymic BALB/c nude mice. After the tumor size of mice reached 100-200 mm^3, all of them were randomly classified into four groups (n=7/group) and drug administration was initiated. AST-301 (100 μg/animal, intradermal injection, mixed with rhuGM-CSF as an immune adjuvant) was administered once a week to a total of fourth. LCB01 (1 mg/kg, intravenous injection) was administered to once. Enhertu (1 or 3 mg/kg, intravenous injection) was administered to twice for four weeks. The relative tumor size and TGI rate at day 25 were key endpoints of efficacy. To evaluate the mechanism underlying the enhanced anti-tumor effect due to the combined administration of AST-301 and HER2-ADCs, immune-cell profiling was also conducted using FACS analysis.

Results: Our previous study has shown that AST-301 has anti-tumor effects in human gastric cancer xenograft athymic BALB/c nude mouse model. It was showed that adding AST-301 to LCB01 or Enhertu inhibited tumor growth based on a TGI rate at days 25; AST-301 combining with LCB01 vs LCB01 mono (52 % vs 43 %), AST-301 combining with Enhertu vs Enhertu mono (42 % vs 24 %).As an explorative endpoint, it was observed that myeloid-derived suppressor cells (MDSCs) elevation was modestly inhibited in tumor site in AST-301 mono or certain combination regimen adding AST-301. It was remarkable (or observed or captured) that MDSCs elevation was inhibited in tumor site in the combination groups of all ADCs with AST-301 compared to normal saline groups.

Conclusion: With combining AST-301 and HER2 ADCs, it was demonstrated that anti-tumor effect was likely synergistic in the athymic mouse model. Phase 2 study of AST-301 in HER2-expressed gastric cancer has been on going (CornerStone-003, NCT 05771584).

#4114 AST-201 (pUMVC3-hIGFBP2 N-terminus) demonstrates anti-tumor effect in an ovarian cancer mouse model.

J. Lim[1], **J. Kang**[1], H.-H. Park[1], J. Choi[2], J. Choi[1], S.-Y. Jang[3], M.-A. Kim[3], M.-K. Park[3], M. Disis[4], E. Joung[1], A. Y. Kim[5], H. Jung[1];
[1]Aston Sci., Seoul, Korea, Republic of, [2]Jeonbuk National University Medical School, Jeonju, Korea, Republic of, [3]Korea testing & research institute, Hwasun, Korea, Republic of, [4]Center for Translational Medicine in Women's Health University of Washington, Seattle, WA, [5]Aston Sci. USA, Inc., Seattle, WA

Background: IGFBP2, known to enhance the invasion capacity of ovarian cancer cells, has been suggested that its inhibition could be potentially a treatment strategy of ovarian cancer. AST-201 (pUMVC3-hIGFBP2) is a therapeutic cancer vaccine using a plasmid DNA encoding IGFBP2 N-terminus. In a phase 1 study (NCT01322802) completed, 100 μg AST-201 (intradermal immunization, id) showed not only a significant efficacy by inducing the Th1-cell immunity against IGFBP2 but also safety and tolerability profiles in ovarian cancer patients. The primary objective of this study is to evaluate whether the administration of AST-201 alone and the combination with pembrolizumab could show anti-tumor efficacy and/or synergic effect in the ID8-Luc2 ovarian cancer mouse model. Also, immunological responses were observed as explorative endpoint.

Methods: AST-201 (100 μg/animal, id, mixed with mGM-CSF as an immune adjuvant) was immunized to mice (C57BL/6) once a week for a total of 4 times on different days, either alongside pembrolizumab (10 mg/kg, intraperitoneal injection) twice a week for a total of 3 times on different days. Also, AST-201 was immunized was a mono treatment. The efficacy was evaluated by a tumor growth inhibition (TGI) rate at the last day, and immune cell profiling via FACS analysis was conducted with splenocytes and tumor tissues collected at 8 weeks after the first injection.

Results: As a primary endpoint, a TGI rate at Day 55 of AST-201 mono treatment was 67%, comparing to a control group ($p<0.05$). The anti-tumor effect of AST-201 combining with pembrolizumab was better than standard dose pembrolizumab, based on a TGI rate at Day 55 (78% vs 66%, not significant). Immune profiling showed that AST-201 and pembrolizumab combination regimen could inhibit a tumor growth by transforming TME into inflamed-type (‘hot’) form the low immunoreactivity, which was supported by increased $CD4^{+}T_{EM,}$ and $CD8^{+}T_{EM}$ and T helper cells in splenocyte and TIL analysis.

Conclusion: A study demonstrated that AST-201 (IGFBP2 cancer vaccine) showed an anti-tumor effect as mono treatment and would be potentially leading to a synergistic effect with a combination regimen of pembrolizumab. Phase 2 randomized-controlled study of AST-201 in ovarian cancer will be initiated under the MRCT strategy (CornerStone-004 study, NCT05794659).

#4115 Unleashing the power of MHC associated peptide proteomics: Immunogenicity assessment of oncology drugs.

S. Pattyn;
ImmunXperts, a Q2 Solutions Company, Gosselies, Belgium

Bispecifics targeting multiple antigens or epitopes have been showing great promise for treatment of cancer. However, managing unwanted immunogenicity has become a challenge in the development cycle of these promising therapeutics as there is a trend towards higher unwanted immune responses compared with classical monoclonal antibodies. A thorough assessment of their immunogenic potential leads to safe biotherapeutics with high treatment efficacy. MAPPS assays (MHC associated peptide proteomics) enable the precise identification of all the regions of a protein that may evoke an immune response. This information is key for correct risk assessment and for modulating biotherapeutics. High-sensitive MAPPS workflow leads to higher numbers of identified peptides (self + non-self peptides) and gives the deepness of analysis required for confident immunogenicity derisking and modulation. We show the importance of peptides presented by HLA-DP and HLA-DQ (next to the standard HLA-DR presented peptides). Next, we also show the first ever comparison of presented peptides in true immune cells: dendritic cells (as compared to monocyte derived dendritic cells) and B cells.

TUMOR BIOLOGY: Detection, Treatment, and Prevention of Metastasis
Poster Session

#4119 CXCR4/CB2 heterodimer antagonizes CXCR4-mediated metastasis and tumor growth *in vivo*.

N. M. Pennant[1], A. B. Hartono[2], S. Liu[2], C. Massey[2], C. Lee[2], T. Stoyanova[2], C. V. Hinton[1];
[1]Clark Atlanta University, Atlanta, GA, [2]University of California, Los Angeles, Los Angeles, CA

The G-protein-coupled chemokine receptor (GPCR), CXCR4, is ubiquitously expressed in malignant tumor tissues, and controls migration and other tumor survival mechanisms upon interaction with its chemokine agonist, stromal cell-derived 1α (SDF1α). The CXCR4/SDF1α axis is relevant to shaping the tumor microenvironment mainly the metastatic spread of primary tumors to distal organs and immune response; thus, expression of CXCR4 in tumors is vital to tumor aggressiveness, survival probability, and metastasis-associated mortality. CXCR4 signals through a homodimer, but also forms heterodimers with other chemokine and non-chemokine GPCRs. We've demonstrated that CXCR4 forms a heterodimer with the GPCR, cannabinoid receptor 2 (CB2), in human breast and prostate cell lines *in vitro*. The cannabinoid system has earned interest as anticancer therapeutic targets by modulating growth, migration, angiogenesis, *etc*. In our model, CXCR4-mediated, pro-tumor signaling was reduced by the physical heterodimer, and the dimer was induced by simultaneous treatment with agonists (*SDF1α and AM1241*) for respective receptors. The resultant heterodimer negatively interfered with migration, cytoskeletal rearrangement, motility associated proteins, and signaling that coordinates movement. Given that cannabinoids have been shown to reduce metastasis and profession of clinical tumors, **we hypothesize that a heterodimer of CXCR4 and CB2 disrupts CXCR4-mediated metastasis, and ultimately, decrease tumor progression *in vivo***.Herein, we tested our hypothesis in an *in vivo* model of spontaneous metastasis NSG male mice. Luciferase-containing human prostate cancer cells (DU145 RFP/Luc) were implanted subcutaneously. Once tumors reached 40mm^3, mice were randomized by volume, weight and age, and divided into 4 treatments: vehicle, SDF1α, AM124, and SDF1α/AM124(combo) for daily intraperitoneal injections. Tumors reaching 400mm^3 were excised, and treatments continued for 3 weeks. Spontaneous metastasis was monitored via IVIS imaging at 2- and 3-weeks post-tumor removal. We observed reduced tumor growth, and decreased incidence rates of metastasis to the lung in the combination treatment group, which, based on our *in vitro* data, is representative of a CXCR4/CB2 heterodimer. This novel definition of heterodimerization could reveal and exploit new mechanisms for CXCR4 regulation in tumor metastasis. The CXCR4/CB2 heterodimer may attenuate responses triggered individually by CXCR4 without toxicity and side effects experienced with current CXCR4 antagonists.

#4120 Adherent-to suspension transition by hematopoietic factors in metastatic dissemination of circulating tumor cells.

H. Park;
Yonsei University, Seoul, Korea, Republic of

Although metastasis is the foremost cause of cancer-related death, a specialized mechanism that reprograms anchorage dependency of solid tumor cells into circulating tumor cells (CTCs) during the metastatic cascade remains elusive. We discovered a biological phenomenon referred to as Adherent-to-Suspension Transition (AST) that reprograms adherent cells into suspension cells via aberrant induction of hematopoietic transcriptional regulators, which are hijacked by solid tumor cells to disseminate into CTCs. During dissemination, tumor microenvironment triggers epigenetic alteration of AST factors in the invasive front of solid tumors to evoke spontaneous cell-matrix dissociation, acquire anoikis resistance, and bypass immune surveillance of CTCs, however, in the absence of lineage differentiation and EMT. Using mouse models and de novo metastatic patient specimens, we uncovered how Adherent-Suspension Plasticity (ASP) dictates anchorage plasticity during the dissemination and colonization process within the metastatic cascade. Finally, we demonstrate therapeutic strategies that target AST factors to specifically abrogate CTC formation and suppress distant metastases. Together, these findings underscore an important early mechanism of how cancer cells spread and highlight novel targets for the development of anti-metastatic therapy. Furthermore, AST opens unexplored scenarios how reprogramming anchorage dependency orchestrates physiological events such as development, organ morphogenesis and immune cell activation.

#4121 Unveiling discordant views of a novel drug's influence on cell motility from proteomics and immunofluorescence perspectives.

W. Chen[1], N. Woods[1], H. Law[1], F. Qiao[1], S. Jagadesan[2], C. Guda[2], R. Bergan[1];
[1]UNMC Eppley Institute, Fred & Pamela Buffett Cancer Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE

Introduction: Metastasis is a leading cause of death in patients with solid tumors. Our group has discovered KBU2046, a selective inhibitor of cell motility (Nature Communications 2018). We conducted a time-course immunofluorescent staining to investigate the impact of KBU2046 on the cell adhesion and motility components of human prostate cancer cells. Our objective was to compare our findings with our proteomic analysis results in order to gain insights into the novel molecular mechanisms of KBU2046 in modulating cell motility.
Experimental Procedures: Proteomics analysis. We treated PC3 cells with KBU2046 or vehicle (N=3/group) and quantified protein expression using Liquid Chromatography/Tandem Mass Spectrometry (LC-MS/MS). In separate experiments (N=4), we performed LC-MS/MS after Tandem Mass Tag (TMT) labeling on isolated membrane fractions. We used bioinformatics tools, including Gene Set Enrichment Analysis (GSEA), Gene Ontology (GO), Kyoto Encyclopedia of Genes and Genomes (KEGG), Ingenuity Pathway Analysis (IPA), and protein-protein interaction (PPI) network analysis, to characterize significantly differentially expressed proteins upon KBU2046 treatment and tried to verify by Western blots. Immunofluorescence (IF) staining. Following treatment of PC3, 1532CPTX, and 1532NPTX cells with KBU2046 or vehicle at various intervals, cells were stained for β1, β5 integrin, actin, and DAPI. Images were acquired by a Zeiss LSM 800 Confocal Laser Scanning Microscope.
Results: The proteomics analysis demonstrated that KBU2046 was having a major impact on cell motility processes, consistent with our prior functional studies. Despite conducting Western blot analysis, we could not confirm the candidate proteins linked to cell adhesion. Using IF, we examined changes in cell adhesion proteins over time in response to KBU2046 treatment. The time-course IF investigation revealed that KBU2046 affects adhesion proteins kinetically by altering their subcellular localization over time rather than altering their total expression level. This finding corroborates KBU2046's known effects on cell motility, demonstrating that a kinetic-based analysis yields important new information not directly represented in a single time point screen, although functionally related.
Conclusions: Our study underscores the importance of integrating proteomic and imaging methodologies to procure a holistic comprehension of the molecular mechanisms that govern cell behavior, especially those that relate to highly dynamic processes. Through these methodologies, we have obtained a more profound understanding of how cells regulate motility and how that process can be therapeutically modulated.

#4122 Integrin avb3 and HSPG targeting agents prevent extracellular vesicles uptake and breast cancer metastasis.

E. Muro-Blanc[1], R. Bayona-Ramon y Cajal[2], M. Cano-Galietero[3], S. Garcia-Ortega[1], C. Falciani[4], L. Bracci[4], A. J. Schuhmacher[2], S. Hummer[1], S. Ramon y Cajal[1];

[1]Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, [2]Aragon Health Research Institute (IIS Aragon), Zaragoza, Spain, [3]Spanish Biomedical Research Network in Oncology (CIBERONC), Madrid, Spain, [4]University of Siena, Siena, Italy

INTRODUCTION: Metastasis is the major cause of cancer-related deaths (90%). Intercellular communication between cancer cells and with cells in their environment plays a significant function in tumor progression. In fact, secreted factors like cytokines and extracellular vesicles (EVs) can either halt or stimulate tumorigenesis as well as metastasis. We have previously reported, that the integrin B3 (ITGB3) is required for metastasis of breast cancer cells in vivo (Sese et al. Oncotarget, 2017). We furthermore demonstrated, that EVs mediated colony growth is dependent on ITGB3 and that endocytosis mediated uptake of EVs relies on the interaction of ITGB3 with integrin av (ITGav) and heparan sulphated glycoproteins (HSPGs) (Fuentes et al. Nat. Commun., 2021).
OBJECTIVE: The objective of this work is focused on identifying inhibitors targeting the ITGav/B3/HSPGs complex to prevent extracellular vesicle uptake in cancer cells and to test their ability to prevent metastasis.
METHODOLOGY. Inhibitors targeting ITGB3/ITGAV or HSPGs were either commercially available or obtained through collaborations and single chain antibodies (scFv) were produced in house. Inhibition of fluorescent labeled EVs was determined by FACS analysis or Incucyte based measurements and the efficacy of inhibitors was determined in a dose dependent manner. Toxicity of inhibitors was studied by crystal violet-based assay in normal and tumor cell lines. Tail vein injection of luciferase labeled MDA-MB-231 cells into nude mice was used as model to study metastatic diseases under treatment with the identified inhibitors. Metastasis formation was monitored by bioluminescence imaging and lungs were examined pathologically at end point. Overall survival was determined.
RESULTS: Among the tested Integrin and HSPGs targeting compounds, we identified an integrin-binding antibody, an integrin binding scFv, an RGD-mimetic compound and an HSPGs-binding peptide as inhibitors of EV uptake. Inhibition was validated in a dose dependent manner and toxicity studies did not show adverse effects. Three of those inhibitors, targeting either ITGB3/ITGAV or HSPGs were tested in mice models in vivo and all inhibitors could significantly reduce the formation of metastasis and strongly increase the overall survival.
CONCLUSION: We have identified four drug candidates that target the ITGav/B3/HSPGs complex and are able to prevent EV uptake, demonstrating that EV uptake is a druggable process. Even more, the inhibitors tested in vivo could strongly reduce metastasis formation and increase overall survival. This data supports our hypothesis, that targeting EV mediated intercellular communication is a valuable approach to combat cancer metastasis.

#4123 Attenuating breast cancer metastasis with BCL-X_L-targeting PROTACs.

M. E. Carelock[1], P. Zhang[2], M. Jiao[1], U. De[1], Z. Jin[1], R. M. Stump[3], S. G. Williams[3], G. Zheng[2], W. Zhang[1];
[1]University of Florida College of Medicine, Gainesville, FL, [2]University of Florida College of Pharmacy, Gainesville, FL, [3]University of Florida College of Agriculture and Life Science, Gainesville, FL

B-cell lymphoma X-large (BCL-X_L) emerges as a significant player in cancer progression. In our recent findings, we unveil the efficacy of proteolysis-targeting chimeras (PROTACs) directed against BCL-X_L, demonstrating their capacity to not only eliminate cancer cells but also target tumor-induced regulatory T cells (TI-Tregs). Notably, BCL-X_L's role in promoting breast cancer metastasis extends beyond its anti-apoptotic function. We posit that BCL-X_L-targeting PROTACs (BCL-X_L-Ps) hold promise for treating metastatic breast cancer. Their potential lies in directly eliminating circulating tumor cells during vulnerable stages and/or triggering anti-cancer immunity through Treg cell depletion. Our experiments underscore the potency of IAP-based PROTACs in facilitating BCL-X_L degradation via the ubiquitin-proteasome system (UPS) while mitigating on-target platelet toxicity. Treatment of breast cancer-bearing mice with these compounds demonstrates a tangible reduction in breast cancer metastasis to the lungs. Additionally, our studies reveal a significant depletion of tumor-infiltrating Tregs in mice treated with BCL-X_L-Ps. While affirming BCL-X_L as a viable therapeutic target for breast cancer metastasis, further exploration into the mechanisms behind BCL-X_L-P targeting is imperative. Our future endeavors will be devoted to unraveling whether our BCL-X_L-Ps effectively target both tumor-intrinsic BCL-X_L, potentially inducing tumor cell death, and tumor-infiltrating Tregs, thereby fostering an adaptive immune response against the tumor cells.

#4124 Patient-derived ex vivo models to test drug responses of disseminated cancer cells in various metastatic niches.

L. Wohrl[1], C. Botteron[1], K. Weidele[1], S. Treitschke[1], D. Das[1], M. Werner-Klein[2], M. Hoffmann[1], N. Stojanović Guzvić[1], S. Materna-Reichelt[1], F. Weber[2], S. Engelmann[3], R. Mayr[3], M. Guzvić[3], S. Haferkamp[4], S. Seitz[3], C. A. Klein[2], C. Werno[1];

[1]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Regensburg, Germany, [2]University of Regensburg, Regensburg, Germany, [3]Caritas St. Josef, Regensburg, Germany, [4]University Medical Center, Regensburg, Germany

Metastases arise from disseminated cancer cells (DCCs) that often lodge to distant organs long before diagnosis of the primary tumor. Unfortunately, the efficacy of (neo-)adjuvant therapies against DCCs remains uncertain. Here, we harnessed novel patient-derived ex vivo models to identify promising candidate therapies targeting DCCs and explored the impact of the unique microenvironment of metastatic target organs on the phenotypes and drug responses of DCCs. We screened disaggregated lymph node (LN) or bone marrow (BM) samples from melanoma, breast, and bladder cancer patients without distant metastasis for the presence of DCCs. Then, we expanded DCCs in patient-derived xenografts, adherent cell culture, or three-dimensional culture. LN and BM suspensions were spiked with allogeneic and autologous tumor cells to unravel the impact of different metastatic niches on DCCs. Automated high-throughput microscopy of disaggregated patient LNs was used to evaluate drug effects on DCCs in the autologous microenvironment. We established 13 cell lines from melanoma DCCs, three organoid models from breast cancer DCCs, and two organoid models from bladder cancer DCCs. The origin of each model was confirmed by assessment of histomorphology, marker expression, and genetic profiles. We screened a comprehensive panel of chemotherapeutics, targeted drugs, and antibody-drug conjugates across these in vitro models, and thereby identified compounds with the potential to eradicate DCCs. We further found that the LN and BM microenvironments differentially affected phenotypes and drug responses of cancer cells particularly when immune modulating drugs were used. Of note, ex vivo drug testing, performed directly on LN suspensions containing DCCs, revealed candidate therapeutics within a time frame acceptable for personalized treatment decisions. In conclusion, we report that the microenvironment of the specific metastatic niche impacts DCC drug responsiveness. Employing DCC-derived in vitro models in drug response assays that include specific niches may help to develop (neo)-adjuvant, personalized therapies and to discover novel therapeutics against metastasis.

#4125 Exploring the efficacy of alpelisib and combined PI3Kα-S6K inhibition in LIN28B-mediated colorectal cancer metastasis.

A. E. Shin[1], K. Sugiura[1], S. W. Kariuki[1], D. A. Cohen[1], C. J. Lengner[2], P. A. Sims[1], J. T. Gabre[1], A. K. Rustgi[1];

[1]Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY, [2]University of Pennsylvania, Philadelphia, PA

Introduction: Colorectal cancer (CRC) is the third most diagnosed cancer worldwide. LIN28B, an RNA-binding protein that regulates mRNA translation, has garnered significant interest in recent cancer research. Our lab has established that LIN28B is an oncogene and promotes CRC metastasis. However, the exact mechanisms through which LIN28B exerts these effects remain elusive.

The phosphatidylinositol 3-kinase (PI3K)/AKT signaling pathway is altered in 50-70% of CRCs and is characterized by *PIK3CA* gene mutations in 20-30% of CRC cases. *PIK3CA* encodes the catalytic subunit p110α of the PI3Kα enzyme, which is critical for PI3K/AKT signaling. Activation of this pathway is associated with worse CRC prognosis. Among the components of this signaling cascade, the ribosomal protein S6 kinase (S6K) is a crucial downstream effector, playing a pivotal role in protein synthesis and cell growth. Despite the frequent occurrence of *PIK3CA* mutations in CRC, targeted therapies for *PIK3CA*-mutant CRC are lacking. Alpelisib, a PI3Kα-specific inhibitor approved by the FDA for a subset of *PIK3CA*-mutant breast cancers, remains largely unassessed in CRC. *We hypothesize that LIN28B-mediated CRC metastasis is facilitated by the activation of the PI3K/AKT pathway, representing a potential target for Alpelisib or other related inhibitors.*

Results: Our data indicate that LIN28B expression in CRC cells promotes liver metastasis in mouse models of metastatic CRC (mCRC). Furthermore, LIN28B expression activates the PI3K/AKT pathway, as measured by an AKT phosphorylation array. Treatment of CRC cells with SC79, a pan-AKT activator, enhanced cell migration and invasiveness. Similarly, *Villin*^{Cre}*;R26*^{Pik3ca} transgenic mice, expressing a constantly active mutant form of PI3Kα in the intestinal epithelium, demonstrated crypt hyperplasia and an amplified propensity for tumorigenesis, mirroring the effects of LIN28B expression in CRC. Importantly, Alpelisib effectively hinders LIN28B-driven CRC progression in cell lines, transgenic mice-derived organoids, and mCRC mouse models, as well as the growth rate of CRC patient-derived organoids (PDOs). The effects observed with Alpelisib treatment were replicated with inhibition of S6K using either LY25284702 or PF4708671. Moreover, a combination of low-dose Alpelisib with low-dose LY25284702 or PF4708671 synergistically restricted the growth of PDOs.

Conclusion: Our data provide compelling evidence that the PI3K/AKT pathway regulates LIN28B-mediated CRC metastasis, and its inhibition by Alpelisib is feasible. This underscores the potential for precision medicine in CRC, offering targeted therapies to *PIK3CA*-mutant CRC patients who lack specific treatment options. Furthermore, our study highlights the clinical advantages of combined inhibition strategies for improved anti-metastatic outcomes, a field in dire need of interventions in mCRC.

#4126 The inhibitory effect of statins on distant metastasis and recurrence of endometrial cancer.

K. Kim[1], J. Yoo[2], R. Broaddus[3], E. Jeong[1], M. Hunter[1], T. Kim[1], J.-W. Jeong[1];

[1]University of Missouri, Columbia, MO, [2]Yonsei University MIRAE Campus, Wonju, Korea, Republic of, [3]University of North Carolina, Chapel Hill, NC

Endometrial cancer (EC) is the most common gynecologic malignancy. The most common histological type is endometrioid endometrial cancer (EEC). While the majority of patients present with early-stage and low-grade EEC and have an excellent prognosis, a subset develops distant recurrence derived from EEC after initial treatment of the primary. However, the exact mechanism of distant metastasis and recurrence from EEC is still unclear. In addition, the lack of suitable pre-clinical models is a significant barrier to research for distant metastasis and recurrent cancer derived from EEC. Our preclinical EEC model, the ablation of both *Mig-6* and *Pten* in the uterus (*Pgr*$^{cre/+}$*Mig-6*$^{f/f}$*Pten*$^{f/f}$; *Mig-6*$^{d/d}$*Pten*$^{d/d}$), dramatically accelerates the development of EEC compared to single ablation of either gene. The ablation of both *Mig-6* and *Pten* in the uterus (*Pgr*$^{cre/+}$*Mig-6*$^{f/f}$ *Pten*$^{f/f}$; *Mig-6*$^{d/d}$*Pten*$^{d/d}$ mice) displayed distant metastases into the ovary, diaphragmatic skeletal muscle, lymph node, and lung. However, the *Pten*$^{d/d}$ mice exhibited endometrial cancer without distant metastases. After hysterectomy of EEC confined to uterus, *Mig-6*$^{d/d}$*Pten*$^{d/d}$ mice exhibited recurrent EEC in abdomen and lung. To identify prognostic factors for distant metastatic and recurrent EEC, we performed transcriptomic analysis in endometrial hyperplasia, a precancerous condition, from *Pten*$^{d/d}$ and *Mig-6*$^{d/d}$*Pten*$^{d/d}$ mice. Our transcriptomic analysis identified that cholesterol biosynthesis was the most significantly activated pathway in *Mig-6*$^{d/d}$*Pten*$^{d/d}$ mice compared to *Pten*$^{d/d}$ mice. Statins, also known as HMG-CoA reductase inhibitors, are the most common cholesterol-lowering drugs. We evaluated the effect of atorvastatin on tumorigenesis and recurrence of EEC. *Mig-6*$^{d/d}$*Pten*$^{d/d}$ mice treated with atorvastatin displayed significant reduction of tumor size compared to vehicle treated group. For vehicle-treated group, our pathological analysis revealed EEC outside the uterus, therefore EEC had disseminated to involve the ovary, diaphragmatic skeletal muscle, lymph node, and lung. However, EEC was confined to the uterus in the atorvastatin treated group. Furthermore, atorvastatin treatment reduced the rate of recurrent EEC development. This data demonstrated that atorvastatin has a remarkable inhibitory effect on metastasis and recurrence of EEC in *Mig-6*$^{d/d}$ *Pten*$^{d/d}$ mice. Our results suggest that statins suppress development of distant metastasis and recurrence in mouse models of EEC with *Pten* and *Mig-6* deficiency by inhibiting cholesterol biosynthesis.

#4127 Combined inhibition of RAF, MEK, and FAK attenuates melanoma brain metastases and prolongs survival in preclinical models.

Karly A. Stanley[1], Jared D. Almazan[1], Tursun Turapov[1], David A. Kircher[1], Gennie L. Parkman[2], MiKaela N. Field[1], Katie M. Culver[1], Christopher M. Stehn[1], Silvia Coma[3], Jonathan A. Pachter[3], Howard Colman[1], Sheri L. Holmen[1]

[1]Huntsman Cancer Institute, Salt Lake City, UT,[2]Weber State University, Ogden, UT,[3]Verastem Oncology, Needham, MA

Despite promising results from recent FDA-approved therapies, many advanced melanoma patients develop resistance to both immunotherapy and targeted therapy. A common resistance mechanism to targeted therapy is upregulation of the PI3K/AKT signaling pathway, which has also been shown to promote the development of melanoma brain metastases. Historically, AKT inhibitors have failed in the clinic due to their limited efficacy or intolerable toxicity. Proteomic analysis comparing non-metastatic vs brain metastatic primary tumors in mice revealed focal adhesion kinase (FAK) as an AKT1 specific effector and a potential alternative therapeutic target. FAK is a non-receptor tyrosine kinase that localizes primarily to focal adhesions to regulate cell migration. To determine whether targeting FAK alone or in combination with the RAF/MEK inhibitor avutometinib reduces brain metastases and prolongs survival, we utilized both autochthonous and syngeneic melanoma mouse models. Mice with either subcutaneous tumors or established brain metastases were treated with FAK inhibitor, RAF/MEK inhibitor, or the combination of FAK and RAF/MEK inhibitors. Each cohort was assessed for tumor onset, growth, metastasis, and survival. Our results show that combined RAF/MEK/FAK inhibition significantly delays tumor onset, causes regression of established tumors, prevents the development of brain metastases, promotes the regression of established brain metastases, and prolongs survival. In addition, patient-derived BRAF V600E melanoma xenograft mouse models resistant to the BRAF inhibitor dabrafenib and the MEK inhibitor trametinib, were sensitive to combined RAF/MEK/FAK blockade. The addition of the BRAF inhibitor encorafenib to these models further enhanced the effect on tumor growth. These results support the initiation of a clinical trial evaluating the efficacy of the RAF/MEK inhibitor avutometinib in combination with the FAK inhibitor defactinib in patients with brain metastases from cutaneous melanoma. Additionally, we are assessing non-canonical roles of FAK in modulating the tumor microenvironment to determine whether avutometinib and defactinib also enhance the efficacy of immune checkpoint inhibition in this disease.

#4128 Biofield therapy suppressed invasion and metastases of human pancreatic cancer.

P. Yang, S. Chakraborty, P. Nguyen, D. Deng, A. Cusimano, D. Wei, L. Cohen;
The University of Texas MD Anderson Cancer Center, Houston, TX

The NIH categorizes Biofield Therapy (BT) as therapeutic approaches within energy medicine that involve using the body's energy field (biofield) for therapeutic benefit. Although controversial, in some cases devices have been developed that mimic the electromagnetic fields (EMF) that are emitted from people when delivering BTs. We previously reported that BT significantly inhibited the growth of pancreatic cancer cells and liver metastasis in their relevant animal models mediated in part through modification of the cell cycle, reductions in cell voltage potentials, and down regulation of PI3K/Akt pathways. We expanded this research to examine the potential role of BT in anti-invasiveness in human pancreatic ductal adenocarcinoma (PDAC) cells and animal models. We found that PANC-1 cells treated with BT (15 min) displayed 55% less invading cells than that of untreated incubator control and sham control cells ($P < 0.001$). Similar results were observed in human PDAC L3.7 cells and mouse pancreatic cancer KPCY cells. These experiments were replicated 8 times for Panc-1 cells and 4 times for L3.7 cells. Additionally, migration capacity was tested using the transwell migration and scratch assays. Consistent with the result of cell invasion assays, BT treatment also led to significant reduction of migration of PANC-1 and L3.7 cells by 34% and 41%, respectively, compared to sham controls. Two additional therapists independently replicated the anti-invasiveness and anti-migratory effects of BT on these PDAC cells. This suggests the replicability of these findings across studies and therapists. In a repeated PANC-1 mouse orthotopic model, we found that only a third of BT treated mice had visible liver nodules whereas liver metastasis was observed in more than half of mice in the untreated colony control and sham control groups. Furthermore, BT treatment significantly reduced liver tumor burden by 73% compared to that of the sham control group ($p < 0.05$), which was similar to that observed in the previous study. Similar to the prior PANC-1 mouse model, in the current study BT treatment had only a moderate impact on the growth of primary pancreatic tumor. We assessed certain markers indicative of cell status as well as pathways associated with migration and invasion and these will be presented at the meeting. Our findings suggest that exposure to BT reduced cellular invasion and migration processes and profoundly reduced metastasis of pancreatic tumor in an animal model. This study is in part supported by Emerald Gate Charitable Trust.

#4129 Mitochondria-targeted antioxidant MitoQ inhibits human breast cancer metastasis in mice.

T. Capeloa, **P. Sonveaux**;
Universite catholique de Louvain (UCLouvain), Brussels, Belgium

In oncology, the occurrence of distant metastases often marks the transition from curative to palliative care. Such outcome is highly predictable for triple-negative and HER2-positive breast cancer patients, even if tumors are detected early, and there is no treatment to prevent metastasis. Here, considering that mitochondria are bioenergetic sensors of the tumor microenvironment, we report in preclinical mouse models that human breast cancer relapse is not a fatality: local recurrence and metastatic dissemination can be prevented by MitoQ, a mitochondria-targeted antioxidant that already underwent Phase I safety and Phase II efficacy trials in humans for pathologies other than cancer. Metastatic prevention was confirmed in the MMTV-PyMT model of spontaneously metastatic mouse breast cancer. After oral delivery, MitoQ was effective at nanomolar concentrations at which nonmalignant cells were spared. In anticipation of future clinical trials, a robust signature of the response to MitoQ was defined, applicable to bulk primary tumor biopsies.

#4130 Targeting epigenetically-driven inflammation for PDAC metastasis prevention in high-risk individuals.

J. Handler, R. Kalhor;
Johns Hopkins University, Baltimore, MD

Background: Pancreatic ductal adenocarcinoma (PDAC) is a lethal cancer with a dire prognosis, in large part due to the late stage at which it is diagnosed in most patients. High-risk individuals (HRIs) identified through family history or germline genetic testing are candidates for imaging-based screening, yet even with intensive surveillance, metastasis often occurs between scans. Our study aims to address this critical clinical challenge by investigating the epigenetic determinants of PDAC metastasis and developing novel strategies for metastasis prevention in HRIs.
Methods: Innovative transplantation models of PDAC liver and peritoneal metastasis incorporating DNA barcodes for subclonal tracking were developed to facilitate the identification of subclones with high or low metastatic potential. An in-depth epigenomic characterization and comparison of these subclones was performed utilizing assay for transposase-accessible chromatin with sequencing (ATAC-seq) and RNA-seq.
Results: Metastasis-high subclones demonstrate widespread chromatin accessibility differences relative to their metastasis-low peers. These differences are linked to expression changes for genes involved in motility, differentiation, survival, and particularly inflammation. Top epigenetically activated genes in metastasis-high subclones include the pro-inflammatory cytokines IL-1α and IL-23α and the pro-inflammatory cytokine receptor IL-18R1.
Discussion: These findings highlight the role of epigenetic changes in PDAC metastasis, especially activation of inflammatory pathways resulting from altered chromatin accessibility. These insights provide a foundation for exploring anti-inflammatory agents for PDAC metastasis prevention. Targeting inflammation, alongside imaging-based screening, could significantly improve outcomes for HRIs.

#4131 Combination therapeutic strategy to fight against triple-negative breast cancer.

Laura Svajda[1], Ivan Ranđelović[1], Sara Eszter Surguta[1], Marcell Baranyi[2], Istvan Kenessey[1], Mihaly Cserepes[1], Jozsef Tovari[1]

[1]National Institute of Oncology and National Tumor Biology Laboratory, Budapest, Hungary, [2]Semmelweis University, Budapest, Hungary

Triple-negative breast cancers (TNBCs) lack estrogen-and progesteron receptors and human epidermal growth factor receptor-2 (HER2) which limits the therapeutic approaches. The high metastasizing capability of TNBCs is in correlation with the poor oxygenation of the cancerous breast tissue. This leads to the activation of the hypoxia-inducible-factor 1 (HIF-1), which induces multiple target genes that are involved in tumor progression and metastasis formation. This makes HIF-1 an attractive drug target, however, HIF-1 inhibitors failed if applied in monotherapy. Therefore, our aim is to investigate the combined therapeutic effect of HIF-1 inhibitor acriflavine and paclitaxel, a commonly used taxane in TNBC treatment. The synergy assessment of the two drugs was carried out by utilizing Sulforhodamine B assay on TNBC cell lines. The *in vivo* toxicity and efficacy of the drug combination was tested on NOD SCID mice with orthotopically inoculated MDA-MB-231 cell line. Quantitative and qualitative analysis of multiple genes involved in tumor progression was performed by mRNA and protein expression level assessment with qPCR, western blot and immunohistochemistry methods. HIF-1 stimulation was achieved by either incubating the cells at 1% oxygen level or through CoCl2 treatment. The *in vitro* mRNA expression studies demonstrated that acriflavin possesses a hypoxic-effect-mitigating property on the expression of metastasis-involved- and HIF-1 target genes. Acriflavine alleviated the epithelial-mesenchymal transition of TNBC cells by increasing the expression of the epithelial marker, E-cadherin. At protein level, we detected decrease in HIF-1alpha and Phospho-Protein kinase B (Akt) and increase in p53 tumor suppressor gene expression in response to acriflavine treatment. We further established MDA-MB-231 xenograft model in mice for investigating *in vivo* toxicity and efficacy. The drug combination efficiently reduced the tumor size and the macrometastasis formation compared to the control groups. The protein analysis of frozen tumor tissue samples indicated that the combination therapy decreased the HIF-1alpha expression and the amount of Phospho-Akt and Phospho-Mitogen-activated protein kinases (pMAPK/pERK) in CoCl2treated mice. Additionally, expression of epithelial markers increased and that of mesenchymal markers decreased. The combination therapy led to a decrease in the platelet-derived growth factor receptor beta (PDGFRB) as well. To conclude, we identified a novel drug combination which can efficiently combat TNBC by inhibiting HIF-1 signaling, mitigating cell migration and metastasis formation and suppressing the activation of the Phosphoinositide 3-kinase (PI3K) and MAPK pathways. This work was supported by the Hungarian Thematic Excellence Program (TKP2021-EGA-44) and the National Laboratories Program - National Laboratory for Tumor Biology (NLP-17).

#4132 Low-dose carbon monoxide therapies suppress cancer metastasis.

T. Zhang[1], C. Zhang[1], X. Chen[1], X. Yang[2], Q. Mao[2], G. Zhang[1], Z. Chen[1], A. Tan[1], J. Xiang[1], E. Hissong[1], Y.-T. Chen[1], B. Wang[2], **N. Du**[1];
[1]Weill Cornell Medicine, New York, NY, [2]Georgia State University, Atlanta, GA

Metastasis is the primary cause of cancer-related deaths. Novel systemic therapies for metastatic cancer are urgently needed. Carbon monoxide (CO) is an endogenously produced signaling molecule in the human body with demonstrated pharmacological activities, including organ protection and anti-inflammation. We determined the therapeutic effect of low-dose CO and CO prodrugs on cancer progression in this study. We found that low-dose CO inhibits the migration of cancer cell lines including breast, pancreatic, colon, prostate, liver, and lung cancer. We showed that low-dose CO inhibits lung metastasis of breast cancer and liver metastasis of pancreatic cancer in preclinical mouse models. Further, to provide safer and more reliable CO delivery, we developed metal-free, organic CO prodrugs and showed that CO prodrugs inhibit tumor growth and metastasis. We demonstrated that low-dose CO blocks the transcription of heme importers, leading to diminished intracellular heme levels. Altogether, our work lays a strong foundation for the development of CO-based systemic cancer therapies.

#4133 Hyaluronidase inhibitor delphinidin inhibits cancer metastasis.

J. J. McGuire[1], T. Taguchi[2], G. Tombline[1], V. Paige[1], M. Janelsins[1], N. Gilmore[1], A. Seluanov[1], V. Gorbunova[1];
[1]University of Rochester, Rochester, NY, [2]Salk Institute for Biological Sciences, Rochester, CA

Cancer remains a formidable global health challenge, with metastasis being a key contributor to its lethality. Abundant high molecular weight hyaluronic acid, a major non-protein component of extracellular matrix, protects naked mole rats from cancer and reduces cancer incidence in mice. Hyaluronidase plays a critical role in degrading hyaluronic acid and is frequently overexpressed in metastatic cancer. We investigated the potential of targeting hyaluronidases to reduce metastasis. High throughput screening identified delphinidin, a natural plant compound found in fruits and vegetables, as a potent hyaluronidase inhibitor. Delphinidin-mediated inhibition of hyaluronidase activity led to an increase in high molecular weight hyaluronic acid in cell culture and in mouse tissues, and significantly reduced proliferation, migration and invasion of breast (EO771), prostate (RM1), and melanoma (B16-F10) metastatic cell lines. Addition of exogenous hyaluronidase partially reversed all of these effects. Moreover, delphinidin treatment suppressed melanoma (B16-F10) metastasis in a spontaneous mouse model of metastasis. These results provide a proof of principle that inhibition of hyaluronidase activity suppresses cancer cell migration, invasion and metastasis. These results combined with the lack of adverse effect make delphinidin an attractive potential therapeutic option for inhibition of metastasis. We believe further investigation is warranted to fully elucidate the mechanisms and optimize the use of delphinidin in cancer therapy.

#4134 The abscopal effect of combination IRE with αPD-1 treatment against PDACs.

Q. Cao[1], N. A. Egan[2], W. Peng[2], C. Li[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Houston, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is associated with a high capacity of metastatic dissemination, which results in a dismal 5-year relative survival rate. Irreversible electroporation (IRE) represents an innovative intervention utilizing short high-voltage electric pulses to induce cell death through either permanent membrane lysis or disruption of cellular homeostasis. Previous studies from our lab have demonstrated that the combination of IRE and immune checkpoint blockade using anti-PD-1 antibody (αPD-1) enhances the infiltration of CD8+ cytotoxic T cells, significantly prolonging survival in an orthotopic murine PDAC model. However, the impact of IRE/αPD-1 on metastatic PDAC tumors, known as the abscopal effect, remains unclear. In this investigation, we bilaterally implanted C57BL/6J mice with subcutaneous KRAS* PDAC tumors, treating the right flank tumors with or without IRE, in conjunction with or without αPD-1 administered intraperitoneally. Tumor growth in both the treated (with or without IRE) and untreated (abscopal) left flank tumors was closely monitored until humane euthanasia or long-term survival. In a separate study, mice serum and tumor tissues were collection on the 5th day post-IRE/αPD-1 treatment. Luminex cytokine assays were conducted on the collected serum, and immunostaining was performed on tumor tissue. Results demonstrated significantly enhanced antitumor activity in both IRE-treated and untreated tumors on mice treated with combined IRE and αPD-1, leading to a marked extension of overall survival. Luminex cytokine assays revealed a substantial increase in crucial cytokines, including IL-2, IFN-gamma, IL-18, IL-19, and IL-3, known for their pivotal roles in fostering cytotoxic T lymphocyte development, promoting T cell differentiation into effector T cells, and facilitating the recruitment of effector CD8+ T cells to the tumor microenvironment. Moreover, immunofluorescence staining of tumor tissue illustrated a notable accumulation of CD169+ macrophages in IRE-treated tumors compared to untreated tumors. Tumors from the combined IRE with αPD-1 group exhibited increased CD8+ T cell accumulation compared to other groups. These data suggest IRE combined with PD-1 blockade promotes robust antitumor immune, leading to systemic antitumor activity and robust abscopal effect.

#4135 First demonstration of magnetic particle imaging for sentinel lymph node identification.

O. C. Sehl[1], A. R. Mohtasebzadeh[1], K. Guo[1], P. Kim[1], B. Fellows[1], M. Weyhmiller[1], P. J. Foster[2], P. W. Goodwill[1], J. M. Greve[1];
[1]Magnetic Insight, Inc., Alameda, CA, [2]Robarts Research Institute, Western University, London, ON, Canada

Sentinel Lymph Node (LN) biopsy involves the identification and surgical removal of the first LN(s) that drain from a primary tumor to evaluate for metastasis by histopathology [1]. For several tumor types, the standard of care is to manage the regional LN basin separately from the primary tumor. For head and neck cancer, melanoma, and complex breast cancer cases, pre-surgical imaging is required to determine the number and location of LN(s) to remove. Most sentinel LN biopsies are performed with nuclear imaging, which relies on short-lived radiotracers and can have poor image quality, making it challenging to identify sentinel LNs in complex anatomies. An alternative and non-inferior workflow uses a non-radioactive iron oxide magnetic tracer (ferucarbotran) with a magnetic probe [2], however this tool can only be used intraoperatively. In this abstract we introduce magnetic particle imaging (MPI) as a pre-surgical imaging technology that detects iron oxides with high sensitivity at mm-scale resolution [3]. **Our objective is to demonstrate that MPI provides sensitive and quantitative tracking of ferucarbotran pharmacokinetics from four anatomical sites to primary draining LNs in mice. Methods:** Ferucarbotran was administered intradermally to C57BL/6 mice at a standard clinical dose of 0.675 mg Fe/kg to the forepaw, hindpaw, or base of tail, or tongue (n = 4). Full-body 2D and 3D imaging was performed after 20 mins, 24 h, and 48 h, and 144 h using MOMENTUM imager (Magnetic Insight Inc.). MPI signal was quantified at the injection site and draining LNs. LNs of interest were extracted to verify MPI signals ex vivo then were processed for Perl's Prussian iron staining. **Results:** After 20 minutes, MPI signal was seen at the injection site and primary LNs. The pharmacokinetics of ferucarbotran to LNs varied based on administration site. For hindpaw, signal was present in the popliteal LN (1.4% of tracer). For forepaw, ferucarbotran accumulated in the primary axillary LN (9%). For base of the tail, signal was observed in inguinal LN (2%). For tongue, MPI signal was detected in cervical LNs (14%). In all mice, MPI signal at the injection site decreased over time and signal in primary LNs persisted for at least 6 days. **Conclusions**: We demonstrated MPI is a quantitative, hotspot imaging technique for identifying primary LNs. As iron oxide tracer pharmacokinetics varies with injection site, this imaging technique could provide fundamental information required for surgical planning. Unlike nuclear imaging, persistence of MPI signal for several days provides tremendous flexibility in clinical workflow and introduces the potential for an image-guide delayed SLN biopsy [4] . This preclinical LN imaging is timely as our team is actively building and testing the world's first large-bore, clinical-scale MPI scanner.[1] Leong SP, *Clin Exp Metastasis* (2022). #4136 Tracking metastatic dissemination and tumor growth using longitudinal imaging and ctDNA.

W. Liu[1], B. Ding[2], H. Sonya[1], C. Martinez-Ruiz[1], C. Naceur-Lombardelli[1], C. Richard[1], H. Lee[2], C. Veiga[2], K. Patel[1], A. Huebner[1], A. Hackshaw[3], C. Abbosh[4], A. M. Frankell[5], G. Royle[2], C. Swanton[5], M. Jamal-Hanjani[1];

[1]University College London Cancer Institute, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Cancer Research UK and UCL Cancer Trials Centre, London, United Kingdom, [4]Cancer Research UK Lung Cancer Centre of Excellence, London, United Kingdom, [5]Francis Crick Institute, London, United Kingdom

Metastatic lung cancer is a heterogeneous disease, characterized by different patterns of clinical progression and therapy response. The scale of this heterogeneity on a lesion specific level has yet to be quantified but is of clinical importance because it may provide an indication of molecular mechanisms underpinning metastasis growth. Currently, whether metastasis growth patterns can be predicted by the primary tumor or governed by metastasis specific characteristics is not known. Furthermore, circulating tumor DNA (ctDNA) has proven useful to predict disease relapse, but how closely it reflects metastatic growth post relapse is unclear. In 104 patients enrolled in the TRACERx study with disease relapse post-surgical resection of the primary tumor, lesion volumetric dynamics were tracked in 460 metastases. Total volume growth rate (TVGR) was calculated using CT imaging performed between disease relapse and death. All patients had whole exome sequencing (WES) of the primary tumor. For 19 patients enrolled in the PEACE autopsy study WES and RNAseq from 60 metastases visible on imaging prior to death and subsequently sampled at autopsy were analyses. In 29 patients, ctDNA was used to track 200 tumor-specific mutations to assess tumor burden and detect metastatic subclones. High TVGR correlated with poor survival (hazard ratio for death 1st vs 2nd tertile was 0.21, p<0.001; 2nd vs 3rd tertile was 0.51, p=0.04). Primary tumor subclonal whole genome doubling was predictive of high TVGR. There was considerable heterogeneity in the growth rate of metastases within patients. The anatomical location of metastases contributed to this, extrathoracic soft tissue and pleura had the highest growth rates, whilst lymph node and adrenal the lowest (p<0.001). Molecular attributes differed between metastases, with fast growing metastases being enriched for proliferation pathway gene expression. It was observed that the most prevalent population of cells, or clone, in the fastest growing metastasis within a patient was exclusive to that metastasis, suggesting that genomic features that characterize the clone might support rapid growth. ctDNA tracked with tumor burden post relapse and patients with extrathoracic relapse had higher levels of ctDNA. In 9 patients, metastasis specific mutations identified at autopsy and in ctDNA, were used to determine the proportion of ctDNA shed by different metastatic sites. ctDNA subclonal fraction was found to track with changes in lesion volumes during disease progression. This work highlights significant heterogeneity in metastatic growth rates which can potentially be attributed to the presence of distinct genomic features which may dictate tumor growth rate. ctDNA accurately reproduces patterns of radiological disease progression and when combined with longitudinal imaging and tumor DNA sequencing, can accurately reconstruct the natural history of cancer evolution.

#4137 Feasibility of a novel image guided injection tool for non-surgical implantation of orthotopic tumors.

T. M. Kierski[1], J. D. Rojas[1], N. Beaumont[1], T. Charity[2], R. D. Marek[2], K. H. Young[2], G. M. Palmer[2], R. C. Gessner[1], **T. J. Czernuszewicz**[1];
[1]Revvity, Durham, NC, [2]Duke University, Durham, NC

The purpose of this study was to evaluate a novel device for non-surgical implantation of tumor cells using ultrasonic (US) image guidance. There are a variety of mouse model cancer types (e.g. sub-cu, orthotopic, genetically engineered). Orthotopic tumors are increasingly prevalent but usually require surgery, which reduces throughput and injures the surrounding anatomy. Injections are an alternative to surgery, but usually require image guidance or extensive training. US guided injection systems exist, but are suboptimal because they require significant training, as the US beam is not necessarily coplanar with needle location or trajectory, reducing accuracy and throughput. We tested a new approach to image guided injection which ensures that the US beam is coplanar with the needle. To test the efficacy of the image guided injection device across a variety of common orthotopic tumors, we delivered luc-tagged cells to the prostate (2.5e5 cells in 40 µL, PC3, N=8), liver (2e6 cells in 100 µL, Hep G2, N=5), and brain (1.75e5 cells in 100 µL, U87-MG, N=3). The brain tumor model was introduced via intracardiac injection to simulate metastases. Between 3 and 8 mice were injected for each tumor model. For injection, animals were anesthetized and positioned on motion stage. A 1 mL syringe was mounted to the adjustable injection gantry with the needle co-planar with the US beam, and the target organ was visualized with US. Cells were delivered to the targets using the US live stream as a guide. Between 1 to 3 weeks after the injections, tumors were confirmed via BLI with an IVIS (Revvity, Waltham, MA, USA). For each of the three tumor cell lines, animal preparation and injections could be performed in 10 mins by recently-trained novice users. All three cell lines could be effectively delivered to the orthotopic host tissues, and this was confirmed by using BLI of the cells. This study represents the first time a co-planar US beam and needle delivery mechanism was used for the purpose of non-surgical implantation of orthotopic tumors. Future developments of this platform could include improvements to automation of needle placement and trajectory to ensure successful payload delivery by novice users.

#4138 Evaluation of breast triple-negative 4T1-derived tumor metastatic development in gender-different mouse.

C. Shao, M. He, L.-H. Tsai;
HD Biosciences Co., Ltd., San Diego, CA

Background and Objective: Breast cancer in men is a rare and less-studied case, with therapeutic strategies predominantly relying on clinical treatment protocols established for women. To support the clinical treatment concept, Dr. Martin-Martinez's lab observed no differences in the time of orthotopic breast mammary fat pad tumor development, necrosis, or color change of tumor tissue between male and female mice. However, the clinical treatment readout, especially tumor metastasis, is different in men and women, and current models for breast cancer are inadequate due to the absence of metastases. It is necessary to evaluate the development of breast cancer 4T1-derived tumor metastasis in male and female mice.
Method and Result: 4T1-Luc breast cancer cells were implanted in male and female Balb/c mice via various routes, including inguinal fat pad injection, tail vein injection, caudal artery injection, portal vein injection, and Intratibial Injection. Illuminance images showed no significant differences in tumor metastatic development between genders for inguinal fat pad, tail vein, and intratibial injections. However, following caudal artery injection, early-stage metastasis differed; male mice developed femoral head metastasis, while female mice developed lung metastasis. In the late stage, male mice displayed lung and femoral bone metastasis, while female mice primarily showed lung metastasis with barely bone metastasis.
Conclusion: While both male and female mice showed similar primary breast tumor development, mouse gender affected tumor metastasis differently, particularly when tumor cells went through the caudal artery. Male mice presented earlier femoral head metastasis and less lung metastasis than female mice. Based on this work, sex hormones would affect both hormone-related and nonhormone-related tumor metastasis. To elucidate whether this phenomenon is caused by estrogen or androgen or to test if a drug has any beneficial effects, HD Biosciences provides established tumor metastatic cell-delivering platforms and over 1000 cancer cell lines for target validation and drug efficacy study.

#4139 Prolyl 4-hydroxylase subunit alpha 1 acts as a novel target for lung adenocarcinoma brain metastasis.

Y. He[1], Z. Luo[2], Y. Dong[3], **R. Wan**[4], X. zhang[1], h. Bai[1], J. Wang[1];

[1]CAMS Key Laboratory of Translational Research on Lung Cancer, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical , beijing, China, [2]Department of Clinical Medicine, Southwest Medical University, Luzhou, China, Luzhou, China, [3]Chinese Academy of Medical Sciences and Peking Union Medical College, beijing, China, [4]Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Lung cancer is the most lethal cancer worldwide, with a high incidence of distant metastasis. Many lung adenocarcinoma (LUAD) patients experience brain metastasis during the disease process with unfavorable prognosis. Our previous study has discovered that P4HA1 was exclusively upregulated in brain metastatic cells. Through the analysis of single-cell RNA sequencing of LUAD samples, we found that the expression of P4HA1 in brain metastatic tumor cells is higher than that in primary tumor cells. This finding was further confirmed by immunohistochemical staining. Significantly, a strong presence of P4HA1 in primary tumors is associated with a reduced duration of disease-free survival in individuals with LUAD. Overexpression of P4HA1 in A549 and PC9 cell lines significantly increased the incidence of brain metastasis in BALB/c nude mice, whereas knockdown of P4HA1 in high brain metastatic cells significantly decreased the incidence of brain metastasis and reduced the tumor foci in brain with improved survival. Utilization of DHB, a P4HA1 inhibitor, exerts both therapeutic and preventive effects in relieving brain metastases in nude mice. Furthermore, remarkable inhibition of tumor growth by DHB was observed in patient derived xenograft (PDX) models. RNA sequencing analysis demonstrated that the reduction of P4HA1 expression had a substantial impact on cell adhesion and extracellular matrix (ECM)-receptors interactions. Western blotting analysis verified that the decrease in P4HA1 expression led to a drop in the expression of adhesion molecules ICAM1, VCAM1, NCAM1, as well as integrin molecules ITGA2 and ITGA3. Furthermore, when endothelial cells were co-cultured with conditioned medium from tumor cells, it was observed that the expression of the tight junction molecule ZO1 was reduced after co-culturing with conditioned medium from P4HA1 knockdown A549 cells. The results from the in vitro blood-brain barrier (BBB) model and in vivo biofluorescence imaging indicate that P4HA1 promoted brain metastasis of LUAD via modulating the ability of tumor cells to cross the blood-brain barrier. In conclusion, our study reveals that overexpression of P4HA1 promotes metastatic spread to the brain, and targeting P4HA1 could be a promising therapeutic strategy for the treatment of lung adenocarcinoma brain metastasis.

#4140 Enhanced microglial phagocytosis of metastatic brain tumor cells with *Cd24a/Cd47* depletion.

T. Tsuji[1], H. Hirose[1], M. Shindo[1], R. Hartantyo[1], Y. Saito[1], K. Hosoya[2], H. Yoshida[2], D. Kato[1], A. Yoshizawa[2], Y. Arakawa[1], H. Ozasa[2], T. Hirai[2], H. Wake[1]; [1]Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Kyoto University Graduate School of Medicine, Kyoto, Japan

Despite the robust homeostasis of the brain, its high prevalence of tumor metastasis is intriguing and the underlying mechanism may contribute to the development of novel therapies. Microglia have emerged as promising therapeutic targets due to their role in brain parenchymal homeostasis. However, with evidence for both pro- and anti-tumorigenic functions, their role in brain metastasis (BrM) remains unclear. Here, we show that the microglial response to tumor cells within a single host is heterogeneous and can alter tumor fate. Single-cell RNA sequencing was performed on five surgically resected metastatic brain tumors, and the transcriptome of tumor-associated microglia was extracted by single-cell variational inference (scVI). Evidence for the coexistence of cytokine-secreting and angiogenesis-supporting subsets, as well as subsets associated with phagocytosis and antigen presentation, within each tumor sample was determined. To demonstrate the intra-tumoral functional heterogeneity of tumor-associated microglia, we established a metastatic brain tumor model that allows us to visualize the metastatic process and the dynamic microglial response in vivo by injecting mCherry-tagged allogeneic cancer cells into the internal carotid artery of *CX3CR1-EGFP* mice. Metastasis formation was suppressed in microglia-depleted mice, identifying a dominant microglial response that promotes tumor growth. However, continuous in vivo imaging of the BrM model revealed tumor-eradicating anti-tumor microglia coexisting with pro-tumor microglia in the same host. The transcriptome of anti-tumor microglia supported that they are enriched for phagocytosis, antigen processing and antigen presentation genes. The subset was identified in microglia extracted from human samples. We then examined the immune checkpoint of microglial phagocytosis in the tumor transcriptome and identified *Cd24a* and *Cd47*. Simultaneous deletion of both genes in cancer cells enhanced microglial phagocytosis, reduced tumor volume and improved survival, and rescue of both genes reversed these anti-tumor effects. The microglial dependency was addressed by microglial depletion experiments, and the anti-tumor effects were reproducible in nude mice lacking mature T cells. These results suggest that there are distinct immune cell subtypes that respond to lung tumor metastases in the brain and either promote tumor growth or inhibit metastasis through phagocytosis. Furthermore, anti-tumor activity in mouse models can be enhanced by genetic deletion of *Cd24a* and *Cd47* in tumor cells, which regulate phagocytosis by microglia.

#4141 Quantitative measurement of 3D tumor spheroid invasion using live cell time-lapse imaging.

G. Yang, T. Wang, P. Ye, **X. Zhang**;
Agilent Technologies, Inc., San Diego, CA

90% of the death of cancer individuals is related to cancer metastasis[1]. The invasion and migration of cancer cells into surrounding tissues and chambers is the first step of metastasis[2]. To have a better and more in-depth understanding of the pathophysiological activities involved in metastatic cancer, accurate and reliable methods for evaluating cell invasion are urgently needed. Compared to the 2D cell model, the 3D system mimics the natural physiological properties and conditions, such as structure, physiology, biological signals of living tissues, cell-matrix interactions[4]. In this study, we followed the commonly used protocol for 3D tumor invasion assay[3] to generate spheroids in Ultra-Low-attachment (ULA) round bottom 96-well plate and subsequently embedded them in Matrigel® (5 mg/mL). After polymerization, the Matrigel that contains tumor spheroid was submerged in 100 µL cell culture media. The invasion of the 3D spheroid in the presence or absence of drug treatment was monitored and quantified using the brightfield and fluorescence live cell time-lapse image acquisition and image analysis functions of the Agilent xCELLigence RTCA eSight. The progress of spheroid invasion and the drug-inhibitory effects on tumor invasion were quantified by tracking and calculating the area of invasive protrusion from the spheroid. Our data show that 1) different types of cancer cells had different metastatic potentials demonstrated by the level of invadopodium extending into the Matrigel at desired time points; 2) the invasion of 3D HT1080 spheroid was inhibited by cytochalasin D (Cyto D), an inhibitor of actin polymerization, and GM6001, a potent broad-spectrum inhibitor of matrix metalloproteinases (MMP), in a dose-dependent manner; 3) Cyto D exhibited higher efficacy of inhibiting tumor invasion than GM6001. In summary, our approach by combining the 3D tumor spheroid invasion model with the RTCA eSight's capability of live cell imaging and automatic quantification of the area of invasive protrusion can facilitate and enhance the development of new treatments at the preclinical stage in the future.

#4142 Obesity contributes to CD8+ T cell dysfunction before and after lung metastasis in a mouse model of ER+ breast cancer.

A. E. Williams, L. M. Arendt;
University of Wisconsin-Madison, Madison, WI

Obesity is known to worsen the overall prognosis of breast cancer patients. Breast cancer patients with a body mass index (BMI) of ≥30 kg/m^2 have an increased risk for metastatic disease compared to patients with a BMI in the normal range. Although immune cells like neutrophils and myeloid derived suppressor cells have been studied in breast cancer metastasis of the lung, little is known how T cell populations change before and after metastasis. To investigate these gaps, we fed 3-week-old female FVB/N mice either a low-fat diet (LFD) or high-fat diet (HFD) for 16 weeks to induce obesity. One group was set as a tumor-naïve control and the other was injected estrogen receptor positive (ER+) TC2 cells into the mammary fat pad. Tumors grew to 0.5 cm in diameter then were surgically removed. Lung tissue was collected 8 weeks after tumor removal to examine progression of metastatic disease, and T cell populations were quantified in tumor-naïve and metastatic lung tissue from obese and lean mice using flow cytometry. Lungs from naïve obese mice showed a significant increase of total CD45+ immune cells. CD8+ T cells from naive obese mice expressed higher levels of programmed cell death protein-1 (PD1), a marker of T cell dysfunction or T cell activation. Metastatic lungs also showed increases in CD45+ immune cells and PD-1+ expression on CD3+ cells and CD8+ cells. Overall, metastatic lungs showed higher levels of PD-1 expression than naïve lungs on more cell types, evidence of more immune dysfunction or activation. To further investigate how obesity alters the function of T cells, CD45+ cells were sorted from lungs from lean and obese mice with and without metastasis, and gene expression was examined using the NanoString nCounter Immune Exhaustion panel. Immune cells from the lungs of obese non-tumor-bearing mice showed increased expression of markers for increased TCR signaling. This may indicate more T cell activation which leads to exhaustion in obese naïve mice. In metastatic lungs from obese mice, immune cells showed impaired interferon and tumor necrosis factor signaling. In addition, immune cells from metastatic lungs of obese mice also had upregulated expression of genes associated with senescence which may indicate a combination of both exhaustion and senescent phenotypes are present. This was not seen in immune cells from naïve samples, indicating that obesity leads to more chronic T cell dysfunction in metastatic lungs. Overall, even without pathogenic interference, obesity contributes to more T cell signaling and impaired CD8+ T cell activation that leads to higher T cell dysfunction once metastasis is present.

TUMOR BIOLOGY: In Vivo Imaging and Anatomical and Molecular Pathology
Poster Session

#4146 Brain permeable bioluminescent substrates for NanoLuc based reporters.

C. Gao[1], Y. Su[2], Y. Wu[2], C. Fitzgerald[1], T. H. Uyeda[1], H. Wang[1], T. A. Kirkland[3], M. Z. Lin[2], W. Zhou[1];
[1]Promega Corporation, San Luis Obispo, CA, [2]Stanford University, Stanford, CA, [3]Promega Corporation, Madison, WI

Non-invasive imaging methods for tracking gene expression, cell growth and migration and other biological events in vivo are indispensable tools for biomedical studies. Bioluminescence imaging (BLI) can achieve sensitive detection with low background *in vivo*, which is desirable for body imaging of small animals. Yet, BLI in the central nervous system (CNS) is challenging because many luciferase substrates show limited permeability of the blood-brain-barrier (BBB). To address this issue, we developed a family of new brain-permeant NanoLuc (NLuc) substrates, cephalofurimazine (CFz). CFz family paired with Antares, a fusion of CyOFP and NLuc that emits orange light instead of blue, produces an order of magnitude more signal from the brain than the standard combination of D-luciferin with firefly luciferase and matches the peak output of AkaLumine with AkaLuc but without the need of ATP. One of the substrates in the family, CFz-9, not only produces outstanding signal as other CFz substrates when paired with Antares, but also is able to be formulated into lyophilized cake that can be reconstituted in aqueous buffers for i.p. injections. Toxicity studies demonstrate that CFz-9 and its reconstituted solutions are non-toxic to mice and thus multiple injections are allowed.

#4147 Chitosan luminescent rare-earth doped nanoparticles as cancer cell tracking for imaging tumors and their immune response.

R. Osorio-Arciniega[1], E. Lucero-Meza[1], B. Can-Uc[2], I. Rocha-Mendoza[1], P. G. Fournier[1], G. Hirata[2], **P. Juarez**[1];
[1]Center for Scientific Research and Higher Education of Ensenada (CICESE), Ensenada, Mexico, [2]CNYN: Centro de Nanociencias y Nanotecnologia, Ensenada, Mexico

Background: Cancer is a group of diseases characterized by the unregulated growth of cells, which can be hard to diagnose due to the high false negatives or positives derived from technical and human mistakes.The detection of solid tumors during resection surgery is also a common issue, so contrast agents are used for both cancer diagnosis and tumor visualization during surgery, facilitating the tumor resection procedure. Nevertheless, they cause long-term problems because they accumulate in specific tissues, low penetration, and rapid clearance from the circulation. It is necessary to study new contrast agents that improve tumor detection to address these issues.Here, we synthesized two different kinds of luminescent nanoparticles (LNPs) conjugated with chitosan (Ch) and functionalized with folic acid (FA) for breast cancer detection. We compared *in vitro* its physicochemical characteristics and effects on the proliferation of cancer cells. Evaluated its impact on the immune system *in vivo* and implemented a differential imaging process to resemble a refined 3D visualization of cluster cells using Light Sheet Microscopy.
Results: Luminescent nanoparticles (LNPs) synthesized by sol-gel method and functionalized with FA using EDC-NHS coupling revealed high-intensity yellow emission at 540 nm wavelength with a quantum yield of ~ 36%. *In vitro* viability assay at different times with 293T epithelial cells, MDA-MB-231, and T-47D cancer cells demonstrated biocompatibility and high improvement of cellular uptake by LNP functionalized with FA for cancer cells versus normal cells. Light-sheet microscopy analysis of cell-LNP interactions to visualize tagged MDA-MB-231 clusters with LNP/Ch-FA showed positive interactions due to higher stability and adherence. Biodistribution and effects on the immune system by LNP/Ch-FA nanoparticles inoculated in mice were evaluated by flow cytometer analysis. LNP/Ch-FA were well tolerated *in vivo.* No adverse effects were observed macroscopically. Peripheral blood analysis from animals injected with LNP/Ch-FA after 2 or 6 days of the treatment showed that a single injection of the different NPs did not have any effects on the amount of circulating neutrophils or monocytes in peripheral blood when assessed 2 or 6 days after the injection. With T cells, the core NP induced a significant decrease in circulating T cells (-31%, p=0.045) that seemed specific to the CD4+ T cells (-33%, p=0.0479). However, conjugation of the NP to chitosan prevented this effect.
Conclusions: Our work presented significant evidence that could allow a better understanding of LNPs conjugated with Ch and functionalized with FA for possible upcoming clinical applications that could work singly or in synergy with the present detection techniques to boost accuracy and precision for cancer detection without compromise the inmunosystem.

#4148 Extracellular matrix biophysical properties change during nevus to melanoma progression.

A. Kavuturu, M. A. Constantino, A. Sassano, G. Merlino;
National Institutes of Health, Bethesda, MD

Cutaneous malignant melanoma is one of the most aggressive forms of skin cancer and its major etiological risk factor is ultraviolet (UV) solar radiation. The extracellular matrix (ECM) has been shown to influence many of the hallmark characteristics of tumor development, survival, and progression across several types of cancer, including melanoma. Interactions between the tumor and the ECM often results in rearrangement, cross-linking, and deposit of specific ECM proteins, which can contribute to stiffening of the tissue and tumorigenesis. To simulate tumorigenesis, we have previously used a hepatocyte growth factor (HGF) transgenic mouse model, which develops melanoma nevii when exposed to UVB radiation. This model is highly representative of human melanoma lesions in terms of biological, genetic, and etiologic criteria. In general, microrheology involves injecting beads into a medium, tracking movement of the beads using two-photon microscopy, and using the movement to calculate the viscosity and elasticity of the medium. The physical properties of the ECM during tumorigenesis have not been well studied at the cellular level, and microrheology has rarely been used *in vivo.* In our *in vivo* microrheology study, we injected fluorescent beads into the skin of these transgenic mice. Then, we used intra-vital microscopy with particle tracking to image the beads and measure changes in ECM elasticity as nevii grow into melanoma tumors. These results, combined with transcriptomic analysis of ECM regulation and proteomic analysis of ECM signaling, could provide unique insights into components of the extracellular matrix that are involved in melanoma tumor development and offer opportunities for therapeutics to target oncogenesis. <!--EndFragment-->

#4149 Real-time intravital trafficking of tumor infiltrating lymphocytes in breast cancer models.

S. Ahn[1], K. Akyildiz[1], H. Kim[1], P. Kim[2];

[1]IVIM Technology, Seoul, Korea, Republic of, [2]KAIST (Korea Advanced Institute of Science and Technology), Daejeon, Korea, Republic of

Cancer immunotherapy utilizing the immunoreactive efficiency of immune cells via adoptive cell therapy (ACT) has been a novel method of cancer treatment. In tumor microenvironment, immune cell reactivity of tumor-infiltrating lymphocytes (TILs) can facilitate cancer cell attack, which finally derives efficient suppression of tumor growth. However, the conventional evaluation for cancer immunotherapy has been generally performed by *ex vivo* methods, providing restricted information on lymphocyte motility and immune cell dynamics within the tumor microenvironment. *In vivo* data with the dynamic behavior of TILs in breast cancer can provide new insight to investigate novel targets of immune checkpoint inhibitors. In this research, longitudinal intravital imaging of motility trafficking of TILs in breast cancer animal models has been performed by utilizing intravital microscopy to unveil the immunoreactive dynamics of T cell activity in early stage. In vivo analysis of TIL motility within different breast cell lines, including 4T1 (mouse breast cancer cell), MDA-MB-231 (human triple-negative breast cancer cell), and MCF7 (human breast cancer cell), respectively, has been investigated for immune responses to cancer. We've monitored spatiotemporal dynamics of TIL over 11 days in breast cancer xenograft mouse model generated by tumor implantation into the dorsal skinfold imaging chamber and adoptive T cell transfer by blood circulation. In the results, the adoptive immunoreactivity of TIL has been differentiated by the timepoint of adoptive T cell transfer, distance proximity of T cells in tumors, and breast cancer types. Furthermore, anti-cancer effect coordinated with dendritic cells behaviors showed induced immune responses with accumulated dendritic cells with increased TIL count over time in breast cancer model treated with various cancer therapy such as immunotherapy, radiation therapy and anti-cancer drug (anti-PD-L1), which implied a relationship between programmed death-ligand 1 expression levels and TIL/ dendritic cell motility. The result demonstrates that intravital TIL motility trafficking analysis in cancer model can be an invaluable assessment method to explain the detailed cellular/molecular mechanism of immune response to cancer involved with T lymphocytes, dendritic cells, and immune checkpoint inhibitors to accelerate the efficiency of cancer immunotherapy.

#4150 Development of a three-dimensional spatialomics map of lethal prostate cancer driven by clinical imaging.

J. E. Ippolito[1], D. H. Ballard[1], K. Bergeron[1], R. Chidambaram[2], A. Elumalai[1], T. J. Fraum[1], H. Jing[1], P. Kamelin[2], E. H. Kim[1], C. Kita[3], A. Klim[1], A. Knesis[2], M. Lim[3], J. Luna[1], H. Nakhoul[1], T. Ragan[2], K. J. Rothschild[3], S.-K. Song[1], K. Utt[1], C. Weimholt[1], G. Yagnik[3], E. Yew[2], P. M. Angel[4], R. R. Drake[4]; [1]Washington University School of Medicine in St. Louis, Saint Louis, MO, [2]TissueVision, Inc., Newton, MA, [3]AmberGen, Inc., Billerica, MA, [4]Medical University of South Carolina, Charleston, SC

Prostate adenocarcinoma (PCa) is the most common malignancy and the second leading cause of cancer-related mortality in United States men. Following treatment for localized PCa, up to 50% of these men can experience disease recurrence, with subsequent metastasis and death. This indicates that there is suboptimal identification of lethal PCa at the time of diagnosis, despite advancements in imaging, genomics, and biomarkers. To improve the noninvasive diagnosis of lethal PCa at initial diagnosis, we have developed a novel magnetic resonance imaging (MRI) method, diffusion basis spectrum imaging (DBSI), that noninvasively measures cancer, stromal, and immune cell contributions to the prostate tumor microenvironment (TME). To validate DBSI for PCa, we have applied novel technologies to matched prostatectomy specimens that include (i) fully automated tissue section processing with serial 2-photon tomographic (STP) imaging of the sections to generate 3D volumetric structural maps of the tumor tissue and (ii) multiplex MALDI mass spectrometry imaging of untargeted glycans and extracellular matrix (ECM) peptides and of proteins targeted with novel photocleavable-mass-tagged antibodies (MALDI-IHC) to spatially resolve hundreds of biomolecules from the TME. To establish the feasibility of this approach, we recruited a patient with an unusually aggressive prostate cancer consisting of Gleason 5+4 acinar adenocarcinoma histology with intraductal growth that was locally invasive and lymph node positive at prostatectomy (stage T3bN1). This patient also had the unusual finding of low activity on prostate specific membrane antigen positron emission tomography (PSMA-PET). Following gross sectioning of the prostate with MRI-guided 3D printed molds to co-register clinical DBSI with histology, a 5-mm thick tissue cross-section containing tumor and normal prostate was imaged with high resolution ex vivo DBSI followed by 3D structural mapping with STP imaging. Selected slides in the 3D stack were subject to multiplexed MALDI imaging to identify relationships between cellular and molecular heterogeneity with tumor structure identified with DBSI and STP imaging. We discovered unique structural differences in the prostate tumor compared with the surrounding stroma based upon collagen and glycan modifications to the ECM that were recapitulated with second harmonic maps of collagen from STP imaging as well as stromal maps generated from DBSI imaging. Additional novel protein and glycan ECM components were expressed in this tumor known to be associated with poor patient outcomes. Together, these data represent the first evidence successfully linking noninvasive in vivo clinical imaging and de novo spatialomics technologies with potential to improve PCa diagnostics. This advanced imaging workflow can be applied to any tissue type, underscoring its relevance to translational cancer research.

#4151 Development of a cancer-activated biologic imaging platform for early lung cancer diagnosis.

M. Goryawala[1], H.-Y. Lee[1], L. Tong[2], T. Patil[1], A. Harwig[1], C. Xia[1], S. Ramachandran[1], D. Wodziak[1], D. Felsher[2], T. Sproul[1], D. Suhy[1];
[1]Earli Inc., Redwood City, CA, [2]Stanford University, Palo Alto, CA

Current modalities, such as LDCT and fluorodeoxyglucose positron emission tomography (FDG PET), for early lung cancer imaging, rely upon proxies resulting in poor specificity and/or sensitivity. They are also unreliable for discriminating benign versus malignant lesions resulting in the requirement of longitudinal analyses euphemistically called “watchful waiting”. Lung biopsies are marred by significant false negative rates and pose complications of collapsed lungs or bleeding in up to 22% of procedures and death rates up to 1%. To overcome these obstacles, Earli is developing a non-invasive, highly specific cancer-activated imaging platform that usurps dysregulated gene expression within malignancies to force only cancer cells to produce a synthetic biomarker that can be localized using PET imaging. EARLI-204 is a lipid nanoparticle that contains a DNA nanoplasmid comprised of a cancer-activated promoter driving selective expression of a functionally inactivated somatostatin receptor 2 ($SSTR2_{fi}$) gene. Abrogation of internalization and signal transduction allows the safe use of $SSTR2_{fi}$ as an ectopically expressed PET reporter gene (PRG). Following administration, EARLI-204 transfects tumor and normal cells but transcriptional activation only within cancer cells results in selective cell-surface expression of $SSTR2_{fi}$ that can be imaged with FDA-approved SSTR2 PET tracers. H1299 human lung cancer cells engineered to express SSTR2 (H1299-SSTR2) revealed a discernable PET signal with as little as 31,000 engineered cells. Mixed cell titration studies using subcutaneous (SQ) tumors with H1299-SSTR2 and non-expressing H1299-wt cells suggest tumors with between 0.1% and 1% H1299-SSTR2 cells had a significant PET signal, compared to tumors with 100% H1299-wt. This result sets a benchmark transfection of ~1% to achieve a PET signal. Intratumoral (IT) dose titration of EARLI-204 revealed that 5 ug of EARLI-204 generates a significant PET signal. Consistent with the H1299-SSTR2 studies, IHC shows ~1% of tumor cells express the PRG at a 5 ug IT dose level. Furthermore, we measured 70 copies of EARLI-204 DNA per cell resulting in 22,629 SSTR2 mRNA copies/25 ng at a 5 ug IT dose level. IV dosing of EARLI-204 in SQ and intralung tumor models results in cancer-activated expression of $SSTR2_{fi}$ in both SQ and small (<4 mm) lung tumors with significantly increased ($p < 0.05$) PET signal. For lung tumors, analyses showed 1 copy of EARLI-204 DNA/ cell resulting in 780 SSTR2 mRNA copies/25 ng. The results demonstrate an effective molecular imaging platform for drug discovery ranging from in vivo screening to building PK-PD-efficacy relationships and enabling human dose projection for the Earli PET localization drug. The benchmarks and findings established with this preclinical imaging pipeline are currently being evaluated in large animals such as dogs and pigs, and will be translated to humans in planned clinical trials.

#4153 PET/CT imaging of pancreatic ductal adenocarcinoma with a claudin-4 binding peptide in preclinical mouse model.

J. Seo, J. Wang, A. J. Kare, S. K. Tumbale, B. Wu, M. N. Raie, M. Pandrala, K. W. Ferrara;
Stanford University, Palo Alto, CA

There is a critical need to develop new imaging and therapeutic strategies for pancreatic cancer. Current positron emission tomography (PET) imaging assessments of pancreatic ductal adenocarcinoma (PDAC) rely on ^{18}F-FDG as a radiopharmaceutical. To increase the sensitivity of PDAC detection, we identified Claudin-4 (CLDN4), a tight junction transmembrane protein, as a PDAC biomarker through spatial transcriptomic and proteomic analyses. CLDN4 expression has previously been reported to be enhanced in 99% of primary and 100% of metastatic pancreatic cancer tissue samples and in 10 of 11 precancerous pancreatic intraepithelial neoplasia (PanIN) specimens. A small fragment of naturally occurring Clostridium perfringens enterotoxin (CPE) was previously reported to bind to the extracellular loop domain of CLDN4 protein (PDB:7kp4) with nanomolar (nM) affinity (K_d). A CLDN4 binding peptide (C4BP) was developed as a radioligand by modifying the n-terminus of C4BP which does not impact receptor binding. Here, we designed and synthesized a DOTA-PEG_1-C4BP ligand on a rink amide resin using a microwave-assisted peptide synthesizer. Radiolabeling of DOTA-PEG_1-C4BP (2 nmol) with $^{64}CuCl_2$ (70 MBq) conferred ^{64}Cu-C4BP (28 MBq/nmol) with 80% non-decay corrected yield and >99% radiochemical purity. PET/CT imaging of ^{64}Cu-C4BP (~0.1 µg/mouse) performed in an inducible PDAC (*Kras*$^{LSL\text{-}G12D/+}$;*Rosa26*$^{LSL\text{-}tdTomato/LSL\text{-}tdTomato}$(*KT*);*Ptf1a*^{CreER};*Trp53*$^{fl/fl}$) model at 84 day after tamoxifen injection resulted in ~25% injected activity per cubic centimeter (IA/cc) accumulation in metastases and at ~18% IA/cc retention in pancreatic tumors within 30 minutes of tail vein injection with minimal background accumulation. *Ex vivo* PET imaging confirmed the localized accumulation of ^{64}Cu-C4BP in transgenic mice within the colon, pancreas, and liver. Blocking of ^{64}Cu-C4BP accumulation with the cold compound in a xenograft model (NOD/SCID) bearing Capan-1 PDAC tumors demonstrated the specificity of ^{64}Cu-C4BP binding. Here we report that CLDN4 is a promising target and ^{64}Cu-C4BP is a promising ligand for the detection of pancreatic cancer.

#4154 PET imaging to characterize the tumor microenvironment in a breast cancer model of obesity.

S. E. Lynch, C. Crawford, A. Hunt, L. Sligh, B. M. Larimer, S. E. Lapi, A. G. Sorace;
The University of Alabama At Birmingham, Birmingham, AL

Introduction: Obesity is known to reduce efficacy for cancer treatment patients and is thought to modulate the tumor microenvironment and glucose metabolism. In this study, we aim to quantify obesity-induced differences in the breast cancer tumor microenvironment with positron emission tomography (PET) imaging of hypoxia, glucose metabolism, and granzyme B. These experiments are testing the hypothesis that tumors in obese mice have increased glucose metabolism and hypoxia, measured by [^{18}F]F-fluorodeoxyglucose (FDG) and [^{18}F]F-fluoromisonidazole (FMISO) uptake. We also hypothesize that immunotherapy (IMT) increases immune activation, as measured by [^{68}Ga]Ga-Granzyme B peptide (GZP), and that obese mice will respond less to immunotherapy than lean mice.
Methods: C57/Bl6 mice were placed on a high-fat diet (HFD) with 60% kcal fat (n=18) or low-fat diet (LFD) composed of 10% kcal fat (n=18) to induce obesity. Blood serum was collected for analysis of cholesterol levels prior to tumor implantation. Body weight and food intake were measured weekly. 14 weeks after initiating each diet, $5x10^5$ E0771 cells were implanted into the 3rd mammary fat pad and allowed to grow to 50-150mm^3. Tumor-bearing mice were imaged with [^{18}F]F-FDG and [^{18}F]F-FMISO PET to measure glucose metabolism and hypoxia, respectively prior to treatment. Following imaging, mice began treatment with either saline (n=6/diet) or checkpoint blockade IMT with 200 ug anti-PD-1 and 100 ug anti-CTLA-4 (n=12/diet). After 3 doses of IMT, mice were imaged with [^{68}Ga]Ga-GZP PET to measure immune activation. Tumor volume measurements and treatment administration occurred every 3 days. Metrics of standardized uptake value (SUV) including mean, max, and peak were quantified from imaging data. A one-way independent ANOVA or independent t-test was used to compare differences between groups.
Results: HFD-fed mice had significantly increased body weight ($p<0.0001$) and serum cholesterol ($p=0.005$) compared to LFD-fed mice. SUVmean for tumor hypoxia ($p=0.003$) and glucose metabolism ($p=0.02$) were significantly increased at baseline in HFD-fed mice compared to LFD-fed mice. IMT increases immune activation for both LFD-fed ($p=0.009$) and HFD-fed mice ($p=0.05$). IMT treatment significantly reduces tumor burden for LFD mice ($p<0.0001$), but not HFD mice ($p=0.096$).
Conclusions: Obesity plays a role in the reduction of the effectiveness of immunotherapy. At baseline, tumors of obese mice have increased tumor glucose metabolism and hypoxia. Although immunotherapy increases immune activation, this is not sufficient to reduce tumor burden or improve overall survival. Understanding obesity-induced differences in tumor biology may provide imaging-directed treatment decision making.

#4156 Monitoring early chemotherapy response in murine pancreatic ductal adenocarcinoma using non-invasive hyperpolarized magnetic resonance spectroscopic imaging with ^{13}C-pyruvate.

Irina Heid, Anna-Maria Schmidmuller, Simon Baller, Jason G. Skinner, Geoffrey J. Topping, Wolfgang Gottwald, Hussein Trabulssi, Rupert Ollinger, Katja Steiger, Roland Rad, Franz Schilling, Rickmer F. Braren

TUM School of Medicine and Health, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany

Background: Pancreatic ductal adenocarcinoma (PDAC) is a rarely operable cancer with a very poor prognosis. Nearly 100% of affected patients receive one of two alternative first-line chemotherapies during the course of their disease: 1.) Gemcitabine-Abraxane (G/A) or 2.) FOLFIRINOX. Treatment success varies widely between the patients due to individual molecular, structural tumor and metabolic heterogeneity. In this project, we use hyperpolarized 13C-pyruvate magnetic resonance spectroscopic imaging (HP-MRSI) to non-invasively characterize early metabolic changes in murine endogenous PDAC in response to the mentioned chemotherapies.

Methods: 18 KPC (*Ptf1a*$^{wt/cre}$(C)*Kras*$^{wt/G12D}$(K)*Trp53*$^{fl/fl}$(P)) mice with 74 distinct tumour nodules, visually identified based on T2-weighted anatomical imaging, were used in this study. The conversion of pyruvate to lactate was detected by HP-MRSI, performed on 7 T preclinical system using modified 3D balanced steady-state free precession (bSSFP) sequence on day 0 pre-therapy and on day 3 post-therapy. 100µg/g G (intraperitoneally) and 30µg/g A (intravenously) were applied twice on day 0 post-scan and day 2 (n=6). FOLFIRINOX (60µg/g 5-Fluoruracil, 27µg/g Irinotecan, 12.8µg/g Oxaliplatin, 60µg/g Leucovorin) was injected intravenously once on day 0 post-scan (n=6). Vehicle mice (n=6) were left untreated. Area under the curves (AUC) of lactate to pyruvate time-courses (AUC_l/AUC_p) were calculated. Primary murine PDAC cell lines were established from biopsies of 58 imaging region, sequenced using 3'RNA-Seq (Poly-ASeq) method and analysed using Dseq2 R package.

Results: G/A and FOLFIRINOX-treated tumors exhibited heterogeneous metabolic responses in distinct nodules, while non-treated group tumors remained stable. A significant difference in metabolic changes (p = 0.01, ANOVA) from day 0 to day 3 was observed between FOLFIRINOX, G/A, and non-treated groups. Low glycolytic tumors showed a positive trend, more pronounced with FOLFIRINOX than G/A treatment. Metabolically active nodules with high AUCl/AUCp on day 0 reduced lactate turnover under therapy. These findings suggest that metabolic HP-MRSI can detect treatment-induced changes in tumor composition and subtype-specific epithelial/mesenchymal plasticity, correlating with the metabolic phenotype. Further investigation will include histology, subtype-specific biomarkers, transcriptional signatures, and regional transcriptome analysis to explain molecular changes in metabolism.

Conclusions: We have applied a non-invasive approach for detection of metabolic changes under chemotherapy in murine PDAC. These findings will contribute in the long term to the establishment of predictive imaging biomarkers for PDAC.

#4157 Combining hyperpolarized magnetic resonance and positron emission tomography to interrogate prostate cancer metabolism.

M. Wang[1], J. S. Enriquez[1], P. Dutta[1], J. Han[1], P. Shepherd[1], D. Frigo[1], F. Pisaneschi[2], P. K. Bhattacharya[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]UT Health Houston, Houston, TX

Background: There is an unmet clinical need for imaging biomarkers to distinguish indolent from aggressive prostate cancer (PCa). Many advanced and aggressive PCa patients receiving anti-androgens (enzalutamide) develop resistance. It is hypothesized that dysregulated cell metabolism is a key driver for PCa progression and therapy resistance. Two pathways commonly involved in PCa are glycolysis and fatty acid metabolism. Therefore, metabolic imaging and metabolomics were performed on enzalutamide sensitive/resistant, Androgen Receptor dependent (AR+) and AR independent (AR-) patient derived xenograft (PDX) tumors. To interrogate both pathways, [1-^{13}C]-pyruvate hyperpolarized magnetic resonance spectroscopy (HP-MRS) and [^{18}F]-fluorodeoxyglucose positron emission tomography (^{18}F-FDG) for glycolysis, and [^{18}F]-fluoro-pivalic acid positron emission tomography (^{18}F-FPIA) for fatty acid metabolism were employed. ^{1}H Nuclear Magnetic Resonance (NMR) spectroscopy and liquid chromatography with tandem mass spectrometry (LC-MS-MS) were employed for validation purposes.

Methods: [1-^{13}C]-labeled pyruvic acid was hyperpolarized using a DNP HyperSense polarizer following standard protocol. Anatomical MRI and ^{13}C-MRS were obtained on different PCa PDX mouse models at two different time points using a Bruker 7T scanner. The PDX models included AR+ enzalutamide sensitive (183-A, 180-30), AR+ enzalutamide resistant (274-4), and AR- (144-4, 114-B). The time points imaged were before and after 7 days of treatment with enzalutamide. ^{1}H-NMR spectroscopy was performed on extracted tissue. Simultaneously, ^{18}F-FPIA-PET imaging were acquired on the same models on an Albira trimodal PET station.

Results: The dynamic metabolic flux ratio, lactate-to-pyruvate (Lac/Pyr) was determined *in vivo* and used as a treatment response marker. The Lac/Pyr ratios were significantly higher in resistant tumors compared to sensitive tumors ($p<0.01$). The enzalutamide sensitive group had a lower Lac/Pyr ratio after treatment, while the enzalutamide resistant group had a higher Lac/Pyr ratio. After treatment, there was also a decrease in [^{18}F]-FDG uptake, corresponding to the HP-MRS data. This was expected as both Pyruvate and [^{18}F]-FDG interrogate the glycolytic pathway. As for the fatty acid metabolic imaging, PET imaging also revealed that [^{18}F]-FPIA is transported into the tumors, and we are currently exploring how its uptake varies between AR (+/-) PCa-PDX tumors and enzalutamide resistant/sensitive models. *Ex vivo* NMR and mass spectrometry-based metabolomics validated the *in vivo* HP-MRS data with higher lactate levels in drug resistant tumors.

Conclusion: Combining HP-MRS and PET presents an exciting opportunity to realize imaging-based personalized medicine in different AR (+/-) PCa-PDX preclinical models by interrogating glycolysis and fatty acid oxidation pathways.

#4158 Non-invasive mapping of acidosis and extracellular lactosis for assessing tumor invasion *in vivo*.

Anais Choffart[1], Remy Chiaffarelli[1], Max Zimmermann[1], Laura Kuebler[2], Andre F. Martins[3]

[1]Werner Siemens Imaging Center, Department of Preclinical Imaging, Universitatsklinikum Tubingen, Tubingen, Germany,[2]Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", Universitatsklinikum Tubingen, Tubingen, Germany,[3]German Cancer Research Center (DKFZ), German Cancer Consortium (DKTK), partner site Tubingen, Heidelberg, Germany

Tumor cells typically display a hyperglycolytic metabolic phenotype characterized by increased lactate production, known as the Warburg effect. This drift in oxidative metabolism often results in a more acidic microenvironment. This adverse microenvironment represents a unique metabolic signature in cancer cells with more invasive phenotypes. However, to date, there are no effective methods available to evaluate cancer progression and metastatic potential *in vivo*. To bridge this gap, we have developed a molecular imaging technique (CEST-MRI) that can track extracellular pH (pH_e; acidoCEST) and extracellular lactate levels (shiftCEST) simultaneously to discern different cancer phenotypes.

In this study we have generated and selected *in vivo* two PyMT derived murine breast cancer cell lines, a parental and a G6 metastatic. We first characterized the cell's metabolism by analyzing key biomarkers with qPCR, Western Blot and microscopy, and confirmed their distinct metabolic profiles with Seahorse and RNA Sequencing. Notably, the metastatic PyMT exhibited a more active metabolism, aligning with the invasive phenotype observed by spheroid invasion assay. Herein, we combined the injection of iopamidol and shift reagent (SR) to perform quasi-simultaneous acidoCEST and shiftCEST. First, we assessed the approach *in vitro* by introducing iopamidol and SR into phantoms containing the individual contrast agents, and the combination in pure water and cells supernatants at different pH_e and lactate levels. We performed LDH assays to cross-validate the extracellular concentrations and monitored the pH with a micro pH meter (Mettler-Toledo). *In vivo*, the cells were injected orthotopically in the 4th mammary fat pad of C57BL/6N mice. Hybrid shift/acidoCEST sequences were optimized and acquired following the injection of the iopamidol+SR solution. Preclinical shift/acidoCEST enabled the simultaneous and accurate determination of extracellular acidosis and lactosis, revealing increased acidification in the metastatic models despite lower lactate secretion. Metastatic tumors exhibited a negative correlation between tumor volume and pH_e, indicating the significance of acidity in mutagenesis and invasion. In contrast, no correlation was observed for the parental non-metastatic tumor. Additionally, the metastatic tumors had lower levels of lactate than the parental tumors, which could be attributed to their higher mitochondrial activity, reflecting a diverted metabolic fitness.

In summary, our study highlights the efficacy of shift/acidoCEST as a reliable method for non-invasive metabolic imaging, enabling the simultaneous detection of extracellular acidity and lactate production by MRI. This research introduces a unique platform for assessing the metabolic aggressiveness of cancer, emphasizing the significance of acidity and lactate production as crucial biomarkers in cancer invasion.

#4159 Noninvasive measurement of murine glioblastoma *in vivo* with a benchtop ultrasound instrument.

T. M. Kierski[1], J. D. Rojas[1], M. Thang[2], S. D. Hingtgen[2], P. G. Durham[2], P. A. Dayton[2], **T. J. Czernuszewicz**[1], R. C. Gessner[1];
[1]Revvity, Durham, NC, [2]UNC Chapel Hill, Chapel Hill, NC

The purpose of this study was to evaluate a new *in vivo* approach for rapidly measuring tumor volumes in rodent models for glioblastoma (GBM). GBM is the most common primary brain tumor with <5% of patients surviving >5 years post diagnosis. These poor outcomes underscore the importance of researching new treatment options, and murine models play a vital role in this. Noninvasive measurements of murine GBM tumors are commonly performed using CT and MRI but these tools are costly and time-consuming to use. BLI can quickly detect the presence of GBM cells *in vivo*, but image data can be challenging to correlate to tumor volume. In this study we demonstrate the feasibility of imaging GBM *in vivo* through the intact mouse skull using a benchtop robotic ultrasound scanner. This approach could offer researchers a means to quickly size tumors in the murine brain noninvasively. To test feasibility of this approach, a female athymic nude mouse aged 16 weeks was implanted with 2e5 U87 GBM cells in the brain. The tumor was given 25 days to develop prior to ultrasound imaging. After imaging, the brain was harvested for *ex vivo* validation of tumor presence and volume. Imaging was performed using a Vega ultrasound system (Revvity, Waltham, MA, USA) with the mouse in supine position and fur removed from head with depilatory cream. *In vivo* imaging consisted of a contrast-enhanced acoustic angiography (AA) scan to assess tumor perfusion. An *ex vivo* B-mode scan of the brain was collected after sacrificing the animal to validate the location and size of the tumor without interference from the skull. The tumor volumes were measured in each image and compared. 3D segmentations in the *ex vivo* and *in vivo* images yielded volumes of 43.1 mm^3 and 44.6 mm^3, respectively, a 3.5% variance. In the *in vivo* AA image, the borders of the tumor were adequately well-defined for volume estimation, despite some shadowing from the sagittal suture of the skull. In the B-mode image of the excised brain, the tumor appeared hyperechoic compared to the contralateral hemisphere. Images were acquired in < 2 min. This pilot study demonstrates a potential alternative to CT and MRI for monitoring of GBM volumes *in vivo*.

#4160 V7 targeted liposomes detect pancreatic adenocarcinoma via multispectral optoacoustic tomography.

H. Agarwal[1], P. Chuong[2], W. E. Grizzle[3], B. H. Edil[1], A. Jain[1], L. R. McNally[1];

[1]OU Health Stephenson Cancer Center, Oklahoma City, OK, [2]University of Louisville, Louisville, KY, [3]University of Alabama at Birmingham, Birmingham, AL

Purpose: Pancreatic ductal adenocarcinoma (PDA) remains one of the most aggressive malignancies with a 5-year survival rate of 9-10%. Insufficient early detection coupled with limitations in operating surgery renders PDA as one of the most challenging tumors to treat. Accurate localization of tumor margins can tremendously improve surgical treatment outcomes in patients. Recently, nanotechnology has emerged as a promising platform for theranostic applications in the field of drug discovery, although the clinical success is limited by their tumor-specific uptake. Hypoxia due to aberrant vascularization is a hallmark of PDA and can be exploited for active targeting. pH-low insertion peptide variant 7 (V7) is used as hypoxia and acidosis-dependent biomarker for selective targeting of pancreatic cancer tissue. This work is focused on using IR 780 contrast agent loaded, V7 peptide conjugated liposomes for the active targeting of PDA towards enhanced surgical outcomes.

Methods: Liposomes encapsulating IR780 dye were prepared using thin film hydration technique. V7 peptide was conjugated to liposomes using an SMCC linker and liposomes were characterized for their size, polydispersity and surface potential. In-vitro uptake of IR780-V7-liposome by S2VP10 at pH 7.4, 6.8, and 6.6 was evaluated through NIR fluorescence imaging using an Odyssey Infrared System. Athymic mice were orthotopically implanted with S2VP10 cells. After tumors were 3 mm, V7-liposomes and untargeted liposomes (0.01 OD) were intravenously injected and biodistribution and tumor specific uptake was accessed using multispectral optoacoustic imaging (MSOT).

Results: Dynamic light scattering (DLS) revealed the size of liposomes to be 109 nm with a polydispersity index of 0.198 and zeta potential of +35.8 mV. Surface conjugation of V7 peptide was confirmed using the zeta potential measurement. NIR fluorescence imaging in S2VP10 cells established enhanced tumor specific uptake of V7 conjugated liposomes than passively targeted liposomes ($p<0.05$). Biodistribution of V7-liposomes demonstrated tumor specific accumulation (PDAC tumor 23.7 a.u, liver 3.6 a.u., and kidney 1.1 a.u.) while untargeted liposomes had the greatest uptake in liver (PDAC tumor 2.1 a.u., liver 6.3 a.u., and kidney 0.7 a.u.) $p<0.05$.

Conclusion: pH-specific actively targeted liposomes can be used to specifically target PDA with minimal off-target binding effects. V7-IR780-liposome formulation can be used to efficiently deliver contrast agent for imaging tumor margins and to expand the potential of MSOT towards clinical applications.

#4161 Identification of pancreatic adenocarcinoma using urokinase plasminogen activator probe detected using optoacoustic imaging.

V. Kim[1], P. Chuong[2], R. Bynum[1], W. Grizzle[3], L. R. McNally[1];
[1]OU Health Stephenson Cancer Center, Oklahoma City, OK, [2]University of Louisville, Louisville, KY, [3]University of Alabama at Birmingham, Birmingham, AL

Purpose: Diagnosing and treating pancreatic cancer remains a challenge. The hypovascularized nature of pancreatic cancer renders modern chemotherapeutics and cancer detection contrast agents ineffective. A promising approach to the challenges is the adoption of a novel imaging technique known as Multispectral Tomography (MSOT). We hypothesize that a urokinase plasminogen activator (UPA) probe will enhance the detection of orthotopic pancreatic cancer xenografts.
Methods: Pancreatic tumor cell lines (Panc1, MiaPaca-2, S2VP10, and S2C9) were assessed for UPA-receptor expression using western blot analysis. UPA peptide was synthesized and to the HiLyte-750 NIR dye. Flow cytometry and immunofluorescence were utilized to examine the specificity and activity of this UPA-750. The UPA-750 binding efficiency was assessed through a competitive inhibition assay with a UPAR-blocking antibody using fluorescence microscopy. Then SCID mice (5 mice/group) received orthotopic implantation of S2C9 (1.5 x 105) or MiaPaCa2 (2.0 × 106) pancreatic tumor cells. UPA-750 or 750 dye alone was IV injected into mice after the tumors reached 3mm. Biodistribution and accumulation of UPA-750 were observed through MSOT images taken at 2-hour intervals over 8 hours and at 24 hours. UPA-750 in the tumor, liver, and kidney was confirmed through ex vivo fluorescent imaging.
Results: UPAR expression was observed in every pancreatic cancer cell line, with the greatest relative abundance in S2P9 cells (3.0X), followed by S2VP10 (2.5X), Panc1 (1.77X), and MiaPaca-2 (1.3X). Application of the UPAR blocking antibody on S2CP9, S2VP10, MiaPaCa2, and SKOV3p1 (positive control) cell lines resulted in the inhibition of cellular binding of the UPA-750, as evidenced by fluorescence microscopy. UPA-probe was successfully observed in pancreas tumor slices with peak intensity at 4-hrs of imaging by MSOT. Ex vivo NIR fluorescence imaging confirmed UPA-750 signal in pancreatic tumors but not in liver or kidney.
Conclusion: UPA-probe exhibits potential as a marker for pancreatic cancer.

#4162 Peptide-targeted probe identifies pancreatic cancer using optoacoustic imaging.

E. Sanderson[1], T. Husarova[2], L. McNally[3],

[1]University of Oklahoma, Norman, OK, [2]Military University Hospital Prague, Prague, Czech Republic, [3]University of Oklahoma, Oklahoma City, OK

Introduction: Advanced pancreatic ductal adenocarcinoma (PDAC) suffers from inadequate early detection, inoperability, and poor outcomes. While tumor identication in an intraoperative setting largely utilize ultrasound, ultrasound suffers from insufficient resolution and lacks the ability to identify molecular features to differentiate tumor from non-tumor. To overcome these limitations, we utilized optoacoustic imaging combined with a pH-sensitive peptide-based probe, V3, to identify pancreatic cancer in orthotopic mouse models.

Methods: The V3 peptide was synthesized using microwave chemistry which resulted in a peptide of >90% purity. The V3 peptide was conjugated to a fluorescent dye and dialyzed to make the V3-750 probe. S2VP10 cancer cell line was plated in a 6-well plate and acclimated to 7.4, 6.8, and 6.6 pH media to mimic a healthy microenvironment and the acidic tumor microenvironment found in pancreas cancer. Cells were treated with 1 micromolar of V3-750 probe for 1 hour, then imaged on the near-infrared fluorescence imager. Treated cells were loaded into tissue mimicking phantoms and imaged using multispectral optoacoustic tomography. Athymic mice were orthotopically implanted with S2VP10 cells and tumor grew to 3 mm. V3-750 was intraveneously injected and mice were imaged 3h after injection with MSOT.

Results: Signal values for the samples displayed a trend that the V3-750 probe has higher signal values in the 6.8 and 6.6 pH as compared to the 7.4 pH. MSOT data supported this trend, with the signal values from the 6.8 and 6.6 pH being greater than the 7.4 pH by 10-fold ($p<0.05$). Biodistribution demonstrates peak tumor-specific uptake at 3h post injection (3.1 a.u., 0.003 a.u. liver, 0.002 a.u. kidney).

Conclusion: The heightened signal values for the acidic pH's from the fluorescence imaging and the MSOT suggest that the V3-750 probe can contrast acidic cancer cells from healthy cells because it targets the acidic cancer microenvironment.

#4163 Improving the dynamic range of pH low insertion peptides for targeted imaging of pancreatic tumors.

R. Bynum, E. Sanderson, B. H. Edil, A. Jain, L. R. McNally;
OU Health Stephenson Cancer Center, Oklahoma City, OK

Objective: Current intraoperative imaging modalities such as near-infrared fluorescent imaging (NIR) or ultrasound are limited due to operator experience and depth, and targeted imaging of pancreatic tumors would be beneficial. However, specific pancreatic tumor biomarkers available for targeting in a novel imaging protocol are lacking. As such, we focus on developing a novel targeted imaging paradigm utilizing multispectral optoacoustic imaging (MSOT) to target the acidic microenvironment of pancreatic tumors. Peptides know as pH low insertion peptides (pHLIPs) when bound to dye allow for contrasted imaging selectively based on pH using MSOT. We have identified the need for a pHLIP with improved dynamic range to improve imaging accuracy. Here, we synthesize the novel pHLIP V7FS for comparison to V3 with aims of improving the dynamic range of imaging with MSOT in pancreatic cancer.
Methods: Using microwave chemistry, V7FS and V3 were synthesized with >90% purity. Peptides were conjugated to HiLyte 750 dye, and peptide-dye conjugation confirmed via spectroscopy. Intraoperative measurements of human pancreatic tumor and surrounding uninvolved tissue were obtained using a microsensor. Near-infrared fluorescent imaging was used to measure probe uptake in S2VP10 and S2013 pancreatic cancer cells lines grown in pH specific media (7.4, 6.8, 6.6) in replicates. MSOT was then used to image probes in phantoms mimicking tissue and then in mice with pancreatic tumors from orthotopically implanted S2VP10. Statistical analysis was performed using ANOVA.
Results: Compared to surrounding uninvolved pancreatic tissue, human pancreatic tumor was more acidic with pH 6.2-6.7 vs 7.2-7.3 ($p<0.01$). Signal at pH 7.4, 6.8 and 6.6 was higher for V7FS-750 compared to V3-750 ($p=0.0105$). Signal for V7FS-750 was centered around pH 6.6 and signal for V3-750 centered around pH 6.8. Interaction between probe and pH did not reach significance ($p=0.745$). Peak uptake in orthotopic murine models was observed at 3 hours following intravenous injection.
Conclusions: V7FS-750 was shown to have higher signal accumulation compared to V3-750 favoring a more acidic environment (pH 6.6 vs pH 6.8). This novel pHLIP was demonstrated to be viable for use in an imaging paradigm utilizing MSOT in an orthotopic murine model. Continued improvement in the dynamic range of these probes is promising for the use of pHLIPS in imaging of pancreatic cancer with MSOT.

#4164 Hybrid photoacoustic imaging and fast ultrasound localization microscopy to probe the tumor microenvironment.

S. Zhao, S. Basu, R. H. Campbell, Y. Zhao, Y.-S. Chen;
University of Illinois Urbana Champaign, Urbana, IL

Photoacoustic (PA) imaging can map the physiological conditions of tissues and track the biodistribution of contrast agents. Ultrasound localization microscopy (ULM) with microbubbles provides deep-tissue super-resolution blood vessel images and blood velocity maps. The integration of these techniques offers a potential tool for oncological applications, such as visualizing tumor hypoxia and vasculature. Additionally, because PA imaging and ULM can share the same ultrasound detector and data-acquisition system, PA images can seamlessly fuse with ULM images without requiring post co-registration processing. However, the acquisition time of ULM is considerably longer (several minutes per frame) compared to PA imaging (10 milliseconds to 100 milliseconds per frame), limiting the simultaneous acquisition of the two imaging modalities. To address this issue, we developed a deep learning model based on U-Net to accelerate the frame rate of ULM using information from sparse microbubble locations and power Doppler images. By enabling fast ULM acquisition, we developed an interleaved PA/fast ULM imaging technique to simultaneously capture photoacoustic and ULM images. Our experiments demonstrated up to a 16 times improvement in acquisition speed with U-Net, utilizing in vivo mouse brain and skin tumor data. The hybrid imaging sequence achieved super-resolution vascular and tissue oxygenation imaging with less than 2 seconds of acquisition time per frame in vivo. The implementation of this rapid dual imaging scheme enables the longitudinal monitoring of 3D tumor microvasculature and hypoxia conditions using a common linear ultrasound transducer. We monitored tumor growth of epidermoid carcinoma (A431) in a mouse model from Day 7 to Day 17 of tumor implantation, and the results reveal a significant decrease in tumor vasculature density and oxygen saturation as the tumor grew larger over time. The results indicate a positive relationship between oxygen saturation and vessel density. Our findings showcase the potential of this innovative technique for advancing deep tissue, high-resolution, multi-biological parameters imaging in oncological research.

#4165 Influence of halogens in squaraine dye on optoacoustic signal.

K. Belligund[1], W. MacCuaig[1], C. Wickizer[2], Y. Shao[2], L. R. McNally[1];
[1]OU Health Stephenson Cancer Center, Oklahoma City, OK, [2]University of Oklahoma, Norman, OK

Optoacoustic imaging has grown in clinical relevance due to inherent advantages in sensitivity, resolution, and contrast, compared to standard modalities, such as fluorescence. However, guiding principles for development of small molecule contrast agents specific for optoacoustic imaging is lacking. This study assesses the influence of specific structural features of small molecule dyes, specifically squaraine dyes, that result in optoacoustic activity. Through computational models, *in vitro* testing, and *in vivo* experimentation this study assesses the effects of halogens on small molecule squaraine dyes to increase optoacoustic signal. By using the aid of our computational model, we decorated the squaraine scaffold with heavy halogenation of squaraines increased optoacoustic activity (2.12 a.u. vs. 0.21 a.u., $p<0.001$). Density functional theory models suggest the origin of increased optoacoustic signal is due to increases in transition dipole moment which manifested experimentally as increased absorbance in the NIR wavelength range and decreased fluorescence quantum yield, respectively. This study provides an insight into the structure-function relationships that lead to guiding principles for designing optoacoustic-specific contrast agents. Further developments of squaraines and other types of optoacoustic agents will further increase relevance of optoacoustic imaging in a clinical setting.

#4166 TSPO-targeted near-infrared optical probe for early identification and localization of high-risk premalignant pancreatic lesions.

S. Sharma, D. Hernandez, X. Wen, J. Wang, C.-D. Pham, B. Huang, H. C. Manning;
The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Pancreatic cancer is the third most prevalent cause of cancer death in the U.S. with a ~10% survival rate. Surgery represents one of the best opportunities for extending survival and potential cures. Fluorescence-guided surgery (FGS) employing near-infrared (NIR) fluorescence-based targeting agents improves resection margins, allowing removal of small lesions not visible under white light. We previously reported a targeted NIR tracer (V-1520) of translocator protein (TSPO) expression that demonstrated proof-of-principle utility in high-grade pancreatic lesions arising in *Ptf1a-Cre; LSL-Kras$^{G12D/+}$; Smad4$^{flox/flox}$ (KCS)* of pancreatic cancer. The purpose of the present study is to evaluate the utility of V-1520 to identify low-grade, premalignant yet high risk lesions in *KCS* mice; in this scenario we attempted to model use of V-1520 to remove lesions likely to manifest as future recurrence. We compared the uptake of the tracer in these mice from weaning to adulthood to systematically evaluate the efficacy of FGS as a function of lesion grade.

Experimental: The tracer, V-1520, was synthesized and *KCS* mice were generated as reported.[1] Mice were injected with 30µg of V-1520 intravenously 24 hours before imaging. Images were acquired using the 800nm channel. *KCS* and WT mice were imaged as a function of from 4 to 11 weeks age. After imaging, tumor tissues and major organs were harvested for *ex-vivo* imaging, histopathology and Cryo-Fluorescent Tomography (CFT).

Summary: We found, V-1520 prominently localized in low-grade, premalignant PanIN cystic lesions with malignancy potential, as well as pancreatic tumors with and without local invasion. In contrast, V-1520 did not accumulate in healthy pancreata of KCS or WT mice. Mice as young as 4 weeks exhibited localized accumulation of the tracer with low grade PanIN and early dysplasia. The fluorescence intensity was further enhanced in mice with higher grade disease, whereby the pathology was characterized by high-grade cyst formation, increased nuclear/cytoplasm ratio, acinar to ductal metaplasia and invasion. Low and high-grade neoplasia was characterized by high TSPO immunoreactivity, consistent with *in-vivo* imaging. Confocal microscopy was used to colocalize V-1520 accumulation and TSPO immunoreactivity; V-1520 was found to prominently localized to premalignant epithelia pancreatic cancer cells. CFT illustrated that the primary localization of V-1520 included the liver, kidneys, and pancreatic diseases.

Conclusion**:** These studies suggest the utility of V-1520 to identify high-risk pancreatic lesions that could be removed with surgery. Encouragingly, the V-1520 was capable of differentiating tumors from surrounding non-tumor tissue at an early stage, which could lead to better resections and delay and/or prevent recurrence in the future. 1. *Clinical Cancer Research* 26(22), 15 Nov. 2020 5914-5925

#4167 Selective imaging of cancer-associated fibroblasts in the breast cancer microenvironment with near-infrared fluorescent probes.

M. S. Michie[1], J. Du[1], J. Ye[1], K. Duncan[1], M. Y. Berezin[1], S. Achilefu[2];
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]UT Southwestern Medical Center, Dallas, TX

Tumors consist of a complex mixture of resident and infiltrating cells that can support their survival and evasion of treatment. Selective detection of genetically stable cells in the tumor microenvironment (TME) offers insight into tumor biology beyond the malignant cells, which are the focus of most molecular imaging approaches to cancer detection. Motivated by the goal of non-invasively understanding the primary breast TME, we have developed fluorescent molecular probes that target cancer-associated fibroblasts (CAFs), a major component of the stromal compartment of many tumors, and emit light in the near-infrared (NIR) spectral window, providing access to deeper tissues than visible probes. We synthesized and characterized a series of CAF-targeted antibody- and small molecule-based fluorescent imaging agents utilizing a highly hydrophilic NIR dye and ligands that target Fibroblast Activation Protein (FAP). FAP is a key cell-surface marker of breast cancer CAFs with an S1 phenotype, which are modulators of immunosuppression, metastatic spread, and are associated with worse outcomes, especially in HER2+ and triple-negative breast cancer. Modifications to the chemical structure of the linker and targeting ligands allowed us to alter the specificity and brightness of the CAF-probes *in cellulo*. Imaging of a co-implanted tumor model of SKBR3 human breast cancer cells and FAP expressing fibroblasts after administering our lead small-molecule CAF imaging agent revealed selective tumor targeting of CAF-rich tumors compared to cancer cell predominant tumors with favorable pharmacokinetics and tumor-to-background ratio (TBR) greater than 2. Similar imaging studies with MMTV-PyMT transgenic mice, an established murine model of breast cancer, showed analogous enhanced uptake in mammary tumors (TBR > 2) and clearance over 24 hours. NIR fluorescence also correlated with CAFs isolated from PyMT tumor tissue via flow cytometry, consistent with our hypothesis that this agent can specifically detect endogenous CAFs. This study identified a novel, bright, and water-soluble FAP-specific NIR agent for *in vivo* imaging, setting the stage for simultaneous optical imaging of malignant cells and activated fibroblasts in the TME to elucidate cancer-host interactions.

#4168 Pre-clinical demonstration of Raman spectroscopy-assisted photothermal therapy for prostate cancer.

S. Lee[1], G. Beaudoin[2], J. Yeoh[2], F. Leblond[2], M. Trifiro[1], M. Paliouras[3];
[1]McGill University, Montreal, QC, Canada, [2]Polytechnique Montreal, Montreal, QC, Canada, [3]Guzzo Nano Research, Terrebonne, QC, Canada

Prostate cancer (PCa) ranks among the most prevalent malignancies in men. The combination of ultrasound and fine-needle aspiration biopsy has greatly facilitated early diagnosis and expanded the range of treatment options. Traditional treatments primarily involve anti-androgens and androgen deprivation therapy; however, a recurrence occurs in approximately 30% of cases following these interventions. Our current focus is on the exploration of photothermal therapies using nanoparticles for precise tumor ablation. Among these nanoparticles, multiwalled carbon nanotubes (MWCNTs) exhibit unique structural, optical, and thermal properties that make them exceptionally appealing for biomedical applications, especially as a foundation for photothermal therapy. Our platform employs the copper (I)-catalyzed azide alkyne cycloaddition of prostate-specific membrane antigen (PSMA)-targeting peptidomimetic (Glu-urea-Lys) ligand to the MWCNTs. We used confocal microscopy to observe a significantly enhanced binding of the targeted Glu-urea-Lys-MWCNTs to the surfaces of PSMA-expressing LNCaP cells compared to IgG-MWCNTs and to PSMA-null PC3 cells. Raman microscopy further confirmed the increased presence of Glu-urea-Lys-MWCNTs on LNCaP spheroids compared to non-targeting MWCNTs. We also confirmed enhanced photothermal cell ablation *in vitro* using the targeted MWCNTs. Based on *in vitro* evidence, we established LNCaP and PC3 xenografts in *nu/nu* mice and evaluated the therapeutic efficacy. Using fluorescence-based imaging, we observed the enhanced localization of Glu-urea-Lys-MWCNTs within the tumors. Furthermore, we collected the tumors and conducted *ex vivo* analysis using Raman microscopy for a label-free detection of the targeted MWCNTs, which complemented the fluorescence imaging and laying the foundation for real-time Raman imaging *in vivo*. Subsequently, we applied photothermal ablation of the tumor xenografts based on a pre-optimized treatment protocol established from COMSOL simulations and prior experiments. This treatment led to complete tumor ablation with minimal recurrence and minimal non-specific damage. In conclusion, we have assessed the effectiveness of our targeted nano-photothermal platform in a pre-clinical model of PCa. Further studies will aid in the transition of photothermal therapy to clinical trials. Moreover, we aim to investigate the role of photothermal therapy in the PCa tumor microenvironment and whether such an approach can trigger post-therapeutic activation of immune responses against the tumor. Ultimately, we anticipate that our nanotherapeutic platform will contribute to a focused therapeutic approach where targeted MWCNT-laser treatment exploits overexpressed tumor markers in conjunction with various irradiation strategies to enhance ablation while minimizing damage to surrounding tissue.

#4169 A deep learning approach to guide acquisition region selection for imaging mass cytometry.

F. Schneider[1], S. Kala[2], S. Lim[2], C. Hupple[2], N. Lane[2], **J. R. Mansfield**[1];
[1]Visiopharm, Horsholm, Denmark, [2]Standard BioTools, South San Francisco, CA

The growth in cancer immunotherapy agents requires an understanding of the immune contexture of the tumor microenvironment. This can be aided by high-plex imaging and analysis to obtain phenotypes of specific cells and study their biodistribution and interactions. Imaging Mass Cytometry™ (IMC) is the method of choice for single-step staining and high-plex imaging of tissues, avoiding the complications of autofluorescence and cyclic imaging.
IMC has expanded its capabilities with three distinct imaging modes: Preview, Cell, and Tissue. The Preview Mode is a rapid scanning system that captures a comprehensive overview of the stained tissue, mapping out the distribution of over 40 markers and revealing tissue heterogeneity. This enables researchers to make informed decisions about which areas warrant closer examination on the same. Building on this, Cell Mode offers high-resolution imaging for detailed analysis of the Regions of Interest (ROI) identified during Preview, all using the same slide. Tissue Mode complements these by providing a fast acquisition of the entire tissue at a lower resolution, which is optimal for quantitative pixel-based analysis of tissue biology. These modes support automated, continuous imaging of more than 40 large tissue samples (400 mm2) weekly. Following Preview Mode, the selection of ROIs for high-resolution imaging is a critical step, enhanced by automated AI algorithms to ensure it is informed by biomarker expression.
Tissue sections of colon adenocarcinoma were stained with a 30-marker IMC panel of structural, tumor, stroma, immune cell, and immune activation markers. Images were acquired on Hyperion XTi™ (Standard BioTools), first in Preview Mode, then in Cell Mode with automatic selection of ROIs using Phenoplex™ (Visiopharm). ROIs were automatically selected based on two criteria: 1) actively proliferating and non-proliferating tumor regions; 2) cold and hot tumor regions as identified by hotspots of lymphoid and myeloid immune markers within stromal or epithelial tumor regions.
Single cell analysis of the high-resolution images obtained in Cell Mode, was performed as a multi-step workflow using Phenoplex. Tissue segmentation was used to divide the tissue into epithelial tumor (E-Cadherin/panCK), stromal, and tumor margin regions; cell segmentation was based on Iridium DNA channels; and phenotyping was performed using the guided highplex workflow. These data were used to compare the immune contexture through a series of t-SNE plots partitioned by spatial region and clinical variables.
This work demonstrates that the multi-modal features of Hyperion XTi can greatly accelerate the ability of IMC users to gain useful insights from complex biological samples. Phenoplex enables a comprehensive workflow for the analysis of this complex data, providing automated ROI selection, and phenotyping and spatial analyses of high-resolution IMC images for biological assessment.

#4170 Artificial intelligence (AI)-based multi-modal approach using H&E and CT image for predicting treatment response of immune checkpoint inhibitor (ICI) in non-small cell lung cancer (NSCLC).

D. Jeong[1], J. Park[2], H. Song[2], J. Moon[2], T. Lee[2], C. Ahn[2], S. Park[1], S.-H. Lee[1], C.-Y. Ock[2], H. Lee[1];
[1]Samsung Medical Center, Seoul, Korea, Republic of, [2]Lunit, Seoul, Korea, Republic of

Background: Previously, AI-powered spatial tumor-infiltrating lymphocyte analysis in H&E whole-slide image (WSI) showed promising performance in predicting ICI outcomes. However, there were several innate limitations of tissue analysis, including the time lag between tissue biopsy and actual ICI administration, during which tumor microenvironment (TME) has changed, and analyzing a part of a single tumor tissue would not fully assess immunogenicity of multiple metastatic tumors. To overcome the challenges, we developed multiple-instance learning (MIL)-based models and applied them to predict the treatment response of ICI in a real-world dataset.

Method: MIL-based models were trained under the cross-validation scheme for CT scans (N=456) separately, based on CT image analyzers. Lunit SCOPE IO (Lunit, South Korea), an AI-based H&E WSI analyzer, identifies various classes of cells within TME and segments tumor regions from WSI (AI-HE-TIL). An AI-based CT image analyzer detects nodules on the CT image (AI-CT). The final ensemble score per patient is computed by the average of all model predictions from CT and pathology image inputs. Single and ensemble performances for predicting responder and non-responder patients to ICI are measured in an independent cohort of 208 NSCLC patients.

Results: In the overall cohort, the AUROC values for AI-HE-TIL, AI-CT, and the ensemble were 0.6372, 0.6759, and 0.7307, respectively. The high ensemble score group (≥ median) has prolonged progression-free survival (PFS) of ICI (median PFS 5.0 months vs 2.1 months, hazard ratio [HR] 0.54, P < 0.0001). It correlates with PD-L1 expression, as tumor proportion score (TPS) ≥ 50% subgroup had higher ensemble score (median 0.312 vs 0.257, P = 0.0295). Interestingly, among TPS ≥ 50% subgroup, the high ensemble score shows significantly favorable PFS of ICI (median PFS 6.7 months vs 2.9 months, HR 0.46, P = 0.0002). In subgroup analysis according to tissue harvest site (primary tumor vs lymph node or distant metastasis), the AUROC values of AI-HE-TIL and AI-CT for the subgroup harvested from the primary tumor (N=111) were 0.6568 and 0.6658, respectively, and those for the subgroup harvested from the metastatic lesion (N=97) were 0.6162 and 0.6973, respectively, implying AI-CT is relatively not affected by tissue harvest site.

Conclusion: AI-powered multi-modal approach of using H&E image and CT image shows complimentary, and synergistic effect to predict ICI clinical outcomes in advanced NSCLC, even in the subgroup of PD-L1 high population.

#4171 Utilizing biopsy-free virtual histology for improved clinical efficiency in the dermatologic surgical setting.

Rachel Wahhab[1], Nelly Kokikian[1], Jingxi Li[2], Jason Garfinkel[3], Stephanie Martin[3], David Beynet[3], Aydogan Ozcan[2], Philip Scumpia[1]

[1]Division of Dermatology, University of California, Los Angeles, Los Angeles, CA,[2]Department of Electrical Engineering and Bioengineering, University of California, Los Angeles, Los Angeles, CA,[3]Dermatology, Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA

The ability to accurately define tumor margins may enhance tissue sparing and increase efficiency in the dermatologic surgery process, but no device exists that serves this role. Reflectance Confocal Microscopy (RCM) provides non-invasive cellular resolution of the skin. The only clinically-approved RCM device is bulky, non-portable, and requires a tissue cap which makes mapping of the underlying tissue impossible. We recently combined “virtual histology”, a machine learning algorithm with RCM images from this standard RCM device to generate biopsy-free histology to overcome these limitations. Whether virtual histology can be used with a portable, handheld RCM device to scan for residual tumor and tumor margins is currently unknown. We hypothesize that combining a handheld RCM device with virtual histology could provide accurate tumor margin assessment. We determined whether our established virtual histology algorithm could be applied to images from a portable RCM device and whether these pseudo-stained virtual histology images correlated with histology from skin specimens. The study was conducted as a prospective, consecutive non-randomized trial at a Veterans Affairs Medical Center dermatologic surgery clinic. All patients greater than 18 years of age with previously biopsied BCC, SCC, or SCCis were included. Successive confocal images from the epidermis to the dermis were obtained 1.5 microns apart from the handheld RCM device to detect residual skin cancer. The handheld, in-vivo RCM images were processed through a conditional generative adversarial network-based machine learning algorithm to digitally convert the images into H&E pseudo-stained virtual histology images. Virtual histology of in-vivo RCM images from unbiopsied skin captured with the portable RCM device were similar to those obtained with the standard RCM device and virtual histology applied to portable RCM images correctly correlated with frozen section histology. Residual tumors detected with virtual histology generated from the portable RCM images accurately corresponded with residual tumors shown in the frozen surgical tissue specimen. Residual tumor was also not detected when excised tissue was clear of tumor following surgical procedure. Thus, the combination of virtual histology with portable RCM may provide accurate histology-quality data for evaluation of residual skin cancer prior to surgery. Combining machine learning-based virtual histology with handheld RCM images demonstrates promise in providing insights into tumor characteristics and has the potential to assist the surgeon and better guide practice decisions to more efficiently serve patients, leading to decreased layers and appointment times. Future work is needed to provide real time virtual histology, convert horizontal/confocal sections into vertical or 3D sections, and to perform clinical studies to map tumors in tissue.

#4172 Pathology supervised approaches for ROI placement and segmentation to overcome caveats and pitfalls in high-plex spatial profiling.

S. Hernandez[1], C. J. Arrechedera[1], P. Rocha[2], L. Kostousov[1], S. Barnes[1], K. Khaja[1], L. M. Solis-Soto[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Hospital del Mar, Barcelona, Spain

Background: Tissue-based high-plex platforms evaluate numerous biomarkers in limited tissue sections. Certain tissue features and assay technical limitations may jeopardize the accuracy of this analysis. In this study, we aim to determine tissue specific features that influence image-based region of interest (ROI) selection and segmentation for spatial profiling of carcinomas, and to develop pathology approaches to overcome them.
Methodology**:** A total of 317 samples from different carcinoma types processed with the GeoMx Digital spatial profiling protein assay protocol were assessed to identify deviations from original strategies for ROI placement and segmentation (Table 1). ROI were selected by a pathologist. The initial strategy for all cases was to place rectangles ROIs of 660*785 µm in tumor area and to segment based on morphology biomarkers as indicated in Table 1. Strategies to overcome technical and tissue specific features were recorded and quantified.
Results: A total of 2068 ROIs and 4422 AOIs were evaluated. In all the cases, tissue displayed specific features that limited planned ROI placement and segmentation. Table 1 describes these features by tissue type and profiling strategies. A total of 970 ROIs were solved using different annotation type or changes in segmentation strategy, 584 bypassed the limitations by changing the processing protocol; and 322 were not solved due to non-compliance with assay requirements.
Conclusions: We identified tissue features that limit the planned ROI selection and segmentation in spatial high-plex profiling, mainly due to tissue processing, distinct histology, type of sample, and presence of adjacent non-neoplastic tissue. A deep understanding of tumor architecture, biology and platform related technical limitations is needed to select areas of analysis for spatial profiling.

TUMOR BIOLOGY: In Vivo Imaging and Humanized Models
Poster Session

#4177 High-throughput *in vivo* monitoring of splenomegaly and tumor burden in a murine breast cancer model.
C. McMannus, **T. J. Czernuszewicz**, R. C. Gessner, J. D. Peterson;
Revvity, Durham, NC

Splenomegaly is a valuable parameter in mouse model cancer studies, as it can reflect the magnitude of cancer burden, hematopoietic activity, immune status, and can provide an indirect measure of cancer treatment efficacy. In liquid cancer models specifically (leukemia/lymphoma), spleen sizing is important as it is usually the only measure of *in vivo* tumor burden that can be assessed noninvasively without genetic labeling of tumor cells. Magnetic resonance imaging (MRI) and contrast-enhanced computed tomography (CT) are highly effective at evaluating spleen size in small animals. However, these techniques can impose limitations on large-cohort study designs due to high cost, long scan time, and ionizing radiation. Ultrasound is an alternative method with lower cost, high frame rate, and no ionization, but can suffer from poor inter-user variability, limited 2D field-of-view, and low throughput due to manual operation. In this work, we evaluated a novel 3D automated ultrasound scanner (Vega, Revvity, Inc.) for rapid assessment of splenomegaly in a murine cancer model. Female BALB/c mice (n=10) were implanted with 5e5 4T1 (ATCC) cells on the right flank. Mice were imaged at five timepoints over 25 days to track longitudinal progression of both spleen and tumor enlargement. Images were segmented manually in 3D using the “Slice Draw” and “Fill Between Slices” effects in SonoEQ v2.0.1 (Revvity, Inc.) to quantify tissue volume. After the final timepoint, mice were euthanized, and spleen weight was measured *ex vivo*. An additional cohort of age-matched mice without tumors (n=7) were imaged at the final timepoint to serve as controls. Imaging revealed a substantial enlargement of the spleen over time, from 30 ± 3 mm^3 to 545 ± 105 mm^3, representing an 18-fold increase. In the same time span, tumor volume grew to 1966 ± 87 mm^3. Correlation analysis demonstrated good agreement between ultrasound volumes and *ex vivo* spleen weights ($R^2 = 0.90$). The results in this study demonstrate that noninvasive, nonlabelled quantification of murine spleen size with automated ultrasound is feasible, robust, and fast. The average time to acquire the spleen image for each mouse was less than 30 seconds. Future studies will apply this workflow in liquid cancer models, as well as explore using machine learning approaches to automatically segment spleen borders for faster data analysis.

#4178 Non-invasive shortwave infrared imaging of cytotoxic T lymphocyte infiltration for monitoring responses to combination immunotherapy and chemotherapy.

Jay V. Shah[1], Jake N. Siebert[1], Xinyu Zhao[2], Shuqing He[2], Richard E. Riman[3], Mei Chee Tan[2], Mark C. Pierce[1], Edmund C. Lattime[4], Vidya Ganapathy[1], Prabhas V. Moghe[1]

[1]Biomedical Engineering, Rutgers University, Piscataway, NJ,[2]Engineering Product Development, Singapore University of Technology and Design, Tampines, Singapore,[3]Materials Science and Engineering, Rutgers University, Piscataway, NJ,[4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Although triple-negative breast cancer (TNBC) can be treated with anti-PD-1 checkpoint immunotherapy in combination with chemotherapy, there remains a challenge in effectively monitoring therapeutic responses. Current non-invasive clinical imaging tools to evaluate response to treatment are reliant upon measurements of tumor volume and may fail to distinguish true progression from increased immune cell infiltration. Invasive biopsy sampling and immunohistochemistry (IHC) can elucidate changes in the immune landscape of treated tumors, but these methods are not conducive to providing real-time information. This study presents shortwave infrared (SWIR) imaging as a potential tool to detect treatment-induced cytotoxic T lymphocyte (CTL) infiltration non-invasively and in real time using rare earth metal-doped nanoparticles encapsulated in human serum albumin nanocomposites (ReANCs). ReANCs were chemically conjugated with anti-CD8α antibodies as targeting ligands to facilitate binding of the nanoprobes to CTLs with high specificity in a syngeneic mouse model of breast cancer. After treating the mice with combination anti-PD-1 and doxorubicin, volumetric analysis of the mammary fat pad tumors did not show any significant impact of treatment compared to single treatment and untreated control mice. However, increased CTL infiltration in the tumors of mice that received combination treatment was detected by *in vivo* SWIR imaging. CTL infiltration was validated with *ex vivo* IHC staining, and a monotonic relationship was observed between SWIR fluorescence and CD8 positivity. IHC staining of other immune markers, including CD45, CD3, CD4, and PD-L1, showed that combination treatment may influence in the expression of these markers, presenting additional targets that could be imaged with ReANCs in the future. In conclusion, the increase in SWIR signal from CD8-targeted ReANCs in tumors treated with combination immunotherapy and chemotherapy and the relationship with IHC staining highlight the ability to use SWIR imaging for non-invasive assessment of changes in immune dynamics following treatment.

#4179 Magnetic resonance imaging and bioluminescence imaging for evaluating tumor burden in orthotopic glioblastoma.

Mingrui Guo[1], Ruisong Su[1], Jeff W H Chor[1], Zheyan Zhang[1], Mandy Tan[1], Xing Qi Teo[2], Haosheng Feng[2], Kuan J. Lee[2], Li Hua[1], Longyun Zhang[1], Jie Cai[1], Guanping Mao[1], Jingjing Wang[1], Keefe Chng[1], Weiping Han[2], Colin Guo[1]

[1]Crown Bioscience, San Diego, CA,[2]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore

Accurate monitoring of orthotopic tumors in oncological research is critical. While conventional surgical exposure method or imaging methods such as bioluminescence imaging (BLI), ultrasound imaging (US) and computed tomography (CT) have different advantages and limitations. Magnetic Resonance Imaging (MRI) offers a non-invasive modality with high sensitivity. This study compares BLI and MRI in tracking tumor progression, focusing on the human glioblastoma multiforme (GBM) orthotopic xenograft mouse model. To establish the GBM model, human glioblastoma cells U87 MG-luc, expressing firefly luciferase, were intracranially implanted in female BALB/c nude mice. In-life tumor growth was assessed longitudinally every 3-4 days using BLI (IVIS Lumina S5, PerkinElmer, US) and MRI (Bruker BioSpec 117/16, 11.7T ultra-high field scanner, Germany) with a T2-weighted sequence. Mice were randomized into two groups (n=8) based on the MRI-derived tumor volume and BLI signal on the 3rd day post inoculation. One day after grouping, each cohort received specific treatments: one with the standard vehicle control and the other with Temozolomide (TMZ) (10mg/kg, 5 days/week, oral gavage). This treatment lasted until day 21, after which whole brains were removed and tumors excised from surrounding normal tissue and weighed. The results from both BLI and MRI showed that the control group exhibited consistent tumor growth, while TMZ treatment significantly inhibited tumor growth by day 21. However, some differences were observed, particularly for small tumor size, with more accurate measurement with MRI compared to BLI. By day 7 (3 days post treatment), MRI indicated a Tumor Growth Inhibition (TGI) of 32.63%, whereas BLI indicated a 5.04% increase in the TMZ-treated group compared to the control group. From day 11 onwards, both methods demonstrated a TGI exceeding 70% with TMZ treatment. Moreover, there was a pronounced difference in tumor weight correlations: MRI assessments showed a strong correlation (R^2=0.9967) with extracted tumor weights, whereas in contrast to BLI showed a weaker correlation (R^2=0.5371). The lower correlation for BLI, could be explained by the hypoxia and necrosis commonly observed in larger tumors or after treatment leading to decrease of ATP and reduction of bioluminescence. BLI offers rapid 2D imaging but lacks precision in determining location and depth of GBM tumor. Moreover, it requires luciferase engineered cell lines. In contrast, MRI provides high-resolution 3D imaging without genetic modifications, providing precise anatomical evaluations. Our study highlights the advantages of MRI over BLI for longitudinal monitoring of orthotopic GBM models. MRI imaging modality opens the possibility to use more clinically relevant patient derived xenograft (PDX) models of GBM in an orthotopic manner, improving the clinical transability to evaluate new GBM treatment modalities.

#4180 Evaluation of CD38 pharmacodynamics in multiple myeloma using PET with a Ga-68 labelled peptide.

A. Sharma, K. Gupta, A. Mishra, G. Lofland, I. Marsh, D. Kumar, G. Ghiaur, P. Imus, S. P. Rowe, R. F. Hobbs, C. B. Gocke, S. Nimmagadda;
Johns Hopkins University, Baltimore, MD

Introduction: Multiple myeloma (MM) is a disease of plasma cells that primarily arises in the bone marrow. CD38 is a receptor expressed uniformly and with high density in MM. Several CD38 targeted therapeutics are in clinic for MM. However, how those therapeutics engage or modulate CD38 is poorly understood particularly in lesions that cannot be assessed with routine blood testing. CD38 specific radiotracers for positron emission tomography (PET) could be helpful for detection of MM and for assessing therapy response early by measuring CD38 pharmacodynamics non-invasively. Here, we report the development of a first-in-class peptide-based PET radiotracer, [^{68}Ga]AJ206, evaluation of its pharmacokinetics (PK), specificity for non-invasive CD38 detection, and its potential to evaluate therapy induced CD38 pharmacodynamics in mouse models of MM.

Methods: A bicyclic peptide, AJ206, was synthesized and its binding affinity for CD38 was determined by surface plasmon resonance. AJ206 was labelled with Gallium-68 in high radiochemical yields and purity. In vitro uptake of [^{68}Ga]AJ206 was carried out in four MM cell lines with variable CD38 expression (MOLP8, MM1S, RPMI8226, and U266). PK and biodistribution of [^{68}Ga]AJ206 were evaluated by PET in cell line derived xenografts, in patient derived xenografts (PDXs) and in a disseminated disease model. PET data was corroborated by ex vivo biodistribution studies. [^{68}Ga]AJ206 in vivo specificity for CD38 was confirmed by co-injection of non-radioactive AJ206 (1 mg/kg) and cross-correlative immunohistochemistry (IHC) of matched xenografts. Furthermore, ability of [^{68}Ga]AJ206 to quantify CD38 pharmacodynamics was established by treating PDX models with all-trans retinoic acid (ATRA) and cross validating PET imaging observations with IHC.

Results: AJ206 exhibits high affinity (K_D,19 nM) for human CD38. In vitro binding assays showed variable [^{68}Ga]AJ206 uptake in MM cells that correlated with receptor density measured by flow cytometry. Dynamic PET-MR imaging revealed high and specific uptake of [^{68}Ga]AJ206 in MOLP8 tumor within 5 min that retained for at least 90 min. In contrast, [^{68}Ga]AJ206 exhibited rapid clearance from normal tissues providing high contrast images at 60 minutes and a high tumor-to-muscle ratio of 27.1±2.7. Tumor uptake was reduced by > 80 % in mice receiving blocking dose, confirming the specificity of the radiotracer. Also, [^{68}Ga]AJ206 could detect CD38 expression in different MM xenografts, PDXs and disseminated disease models which was corroborated by flow cytometry and IHC findings. Moreover, [^{68}Ga]AJ206 successfully quantified the increased CD38 expression in PDXs following ATRA treatment.

Conclusion: [^{68}Ga]AJ206 is a CD38 specific high affinity peptide-based PET imaging agent that can be used to non-invasively quantify CD38 pharmacodynamics in MM, with potential applications in other diseases with CD38 involvement.

#4181 AXL-specific single domain antibodies show diagnostic potential and anti-tumor activity in acute myeloid leukemia.

N. Vandewalle[1], H. Satilmis[1], E. M. Verheye[1], R. Fan[1], Y. Wang[1], T. W. M. De Groof[1], T. Kerre[2], N. De Beule[3], A. De Becker[3], E. De Bruyne[1], E. Menu[1], K. Vanderkerken[1], K. Breckpot[1], N. Devoogdt[1], K. De Veirman[1];

[1]Vrije Universiteit Brussel, Jette, Brussels, Belgium, [2]Ghent University Hospital, Ghent, Belgium, [3]Universitair Ziekenhuis Brussel, Jette, Brussels, Belgium

Rationale: AXL expression has been identified as a prognostic factor in acute myeloid leukemia (AML) and is detectable in approximately 50% of AML patients. In this study, we developed AXL-specific single domain antibodies (sdAbs), cross-reactive for both mouse and human AXL protein, to non-invasively image and treat AXL-expressing cancer cells.

Methods: AXL-specific sdAbs were induced by immunizing an alpaca with mouse and human AXL proteins. SdAbs were characterized using ELISA, flow cytometry, surface plasmon resonance and the AlphaFold prediction software. A lead compound was selected and labeled with ^{99m}Tc for evaluation as a diagnostic tool in mouse models of human (THP-1 cells) or mouse (C1498 cells) AML using SPECT/CT imaging. For therapeutic purposes, the lead compound was fused to a mouse IgG2a-Fc tail and *in vitro* functionality tests were performed including viability, apoptosis and proliferation assays in human AML cell lines and primary patient samples. Using these *in vitro* models, its anti-tumor effect was evaluated as a single agent, and in combination with standard of care agents venetoclax or cytarabine.

Results: Based on its cell binding potential, cross-reactivity, nanomolar affinity and GAS6/AXL blocking capacity, we selected sdAb20 for further evaluation. Using SPECT/CT imaging, we observed tumor uptake of ^{99m}Tc-sdAb20 in mice with AXL-positive THP-1 or C1498 tumors. In THP-1 xenografts, an optimized protocol using pre-injection of cold sdAb20-Fc was required to maximize the tumor-to-background signal. Besides its diagnostic value, we observed a significant reduction in tumor cell proliferation and viability using sdAb20-Fc *in vitro*. Moreover, combining sdAb20-Fc and cytarabine synergistically induced apoptosis in human AML cell lines, while these effects were less clear when combined with venetoclax.

Conclusions: Because of their diagnostic potential, sdAbs could be used to screen patients eligible for AXL-targeted therapy and to follow-up AXL expression during treatment and disease progression. When fused to an Fc-domain, sdAbs acquire additional therapeutic properties that can lead to a multidrug approach for the treatment of AXL-positive cancer patients.

#4182 Development and evaluation of orthotopically and subcutaneously implanted luciferase-labeled prostate cancer xenograft models for therapeutic assessment.

K. Draheim, E. Rainbolt, B. John, C. Clouse, A. Wong, B. Wolff, J. Avery, C. Hall, P. Fadden, **A. Avrutskaya**;
Charles River Laboratories, Inc., Wilmington, MA

Introduction: Prostate cancer is the most common male-specific cancer in many western countries including the US and the second most prevalent cause of cancer deaths in American males after lung cancer. The establishment of clinically relevant prostate cancer models is crucial for advancing our understanding of the disease and evaluating potential therapeutic interventions. In this *in vivo* project we characterize the tumor growth and response to therapy of two luciferase (luc) tagged human prostate cancer xenograft models of metastatic PC3M and non-metastatic DU145 cell lines. These models aim to replicate the variable clinical behavior of prostate cancer to provide valuable pre-clinical platforms to test existing and novel therapies. As a first step, these studies evaluate the effect of standard of care cytotoxic agents paclitaxel and carboplatin and the newer AXL kinase inhibitor bemcentinib alone and in combination on tumor growth kinetics and agent tolerability.
Methods: PC3M-luc and DU145-luc cells were implanted subcutaneously on right flank or orthotopically into the prostate of NCG triple immunodeficient mice (Charles River). Subcutaneous tumor progression and treatment responses were monitored using calipers and bioluminescent imaging (BLI), with the capacity to detect developing metastases prior to necropsy. Orthotopic implants were monitored exclusively using BLI.
Results: Orthotopic and subcutaneous implants of PC3M-luc demonstrated spontaneous metastasis to lungs and bones, replicating the established behavior of this cell line and effectively modeling metastases observed in prostate cancer patients. In contrast, orthotopic and subcutaneous implants of DU145-luc model did not metastasize. Both PC3M-luc and DU145-luc models independent of the tumor implant placement responded to paclitaxel treatment, with enhanced effects observed when combined with carboplatin. Notably, bemcentinib exhibited no activity as a single agent but showed promise when used in combination with cytotoxic agents.
Conclusion: The development of orthotopic and subcutaneous PC3M-luc and DU145-luc prostate cancer models provides a valuable platform for assessing the effectiveness of established and novel therapies. These models mimic various clinical presentations of prostate cancer and promise to offer insights into disease progression and therapeutic strategies. Future studies will focus on durable responses and the assessment of other combination therapies for improved treatment outcomes.

#4183 Utility of the highly immunodeficient SRG rat for combined drug efficacy, pharmacokinetics, and toxicology studies in tumor-bearing animals.

D. Begemann[1], C. Dunn[1], D. Robertson[1], L. Keach[1], E. Baldwin[1], R. Walton[1], A. Van Engelenburg[2], J. Durrant[2], L. Healy[2], K. Aw Yong[3], M. J. Schlosser[1], **F. K. Noto**[1];

[1]Hera BioLabs, Lexington, KY, [2]Dallas Tissue Research, Dallas, TX, [3]Charles River Laboratories, Wilmington, MA

Immunodeficient rodents are vital pre-clinical disease models. Historically, immunodeficient mice have been standard for hosting human cell and tissue xenografts, enabling cancer drug efficacy and tolerability testing. However, an immunodeficient rat that supports a variety of human cancer types provides a larger model for easier surgical manipulation and serial blood and tumor tissue sampling, allowing for efficacy, pharmacokinetics, and toxicology testing in the same animal. We created a Sprague Dawley *Rag2 -/-, Il2rg -/-* rat (*SRG Rat®; SRG)* that is highly supportive of human cell and tissue engraftment. The SRG rat lacks B, T, and NK cells and is more immunodeficient than the Nude rat.

Here we show comparative pathology between the SRG rat and its parental strain, the CRL Sprague Dawley (CD). We also present data from an efficacy study in tumor bearing SRG rats, demonstrating that serial blood draws and tumor biopsies can be performed in tumor bearing animals to assess drug pharmacokinetics and pharmacodynamics within a single study. First, we assessed 10 SRG (5/sex) and 10 CD (5/sex) at 8-10 weeks of age. Body weight, hematology, and clinical chemistry parameters were measured. Microscopic examinations were performed on routine H&E slide preparations.

Male and female SRG displayed lower mean body weight when compared to sex- and age-matched CD. Compared to CD, SRG had reduced lymphoid tissue and circulating monocytes, and highly reduced circulating lymphocytes, neutrophils, eosinophils, and basophils; expected phenotypes for this severely immunodeficient rat. Thymus was not present in SRG rats, spleens were grossly smaller, and bone marrow cellularity was decreased compared to CD. Microscopically, mandibular lymph nodes and lymphoid tissue in spleen, lung, and intestine were not observed in SRG rats, consistent with the 92% decrease in circulating lymphocytes.

To demonstrate the utility of the SRG for tumor inhibition, pharmacokinetics, and pharmacodynamics, we inoculated rats with human VCaP prostate cancer cell-derived tumors, then treated these animals and collected serial blood samples and tumor biopsies to assess tumor biomarkers. Treatment led to decreased PSA and AR, two key proteins expressed in prostate cancer, correlating to decreased tumor growth.

These data demonstrate that the SRG rat is suitable for toxicology studies and has comparable pathology to the CD rat, except for reduced lymphoid tissue and WBCs, which are expected phenotypes. In addition, the SRG rat supports the growth of human cancer tissue for treatment studies. The large size of the SRG rat and comparative pathology to the CD rat support its value as an immunodeficient model for assessing toxicity during efficacy testing for de-risking safety concerns in the presence of the human target tissue.

#4184 Change of oncological features on tumor and immune cells after anti-PD-1 antibody to pancreatic cancer orthotopic model in CD34+ HSC based humanized mice.

Sujin Park[1], Eun-young Koh[2], Inha Yoo[1], Ji Hye Jeong[2], Eunsung Jun[3]

[1]Department of Medical Science, AMIST, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Department of Biochemistry and Molecular Biology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[3]Division of Hepatobiliary and Pancreatic Surgery, Department of Surgery, Asan Medical Center, AMIST, University of Ulsan College of Medicine, Seoul, Korea, Republic of

(a) To investigate novel therapeutic agents in pancreatic cancer, animal models that recapitulate the features of the human immune system are necessary. We aim to analyze an orthotopic model in CD34+HSC-based humanized mice and to prove that is an indispensable model for immune-oncology therapy research.
(b) We established an orthotopic tumor model using luciferase-expressing BxPC3 cells in humanized NSG mice. After inoculation of tumor cells, anti-PD-1 Ab was administered to mice 5 times a week by I.P. injection. Tumor formation and progression were monitored using IVIS. To compare the subsets and immune-check point receptors of human immune cells in blood and tumor tissue, Flow cytometry and immunohistopathology were used. Additionally, we compared the distribution of various cells included in the tumor and the mRNA expression level of each cell through a single cell RNA sequence. We also establish primary cell lines and organoids with the humanized mouse tumor for further evaluation.
(c) After inoculation of BxPC3_Luc cell line into mice pancreas, we monitored tumor growth using a noninvasive imaging method of IVIS. When we compared the tumor growth between the anti-PD-1 treatment and control, there was no significant difference. Using FACS, we analyzed the various markers of human immune cells in mouse blood and tumor tissue. In blood, PD-1 expression of CD8+ T cells decreased, and Tim-3 expression increased in anti-PD-1 group. And, PD-1 expression of CD4+ T cells decreased in anti-PD-1 group. In tumor tissue, we also verified the decrease of PD-1 expression on tissue infiltrating CD8+ T cells and CD4+ T cells in the anti-PD-1 group. Especially in the more responsive mouse among anti-PD-1 group, activation markers in cytotoxic T cells (CD8+), helper T cells (CD4+), and regulatory T cells (CD4+FOXP3+CD25+) increased, and also, M1 macrophage (CD86+) expression was increased. Furthermore, we compared the mRNA expression levels of various cells in the tumor microenvironment according to anti-PD-1 Ab treatment through single cell RNA seq analysis. It was confirmed that the expression of genes related to proliferation and growing decreased, while the expression of genes related to apoptosis increased in cancer cells. Finally, we constructed primary cancer cells and organoids from tumor tissue and confirmed that the immune-oncological characters of these models are maintained after passaging.
(d) We successfully established a pancreatic orthotopic model in a humanized mouse and analyzed the changes in immune cells and tumor cells after anti-PD-1 treatment. In addition, by obtaining tumor tissue-based preclinical models, we laid the foundation for future immune-oncologic experiments. We hope that these attempts and results will help in the development and drug verification of new immunotherapy agents for refractory solid tumors such as pancreatic cancer.

#4185 Neutralizing human IFN-β combined with anti-human PD-L1 and anti-human CTLA-4 treatment increased control of endometrial tumor growth in a novel HLA-A matched BLT humanized mice.

Zhe Yuan[1], Guorui Zu[1], Xiao Sun[1], Emmanouil Papasavvas[1], Lily Lu[1], Joel Cassel[1], Peter L. Lutes[2], Mark Cadungog[2], Joseph Salvino[1], Luis J. Montaner[1]

[1]The Wistar Institute, Philadelphia, PA,[2]Christiana care, Newark, DE

High concentrations of type I interferon can induce growth arrest and apoptosis in cancer cells upon acute exposure, while low concentrations of the same can provide significant pro-survival benefits upon chronic exposure. In vitro data show the dependence of cancer cells on self-generated IFN-I leads to their demise if the IFN-β gene is disrupted, but they manage to persist when provided with IFN-β from an external source. Importantly, murine models show that inhibition of myeloid-associated INF-β can limit tumor growth. As blockage of type I interferon can also restore the CD8+ T cell function after chronic viral infection, we sought to determine the effects of neutralizing anti-human IFN-β antibody 7859 (N-anti-IFN-β) when added to T-cell directed immunotherapy in BLT humanized mice implanted with HLA-A matched human endometrial cancer PDX specimens. Specifically, we tested the combination of immunotherapy with N-anti-IFN-β combined with anti-human PD-L1 and anti-human CTLA-4. N-anti-IFN-β was first characterized for neutralizing activity to confirm specific neutralization of IFNβ and not human IFN-β. HLA-A matched genotyped CD34 stem cells and thymus (BLT humanized mice) and clinical endometrial tumors (PDX) were joined in BLT humanized mice before infusions with N-anti-IFN-β with or without anti-human PD-L1 and anti-human CTLA-4, anti-human PD-L1 and anti-human CTLA-4 alone, and IgG control antibodies intraperitoneally twice per week over three weeks. Tumor sizes were measured weekly and weighted at the end of the study. Human leukocytes infiltrating PDX were assessed by IHC and flow cytometry. Leukocyte subset activation, exhaustion, and tumor-specific T-cell function were measured. Anti-human PD-L1 and anti-human CTLA-4 reduced tumor growth by 82.9% ($p<0.0001$), but quickly increased the T cell exhaustion markers PD-1 and LAG3. The addition of N-anti-IFN-β to immunotherapy significantly decreased the tumor growth rate by 96.2% ($p<0.0001$) also significantly different from immunotherapy alone ($p=0.0009$) N-anti-IFN-β monotherapy reduced tumor growth rate by 42.4% ($p=0.0032$). While there was an increase in infiltrating CD4 and CD8 T-cells in combination therapy, reductions in expression of PD-1 and LAG3 were observed when compared to immunotherapy or N-IFN-β groups alone Analysis was done with Prism software. The use of a novel HLA-A matched BLT humanized mice with human tumor PDX model shows that neutralization of IFN-β can increase the T-cell anti-tumor activity and tumor repression of immunotherapy with anti-human PD-L1 and anti-human CTLA-4 treatment.

#4186 Development of an orthotopic A549 lung carcinoma model in CD34^{+} humanized NCG mice and response to treatment with paclitaxel and pembrolizumab.

A. Avrutskaya[1], E. Rainbolt[1], B. John[1], C. Clouse[1], M. Stackhouse[1], C. Currie[1], S. Scatigno[1], S. Bronson[2], J. Rowe[2], C. Hall[1], **D. P. Harris**[1];
[1]Charles River Laboratories, Inc., Durham, NC, [2]Charles River Laboratories, Inc., Wilmington, MA

Translational in vivo models are needed to expedite the discovery of new treatments for lung cancer. One such approach is the use of humanized mouse models that enable immunotherapies targeting human immune cells to be evaluated for efficacy and tolerability. We developed an orthotopic lung carcinoma model in humanized mice (HuCD34 NCG), utilizing serial bioluminescence imaging to evaluate the activity of paclitaxel and pembrolizumab as single and combination agents. Paclitaxel, which disrupts microtuble function, and pembrolizumab, a PD-1-targeting immunotherapy, are both approved for the treatment of certain types of lung cancer. Paclitaxel kills cancer cells directly, and may also promote anti-tumor responses through enhanced presentation of tumor antigens and activation of T cells. Immunodeficient NCG mice were humanized with cord blood-derived hCD34^{+} stem cells from 3 donors. High levels of human cell engraftment, with expected frequencies of hCD45^{+} cells and other immune subsets, was observed by 14 weeks post-injection. Luciferase expressing A549 cells were implanted orthotopically into the pulmonary space of the left lobe of the lung, and animals were subsequently flux sorted into treatment groups. Tumor burden, measured by luciferase expression, increased progressively in untreated animals, and moribundity was often associated with clinical indications of respiratory distress. Treatment with paclitaxel significantly decreased the tumor burden and extended survival. In contrast, pembrolizumab did not control tumor growth or extend survival. There was no synergistic effect with the combination therapy, in fact, the addition of pembrolizumab was associated with a modest increase in tumor burden and disease progression. Comparative analysis of immune cell composition, function and persistence in lung and other tissues provided insights into the distinct pharmacodynamic responses associated with the different treatment regimens. This model establishes a robust in vivo platform to identify novel therapies for the treatment of lung cancer.

#4187 Transcriptome profiling and characterization of peritoneal metastasis ovarian cancer xenografts in humanized mice.

Sung Wan Kang[1], Ji-young Lee[1], Ok-Ju Kang[1], Yong-Man Kim[1], Eun Kyung Choi[2], Shin-Wha Lee[1]

[1]Obstetrics and Gynecology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Radiation Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Background: Although immunotherapy has not yet been as successful in ovarian cancer (OC), it remains a potential therapeutic strategy. Preclinical models of OC are necessary to evaluate the efficacy of immuno-oncology (IO) drugs targeting human cancer and immune components but have been underutilized. Developing mouse models with a humanized (Hu) immune system can help understand the human immune response to IO drugs, including immune checkpoint inhibitors (ICIs), which have demonstrated limited effectiveness in OC patients.

Methods: We established OC xenograft Hu-mouse models by intraperitoneally injecting luciferase-expressing SKOV-3 Luc and OVCAR-3 Luc OC cells into $CD34^{\pm}$ Hu-mice. Tumor growth was monitored through bioluminescence imaging (BLI). We assessed the efficacy of PD-1 blockade with pembrolizumab in the SKOV-3 Luc Hu-mouse model. The immune profiles of the tumors were characterized using colorimetric immunostaining and flow cytometry. Additionally, we analyzed RNA-seq data to investigate the gene expression signature of pembrolizumab refractory tumors.

Results: We confirmed tumor development in both OC cell lines within $CD34^{\pm}$ Hu-mice. In these models, human lymphocyte and myeloid cell subsets were present in the tumors, draining lymph nodes, blood, and spleens. The SKOV-3 Luc tumor-bearing Hu-mice did not respond to pembrolizumab monotherapy. These tumors exhibited a high presence of tumor-infiltrating macrophages. Tumors in Hu-mice unresponsive to pembrolizumab showed a lower abundance of $CD8^{\pm}$ T-cells, memory B cells, plasma cells, and a higher proportion of naïve M0 macrophages and mast cells compared to the PBS control. Furthermore, we identified 43 significantly enriched gene sets in these tumors. The differentially expressed genes (DEGs) were predominantly enriched in HDAC class I, RB1, KLF1/3, TCF21, MYD88, SMARCE1 target genes, and genes associated with epithelial-mesenchymal transition (EMT) and fibroblasts.

Conclusion: Our xenograft Hu-mouse model of OC provides a valuable tool for investigating the efficacy of IO drugs. The insights gained from this model offer potential avenues to explore mechanisms of resistance to PD-1/PD-L1 blockade in OC.

#4188 Kyinno PBMC humanized mouse platform: Pioneering service in biomedical research.

T. Liu, G. Wu, F. He, L. Luo, Z. Guo, S. Li, J. Ning, **F. Hao**;
Kyinno Biotechnology Co., Ltd, Beijing, China

Tumor immunotherapy is the use of the human immune system to kill tumors. Compared with traditional chemotherapy and radiotherapy, immunotherapy has significant advantages such as significant efficacy, long-lasting effects, and low toxicity. Wild-type mice are widely used as preclinical models for immunotherapy due to their normal immune system, but they have many shortcomings, such as only being able to inoculate mouse tumor cells, differences between mouse and human immune systems, etc., which cannot accurately simulate the interaction between drugs and tumor cells in the human body. Humanized mouse models include PBMCs humanized mouse models, HSC humanized mouse models, and human embryonic bone, liver, and thymus tissue (BLT) transplantation models. Among them, the PBMCs humanized mouse model is widely used due to its simple preparation, short cycle, and high levels of hCD3+ T cells in the peripheral blood of mice. To assist in the development of immunotherapy, KYINNO has established a PBMC humanized mouse platform that can perform in vivo drug efficacy verification of various immunotherapeutic drugs such as CD3 bispecific antibodies or multi-specific antibodies, immune checkpoint inhibitors, etc. We screen many PBMC donors and select PBMC donors with light GvHD and good hCD3+ T cell reconstruction effects. The drug administration window of the PBMC humanized model has been extended to 6 weeks. Platform verification has been performed on subcutaneous and intravenous injection models of various tumors. Overall, we successfully established the PBMC humanized mouse platform, which is a powerful tool for immunotherapy.

#4189 BALB/c-hIL12RB1/hIL12RB2: A robust model for preclinical research in human IL-12 therapy.

Y. Fang, H. Wang, J. Xing, L. Yang, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

Interleukin-12 (IL-12) is a multifaceted cytokine primarily produced by antigen-activated dendritic cells, macrophages, and neutrophils. Its receptor is a composite of IL12RB1 and IL12RB2, and the union of these two subunits forms a high-affinity receptor complex proficient in mediating IL-12 signaling. As a pivotal regulator of innate and adaptive immunity, IL-12 plays a crucial role in steering the differentiation of naïve T cells into Th1 cells. It is renowned as a T cell stimulatory factor, fostering T cell proliferation. Furthermore, IL-12 has the capacity to augment the activation of cytotoxic lymphocytes and natural killer cells (NK), thereby enhancing interferon (IFN-γ) production. Empirical evidence consistently demonstrates that IL-12 synergistically exerts anti-tumor effects in conjunction with various immune cells, such as T cells and NK cells. Its effectiveness in preclinical studies has solidified IL-12 as an appealing drug target, leading to the development of activating antibodies, therapeutic IL-12 proteins, and tumor vaccines as potential treatments.

To delve deeper into the functionality and therapeutic potential of IL-12, we have engineered a humanized mouse model, known as BALB/c-hIL12RB1/hIL12RB2. Notably, this model fully preserves the intracellular domains of mouse IL12RB1 and IL12RB2 proteins, ensuring the normal propagation of intracellular signaling. It also effectively expresses human IL12RB1 and IL12RB2. In vitro functional validation experiments have verified that BALB/c-hIL12RB1/hIL12RB2 mice can proficiently generate IFN-γ when induced by human IL-12.

Furthermore, in vivo efficacy experiments have yielded compelling results. Intratumoral administration of human IL-12 mRNA in BALB/c-hIL12RB1/hIL12RB2 mice led to a significant suppression in the growth of CT26 tumors, culminating in complete tumor regression. Subsequent rechallenge experiments conducted after the discontinuation of treatment revealed no tumor recurrence, signifying the enduring inhibitory effect of hIL12 mRNA on mouse tumors.

In conclusion, the development of BALB/c-hIL12RB1/hIL12RB2 mice stands as a robust model for advancing preclinical research in the realm of human IL-12 therapy.

#4190 Patient-derived xenograft (PDX) models with differential HER2 expression for preclinical evaluation of HER2-targeted therapies.

X. Yang, S. Guo, H. Wang, X. Su, J. Zhao, X. Gao, C. Ju;
Gempharmatech Co., Ltd., Nanjing, China

Human epidermal growth factor receptor 2 (HER2) is a critical therapeutic target in gastric cancer. However, the varying expression levels of HER2 in patients present a significant challenge in selecting the appropriate HER2-targeted therapies. Patient-derived xenograft (PDX) models offer a valuable tool to address this clinical concern.

We established a panel of PDX models derived from gastric cancer patients, each representing a distinct range of HER2 expression levels. These models were subsequently treated with HER2-targeted drugs, including Trastuzumab (Herceptin), Margetuximab, and Enhertu.

Our results demonstrated differential drug responses corresponding to the varying HER2 expression levels in the PDX samples. Trastuzumab, Margetuximab, and Enhertu exhibited distinct efficacies across the HER2 expression spectrum. This underscores the significance of selecting the right therapeutic approach based on the HER2 status of individual patient.

Our collection of PDX models with differential HER2 expression levels provides a robust platform for preclinical evaluation of HER2-targeted therapies. This approach not only addresses the clinical challenge of HER2 heterogeneity but also facilitates a more personalized and effective treatment strategy for gastric cancer patients.

#4191 Delayed onset of GvHD in PBMC humanized NCG-B2m KO mice provides an enhanced model for oncology studies.

S. Bronson, D. Harris, A. Avrutskaya, C. Eberle, J. Rowe;
Charles River Laboratories, Inc., Wilmington, MA

Humanized mice are specialized animal models incorporating components of the human immune system. These models are valuable tools for assessing the efficacy of human immunotherapies on tumors. Humanized mice are created by injecting human $CD34^{+}$ hematopoietic stem cells (HSCs) or human peripheral blood mononuclear cells (PBMCs) into an immunodeficient mouse. PBMC humanized (HuPBMC) mice engraft within a few weeks and can recapitulate a robust human T cell population. One challenge when using HuPBMC mice is the onset of graft versus host disease (GvHD), limiting their lifespan compared to $hCD34^{+}$ HSC humanized mice. The onset of GvHD varies in the HuPBMC model depending on the donor cells. The development of xenogeneic GvHD is dependent on the expression of major histocompatibility complex (MHC) on host cells and lowering MHC expression can delay the onset of GvHD.NCG-B2m KO mice lack beta-2 microglobulin, a component of MHC I, and have lower cell surface expression of MHC I molecules. This leads to a decrease in recognition of host cells by human immune cells. Here we compared the onset of GvHD between HuPBMC NCG-B2m KO mice and HuPBMC NCG mice. PBMC donor variability was also compared between the two PBMC humanized models by evaluating multiple donors and assessing additional collections from the same donor. After the PBMC engraftment was characterized, HuPBMC NCG mice and HuPBMC NCG-B2m KO mice were enrolled in tumor studies comparing outcomes and tumor growth kinetics in mice treated with human immune checkpoint blockade therapy.NCG and NCG-B2m KO mice were injected with $1x10^{7}$ PBMCs from individual donors. Animals were weighed three times a week to monitor for changes in body weight and general health status. Peripheral blood was collected at day 10, 20, 30, 40, 60 and 90 post injection for flow cytometry screening of human immune cell engraftment ($hCD45^{+}$, $hCD3^{+}$, $hCD4^{+}$ and $hCD8^{+}$). Human PBMCs isolated from additional collections from the same donors were also injected into both NCG-B2m KO mice and NCG mice and flow cytometry was performed. HuPBMC NCG-B2m KO mice survived longer than HuPBMC NCG mice allowing for the potential use in longer term tumor studies before the results are confounded by GvHD. PBMC humanized mice are an important model for translational research using immunotherapies and the PBMC humanized NCG-B2m KO model provides an expanded study window ideal for oncology studies.

#4192 In-depth evaluation of chemotherapy-induced mucositis in intestinal organoids using holotomography.

Mahn Jae Lee[1], Jaehyeok Lee[2], Weisun Park[3], Geon Kim[3], Hye-Jin Kim[2], YongKeun Park[3]

[1]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Bioscience, Tomocube Inc., Daejeon, Korea, Republic of,[3]Physics, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Intestinal mucositis is a prevalent adverse event associated with antineoplastic therapies, such as chemotherapy, which still lacks a targeted and effective treatment regimen. The difficulty in preclinical prediction and prevention of drug-induced intestinal mucositis is attributed to the intricate underlying mechanisms of its onset and the broad spectrum of patient-specific responses to chemotherapeutic agents. Advancements in regenerative medicine have enabled the generation of intestinal organoids from adult stem cells, serving as a personalized model to emulate disease pathology and simulate individual drug responses. Various imaging techniques are employed to evaluate the responses of the organoids to pharmacological agents, but the inherent complexity of their three-dimensional (3D) architecture poses significant challenges in organoid imaging. These challenges are exacerbated by the standard preparation processes for imaging, including fixation and staining, which do not allow for the observation of dynamic, real-time effects of drugs on living organoids. In this study, we focused on meticulously examining the histopathological alterations in small intestinal organoids subjected to chemotherapeutic agents that induce mucositis, specifically 5-fluorouracil and irinotecan. Employing holotomography, a label-free real-time 3D imaging technology, we were able to visualize the destructive processes affecting the intestinal organoids, including the breakdown of the epithelial lining, the exfoliation of dead cells, and the alteration of the villus/crypt structure. Furthermore, we propose a novel methodology for quantifying the viability of intestinal organoids. This quantification is essential for assessing the extent of damage caused by the chemotherapeutic agents and for determining the maximum drug concentrations that can be deemed safe for use, thereby minimizing the risk of inducing mucositis while maintaining therapeutic efficacy. These results provide new insights into the toxic mechanisms of chemotherapeutic drugs and highlight the importance of using organoid models in drug safety evaluation throughout the development phase.

#4193 Digital PCR as a novel way to assess chimerism of humanized immune system mice.

N. Smith[1], S. Hansen[2], R. S. Livingston[2], S. Smith[2], P. Roesch[1], M. M. MacBride[1];
[1]Taconic Biosciences, Inc., Rensselaer, NY, [2]IDEXX BioAnalytics, Columbia, MO

Humanized immune system (HIS) mice contain human and murine immune cells. Analysis of chimerism in HIS mice is typically accomplished via flow cytometry, but this requires collecting a 75 µl blood sample and access to a flow cytometer. Repeated bleeding can negatively affect the health of HIS mice, limiting serial analysis. Digital PCR offers a novel method for chimerism analysis, which uses much smaller blood volumes and can be performed on clotted or frozen samples, sample types unsuitable for flow cytometry. A digital PCR assay directly comparing the presence of three human genes and one murine gene was developed. This assay was validated in the huNOG-EXL HIS mouse engrafted with CD34+ hematopoetic stem cells from 3 unique donors via blind comparison with chimerism data from flow cytometry. At 10 weeks post engraftment, the digital PCR assay showed excellent correlation for all three human genes against chimerism as measured by flow cytometry of the peripheral blood. This assay represents a new, user-friendly, rapid tool for the analysis of HIS mice and may permit serial chimerism measurement using 10 µL whole blood. This assay may be useful to investigate other mouse-human chimera models, including mice harboring functional human hepatocytes, tumors, and other cells.

#4194 An in-silico approach to identify genes required for polyamine transport.

V. Millington, L. von Kalm;
University of Central Florida, Orlando, FL

The purpose of this study was to use an in-silico approach to identify genes required for polyamine transport. Polyamines are small positively charged molecules that control vital cellular processes including cell proliferation and growth. Cells obtain polyamines by biosynthesis or transport from the extracellular environment. Cancer cells require high levels of polyamines to sustain rapid growth, and therapies aimed at polyamine depletion are considered promising. The FDA approved drug difluoromethylorthinine (DFMO) blocks polyamine biosynthesis, however, in most cases malignant cells evade the biosynthetic block by increasing transport. Thus, a dual therapy that simultaneously targets polyamine biosynthesis and transport is needed. The mechanism of polyamine transport is poorly understood in multicellular eukaryotes and identification of genes involved in polyamine transport has largely relied on an inefficient hit-or-miss 'educated guess' approach. To increase the probability of identifying genes involved in polyamine transport, we adopted an in-silico approach comparing protein-protein interactions with the protein product of the human ATP13A3 gene across multiple databases. We used ATP13A3 because our work, and the work of others, has shown that ATP13A3 and its Drosophila ortholog 'anne' are required for polyamine transport. We searched for high confidence protein interactors with ATP13A3 in four databases, BioGRID, STRING, NextProt, and GPS-Prot, prioritizing hits that occurred in more than one database. We next asked if any of the high priority hits had orthologs in Drosophila. We chose to study the candidate genes in Drosophila because we have utilized the sophisticated genetic resources available in this organism to develop novel assays to identify positive and negative regulators of polyamine transport. Using the criteria described, we identified four candidates that occurred in three databases, and one that occurred in two databases. In addition, a very high confidence match to the human gene SLC15A was observed in one database and included in the group of candidate genes. To determine the validity of our candidate gene enrichment approach we are currently testing each gene for roles in polyamine transport.

#4195 Activity of IMM-1-104 alone or in combination with chemotherapy in RAS-altered pancreatic cancer models.

P. King[1], J. Funt[1], S. Kolitz[2], P. Nair[1], J. d. Jong[1], A. Yamamura[1], M. Johnson[1], J. Zhang[3], K. Fowler[1], A. Travesa[1], A. Axel[1], C. Walker[1], B. J. Zeskind[3], B. M. Hall[1];

[1]Immuneering Corporation, San Diego, CA, [2]Immuneering Corporation, Cambridge, MA, [3]Immuneering Corporation, New York, NY

Introduction: Addiction to the MAPK pathway drives a large proportion of cancers, and pancreatic tumors almost universally display RAS mutations. IMM-1-104, a once-daily oral treatment being evaluated in a Phase 1/2a trial for RAS-mutant solid tumors [NCT05585320], offers a novel deep cyclic inhibition (DCI) approach in targeting the MAPK pathway at MEK. Traditionally, MAPK-targeted drugs inhibit the pathway chronically causing serious class-effect toxicities and limited durability due to resistance. In contrast, IMM-1-104's unique pharmacokinetic (PK) profile was designed to drive pulsatile MEK inhibition, with the goal of improving tolerability and providing more durable activity across a broad range of MAPK-driven tumors. Phase 1 dose escalation of IMM-1-104 revealed no dose-limiting toxicities, high oral bioavailability, plasma half-life of approximately 2-hours, and pharmacodynamic (PD) data supporting DCI of the MAPK pathway.

Experimental Procedures: IMM-1-104 responses in humanized 3D tumor growth assays (3D-TGA) were combined with NGS data using machine learning (ML) to refine a pharmacogenomic response model. Evaluation of databases such as AACR Project GENIE enabled prediction of patient alignment of preclinical models based on genomic profile, identification of patient populations displaying MAPK pathway addiction and projected sensitivity to IMM-1-104 mono- or combination therapy. To test combinations with approved chemotherapy agents, IMM-1-104, gemcitabine (GEM) and nab-paclitaxel (PAC) and 5-fluorouracil (5FU) were evaluated in tumor xenograft models with drugs alone or across multiple combinations.

Summary of New Data: IMM-1-104 showed promising combination effects when treated with GEM or PAC in 3D-TGA pancreatic cancer models. In a MIA PaCa-2 tumor xenograft model, IMM-1-104 alone showed greater tumor growth inhibition (TGI) than any single or combination chemotherapy tested. Further, combinations of IMM-1-104 plus chemotherapy resulted in near complete responses in a majority of animals. At day 39, antitumor activity (TGI%) was 103% for IMM-1-104 at 125 mg/kg BID PO, 25.2% for GEM at 60 mg/kg IP Q4D, 62.2% for PAC at 10 mg/kg IV Q4D and 36.6% for 5FU at 50 mg/kg IP Q4D. Based on these results and additional 3D-TGA pharmacogenomics data, ML modeling was advanced to query the GENIE database and identify biomarkers of response and resistance with the goal of further informing mono and combination treatment options with IMM-1-104 in pancreatic cancer.

Conclusions: The Phase 2a portion of the ongoing IMM-1-104 clinical study includes five arms, three of which focus on patients with pancreatic cancer, where IMM-1-104 will be evaluated as both monotherapy and in select combinations with approved chemotherapeutic agents. The new *in vitro*, *in vivo* and ML modeling data presented here further support an advancing translational roadmap for IMM-1-104 in pancreatic cancer.

TUMOR BIOLOGY: Models to Study Immune Cells in the Tumor Microenvironment
Poster Session

#4199 Comprehensive 3D liver cancer model to study the tumor microenvironment for therapy development.
F. Bonanini, R. Dinkelberg, V. van Duinen, J. Heijmans, D. Gouber, T. Hagens, N. Kortekaas, M. Caro Torregrosa, D. Kurek, P. Vulto, **K. Bircsak**; MIMETAS, Oegstgeest, Netherlands

Liver cancer, or hepatocellular carcinoma (HCC), is a formidable malignancy characterized by the uncontrolled growth of cells within the liver tissue. It represents a global health concern, with risk factors including chronic viral infections (such as hepatitis B and C), excessive alcohol consumption, fatty liver disease, and certain genetic conditions. The silent progression of HCC complicates early detection, emphasizing the need for a deeper understanding of the liver tumor microenvironment, which plays a crucial role in disease development. The liver model presented here incorporates a wide array of relevant liver cell types, including hepatocytes, endothelial cells, stellate cells, and resident immune cells. This is complemented by a complete vascularization system, allowing for fluid flow across a micro vascular network that faithfully models the dimensions of liver sinusoids. All these elements are seamlessly integrated into an automated and high throughput platform known as the OrganoPlate®. To model the liver tumor microenvironment, hepatocellular carcinoma cells were integrated into healthy liver tissue model. The resulting model allowed for the observation of integrated cancer colonies, providing a more realistic platform for therapy development compared to monocultures. Simultaneously, the liver's particle clearance mechanisms were investigated using fluorescent imaging. Endothelial cell phagocytosis of E. coli particles and resident macrophages' internalization of dextran molecules were studied to explore hepatic delivery of macromolecules and nanoparticles via the systemic circulation. The integration of hepatocellular carcinoma cells within healthy liver tissue revealed the formation of integrated cancer colonies, offering insights into the complex interactions within the liver tumor microenvironment. Fluorescent imaging showcased endothelial cell phagocytosis of E. coli particles and resident macrophages' internalization of fluorescent molecules. These findings elucidate the liver's particle clearance mechanisms, providing a foundation for understanding immunological processes and designing efficient drug delivery systems. Understanding the liver tumor microenvironment is critical for developing effective therapies for HCC. The integration of hepatocellular carcinoma cells within healthy liver tissue offers a more realistic platform for therapy development compared to traditional monocultures. We believe this system holds the potential for a groundbreaking progress in liver modelling which, besides including functional hepatic cells, also reflects the cellular organization and interactions found within the liver lobule. In conjunction with its high throughput capability, this has the potential to revolutionize drug discovery and develop therapies for complex liver diseases.

#4200 A novel 3D culture platform, *E-slice*, retains intact tumor microenvironment and tumor infiltrating immune cells.

Viridiana Leyva-Aranda[1], Thomas Gallup[1], Jose Maldonado[2], Corina Margain[1], Sang Yun[1], David Gallup[1], Min Kim[3], Kyuson Yun[2]

[1]EMPIRI, Inc., Houston, TX,[2]Department of Neurology, Houston Methodist Research Institute/Weill-Cornell Medical College, Houston, TX,[3]Department of Surgery, Houston Methodist Research Institute/Weill-Cornell Medical College, Houston, TX

Human cancer tissue is a complex ecosystem with heterogeneous cell types that communicate with each other dynamically to promote tumor progression and immune evasion. Hence, experimental systems that destroy or select for cancer cells in culture have often failed to accurately predict clinical responses of new drugs. Therefore, a technology that can retain the intact tumor microenvironment (TME) and accurately predict cancer patient's response to anti-cancer treatments, including immunotherapies, will greatly benefit patients and dramatically reduce the cost of new drug development.

E-slice is a proprietary 3D human tumor culture platform that maintains individual patient tumor's unique ecosystem and the TME *ex vivo* for up to 30 days. It is generated by making thin sections of intact, fresh tumor tissues and culturing them in serum-free, defined media. As such, immune components and the TME in *E-slices* faithfully recapitulate human tumors *ex vivo*. We demonstrate that *E-slices* can be used to: 1) measure viability changes upon anti-cancer agent treatment longitudinally; 2) retain the native TME and tissue architecture since *E-slices* are never dissociated or artificially reconstituted; 3) culture any solid tumor types from patient needle biopsy cores or surgical samples, PDX, or mouse models; 4) perform high content drug screening on human tissues; 5) discover secreted biomarkers and to 6) discover or validate molecular mechanisms of action or therapy resistance; and 7) measure immunotherapy responses *ex vivo* from human tissues.

Importantly, it has been shown to accurately predict individual patient treatment responses to chemotherapies and targeted therapies in 4-8 days, paving the way for evidence-based personalized treatment selections in a clinically actionable time frame. Furthermore, single cell RNA-sequencing analysis demonstrates that *E-slices* can retain the viability and molecular phenotypes of tumor infiltrating immune cells for up to 8 days *ex vivo*, providing a unique platform to study human tumor-immune interactions and evaluate efficacy of immune modulators on human tumor tissues *ex vivo*.

#4202 A novel 3D model investigating the pathophysiology of prostate cancer bone marrow metastasis.

Jianhui Yang[1], Hani Awad[2], Hiroshi Miyamoto[3], Omar Aljitawi[4], Peter Van Veldhuizen[5]

[1]Department of Medicine, University of Rochester Wilmot Cancer Institute, Rochester, NY,[2]Center for Musculoskeletal Research, University of Rochester, Rochester, NY,[3]Department of Pathology & Laboratory Medicine, University of Rochester Medical Center, Rochester, NY,[4]Hematology/Oncology Division, University of Rochester Medical Center, Rochester, NY,[5]Department of Internal Medicine, University of Rochester Medical Center, Rochester, NY

Our study is aimed to apply a 3-dimensional (3-D) *in vitro* model emulating the extracellular matrix (ECM) of the bone marrow microenvironment (BMM) to explore the interaction of disseminated Prostate Cancer (PC) cells and ECM. Wharton's Jelly (WJ), which histologically and biochemically resembles the ECM part of the hematopoietic stem cell (HSC) niche, was decellularized as a novel 3-D culture platform, named as decellularized WJ matrix (DWJM). CD133, a critical marker of PC stem cells (PCSC), was chosen to initially evaluate the PCSC phenotype of DU-145 cells cultured using DWJM by flow cytometry and Image-Stream. DWJM was used to culture PC Cell line DU-145 cells. Enriched CD133(+) cells by Fluorescence-Activated Cell Sorting (FACS) were further analyzed for functional phenotypes of PCSC, and the mechanism of reactivated expression of CD133 was also investigated. A small percentage (about 2-5%) of CD133(+) DU-145 cells were detected after DU-145 cell culturing using DWJM for 3-7 days. Sorted CD133+ cells formed more colonies *in vitro* and manifested some characteristics of Epithelial-to-Mesenchymal Transition (EMT), including increased nuclear to cytoplasmic ratio and spindle-cell morphology. The undetectable expression of CD133 mRNA and protein in parental DU-145 cells was at least partly caused by promotor methylation, while culturing using DWJM reactivated the expression of CD133 by demethylating the CD133 DNA promotor. Taken together, our *in vitro* findings provide preliminary findings to support the possible conversion of disseminated PC cells to PCSC by epigenetic modulation in the BMM, and these early findings warrant further validation using an *in vivo* mouse model.

#4204 Subcutaneous vs. orthotopic tumor models: A comparative assessment.

K.-A. Bright, S. Barnes, D. Germain, L. Kucharczyk;
Laboratory Corporation of America, Ann Arbor, MI

The failure of murine tumor models to adequately simulate the native biological milieu and tissue architecture of human malignancies, has fomented much discourse surrounding the discord that exists between experimental outcomes and clinical settings. Orthotopic (OT) models, which are generated by the engraftment of tumor cells or fragments into recipient organs of the same histotype from which they were derived, has the advantage of recapitulating the appropriate vasculature, as well as cellular and stromal components as the site of origin. In the context of immunotherapy, there is increasing evidence that subcutaneous (SC) tumors bear a vastly different immunological profile compared to OT implants, a phenomenon dictated by tissue-specific recruitment of various immune subsets, and subsequently, impacts overall response. Therefore, establishing cancer models that better represent the natural tumor environment is imperative for addressing some of the foibles inherent to preclinical mouse models. To demonstrate the significance of the anatomical site of the tumor, we present a comparative assessment of the MC38 murine colon carcinoma model, in the context of SC and OT settings. In the SC model of MC38, administration of either 5mg/kg anti-mPD1, anti-mPDL1, or anti-mCTLA-4, failed to elicit any notable anti-tumor activity, as evidenced by 0% incidences of complete regressions (CR) and tumor free survivors (TFS) for all three therapeutic agents, and incidences of 11%, 5% and -22% increase in time to progression (ITP), respectively. However, mice bearing OT tumors, exhibited meaningful response to 5mg/kg anti-mPD1 and anti-mPDL1, both evoking incidences of 25% CR, 25% TFS and 108% ITP. Though the anti-mCTLA-4 treated cohort did not produce any CRs or TFS, there was, nonetheless, a 50% incidence of ITP. Taken together, the data clearly illustrates the distinct disparities in response between SC and OT tumors, with respect to immunomodulatory agents. Characterization of immune phenotype within both settings, and interrogation of additional mouse models are ongoing. The exigencies and profound limitations associated with bench to bedside translation have long encumbered the drug development process. Despite staggering financial investment in oncology research, effective treatments for a myriad of cancers remain elusive, and only 3.4% of cancer drug candidates are conferred with clinical approval. Employing modalities that adequately reproduce the molecular and structural frameworks of human tumors, is crucial to better elucidating the natural trajectory of cancer progression, thus facilitating more accurate evaluation of drug activity and therapeutic response in preclinical settings. OT models therefore represent a more disease-relevant preclinical approach compared to their subcutaneous counterparts, as they more reliably preserve the intrinsic infrastructure and complexities of patient tumors *in situ*.

#4205 Investigating micro-environmental changes in a syngeneic radio-recurrent prostate cancer model.

S. D. White[1], X. Huang[2], I. Mills[3], S. K. Liu[4];
[1]University of Toronto, Toronto, ON, Canada, [2]Sunnybrook Research Institute, Toronto, ON, Canada, [3]University of Oxford, Oxford, United Kingdom, [4]Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Approximately 1 in 8 men in Canada will be diagnosed with prostate cancer (PCa) in their lifetime, with ~20% presenting with high-risk disease. A standard treatment is radiotherapy (RT) and while many patients respond well to RT, up to 40% of men with high-risk disease can recur, often within the prostate. It can be challenging to salvage prostate relapses due to the morbidity of re-irradiation and the high rate of subsequent progression. The tumor micro-environment (TME) is altered after radiotherapy with increased immune-suppressor and immune-stimulatory effects occurring concurrently. Therapies capitalizing on these changes in the TME might provide an advantage to tackling radiation-recurrent cancer. Identifying TME changes in radio-recurrent PCa is the first step; however, existing PCa animal models do not accurately model the TME. Our collaborator's lab has created the DVL3 mouse model with a clinically relevant TME. It forms tumors with distinct glandular morphology and displays micro-environmental responses to RT like what is seen in high-risk PCa patients, making this model an innovative tool for investigating radio-recurrence. The objective of this study is to create a radio-recurrent DVL3 PCa cell line to explore changes in the TME both *in vitro* and *in vivo* via orthotopic injection. To generate the radio-recurrent model, the DVL3 Parental cells (DVL3-Par) underwent a conventionally fractionated RT schedule (78Gy/39fx), herein referred to as DVL3-CF cells. The first part of the project involves *in vitro* characterization. Radiation resistance was evaluated via clonogenic assay which demonstrated a significant increase in clonogenic survival in the DVL3-CF cells relative to DVL3-Par. Characterization of DVL3-CF cells demonstrates that they are more proliferative at baseline, they recover quicker following G2/M blocks, they have decreased senescence following high dose radiation, and they are more invasive *in vitro*. The second part of the project evaluates the radio-recurrent model *in vivo* using an orthotopic mouse model as this best emulates the TME and clinical tumor progression. Parental and CF cells will be injected orthotopically into the prostate of C57/BL-6 mice and monitored for growth by MRI which will provide information on tumor volume as well as vasculature. At the time of sacrifice, the prostate and draining lymph nodes will be cryo-preserved and formalin fixed for downstream histological analysis. Transcriptional analyses, MRI data, and histological analysis of the tumors and draining lymph nodes will be compared across the radio-recurrent model and its parental cell line to evaluate environmental changes and potentially implicated mechanisms. This study will elucidate some of the complex interactions that are occurring within the TME of radio-recurrent PCa, increasing our understanding of mechanisms of radio-recurrence.

#4206 Regional transcriptomic profiling of the head and neck squamous cell carcinoma tumor microenvironment paired with murine models identify extracellular matrix components that mediate tumor progression and immune suppression.

John D. Aleman[1], Khoa A. Nguyen[1], Erica Wong[1], Yao Ke[2], Hanne T. Lind[2], Clifford G. Tepper[3], Andrew C. Birkeland[4], Christian D. Young[1], Sana D. Karam[5], Xiao-Jing Wang[2]

[1]Pathology, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Department of Pathology & Laboratory Medicine, University of California Davis, Sacramento, CA,[3]Department of Biochemistry and Molecular Medicine, University of California Davis, Sacramento, CA,[4]Department of Otolaryngology-Head and Neck Surgery, University of California Davis, Sacramento, CA,[5]Department of Radiation Oncology, University of Colorado Anschutz Medical Campus, Aurora, CO

Purpose: A substantial contribution to the poor prognosis for head and neck squamous cell carcinoma (HNSCC) patients is the progression to distant metastasis. This occurs in 30% of patients over the course of their disease, and radically reduces the 5-year survival rate to under 50%. Investigations in recent years have begun to unveil the intricate interplay of the extracellular matrix (ECM) in both tumor-intrinsic signaling and immunoregulation. However, studies conducted in the context of metastatic have been limited. Here, we employ spatial transcriptomics on HNSCC patient biopsies to identify ECM components that may contribute to cancer progression and immune suppression.
Experimental design: Comprehensive transcriptome profiling of HNSCC patient biopsies was conducted using the GeoMx Digital Spatial Profiler (DSP). This approach allowed us to characterize regions of the tumor microenvironment (TME) by immunofluorescent staining for subsequent bioinformatic analysis. To investigate the biological consequences of associations observed in our dataset, we performed *in vivo* murine studies. We have produced a series of SCC C57BL/6 murine cell lines derived from $Smad4^{-/-}Kras^{G12D}$ Keratin15+ stem cells, which faithfully mimic the clinical progression of HNSCC tumors, including metastasis. Using these murine models, we applied relevant pharmacologic inhibitors and genetic knockdown of targets identified with our GeoMx DSP analysis. *In vitro* immune-based and functional assays were conducted to elucidate the underlying mechanisms contributing to SCC progression.
Results: GeoMx DSP analysis revealed that laminins were enriched in stage IV HNSCC patient stroma, relative to lower stage patients. This coincided with TGFβ enrichment and inversely associated with signatures of anti-tumor immune infiltration. Analysis of The Cancer Genome Atlas data revealed similar inverse correlations in SCCs, distinct from breast cancer and lung adenocarcinoma. Our metastatic SCC murine lines likewise exhibited elevated levels of these laminin proteins, accompanied by high levels of laminin-binding integrins and TGFβ-Smad signaling. Independent of impacting cell proliferation, shRNA knockdown of laminin decreased tumor volume in an immune-competent setting. Targeting laminin-integrin signaling with the small molecule inhibitors Galunisertnib and Buparlisib also reduced the metastatic capacity of these cells in C57BL/6 mice.
Conclusions: Spatial transcriptomic profiling of the HNSCC TME uncovers intricate associations and promising targets not readily discernible in bulk RNAseq analyses. Validation through genetic and pharmacological approaches in immune-competent models underscores their potential as strategies to reduce HNSCC burden.

#4207 Zoledronic acid reduces quiescent bone-disseminated human ER+ breast cancer tumor cell burden and estrogen-responsiveness in a pre-clinical model.

J. N. Cheng, J. B. Frye, S. A. Whitman, **J. L. Funk**;
University of Arizona, Tucson, AZ

Unique to early-stage ER+ breast cancer, ER+ tumor cells already bone disseminated at time of diagnosis can remain dormant at this site until an initiating event (e.g., activating ESR1 mutation acquisition) allows for osteolytic bone metastases (BMET) progression even decades later. Adjuvant use of anti-resorptive bisphosphonates, but not denosumab, reduces BMET risk in post-menopausal women with early stage breast cancer, suggesting protective effects may be unrelated to changes in bone turnover. Pre-clinical modeling of dormant, bone-disseminated ER+ breast cancer cells may enhance our understanding and thus our ability to better target these inherently treatment-resistant cells. In studies reported here, a model of bone-disseminated ER+ dormancy was characterized and used to query effects of zoledronic acid (ZA) on dormant cells. When female nude mice were inoculated (intracardiac) with human ER+ MCF-7 cells labelled with DiD, a membrane dye that dissipates with each cell division, DiD-positive tumor cell number in harvested tibial bone marrow remained unchanged from 24 hours to 28 days post-tumor cell inoculation. When 17ß-estradiol (E2) treatment (0.72 mg 60-day pellets) was initiated on D28 following tumor cell inoculation, detectable DiD+ tumor cell number in harvested tibial bone marrow increased 1.8-fold within one week (D35 vs. D28, $p < 0.0001$), consistent with initiation of E_2-stimulated proliferation, and osteolytic, histology-confirmed BMET appeared subsequently with 60% incidence by 6-weeks post-start of E2 treatment. When mice were instead zoledronic acid-treated during the 28d dormancy period (70 ug/kg subcutaneously on D7 and on D21 post-inoculation), DiD-positive cell number in marrow harvested on D28 was reduced by more than half vs. vehicle-treated controls ($p< 0.05$). Moreover, DiD-positive cell numbers on D35, one week after start of E2-treatment, remained unchanged in tibial marrow of ZA-treated mice and were thus substantially (3.8-fold) lower than controls ($p< 0.001$). When followed for 6-weeks after initiation of E2 treatment, no osteolytic BMET were detected in ZA-treated mice. In toto, these results recapitulate clinical findings, thus validating the methodologic approach, and suggest that in addition to reducing dormant ER+ tumor cell burden in bone, bisphosphonates may also alter their estrogen responsiveness. Acknowledgements: Special thanks to undergraduates Alyssa Magee and Geethika Ameneni for assistance with data acquisition, and the METAvivor Foundation and NIH-NCI (NCI R03 CA181893, R01 CA174926, P30 CA023074, T32 CA009213) for financial support.

#4208 In-vitro modeling of Sonic Hedgehog signaling identifies the extracellular matrix as a regulator of tumor invasion outcomes.

E. A. Carrasquillo-Dones[1], H. M. Rosado-Galindo[1], A. M. Reyes-Ramos[1], W. Torres-Garcia[1], S. Cifuentes[1], J. P. Rios-Grant[1], G. Ortiz-Soto[2], N. A. Ramos-Acevedo[1], M. Acevedo-Esquilin[1], M. Colon-Vargas[1], I. Almodovar-Rivera[1], C. Mora[1], M. M. Martinez-Montemayor[2], M. Domenech[1];
[1]University of Puerto Rico - Mayaguez, Mayaguez, Puerto Rico, [2]School of Medicine Universidad Central del Caribe, Bayamon, Puerto Rico

Preclinical models of Sonic Hedgehog (SHH)-driven tumors support the therapeutic benefit of pharmacological inhibitors, yet clinical outcomes are conflicted due to biphasic tumor responses that include complete remission or faster disease progression. In such studies, the activity of the SHH pathway in the tumor-adjacent stroma supported or restrained tumor progression. Our prior studies show that altered SHH ligand levels can lead to faster tumor growth during pharmacological inhibition suggesting a role for the SHH pathway strength in the biphasic tumor responses of a triple-negative breast cancer (TNBC) model. In this study, the role of SHH pathway strength altered by tumor-fibroblast proximity was examined on the tumor growth, invasion, and transcriptional activity using in vitro and in vivo models. Tumor spheroid models composed of TNBC cell lines and fibroblasts were used to monitor SHH signal strength as a function of the culture modality and SHH ligand levels. In vitro, SHH signal strength was altered by tumor-fibroblast proximity and ligand concentration. Mixed cultures exhibited significantly higher SHH activity and reduced invasion than adjacent cultures. This effect was reversed by pharmacological inhibition of SMO, confirming the involvement of an SHH-dependent mechanism. In a tumor xenograft model, tumor metastasis outcomes were suppressed by pharmacological inhibition of the SHH pathway, but opposite results were observed in tumor xenografts composed of co-injected with fibroblasts indicating that the biphasic tumor response can be driven by the fibroblasts. Spatial transcriptional analysis identified extracellular matrix (ECM) activities in fibroblasts as the top altered bioprocesses in both *in vitro and in vivo*. This finding was confirmed in cultures, where fibroblast-derived decellularized matrix stimulated tumor invasion of single TNBC spheroids at levels observed in co-cultures. Further analysis of differentially expressed genes (DEGs) identified a small leucine-rich repeat proteoglycan (SLRP) as the primary ECM target altered by variations in SHH signal strength in fibroblasts. Furthermore, we confirmed the role of SLRP cues in governing tumor invasion potency within spheroid cultures embedded in a collagen hydrogel matrix. While high levels of SLRP in the matrix inhibited spheroid invasion, low SLRP matrix promoted spheroid invasion and increased secondary invasion sites. These findings agreed with the Vimentin expression levels observed in TNBC cells and confirmed the potency of SLRP in regulating tumor invasion outcomes. In summary, our study underscores the significance of ECM remodeling activities in fibroblasts and the role of SLRPs in governing tumor invasion, with implications for understanding the impact of altering SHH signaling activity in TNBC.

#4209 Unraveling the effects of the microenvironment on glioblastoma multiforme invasiveness using a xeno-free 3D hydrogel platform.

A. I. Ferrer Diaz, J. Huang;
TheWell Bioscience, North Brunswick, NJ

Glioblastoma multiforme (GBM) is a grade IV astrocytoma and the most common type of adult brain malignancy. The overall survival of patients diagnosed with GBM is less than 5 years. Therefore, it is imperative to understand the mechanisms contributing to GBM progression, invasiveness, and survival. This study aimed to evaluate the effect of the extracellular matrix (ECM) on GBM cell invasion by performing the traditional invasion assay as well as novel *in vitro* invasion assay strategies. A significant challenge with *in vitro* cell invasion assays is the use of animal-based ECM: the components of animal-based ECM are not characterized; the batch-to-batch variability of animal-based ECM can influence experimental findings and affect potential clinical applications; and the temperature-sensitive operation protocols make the use of animal-based ECM time-consuming and difficult for automated high-throughput assays. These challenges can be circumvented using VitroGel®, a synthetic xeno-free, bio-functional hydrogel resembling the physiological ECM with tunable biophysical and biochemical properties. In this study, we harnessed the properties of the synthetic xeno-free hydrogel system to examine how different mechanical strengths and functional ligands as well as cytokines and serum within the hydrogel matrices or in the outer well, affect GBM cell invasion. The results indicated that adjusting the mechanical strength of the ECM system affects GBM cell invasion. We further showed that the bio-functional ligands within the hydrogel matrix, such as matrix metalloproteinases, RGD peptide, and others, stimulated cell invasion. This finding exemplifies the importance of using a well-characterized ECM system given that it is difficult to evaluate how specific ECM components contribute to cell invasion using the undefined animal-based ECM. Since the composition of the hydrogel system is chemically defined, we could further control the cytokine milieu within the matrix to understand how the ECM composition affects cell migration. To demonstrate this, we added the cytokine TGF-β1 to the hydrogel and examined GBM cell invasion. Indeed, we showed that adding TGF-β1 to the synthetic VitroGel enhanced GBM cell invasion, thus illustrating that incorporating factors inside the matrix is a powerful method to evaluate chemotaxis. Altogether, this study demonstrates the potency and flexibility of using a xeno-free hydrogel for a myriad of invasion assay applications.

#4210 Stromal remodeling danger signals regulate “second-touch” antigenic encounters and promote CD8+ T cell effector differentiation in the TME.

A. Papadas, D. Hong, A. Cicala, A. Gibbons, D. J. Lagal, Y. Huang, Y. Dou, F. Asimakopoulos;
UC San Diego, La Jolla, CA

Tumor immune infiltration (“hot” tumor microenvironment, TME) constitutes a powerful predictor of outcomes and immunotherapy efficacy, however underlying mechanisms remain elusive. Recent evidence shows that TME-repriming of incoming CD8+ T cells is required for full effector functionality. Reminiscent of the “second-touch” hypothesis proposed by Klaus Ley for CD4+ differentiation, tumor-draining lymph node (TDLN) priming (“first-touch”) generates antigen-specific stem-like TCF1+CD8+ T cells. These stem-like CD8+ T cells then migrate to the tumor periphery where “second-touch” antigenic encounters with non-migratory $CCR7^{neg}$ dendritic cells (DC) (importantly, the cross-presenting cDC1 subset) leads to effector CD8+ T cell differentiation and tumor entry. These second-touch encounters occur within specialized stromal niches that are rich in antigen-presenting cells (APC). We have hypothesized that productive APC:CD8+ interactions require stroma-derived signals that emulate provisional matrix remodeling in embryonic development and/or adult wound healing. Thus, stroma remodeling by the expanding tumor translates into a conserved “danger signal” that licenses APC to activate CD8+ T cell responses. We have focused on a prototypical pathway of provisional matrix remodeling, the regulated proteolysis of the matrix proteoglycan versican (VCAN) to generate a bioactive fragment endowed with immunostimulatory activities, versikine. Stromal VCAN proteolysis at the site releasing versikine is associated with T-cell infiltration across human solid and liquid tumors. To investigate the mechanisms by which versikine regulates first- and second-touch antigenic encounters, we dissected the immune microenvironment of versikine-replete tumors of immunocompetent models at single-cell resolution. Non-migratory $Ccr7^{neg}$ cDC1 in versikine-replete tumors overexpress MHC-I and MHC-II antigen presentation machinery (Tap1, Ciita), maturation (Irf7, ISGs, Tlr3) and co-stimulation markers (Cd86, 4-1BBL), while $Ccr7^{pos}$ DC (mregDC) markedly overexpress Cd40 compared to control mregDC. In parallel, Cd4+ Tfh-like cells (overexpressing Cd40lg, Icos and Maf) accumulate in versikine-replete tumors, mirroring the accumulation of CD4+ T-cells in the stroma of human tumors displaying intense VCAN proteolysis. Consequently, versikine-replete tumors demonstrate expansion of late effector CD8+ T cells (Gzmb+Prf1+). Versikine reverses anti-PD-1 refractoriness in the “cold” model, Lewis Lung Carcinoma (LLC). In “warm” tumor models, versikine with anti-PD-L1 suffices to eradicate tumors and establish immune memory with resistance to tumor rechallenge. Our presentation will focus on the mechanistic dissection of stromal signals regulating antigen presentation across models as well as approaches for translation into novel vaccine platforms.

#4212 Mimicking HCC complex biology and diverse treatment response in a patient-derived microfluidic model.

O. Mocellin[1], A. Robinson[1], A. Olczyk[1], S. Treillard[1], T. Olivier[1], C. P. Ng[1], J. Heijmans[1], A. Stok[1], G. van Tienderen[2], M. Verstegen[2], S. Trietsch[1], H. Lanz[1], P. Vulto[1], J. Joore[1], **K. Queiroz**[1];

[1]MIMETAS, Oegstgeest, Netherlands, [2]Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands

Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and is closely associated with progressive stages of liver diseases. Its transformation, survival, progression and metastasis have been associated with regulation mechanisms orchestrated by the tumor stroma. Patient differences in tumor composition and cellular signaling are reflected in the diversity of therapy response. Hence, comprehensive in vitro models that capture patient-specific tumor and stromal components are necessary to elucidate and evaluate anticancer therapy. Patient-derived dissociated HCC cells from eight different patients were combined with tumor-derived fibroblasts and endothelial cells within a microfluidic setup comprising 64 parallel chips in a microtiter plate format. Cultures were challenged with an individual or combinatorial treatment from a panel of tool compounds for 72 hours in an automated setup. We used immunofluorescence and high content confocal imaging to assess the structural and biological interaction between cancer cells and the associated stroma. Viability assessment, artificial intelligence-based vascular morphology characterization and multiplexed chemokine/cytokine release measurements were used to elucidate patient and drug-dependent effects of single or combinatorial treatments. Cellular interaction within the microfluidic platform led to a vascularized tumor construct, with hepatocellular carcinoma aggregates being enveloped and traversed by a lumenized and interconnected vascular plexus, in association with tumor-derived fibroblasts. Compound treatment led to profound differences across the tested parameters, indicating different anticancer effects in conjunction with the biological diversity of the patient material. Finally, morphological assessment revealed distinct compound-induced effects on the tumor's vascular organization. We present a vascularized patient-derived HCC model that includes relevant cellular players of the tumor microenvironment found in vivo. These co-cultures are highly suitable for studying specific cell types as well as patient-specific responses. We envision that this system has the potential to provide a platform for understanding the interplay between different cell types present in hepatocellular carcinomas, with sufficient scalability ease of use for industrial and clinical implementation.

#4213 Multiplex digital spatial profiling of proteins and RNA in MC38 mouse colorectal cancer syngeneic model.

M. Chen, H. Liu, X. Tu, S. Guo, **X. Chen**;
Crown Bioscience, Inc., Suzhou, China

Introduction Characterization of the tumor microenvironment (TME) has become an essential step for the understanding of the complexity of cell interactions and the discovery of biomarkers for prediction and prognosis of immunotherapy response[1]. The NanoString GeoMx® Digital Spatial Profiler (DSP) technology includes the ability to quantitatively assess RNA and protein levels as well as sample multiple user-defined regions of interest, specifically focused on defining heterogeneity and TME interactions[2]. This technology has been widely used to identify biomarkers in clinical surgical specimens, but its applications in preclinical models are still needed. MC38 colorectal cancer syngeneic model is one of the most utilized models for assessing anti-cancer immunotherapies. In this study, we present the spatial profiling of proteins and RNA on MC38 model treated with anti-PD-1 through GeoMx® DSP technology.

Methods GeoMx protein panel was used to detect the target protein expression differential in tumor-rich region and immune-rich region within MC38 subcutaneous tumor sections treated. Mice were treated with vehicle or anti-PD-1 (10mg/kg, BIW x 4 doses, ip). Whole Transcriptome Atlas (WTA) was employed, and then a comprehensive assessment of the data and comparison was performed.

Results Two morphology markers, CD45 and PanCK, were used to separate tumor-rich region and immune-rich region. The GeoMx® protein data showed that the abundance of VISTA in tumor-rich region differed significantly (log2(fold-change) = 0.67, $p < 0.01$) in anti-PD-1 group compared to vehicle group. While in immuno-rich region, GITR was significantly altered (log2(fold-change) = 0.79, $p < 0.05$) in anti-PD-1 group (TGI value = 50.39%). From WTA data, we observed the upregulation of 839 genes, while 1048 genes were downregulated in immuno-rich region in anti-PD-1 group compared with vehicle group ($p < 0.05$). For tumor-rich regions, 550 genes were upregulated while 782 genes were downregulated in anti-PD-1 group versus vehicle group ($p < 0.05$). From the gene set enrichment analysis, we found that interferon alpha and interferon gamma, which are related to tumor immunity and immunotherapy response, were upregulated in anti-PD-1 group.

Conclusion Both the differential expressing genes and proteins in TME of MC38 syngeneic models treated with anti-PD-1 could be well detected by GeoMx® DSP, which has the potential to provide insightful data for use in biomarker discovery in preclinical cancer models.

#4214 Tissue-engineered 3D model for elucidating the role of the bone niche in osteosarcoma therapy response.

A. D. Peasah[1], C. Monette[1], J. Lee[1], M. Tai[1], E. Sweet-Cordero[2], F. Yang[1];
[1]Stanford University, Stanford, CA, [2]University of California San Francisco, San Francisco, CA

Introduction. Osteosarcoma (OS) is an aggressive pediatric bone cancer whose 5-year survival rate has remained stagnant for nearly 40 years, and often exhibits high therapy resistance. Experimental models that can elucidate how the OS bone niche modulates OS signaling and drug response could accelerate discovery of new targeted therapies. Our group has recently reported a biomaterials-based 3D *in vitro* model of OS with bone matrix mimicking cues: a gelatin microribbon scaffold coated with hydroxyapatite particles (GelHA μRBs). We demonstrated this 3D OS model can better mimic *in vivo* signaling and drug responses than standard 2D culture. However, the potential of this 3D model for probing OS-bone niche crosstalk has not yet been investigated. We hypothesize that OS-bone crosstalk will modulate OS drug response and signaling. To test this hypothesis, here we aim to establish a 3D model to assess the effect of tissue engineered (TE) bone on OS drug response and signaling.

Methods. Gel μRBs were fabricated by wet spinning as previously described. To generate tissue engineered bone, human mesenchymal stem cells (hMSCs) were encapsulated (15 M/mL) in GelHA μRBs and cultured in osteogenic medium for 28 days. A PDX-derived OS line (OS052) was used. Three groups were studied: OS monoculture, separate coculture (paracrine only), and OS cells seeded directly on TE bone (paracrine plus direct contact). For all groups, 96K OS cells were seeded per sample. OS cells were labeled with firefly luciferase to allow tracking of OS cell viability and proliferation using bioluminescence. Gemcitabine, a standard chemotherapy drug for OS, was used as the model drug (0.001 to 1 uM). Outcome analyses include cell viability, proliferation, gene expression, and immunostaining.

Results. TE bone enhances OS resistance to gemcitabine in both separate coculture and direct seeding on bone, as shown by bioluminescence. At 1 uM, OS cell death in monoculture, separate coculture, and seeding on bone was on average 98.19%, 82.05%, and 64.44%. These results indicate that both paracrine signaling from osteoblasts and direct contact with bone ECM contribute to OS drug resistance. TE bone did not significantly impact OS proliferation over 7 days as shown by bioluminescence. Ongoing studies will assess the effect of TE bone on OS expression of key proteins in the bone niche (RANK/RANKL/OPG) and OS response to cabozantinib, a cMET inhibitor whose antiproliferative effect may be osteoblast-mediated.

Conclusions. Here we report a tissue engineered 3D model to study the crosstalk between OS cells and bone niche. The results support our hypothesis that bone niche contributes to OS drug resistance, which is mediated through both paracrine signals and ECM. This model can be used to further elucidate the mechanisms through which the bone niche influences OS progression and drug resistance, and for screening potential drug candidates that target such crosstalk.

#4215 Single-cell proteomic characterization of the tumor microenvironment in humanized NOG-EXL patient-derived xenograft (PDX) models.

D. Stueckmann[1], J. Meens[2], S. Zhang[2], S. Hui[2], S. Sivapatham[3], S. Chevrier[3], J. Pfeil[1], L. Martin[2], M. Komisarenko[2], P. Dube[4], S. Prendeville[5], H. Jackson[1], A. Finelli[2], G. Bader[1], B. Bodenmiller[3], K. A. Lawson[2], L. Ailles[2];

[1]University of Toronto, Toronto, ON, Canada, [2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada, [3]University of Zurich, Zurich, Switzerland, [4]Taconic Biosciences, Inc., Rensselaer, NY, [5]University Health Network, Toronto, ON, Canada

Introduction:

$CD34^{+}$ hematopoietic stem cell (HSC) derived humanized mice engineered to express human cytokine transgenes are promising models for the evaluation of novel immunotherapeutic treatments. While flow cytometry-based analyses have confirmed the presence of many human immune cell populations within humanized mice bearing patient-derived tumor xenografts (PDX), comprehensive high-dimensional immunophenotyping of the tumor microenvironment (TME) of these models remains limited. Beyond this, the relative influence of PDX vs. donor CD34+ HSC populations on TME composition is poorly understood. Here, we characterize the quantity and diversity of immune cell subpopulations in the TME, bone marrow, and spleen of humanized NOG-EXL (huNOG-EXL) mice using Cytometry by Time-Of-Flight (CyTOF) data with > 60 features.

Methods:

We performed CyTOF analysis on 250 dissociated samples from primary tumors (n = 15; n = 6 head and neck cancer, n = 6 ovarian cancer, n = 3 renal cell carcinoma), as well as xenograft (n = 59), spleen (n = 88), and bone marrow (n = 88) samples from huNOG-EXL mice (Taconic). Each sample was profiled with two partially overlapping antibody panels; an innate immunity-focused panel (40 features), and an adaptive immunity-focused panel (40 features).

Results:

CyTOF data were collected from over 10 million live immune cells for each of the adaptive and innate antibody panels. Unbiased clustering of single-cell marker expression revealed clusters corresponding to all major lymphoid and myeloid cell types. Therapeutically relevant cell states were identified including exhausted CD8+ T cells marked by PD-1 and Tim-3 expression, and PD-L1+ macrophages. Hierarchical clustering of bone marrow and spleen samples suggested that systemically, immune composition was not driven by tumor-intrinsic factors alone with many samples clustering on the basis of CD34+ stem cell donor ID. Conversely, clustering PDX samples revealed strong consistency in xenografts originating from the same primary tumor sample regardless of the chosen stem cell donor. The immune composition of primary tumor samples showed greater similarity with matched PDX samples versus unmatched PDX samples, further supporting that tumor-intrinsic factors drive immune composition in xenografts.

Conclusions:

We provide a high-resolution characterization of the immune phenotypes present in huNOG-EXL PDX models across three cancer types. These data captured substantial heterogeneity in the immune composition of humanized xenograft samples, and we demonstrate that immune composition in humanized xenografts is strongly driven by tumor-intrinsic features. Overall, this resource data supports the use of these models for immuno-oncology studies with future work focused on functionally validating specific immune cell populations of interest.

#4216 Indication agnostic evaluation of CAR T cell function using patient-derived immunocompetent tumoroid modelling platform.

D. O. Ochola[1], H. Dell mundo[1], P. Samuel[1], N. Korkorina[2], **B. Dave**[1];
[1]Spanios, Houston, TX, [2]SNAP Biolabs, Houston, TX

Introduction: Engineered T cells redirected towards tumor-specific cytotoxicity is a promising immunotherapeutic modality that has been well characterized for efficacy against B cell malignancies and evaluated in multiple tumor types. However, the development and optimization of CAR T cell therapies requires a rigorous preclinical model for the evaluation of CAR T cell function, tumor killing, cytokine production, and memory responses.
Experimental Procedure: We are evaluating our model platform Custom Organoid Modelling Platform for Accurate and Speedy SolutionS (COMPASS 2) as a comprehensive platform for testing developmental and functional stages of CAR T cells including activation, memory, and exhaustion. We are performing qualitative and quantitative analyses of surface markers to recapitulate the complexity of human cancer. Additionally, since CAR T cells mediate crosstalk with other immune components in the TME, we also evaluate and monitor the presence of B cells, NK cells, macrophages, and endogenous T cells. Triple Negative Breast Cancer (TNBC); Immunophenotyping (IP); Immunofluorescence (IF); Fluorescence Activated Cell Sorting (FACS); T regulatory (Treg).
Summary of Results: Our evaluation of COMPASS 2 for functional testing of CAR T cells demonstrates the feasibility of the platform in preclinical CAR T cell evaluation. We showed T cell infiltration and analyzed cytokine production that may alter tumor cells and TME. Crosstalk with other immune cells will be evaluated. We are currently evaluating the tumor volume changes using an EGFRvIII-targeted CART cell therapy on TNBC model systems, followed by apoptosis and EGFR analysis using FACS.
Conclusion: Our COMPASS 2 model platform enables studies that require recapitulating hurdles to CAR therapy, including antigen escape, T cell dysfunction and trafficking; to reveal an essential role of the endogenous immune response mediating the antitumor effect following CAR therapy.

#4217 An engineered breast tumor microenvironment model, with single-cell spatial resolution, to assess spatial dynamics of tumor evolution.

H. R. Helms, K. A. Oyama, A. E. Davies, E. M. Langer, L. E. Bertassoni;
Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Cellular heterogeneity is a prominent feature of the tumor microenvironment, and the organization of these cells has been linked to clinical outcomes such as disease progression and drug resistance. While retrospective analysis of patient tumors has produced a myriad of insights, samples are limited and highly complex making it challenging to validate causality. Here we present an engineered breast tumor microenvironment model, with single cell spatial resolution, to systematically identify which cell phenotypes and their spatial arrangements may be driving ductal carcinoma in situ disease progression. A microfluidic dispenser (Biopixlar, Fluicell) was optimized to enable the spatial patterning of single cells to replicate native histology. To demonstrate the high spatial precision of our method, we first replicated an annotated 2D section of a breast tumor biopsy region of interest (ROI) using MCF10A, MDA-MB-231, primary mammary fibroblasts, THP-1 derived macrophages, and primary mesenchymal stem cells. The XY coordinate of each cell was identified to create a print map matching the original biopsy. Deposited cells adhered to their intended target with an average print fidelity of 2.4 µm. Next, the stromal compartment of the ROI was altered to include phenotypes associated with tumor promoting microenvironments (i.e. cancer associated fibroblasts, M2 macrophages) and the core of the MCF10A ring filled with MDA-MB-231. Each deposited cell contained a fluorescent tag corresponding with its cell type to facilitate real time spatial tracking and annotation. The tumor microenvironments were live cell imaged for 24 hours at 5 minute intervals. MCF10A cells spread to form their junctions and create a cohesive ring, MDA-MB-231 cells proliferated and rapidly moved around within the confined space, and the cells of the stromal compartment spread to create a dense tissue like structure. The microenvironments were cultured for an additional 2-6 days, fixed, and stained for markers of proliferation, phenotype shifts, cell-cell junctions, and morphology. Unlocking the relative contributions of the specific cell types in ductal carcinoma in situ tumor microenvironment to the overall evolution of invasive breast cancer may hold the answer for many questions in early detection, treatment, and cancer avatar models.

#4219 Establishing CAF-like and TAM-like transformation induced by TNBC culture supernatant in 3D in-vitro culture as a model for targeted drug testing.

B. Sapkota[1], N. Chintalaramulu[1], A. Pandit[1], S. Thota[1], R. Begum[1], A. Mansouri[2], J. Adamec[2], J. Francis[1];
[1]Louisiana State University, Baton Rouge, LA, [2]Louisiana State University Health Sciences Center, New Orleans, LA

Several previous studies have highlighted the significance of cell-to-cell communication, or crosstalk, between tumor cells and non-tumorigenic cells in the context of cancer progression and metastasis. Within the tumor microenvironment (TME), these interactions have the potential to alter the phenotypes and behaviors of normal cells. The use of 2D in-vitro cultures has been limited due to their inability to accurately replicate the intricate in-vivo TME. Conditioned medium (CM) derived from cultured cancer cells contains secreted factors that may influence the phenotype and functionality of normal cells. In our investigation, the exposure of normal murine fibroblast NIH3T3 and macrophage RAW 264.7 cells to conditioned medium (CM) obtained from malignant mammary epithelial 4T1 cells (4T1CM) resulted in a modified phenotype with enhanced cell viability. Treatment with 4T1CM led to the upregulation of genes, including α-smooth muscle actin (αSMA), IL-10, CD206, and vascular endothelial growth factor (VEGF), in NIH3T3 and RAW 264.7 cells compared to their respective control cells. Additionally, NIH3T3 cells treated with 4T1CM exhibited an epithelial-mesenchymal transition (EMT) phenotype, as indicated by the regulation of EMT markers such as E-cadherin, β-catenin, N-cadherin, and Vimentin. Notably, RAW 264.7 cells treated with 4T1CM showed an upregulation of cyclooxygenase-2 (COX-2) and programmed death-ligand 1 (PDL-1), suggesting a propensity for an inhibitory immune response. Moreover, NIH3T3 cells conditioned with 4T1CM demonstrated an upregulation of stemness markers, including sex determining region Y-box 2 and Aldehyde dehydrogenase. In summary, our study highlights the potential role of 4T1CM in transforming normal NIH3T3 and RAW 264.7 cells into cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs). Ongoing proteomics analysis aims to map differentially expressed proteins potentially regulating the 4T1CM-induced transformation. To further investigate, a series of experiments using mono- and co-cultures of these cells are underway, specifically targeting the transformed macrophages and fibroblasts with the aim of either re-educating or eliminating them. This treatment involves drug combinations that specifically target the identified signaling pathway intermediates, offering novel therapeutic intervention strategies.

#4220 Combined light sheet and multispectral imaging facilitates the detection of tumor-associated tertiary lymphoid structures in the KP NSCLC model.

N. O'Brien[1], B. Appelt[2], M.-L. Moerbitz[2], J. P. J. Mueller[1], F. Herting[1], P. Umana[2], C. Murgia[2], S. Colombetti[2], T. Poschinger[1];
[1]Roche Diagnostics GmbH, Penzberg, Germany, [2]Roche Glycart AG, Schlieren, Switzerland

Tertiary lymphoid structures (TLS) have recently emerged as a predictive biomarker in cancer immunotherapy. Their consideration in preclinical drug development is impeded by rare and transient appearance and random distribution, making them difficult to analyze with conventional sampling methods. We applied whole-organ tissue clearing and 3D staining of B and T cell clusters to comprehensively identify TLS in a KP GEMM of NSCLC using 3D Light Sheet Fluorescence Microscopy (3D LSFM). To further investigate cellular composition of TLS we performed 3D LSFM-educated sectioning of relevant ROIs and cyclic immunofluorescence of the same samples. 3D LSFM facilitated correlation of tumor features and location with T cell infiltration as well as the analysis of number, size and location of TLS. The majority of TLS were located in proximity to bronchi instead of intratumorally. LSFM-guided multiplex immunofluorescence revealed further details on cellular composition and maturation status of TLS. This combination of 3D and 2D imaging modalities offers a holistic approach for the identification of TLS in whole murine tumors or organs. The technology could help studying effects of immunotherapy on de novo formation or maturation of TLS.

#4221 Characterization and comparison of hypoxia inducing factors on tumor growth and metastasis in 2D and 3D tumor models.

J. McDonald[1], L. L. Chan[1], S. Kessel[1], B. Lin[1], P. Weingarten[2],

[1]Revvity Health Sciences, Inc., Lawrence, MA, [2]ImmunityBio, Culver City, CA

The monocarboxylic acid transporter 4 (Mct-4), a downstream biomarker of hypoxia inducing factor (HIF)-1α, is involved in the cellular response to hypoxia, as indicated by the hypoxic response element in its promoter region. Using a tumorsphere assay as an in vitro 3-dimensional (3D) model generated using 384-well ultra-low attachment (ULA) plates for cell proliferation analysis using a plate-based image cytometer, we identify a hypoxic response in the tumorsphere model that is distinct from that of cells grown under 2-dimensional (2D) normoxic conditions and demonstrate a key role for Mct-4 in enabling 3D growth. The tumorsphere model yields evidence of an essential role for Mct-4 in multiple cell lines which were genetically modified to underexpress and overexpress Mct-4, evidence not apparent in a standard 2D model of growth in the same cell lines. In addition, we identify the effects of overexpressing Mct-4 in cancer cell migration using a transwell chamber assay. We also show that the response to hypoxia may be circumvented by transfection with a CMV promoter driven Mct-4, which confers constitutive 3D growth, wherein tumorsphere growth inhibition by small molecule HIF-1α inhibitors is mitigated. Finally, we demonstrate quantifiable gene/protein expression differences between 2D and 3D cancer models based on the normoxic and hypoxic conditions. Therefore, the tumorsphere 3D model generated using 384-well ULA plates in combination with high-throughput image cytometer is demonstrated to provide a convenient, robust, and reproducible tool and method for the elucidation of mechanisms of action underlying tumor growth and migration in the hypoxic tumor microenvironment.

#4223 The dual immunestimulatory and immunesuppressive role of MRC5 fibroblast cells in 3D coculture with T cells and tumor cells.

I. Arnkil, C. Hekim, E. Narvi, E.-L. Ihantola, E. Elbasani, A. Thotakura;
Immuno-Oncology, Oncology R&D, Orion Corporation, Turku, Finland

Introduction: Cancer-associated fibroblasts (CAFs) alter anti-tumor immune responses and modulate resistance to immune checkpoint inhibitors. The mechanisms of crosstalk between tumor cells, CAFs, and T cells remain not fully understood, and studying these multicellular interactions requires adoption of novel tools in preclinical research. Here, we established a spheroid co-culture model comprising of tumor cell lines, a fibroblast cell line, and primary human T cells, for studying the immunomodulatory effects of fibroblasts on T cell responses *in vitro,* in the context of immunotherapies.
Methods: For setting up the 3D co-culture, A375 or OV-90 tumor cells were seeded alone or with MRC-5 fibroblasts in 96-well ultra-low attachment round bottom plates in complete growth medium supplemented with 1% Geltrex matrix. The cells were centrifuged, and spheroids were allowed to form for 24 hours. After spheroid initiation, activated T cells and treatments with anti-PD1 antibody or an immune stimulatory drug were added. Spheroid co-cultures were live imaged by Incucyte SX5 for 72 hours taking images every 4 hours, after which treatment responses were evaluated by flow cytometry and measuring IFN-γ accumulation with ELISA.
Results: To mimic fibroblast and T cell interactions in tumor microenvironment we built and optimized an *in vitro* 3D co-culture assay using various tumor cell lines. With this assay we found that depending on the tumor cell interaction, fibroblasts MRC-5 cell line have either immune-suppressive or immune-promoting properties. IFN-γ secretion of T cells in the assay indicated that MRC-5 cells suppressed T cells when co-cultured with A375 cells, while with OV-90 cells T cells activation was enhanced. In addition to the IFN- γ secretion, T cells in MRC-5 OV-90 interaction significantly upregulated 4-1BB expression on both CD4 & CD8 T cells. Interestingly we noticed that MRC-5 fibroblasts could modulate T cell responses to anti-PD-1 treatment in the co-culture depending on the tumor cell used.
Conclusion: Here, we established a spheroid co-culture model, which will allow studies of the immunomodulatory crosstalk occurring in tumor microenvironment. Our model revealed a bifunctional role of MRC-5 fibroblasts in altering T cell phenotype. This finding is in line with literature highlighting the ability of fibroblasts to act as either tumor promoters or tumor suppressors depending on tumor microenvironment. We believe that this model, would aid in elucidating mechanisms of interaction between CAFs and T cells, potentially leading to discoveries of novel targets for immuno-oncology drug development. Additional studies, such as gene expression analysis using single cell RNA sequencing, are warranted to further validated the model and to better understand the kinetics of these interaction occurring in the co-culture with various tumor cell lines.

#4224 The application of sophisticated image analysis to a T cell killing assay in 3D deciphers the dynamics of the different components of the tumor microenvironment.

R. Kerwin[1], I. Rohleff[2], M. Blanchard[1], K. Lashuk[2], B. Walker[1], **J. B. Schueler**[2];
[1]Animantis, San Diego, CA, [2]Charles River Laboratories, Inc., Freiburg, Germany

We developed an in vitro protocol to generate tumor-specific cytotoxic lymphocytes (CTL) by priming T cells from healthy donors on HER2+ breast cancer cell line SKBR-3. Subsequently, these primed CTLs were tested in a 3D immune cell killing assays in a life cell imaging device. An image analysis workflow was applied to understand the T cell movement in spatial relation to the tumor and the kinetic of tumor cell killing. The activity of the CTLs was compared with non-activated CD8+T cells, staurosporin and CD8+ T cells, unspecifically activated by αCD2/αCD3/αCD28 beads. The tumor cells were expressing mKate whereas the T cells were label-free. By analyzing a combination of different masks, we could computationally measure tumor spheroid characteristics and dynamic attributes such as changes in shape, percent of cells expressing red fluorescentce, and relative average distance of T cells from the spheroid in each timelapse assay. This process was applied at each frame to determine the average T cell distance from its corresponding spheroid center and subsequently calculate the average T cell flux over the course of each assay by linking data between image frames. Additional measurements allowed for the quantification of tumor debris accumulation over time both relative to the primary tumor mass and in absolute terms. Our analyses revealed that bead-activated T cells approached the tumor spheroid with the highest speed and infiltrated the spheroid homogeneously. In contrast the CTLs approached the spheroid slower and started tumor cell killing from the rim of the spheroid towards the center. The reduction of spheroid area over time displayed a very similar kinetic when co-cultured with CTL or bead-activated T cells. At the end of the experiment the CTLs induced a more pronounced shrinkage of spheroid size. Interestingly the size of the spheroid and the red fluorescence intensity were not necessarily aligned. The positive control Staurosporin induced a fast reduction of the mKate signal, whereas the spheroid area did not change over time. In summary, the bead-activated T cell approached the spheroid fast, infiltrated the complete area and induced tumor cell killing homogenously across the tumor area. The CTL approached the spheroids slower but started killing earlier from the outside towards the center of the spheroid. The observed differences in infiltration and killing characteristics of the investigated T cell types lead to a better understanding of T cell biology in the context of the tumor biology, which can be translated into applications during dug development. Taken together, with the applied image analysis algorithm we were able to deconvolute the biological processes in the assay in much more detail. The additional read-outs increase the translational value of the assay tremendously in the context of drug development as well as precision medicine.

#4225 Analysis of the landscape of cancer-associated neurons (CANs) in diverse cancers through retrograde tracing and single cell molecular profiling.

V. Thiel, S. Renders, J. Panten, Daniel Azorin, Nicolas Dross, Albrecht Stenzinger,Sebastian Scholch, Frank Winkler, M. Sprick, A. Trumpp;
German Cancer Research Center, Heidelberg, Germany

Hyperinnervation emerges as a common hallmark in the tumor microenvironment (TME) of most cancers, with clinical studies establishing a direct link between increased innervation and poor prognosis. Despite the acknowledged pivotal role of the TME, previous molecular profiling excluded tumor-infiltrating neurons due to the unique anatomical characteristics of peripheral neurons. While their axons extend into tumor masses, their DNA- and mRNA-containing cell bodies reside in adjacent ganglia, rendering them absent from virtually all large data sets analyzing tumor material. To fill this critical gap of the role of neurons for cancer growth, therapy resistance and metastasis, we developed a multi-layered approach to unravel the molecular basis of the neural influence in a.o. pancreatic (PDAC), colon cancer and melanoma including their metastasis. First, we unveiled a complex neural network within tumors and metastases through tissue clearing and 3D imaging of patient-derived xenografts, GEMMs, and human samples. This approach was complemented by the introduction of 'Trace-n-Seq,' a novel methodology integrating retrograde axonal tracing, FACS analysis, and single-cell RNA sequencing of neurons innervating both healthy organs and tumors. Expanding this technique unveiled the molecular profiles of over 3000 individual sympathetic, parasympathetic, and sensory neurons infiltrating various tumors, metastases, and pancreatitis, which were compared to neurons innervating healthy organs. Thereby we identified novel neuronal subtypes and observed tumor-induced neuronal reprogramming. Our single-cell data, when integrated with scRNA sequencing of PDAC, unveiled comprehensive neuronal interactions. An interactome analysis identified key genes in tumor/stroma-nerve signaling. To address the functional consequence of hyperinnervation of PDAC tumors, we show data demonstrating that surgical or pharmacological denervation of tumors caused a reduction in tumor size, concomitant with diminished stromal and increased immune compartments. Our data also suggest that the anti-cancer activity of paclitaxel -not oxaliplatin- was partially dependent on its ability to directly target CANs. In fact, in a neoadjuvant setting, PDAC patients treated with Gemcitabine/nab-paclitaxel, but not FOLFIRINOX, displayed a reduction in neuronal structures, underscoring the clinical significance of these observations. In summary, our comprehensive approach has elucidated the role of neurons in PDAC, melanoma, pancreatitis, and metastasis, leveraging innovative tools for studying the molecular programs of CANs at the single-cell level. These insights not only unveil novel mechanisms orchestrated by neuronal activity but also pave the way for imminent clinical trials, aiming to combat PDAC by targeting cancer-associated neurons.

#4226 Human-derived hydrogels for 3D models of bone and osteosarcoma organoids and adipose tissue interactions.

C. G. Sanchez[1], A. Raz[2], H. Lassiter[1], T. Frazier[1];
[1]Obatala Sciences, Inc., New Orleans, LA, [2]Tulane Medical School, New Orleans, LA

The goal of the study was to determine the metabolic and morphological changes, via high Content Imaging, in 3D models of osteosarcoma cancer cells using human derived hydrogels with different protein composition, Obagel and Obagel ECM. Furthermore, we evaluated the relevance of the adipose tissue microenvironment in Adipose Derived Stem Cells (ADSC) linage and Tumoroids development.
Methods: Adipose derived Stem cells were cultured in a modified 3D human and fat and bone linage differentiation as studied via histology and Immunofluorescence. Osteosarcoma spheroids were cultured in Obatala Sciences' human-derived hydrogels ObaGel and ObaGelECM and control media. Organoid structure and phenotypic changes were analyzed via live cell imaging on the Incucyte S3 and Nikon high content imaging device. Then, adipocyte-cancer cell crosstalk was evaluated using pooled adipocytes co-cultured with KHOS spheroids. Adipose derived Stem cells were cultured in a modified 3D human derived hydrogel dictates that promotes the differentiation potential toward fat and adipose tissue simultaneously in microenvironments within the organoid. Furthermore, the results demonstrated that ObaGel and ObaGel-ECM 3D cultures can support the growth and proliferation of KHOS tumor spheres during an extended culture period. Metabolic changes and phenotypic changes associated to ObaGel and ObaGel-ECM differentially facilitated tumoroids growth and migratory behavior.
Conclusions: Human derived hydrogels are developed to support 3D culture of Bone and Osteosarcoma cells to recapitulate the phenotypic changes associated with their metastatic potential. The use of human derived 3D culture systems can accelerate the understanding of the role of the microenvironment in bone development and the pathogenesis and progression of Cancers like Osteosarcoma as well as screening for drug development.

#4227 Human-derived hydrogels to support phenotypic changes in ER+ breast cancer cell line.

C. G. Sanchez[1], K. Hamel[1], E. Rogers[1], J. Robinson[1], H. Lassiter[1], T. Frazier[1], C. Williams[2];
[1]Obatala Sciences, Inc., New Orleans, LA, [2]Xavier University, New Orleans, LA

Adipose tissue plays a critical role in breast cancer incidence, progression, and response to therapy. The development of human derived 3D culture systems can accelerate the understanding of the role of environmental factors in the progression of Breast cancer as well as a model for preclinical studies during drug development. MCF-7 spheroids were cultured in Obatala Sciences' Obavate and human-derived hydrogels ObaGel® and ObaGel®-ECM and control media. Organoid structure and phenotypic changes were analyzed via live cell imaging on the Incucyte S3. Migration studies were performed and gene expression analysis of EMT markers. Finally, adipocyte-breast cancer cell crosstalk was evaluated using pooled adipocytes co-cultured with MCF-7 spheroids. The results demonstrated that ObaGel® and ObaGel®-ECM 3D cultures support the growth and proliferation of MCF-7 tumorspheres during an extended culture period. In addition, MCF-7 cells exhibit the characteristic morphology of tumorsphere-forming cells when cultured in Obavate, with morphological changes in the ObaGel® and ObaGel®-ECM 3D. ObaGel® and ObaGel®-ECM differentially supports MCF-7 migratory behavior and phenotypic changes characteristic of EMT. Conclusions: Human derived hydrogels are developed to support 3D culture of breast cancer cells and to recapitulate the phenotypic changes associated with their metastatic potential. Furthermore, the use of a human derived 3D coculture system provides a platform for the understanding of adipose tissue-breast cancer cell interactions as it relates to breast cancer initiation, progression, and treatment response. Defining these interactions will support the development of a tool for future use in patient stratification and precision medicine in identifying underlying causes of breast cancer progression and response to treatments.

TUMOR BIOLOGY: Organoid Models of Cancer 2
Poster Session

#4230 Patient-derived tumoroid platforms with progressing tumor microenvironment representability reveals efficacy and resistance patterns in pre-clinical HSP90i regimen testing for improved clinical insights.

H. Del Mundo, D. O. Ochola, **B. Dave**, P. Samuel;
Spanios, Houston, TX

Introduction: Drug candidates advance to phase I clinical trial after rigorous optimization at preclinical stage and yet nine out of ten drug candidates fail during clinical trials and approval stage. Lack of clinical efficacy is a major contributor (~ 50%) towards this 90% of the failure at clinical trials. Tremendous efforts are being taken to demonstrate drug efficacy in preclinical studies by mitigating the biological discrepancy of molecular target between human disease and the model used for the validation. Herein this study, we aim to showcase therapeutic responses of heat-shock protein 90 (HSP90) inhibitor regimens (HSP90i only and HSP90i + Doxorubicin combination) against three-dimensional (3D), patient-derived tumoroid (PDT) model platforms with progressing tumor microenvironment (TME) representability by incorporating supplementary TME structure, immunity, and oxygenation. Revelations on efficacy and resistance patterns of such drug treatments on increasingly complex models is aimed at providing unique insights to tumor and drug-drug interplay.
Methods: Human Uterine Adenosarcoma PDT models were prepared across three COMPASS (Custom Organoid Modeling Platform for Accurate SolutionS) platforms: 1) COMPASS 1a - Non-scaffold 2) COMPASS 3b - Scaffold + Immune cells and 3) COMPASS 3d - Scaffold + Immune cells + Oxygenation. The various platforms were tested against two regimens A) HSP90i only [50 nM and 100 nM] and B) HSP90i [50 nM and 100 nM] + Doxorubicin [50 nM]. Tumor size and volume assessment were carried out on Days 3 and 7 post-treatment -with statistical done via one-way ANOVA, followed by student's t test for significance ($p<0.05$, n=3).
Results: While a simpler platform COMPASS 1a showcased the therapeutic efficacy of monotherapeutic HSP90i [at 100 nM] ($p<0.05$), progressively complex models (COMPASS 3b and COMPASS 3d) have otherwise indicated the lack of significant tumor volume changes. On the other hand, current findings on combination therapies of HSP90i and Doxorubicin have revealed persistent therapeutic resistance (even suggestive of patterns of increasing tumor growth) on COMPASS 1a, necessitating further comparisons on the more complex models.
Conclusion: Our results demonstrate the need to test drugs in context of TME and oxygenation to help stratify patients to develop better clinical trials based on patient tumor characteristics of vascularization and immunogenicity. We plan to test several different drug modalities and cancer types for these parameters to demonstrate the need and effectiveness of testing prior to taking the drugs to the clinic.

#4231 A biobank of bladder cancer organoids as a platform for screening new therapeutic approaches.

Emilie Decaup[1], Claire Beraud[1], Anne Sophie Bajeot[2], Xavier Game[2], Nicolas Monjotin[1], Pascal Rischmann[2], Philippe Lluel[1], Mathieu Roumiguie[2]

[1]Urosphere SAS, Toulouse, France,[2]CHU Toulouse, Toulouse, France

In patients with bladder cancer (BC) immune therapies have recently demonstrated an improvement for overall survival rates compared to chemotherapy alone. However, several challenges persist and it remains an unmet need to develop novel therapeutic strategies. Organoids have emerged as a promising animal-free tool revealing patients' heterogeneity and allowing large preclinical therapeutic screening. Urosphere developed a BC organoids biobank with phenotypic, pharmacological and molecular characterization. The aim of this study was to demonstrate the relevance of our organoids models and their use for validation of therapeutic approaches such as targeted or CAR-T cell therapies using EGFR as target. Molecular characterization of the organoids was performed by exome and whole transcriptome sequencing. Cell architecture and differentiation were assessed by labeling cytokeratins (CK) 5, 17 and 20, and uroplakin 3 (UPK3). Proliferation and tumor status were validated with Ki67 and GATA3, respectively. To evaluate targeted-therapy, organoids were treated with erlotinib for 5 days and cell viability was measured with CellTiter-Glo3D® (CTG) assay. To validate CAR-T cell approach, organoids were co-cultured with anti-EGFR or control anti-CD19 CAR-T cells at 4 effector:target ratios. Cell viability was measured with CTG and Caspase-Glo® 3/7 3D assays. Pro-inflammatory and granzyme B release were analyzed by Luminex® assay. Phenotypically, organoids showed proliferating structures whose tumor status was confirmed by GATA3 expression. Cellular heterogeneity present in original tumors was also found, with differential expression of CKs showing the presence of basal (CK5/CD17) and/or differentiated superficial (CK20/UPK3) cells. Organoids from 2 models with high transcriptomic EGFR expression were selected and protein expression was confirmed by immunofluorescence. For targeted therapy, erlotinib presented significant efficacy in both models with a better activity in the model presenting the highest EGFR expression. After 48h of co-culture with anti-EGFR CAR-T cells, a decrease of cell viability associated with an increase of apoptosis was observed. After 72h of co-culture, an increase in the secretion of pro-inflammatory cytokines (IFN-γ and TNF-α) and granzyme B by anti-EGFR CAR-T cells was also observed. In co-cultures with organoids higher expressing EGFR, CAR-T cells activation appeared higher compared to those co-cultured with organoids lower expressing EGFR. Organoids reproduce characteristics of the tumor from which they are derived, making them a predictive preclinical model. In an EGFR targeting approach, the use of organoids to evaluate both targeted- and CAR-T cell therapies was validated with concordant results. This robust translational model is fully transposable to other therapeutic approaches, whether in a traditional culture model or in a co-culture system.

#4232 Exploring chemotherapy resistance in pancreatic cancer: Insights from a 3D organoid model.

H. Lee;
Yonsei University College of Medicine, Seoul, Korea, Republic of

Pancreatic cancer is marked by a dismal prognosis, with a 5-year survival rate at approximately 10%. A key contributor to its lethality is the development of chemotherapy resistance, followed by early metastasis. However, studies elucidating the mechanisms behind chemotherapy resistance in pancreatic cancer are limited. Previous research has relied on 2D cell line models, which present limitations, such as uniform cell types that fail to capture tumor heterogeneity and an inaccurate representation of clinical realities, wherein resistance often develops gradually rather than through continuous exposure to high drug concentrations. In this study, we developed a more sophisticated organoid model of chemotherapy resistance. Six organoids from three patients were matched to study chemotherapy resistance in a personalized context. Comprehensive whole-exome sequencing and transcriptomic analyses were performed, along with an examination of chemotherapy resistance protein expression and EMT-related markers. Notably, differential expression levels of CK19 and Vimentin were observed between samples. Our analysis also focused on the expression of the ATP-Binding Cassette Subfamily G Member 2 (ABCG2) gene in chemoresistant organoids. Western blot analysis indicated a significant increase in ABCG2 expression in these organoids compared to controls. According to the Moffitt RNA signature, the primary and corresponding chemoresistant organoids retained their molecular subtype classifications both before and after developing chemoresistance. Gene set enrichment analysis uncovered significant upregulation of pathways related to DNA repair and cell cycle regulation, particularly the G2M checkpoint, in chemoresistant organoids. Furthermore, gene ontology functional analysis suggested a notable overrepresentation of activities related to amino acid transmembrane transport and extracellular matrix constituents, underscoring their potential role in the chemoresistance phenotype.

#4233 Rapid and robust generation of ex vivo tumoroid samples from fresh patient samples in a serum-free, conditioned medium-free system.

C. Paul, A. Bullock, A. Chatman, B. Balhouse, C. Yankaskas, P. Shahi Thakuri, M. Dallas, D. Kuninger;
Thermo Fisher Scientific, Frederick, MD

Functional precision oncology describes a method in which an individual patient's cancer cells are tested for response to various treatments ex vivo to aid in therapy selection. In many cases, these cultures take the form of tumoroids, which are 3D, patient-derived "mini tumors" that retain phenotypic and genotypic characteristics of the patient cancer. While interest in functional precision oncology is increasing due to strong correlation between patient responses and those experimentally observed using matched tumoroid models in the literature, a lack of standardization has precluded its widespread translation to clinical settings. To study the ability to generate short-term tumoroid cultures using a commercially available, serum-free, and conditioned medium-free system, we processed fresh tumor resection samples and performed culture in Gibco™ OncoPro™ Tumoroid Culture Medium. Tumor resection samples spanning a variety of indications were stored in supplemented Hibernate™-A Medium (including antibiotics) and shipped overnight on gel packs to a central tissue processing site. Samples were minced, enzymatically dissociated, and counted. Average yields of ~2000-12,000 cells per mg of tumor resection tissue were observed, with lower yields in lung, head and neck, and breast cancer samples and higher yields in endometrial and colorectal cancer samples. Donor-to-donor variability generated a wide range of yields within a given indication. Similarly, cell viability following dissociation ranged widely, reaching as low as 20% for some samples and exceeding 90% for others. Though yields and initial viability varied, dissociated cells that were plated in OncoPro Tumoroid Culture Medium formed tumoroids in >85% of samples within 7 days of tissue receipt. Both mutational profiles and gene expression patterns were highly conserved (>90%) between initial tumor samples and cells cultured in OncoPro for 7 days. Computational approaches designed to identify cell-type specific signatures from bulk RNA sequencing data indicated that immune cell population signatures were present after one week in OncoPro medium. Additionally, we have developed methods to analyze tumoroid response to compounds and candidate cell therapies by both plate reader- and imaging-based analyses using ~1.2e6 initial tumor cells per 96-well plate. Due to the high success rate of tumoroid formation from fresh tumor samples and retention of donor-specific characteristics in OncoPro Tumoroid Culture Medium, we believe that it will be a valuable tool for functional precision oncology of solid tumor samples.

#4234 Personalized therapeutic screening in patient derived organoids for gastroenteropancreatic neuroendocrine tumors.

Steven D. Forsythe[1], Srujana V. Yellapragada[1], Stephen G. Andrews[1], Jaydira del Rivero[2], Jonathan M. Hernandez[3], Naris Nilubol[1], James P. Madigan[1], Samira M. Sadowski[1]

[1]Neuroendocrine Cancer Therapy Section, National Cancer Institute, Bethesda, MD,[2]Developmental Therapeutics Branch, National Cancer Institute, Bethesda, MD,[3]Surgical Oncology Program, National Cancer Institute, Bethesda, MD

Introduction Gastroenteropancreatic Neuroendocrine Neoplasms (GEP-NENs) are a rare subset of cancers which nevertheless are a rising health burden. Development of new therapies suffers from several bottlenecks, including low patient accrual and poor understanding of tumor characteristics. Patient tumor organoids (PTOs) are a novel model capable of improving screening of patient tissue in an accurate, standardized, and high-throughput capacity. In this study, we utilized patient tumors for creation of high-fidelity PTOs from a variety of GEP-NEN primary origins to evaluate therapy responses.

Methods Tumors from patients undergoing clinically guided surgeries were processed within two hours of resection and dissociated into single-cell suspension. Cells were encapsulated into Matrigel and cultured into two groups. The first group was grown for 10 days to assess viability then treated with a panel of clinically approved therapies and novel treatments recommended by high throughput NEN cell line screening for treatment sensitivity using the MIPE 5.0 library. The second group was grown for long-term expansion and biobanking, followed by characterization using immunohistochemistry and genetic profiling to ensure tumor cell maintenance.

Results From March 2023-November 2023, 14 patients provided 30 tumors for PTO development. These included small intestine (n=5), pancreatic (n=8), and gastric (n=1) neuroendocrine tumors. Long-term culture (>3 passages) was successful for 23/30 (77%) specimens, with passage timing related to tumor grade. PTOs maintained immunohistochemical characteristics of the parent tumor types and demonstrated similar genetic profiles, including neuroendocrine tumor cell markers synaptophysin, chromogranin A, and matched grade-based Ki67 proliferative index. The early-stage therapeutic screening was performed for 12/14 (86%) patients, demonstrating tumor grade dependent treatment efficacy and showing clinically dose relevant sensitivity towards approved small molecule inhibitor therapies including cabozantinib and sunitinib in a patient and tumor origin-dependent manner. Testing of effective therapy classes recommended by cell line treatment panels suggested high level treatment efficacy for proteosome inhibitors, MEK inhibitors, and topoisomerase inhibitors.

Conclusion Development of GEP-NEN PTOs is feasible for long term culture and standard of care therapy testing. Further study demonstrated the successful application of novel therapeutic options in PTOs for patients with GEP-NENs.

#4235 PD3D® models as jacks-of-all-trades for cancer research and therapy response prediction.

Lena Wedeken[1], Samantha Forbrig[1], Katja Herrera-Glomm[1], Juergen Loskutov[1], Ulrike Pfohl[1], Irina Piven[1], Michael Poehle[1], Manuela J. Regenbrecht[1], Barbara Seller[1], Cynthia Yapto[1], Sabine Finkler[2], Larissa Ruhe[2], Quirin Graf Adelmann[2], Christoph Reinhard[1], Marie Flechner[3], Katja Uhlig[3], David Kaul[4], Siyer Roohani[4], Maya Niethard[5], Rica Sauer[6], Christian R. A. Regenbrecht[1]

[1]CELLphenomics GmbH, Berlin, Germany,[2]ASC Oncology GmbH, Berlin, Germany,[3]Branch Bioanalytics and Bioprocesses IZI-BB, Fraunhofer Institute for Cell Therapy and Immunology, Potsdam, Germany,[4]Department of Radiation Oncology, Charite - Universitatsmedizin Berlin, Berlin, Germany,[5]Department of Orthopedic Oncology, Sarcoma Center, Helios Klinikum Berlin-Buch, Berlin, Germany,[6]Institute of Pathology, MVZ am Helios Klinikum Emil von Behring GmbH, Berlin, Germany

Physiologically relevant *in vitro* tumor models are crucial in any research setting from preclinical drug development to functional precision oncology. Patient-derived 3D cell culture models (PD3D®) are validated cancer models which recapitulate the biology of the original tumor tissue. PD3D® can be used to model intratumoral heterogeneity in medium and high throughput screens. Using a reverse clinical engineering approach, PD3D® models are already applied in personalized oncology to identify treatment for an individual patient. We successfully established a living biobank of more than 500 PD3D® models, spanning from common cancers like colorectal, breast (incl. TNBC), non-small cell lung and pancreatic carcinoma, to orphan indications including various subtypes of sarcomas. Not surprisingly, PD3D® model morphology and culture requirements differ between tumor entities. Treating PD3D® models with standard of care drugs in a semi-automated high-throughput assay, we observed heterogeneity in drug sensitivity between models of the same cancer type, recapitulating clinical response of patients. Combining drug sensitivity profiles with genomic and proteomic data of the same PD3D® models, we successfully identified a biomarker for predicting chemosensitivity towards MEK-targeting drugs. For application of PD3D® in truly personalized oncology, we developed a protocol that allows us to generate a PD3D® culture and perform a drug sensitivity assay for an individual patient within a therapy-relevant timeframe. Within 38 days we identified a systemic therapy for a young patient with a relapsed metastasized synovial sarcoma. After surgery and initiation of recommended chemotherapy, the patient is now under remission. To further expand the scope of PD3D® for therapy response prediction, we established a method for irradiation of PD3D® cultures with different dosages of photon and proton radiation. We observed significant, model specific differences in radiosensitivity between PD3D® sarcoma models which also reflect clinically heterogenous responses. Additionally, PD3D® models can be employed for a tumor organoid-on-chip platform (TumOC), delivering real-time information on physiological parameters like drug response-mediated oxygen consumption in a microfluidic system. In conclusion, PD3D® models act as jacks-of-all-trades in current and future cancer research, delivering robust and reliable data that not only is of academic value, but speeds up the drug development process, and are ready for prime time in functional precision oncology.

#4236 PDX-derived organoids (PDXO) are valuable tools to unveil the shortcomings of new anti-cancer drug candidates.

Y. Wang, L. Feng, H. Liu, J. Zhang, K. Hu, P. Pan, F. He;
Pharmaron, Inc., Beijing, China

Introduction: Tumor organoids are increasingly being used as predictive preclinical cancer models, as they reflect the original tumor features and patient drug responses. However, systematic comparisons between organoids and traditional 2D cell lines or 3D spheroids are lacking.
Method: We established over 30 PDX-derived organoid (PDXO) models with KRAS mutations and tested three inhibitors targeting the KRAS pathway: VS-6766(RAF/MEK inhibitor), Trametinib (MEK inhibitor), and MRTX1133 (a Phase II drug targeting KRASG12D) against these models.
Results: IC50 results indicated that most models responded to treatment. For some cell lines we detected differential drug responses in 2D vs. 3D testing with 3Dspheroids being more sensitive to inhibitors than 2D cell lines (on average ~10 fold). PDXO models exhibited greater individual differences in drug response, with a subset of models demonstrating no sensitivity to MRTX1133. This is consistent with published results showing that some KRASG12D-mutant PDX models were less sensitive to MRTX11331. Similarly, the clinical trial data for the KRASG12C inhibitor Adagrasib revealed distinctions in the response of patients2. Further analysis with WES (whole exome sequencing) and RNA-sequencing identified potential genotypic mutations and differential expressions of signaling pathways related to drug resistance. Subsequent drug combination testing showed that targeting these pathways could enhance the MRTX1133 efficacy in the resistant PDXO models.
Summary: Our research confirms that drug testing on organoids predicts responses in mouse models and clinical trials. In combination with multi-omics and bioinformatics analysis, the platform can be used for evaluating drug resistances, identifying new targets, developing new drug combination therapies, and ultimately improving the creation of new cancer therapeutics.

#4238 Modeling*RET*-rearranged non-small cell lung cancer (NSCLC): Generation of lung cell progenitors from patient-derived induced pluripotent stem cells (iPSCs).

P. Marcoux, J. Hwang, C. Desterke, J. Imeri, A. Bennaceur Griscelli, **A. Turhan**;
Universite Paris Saclay, Villejuif, France

Rearranged during Transfection (RET) oncogenic rearrangements can occur in 1-2% of lung adenocarcinomas. While RET-driven NSCLC models have been developed using various approaches, no model based on patient-derived induced pluripotent stem cells (iPSCs) has been described yet. Patient-derived iPSCs hold great promise for disease modeling. However, generating iPSCs with specific oncogenic drivers, like *RET* rearrangements, presents challenges due to reprogramming efficiency and genotypic variability within tumors. To address this issue, we aimed to generate lung progenitor cells (LPCs) from patient-derived iPSCs carrying the somatic mutation RET^{C634Y} which is commonly associated with hereditary medullary thyroid carcinoma. Additionally, we have established a RET^{C634Y} knock-in iPSC model to validate the effect of this oncogenic mutation during LPC differentiation. We successfully generated LPCs from RET^{C634Y} iPSCs using a 16-days protocol and showed an overexpression of cancer-associated markers as compared to control iPSCs. Transcriptomic analysis revealed a distinct signature of NSCLC tumor repression, suggesting a lung multilineage lung dedifferentiation, along with an upregulated signature associated with RET^{C634Y} mutation potentially linked to poor NSCLC prognosis. These findings were validated using the RET^{C634Y} knock-in iPSC model, highlighting key cancerous targets such as *PROM2* and *C1QTNF6*, known to be associated with poor prognostic outcomes. Furthermore, the LPCs derived from RET^{C634Y} iPSCs exhibited a positive response to the RET inhibitor Pralsetinib, evidenced by the downregulation of the cancer markers. This study provides a novel off-the-shelf iPSC model of RET-driven NSCLC, paving the way for exploring the molecular mechanisms involved in RET-driven NSCLC to study disease progression and to uncover potential therapeutic targets.

#4239 Pancreatic cancer organoids from the Human Cancer Models Initiative biobank reflect disease genotypes, capture patient heterogeneity, and are amenable to therapeutic screening.

S. Friend, R. Demerath, M. Graziano, **J. Clinton**;
ATCC, Gaithersburg, MD

Pancreatic cancer is the fourth leading cause of cancer-related death in the United States (~3% of all cancer cases) and has one of the lowest 5-year relative survival rates. There is a lack of clinically representative, easily available, validated, in vitro pancreatic cancer models that reflect the genomic and phenotypic diversity of the disease. The Human Cancer Models Initiative (HCMI) is an international collaborative project devoted to the development and distribution of approximately 1,000 novel human primary tissue-derived tumor models supported with clinical and molecular annotation. These models were manufactured, characterized, and validated at a not-for-profit biobank and made available for academic and commercial use in basic research, compound screening, and drug development. Available pancreatic cancer organoids (PCOs) from the HCMI biobank (n=46 unique models, n=41 unique donors) were acquired and subjected to a targeted next-generation sequencing hybridization capture, pan-cancer panel of 663 genes. Data were compared to publicly available clinical and genotyping results from the patient's tumor (n=42) that the model was derived from as well as cancer datasets such as The Cancer Genome Atlas (TCGA). A subset of models was cultured following standard procedures and tested for response to chemotherapeutics (cisplatin, nab-paclitaxel), KRAS-targeting inhibitors (MRTX1133, KR-pep-2D), or PARP inhibitors (PJ34, olaparib) at three time points. A luminescent ATP viability assay was used to assess response. PCOs from the HCMI were predominantly derived from primary tumors (75%), had an adenocarcinoma ductal histological type, and were from female patients (56%) with an average age of 65 years at diagnosis. Models had mutations in key disease-relevant driver genes including KRAS, TP53, SMAD4, and/or CDKN2A at frequencies similar to the TGCA cohort. Sequencing revealed mutations in genes less commonly associated with pancreatic cancer, including BRCA, APC, BRAF, TGFBR2, and ARID1A, albeit at lower frequencies. Most models had mutations in KRAS including G12D, G12V, G12C, and G12R variants. Significant but not complete concordance was seen in comparison with the mutation status of the patient's respective tumor, indicating potential genotypic drift had occurred. Response to acute treatment varied by model, genotype, timepoint, and drug. Chemotherapeutics like Cisplatin were broadly cytotoxic while MRTX1133 exhibited greater toxicity in models with KRAS G12D variants as compared with KRAS wild type. Patient-derived cancer organoids from the HCMI recapitulate genotypes seen in patient populations and respond to therapeutic treatment in vitro.

#4240 A comprehensive i*n vitro* tumor model: One-stop simultaneous isolation and culture of tumoroids, CAFs and TILs for advancing immuno-oncology research.

Y. KO[1], S. Kim[1], H. Park[1], S. Jang[2];

[1]AMIST, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

The tumor microenvironment (TME), composed of a diverse array of cells, jointly participates in tumor formation and has attracted attention as a direct or indirect therapeutic target. Among the tumor-forming cells, cancer cells, cancer-associated fibroblast (CAF), and tumor-infiltrating lymphocytes (TILs) comprise major proportion and players in tumor biology. Therefore, an in vitro tumor model composed of at least above three major cellular players better mimics a patient's tumor. Here, we developed a patient-derived tumor model containing tumoroids, CAFs and TILs isolated from the patient's tumor tissue by using one-stop isolation culture system. Our one-stop culture system utilizes a Transwell-based method that concurrently segregates cancer cells, CAFs, and TILs based on distinct characteristics such as cell size, migration speed, and growth. Lung tumoroids, fibroblasts, and TILs segregated in Matrigel-coated upper Transwell chamber, Transwell pores and in the lower chamber, respectively. Lung tumoroids maintain the patient's lung cancer tissue characteristics and genetic features during extended *in vitro* cultivation. Fibroblasts extracted from the Transwell pores exhibit significant similarity to CAFs found in patient tissue. TILs in the lower part of the Transwell chamber closely resemble those found in the original cancer tissue analyzed by FACS. We have also refined the functionality of TILs through a two-week expansion process. Patients' tumor composed of 0.15 to 95.3 % of EpCAM positive tumor cells, 0.14 to 19.4 % of CD90 positive fibroblasts and 3.98 to 91.2 % of immune cells in FACS analysis. By reassembling three main cellular components of the tumor in a proper proportion, we developed a co-culture platform for a patient-derived tumor model reproducing patient-specific TME conditions. The co-culture platform showed a potential not only for an experimental model but also to use a predictive test of personalized immunotherapy responses for lung cancer patients.

#4241 Development of stroma cells-rich oral cancer organoid for functional analysis of tumor microenvironment.

A. Shimoda, S. Shiiya, H. Yoshii, K. Mitsudo, M. Kioi;
Yokohama City Univ. School of Medicine, Yokohama, Japan

Background: Tumor microenvironment (TME), composed of cancer cells, endothelial cells, fibroblast, immune cells, and etc, plays crucial roles in tumor progression and treatment resistance. Thus, it is extremely important to find its role involved in the interaction of TME. However, it is more difficult to examine the biological activities of those cells in vitro assay. The purpose of this study is to develop stroma cells-incorporating preclinical model, termed stroma cells-rich oral cancer organoid, for functional analysis of TME.
Materials and Methods: We have first developed the stroma cells-rich oral cancer organoid by selecting the types of stroma cells such as endothelial cells, fibroblast, ratio of those cells, culture method, 3-D methods, culture media, and supplement of growth factors. Then, growth rate, morphology, radiosensitivity, and drug response were analyzed to investigate the effect of TME. Finally, the function of tumor-associated macrophage was determined using this organoid model. The growth rate of cancer cells and drug response were investigated using the organoid treated with supernatant of M1 and M2 macrophages polarized from THP-1 monocyte.
Results: Oral cancer cells were co-cultured with endothelial cells (ECs) and mesenchymal stem cells (MSCs) in a particular ratio in 3D-culture, and the formed organoid became sphere. The vascular formation in the organoid was confirmed by immunofluorescent analysis. The organoid also showed higher tumorigenicity in nude mice when inoculated, compared to cancer cells alone or mixed cells with ECs and MSCs. Cell viability of luciferase-expressing tongue cancer cells (OSC-19-luc) in the organoid was assessed after treatment with cisplatin using the IVIS system showing that OSC-19-luc organoid was resistance to cisplatin compared to 3D-cultured OSC-19-luc alone or OSC-19-luc co-cultured with ECs/MSCs. The supernatant of M1 or M2 macrophage had no effect on cancer cell growth in the organoid. However, when the organoid was treated with cisplatin in the presence of M2 macrophage supernatant, the drug sensitivity was low compared to those of M1 suggesting that secretory factor from M2 macrophage may lead to drug resistance of oral cancer cells in the presence of TME.
Conclusions: We have successfully established stroma cells-incorporating preclinical model that recreates the tumor microenvironment by co-culturing stromal cells. This will serve as a platform that can recapitulate the tumor biology and drug response profiles of cancer cells derived from individual oral cancer patients. This will also enable us to elucidate the role of other factors in TME and to identify novel targets for the treatment of chemo-resistant oral cancer.

#4242 Preserving lung cancer patient mutations in 3D organoid models: Advancing cancer research through innovative culture systems.

J.-y. Park, S. Gu, J. Lee, N.-G. Lee, D. Choi, S. Park, J. Kim, J. Rheey;
Gradiant Bioconvergence, Seoul, Korea, Republic of

Lung cancer is one of the most prevalent cancers worldwide. There are currently many anticancer drugs available, but they have numerous issues in terms of treatment, such as drug resistance and recurrence. Culturing systems that can replace a patient's cancer tissue are crucial, and the existing 2D culturing systems have many limitations. Patient-derived cancer organoid culture is the most advanced culture system for understanding mechanism of cancers. Using a 3D organoid culture system, we have successfully established a culture system for lung cancer using biopsy/surgical specimens and malignant effusions, including a long-term culture system. There are two critical indicators to determine the success of 3D organoid culture. One is whether the organoids retain their cancer-specific mutations from patient's lung cancer tissue, and the second is whether the organoids grow well and can be maintained in long-term culture for more than 20-30 passages. We typically assess gene mutations in EGFR, ALK, ROS, and P53 when evaluating lung cancer organoids. We confirm these mutations when we establish organoids, and currently we have established a total of 127 patient-derived lung cancer organoids. Among the 127 organoids, we completed NGS analysis on 108 of them and validated that 86.5% exhibit similarity when compared to lung cancer tissues. Additionally, we achieved a 100% retention of mutations in the long-term culturing of these organoids. Our studies indicate that patient-derived lung cancer organoids represent a meaningful organoid system for cancer tissue replacement and treatment response in the context of precision cancer medicine.

#4243 Revolutionizing cancer research, new drug screening approach with vascularized cancer organoid platform mimicking patient tumor microenvironment.

M. Lee, Y.-J. Yoon, **Y.-S. Lee**, J. Rheey;
Gradiant Bioconvergence, Seoul, Korea, Republic of

Patient-derived organoids (PDOs) are improving our understanding of cancer heterogeneity and personalized medicine. In particular, patients' intrinsic and acquired treatment resistance is being evaluated with PDOs, which has become an essential factor in developing new anticancer drugs and designing successful clinical trials. However, there are obstacles to cancer heterogeneity and patient-specific cancer therapy due to lack of understanding of tumoral diversity resulting from the tumor microenvironment (TME). Complex direct and indirect interactions between various types of TME cells and the resulting tumoral diversity are challenges that must be addressed for customized cancer therapy. Standard cancer therapy targets tumor cells without considering possible damage on the tumor microenvironment that could impair therapy response. Therefore, the construction and analysis of a platform for co-culturing cancer organoids with other cell types that make up the TME over a long period of time is necessary. We generated and performed characterization of blood vessel organoid (BVO). The BVO expressed endothelial marker CD31 and pericyte marker PDGFRβ. We attempted to co-culture with patient-derived lung cancer organoid (LCO) on Matrigel by dissociating the constructed BVO, and it was confirmed that BVO and LCO were interconnected after 10 days. This new platform was treated with Gefitinib and Poziotinib, and after 5 days of drug treatment, the IC50 value increased compared to LCO-only culture. Additionally, flow cytometry analysis confirmed that co-culturing with BVO during drug treatment resulted in a lower percentage of dead LCO cells compared to LCO-only culture. Image-based analysis also verified that co-culturing with blood vessels enhances the viability of LCOs when treated with drugs. Taken together, the co-culture of cancer organoids and BVOs present a platform that closely mimics the in vivo TME compared to the existing cancer organoid culture method. This innovative platform demonstrates higher drug resistance than existing approaches, offering a novel method for drug screening.

#4244 Clinical response assessment of immune checkpoint inhibitors in mismatch repair-deficient endometrial cancer using a T cell organoid coculture system.

Ju Hee Oh, Eun Hye Choi, Ji Eun Lee, Eun Ji Nam

Yonsei University College of Medicine, Seoul, Korea, Republic of

Endometrial cancers with the mismatch repair deficiency (MMR-D) phenotype exhibit characteristics such as an increased burden of tumor mutations and the presence of tumor-infiltrating lymphocytes (TILs) involved in tumor invasion. While monotherapy using immune checkpoint inhibitors (ICIs) has shown clinical improvement in MMR-D endometrial cancer (EC), observed response rates ranging from 30% to 50% suggest the existence of inherent resistance mechanisms. One notable feature of MMR-D tumors is the high proportion of tumor-infiltrating lymphocytes (TILs) encompassing various lymphocytes with diverse effects on immune interactions. Therefore, we aim to assess the feasibility of a self T-cell-tumor organoid co-culture platform for individual MMR-D endometrial cancer patients. We provide evidence that co-culturing self-tumor organoids with peripheral blood lymphocytes can be utilized to evaluate ICI responsiveness in MMR-D endometrial cancer patients. The application of a specific T-cell organoid co-culture platform to a cohort of patient resistant to monotherapy ICIs offers a means to anticipate the timing for minimal immunotherapeutic intervention and the appropriate timing for combination therapy.

#4245 Selection of AAV capsids by evaluating transgene delivery using human organoid models.

Y. Fu[1], Z. Qi[2], Z. Zuo[2], S. Chiang[2], **A. Ouyang**[3], G. Gao[2], S. Guan[2], J.-Q. Chen[3], R. Zhang[2], C. Wang[1];
[1]Innovec Biotherapeutics, Beijing, China, [2]ACROBiosystems, Beijing, China, [3]ACROBiosystems, Newark, DE

Recombinant adeno-associated viruses (AAVs) play a pivotal role in gene therapy, a promising approach aimed at treating various genetic disorders by introducing modified genetic material into cells or tissues. These AAV capsids are utilized as a vector in transferring genetic material into host cells. In discovery research, many AAV serotypes are developed in parallel to identify the optimal subtype for subsequent preclinical and clinical use. However, gene therapies have found limited success in clinical translation, in part, due to variable transgene delivery efficacy between traditional in vitro and in vivo models and human models. This study presents an organoid-based approach that mimics human physiology, as well as organ-specific features and cell diversity within an organ. Organoids are 3D structures derived from stem cells that resemble the cellular architecture and functionality of a specific organ. Compared to conventional 2D cell cultures, organoids provide a more comprehensive modeling of complex cell signaling, cell-cell and cell-extracellular matrix interactions, simulating the complex interplay between various cell types and functions. Within this study, several human-based organoid models were built, cerebral and cardiac, and verified by identifying the expression level of known marker genes through RNA sequencing. Five different AAV serotypes were utilized to evaluate transgene efficacy using each type of organoid model. Expression of delivered GFP transgene within each organoid was then compared to evaluate transduction and select the optimal AAV serotype in comparison to commercial wild-type AAVs. We outline the use of human organoid as an improved preclinical model for selecting AAV serotypes and evaluating transgene delivery efficacy to help provide better guidance for gene therapy development when moving into clinical research.

#4247 Miniaturizing patient-derived organoid screening assays for predictive drug testing.

Y. Abouleila[1], R. Verkerk[1], M. Doorn[1], T. Voskuilen[1], G. Harada[2], M. Watanabe[2], L. Smabers[3], H. Kyan[2], T. Kumagai[2], Y. Hikichi[2], R. Overmeer[1], J. Roodhart[3], K. Matsuno[2], C. Verissimo[1], S. Boj[1];

[1]HUB Organoids, Utrecht, Netherlands, [2]Yamaha Motor, Shizuoka, Japan, [3]Utrecht Medical Center, Utrecht, Netherlands

Colorectal cancer (CRC) ranks as the third leading cause of both cancer incidence and cancer-related mortality. A significant portion of CRC patients diagnosed with de novo metastatic disease face limited benefits from conventional treatment options, often accompanied by substantial side effects. This underscores the pressing need for more effective preclinical models to predict patient responses in clinical settings. Patient-derived organoids (PDOs or HUB Organoids®) represent a pivotal breakthrough in preclinical modeling. These organoids are directly derived from patient tissue, faithfully mirroring the patient's disease. While HUB Organoid Technology is currently applicable for preclinical drug screening, it is essential to expedite the transition from patient diagnosis to the delivery of PDO-based results to directly benefit patients. In a collaborative effort with Yamaha Motor, we have optimized the Yamaha CELL HANDLER™ for the automated transfer of organoids, offering enhanced precision and efficiency in handling a significantly reduced number of organoids per screening plate, compared to conventional methods. Moreover, we have developed an image-based readout system that enables precise quantification of organoid numbers, ensuring high assay quality. Utilizing this developed automated platform, we conducted a proof-of-concept investigation into PDO responses to chemotherapy in comparison to corresponding patient responses. The correlation between PDO and patient responses demonstrated a strong connection, highlighting the potential of the developed automated platform for predictive drug testing. In summary, this work signifies the development of an automated workflow that synergizes patient-representative HUB Organoids® with cutting-edge robotics from Yamaha Motor. The described workflow reduces the number of organoids needed per screening well, streamlining patient response prediction, potentially leading to faster diagnoses, and ultimately optimizing patient outcomes.

#4248 Patient-derived MTAP-deleted bladder cancer organoid model: A unique platform for drug development.

M. Schwermann[1], B. Carneiro[2], S. Lu[2], A. De Souza[2], M. Hadfield[2], A. Mega[2], G. Lagos[2], S. Khaleel[2], D. Golijanin[2], S. Holder[2], P. Srinivasan[1], W. MacDonald[1], A. George[3], L. Zhou[1], L. Zhang[1], W. El-Deiry[2];

[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]Legorreta Cancer Center and Lifespan Cancer Institute at Brown University, Providence, RI, [3]Yale School of Medicine, Providence, RI

Introduction: Approximately 30% of advanced bladder cancer (BCa) tumors exhibit MTAP gene deletion, which has been associated with luminal subtype BCa, poor response to chemotherapy, and shorter progression to metastatic disease (De Souza 2023). MTAP deletion has been proposed as a potential biomarker for response to pemetrexed and an emerging class of PRMT5 and MAT2A inhibitors in development for MTAP-deleted tumors. Here, we describe the first patient-derived 3D model of BCa with MTAP deletion and its translational potential as a drug sensitivity platform.

Methods: A patient (pt) with metastatic BCa harboring MTAP deletion underwent a pelvic lymph node biopsy. A fresh tumor sample was processed under collagenase/dispase solution for 30 minutes and filtered through a 70-um cell strainer. Cells were cultures in low attachment plates with MammoCult™ Basal Medium (Stem Cell Technologies). After 5 passages and 3D spheroid formation, immunostaining for cytokeratin (CK) 5 and 6, GATA3, CK20, and Ki67 staining were performed to confirm the urothelial origin. The MTAP-del was confirmed by a western blot of the organoid specimen and compared to other BLCa cell lines (UMUC, RT4, J82, and 5637). The viability assays were performed using the CellTiter-Glo® 3D Cell kit. Next-generation sequencing (NGS) of primary BCa tumor revealed deletion of MTAP, CDKN2A, CDKN2B, and mutations in p53, TERT, and KDM6A.

Results: The patient organoid sample was positive for the luminal CK5/6 markers and negative for GATA3. Ki67 and CK20 were primarily expressed in the nucleus of the same sample. The organoid retained morphologic and immunohistochemical features of the patient's primary bladder tumor, showing the same squamous differentiation and similar Ki-67 proliferative index. The organoid displayed no evidence of the MTAP protein by western blot (similar findings with the MTAP-del cell lines UMUC and RT4). The organoid showed sensitivity to pemetrexed [pemetrexed IC50=0.12 uM (other MTAP-del BLCa IC50: 0.1-0.23 uM)] and resistance to gemcitabine and cisplatin [Gem IC50=55 nM (other BLCa IC50: 1-29 nM), Cis IC50=90.5 uM (other BLCa IC50: 2-17 uM).

Conclusions: We describe the first patient-derived MTAP-deleted BCa organoid recapitulating the features of the primary tumor. The organoid displayed sensitivity to pemetrexed as described with MTAP-deleted BCa. The organoid represents a unique platform for testing novel therapeutic strategies for MTAP-deleted BCa.

#4249 Establishment and analysis of patient-derived high-grade serous ovarian cancer organoids for disease modeling and drug testing.

T. Kallunki[1], A. R. Lauridsen[1], A. Skorda[1], A. Lahtinen[2], M. L. Bay[1], B. Rasmussen[1], K. Huhtinen[2], T. Muranen[2], J. Oikkonen[2], J. Hynninen[3], S. Hautaniemi[2]; [1]Danish Cancer Institute, Copenhagen, Denmark, [2]University of Helsinki, Helsinki, Finland, [3]University of Turku and Turku University Hospital, Turku, Finland

Purpose: Ovarian cancer is the most lethal gynecologic cancer. Majority of ovarian cancers belong to the subgroup of high-grade serous ovarian cancer (HGSC). Its standard treatment is surgery and chemotherapy with platinum and taxane-based compounds, for which almost all patients become resistant. We have established a panel of patient derived 3-dimensional (3D) HGSC long-term tumor organoid cultures for personalized disease modeling, drug screening and evaluation of the efficiency of potential new treatments to be used in preclinical research.

Methods: Tumor tissues or ascites from > 30 HGSC tumors were set up as long-term 3D organoid cultures (PDOs). RNA and whole genome sequencing was performed from the original tumors and from PDOs. Pluripotency and proliferation were assessed via high-throughput immunofluorescent detection of PAX8 and Ki67. Resistance towards standard treatment and response to additional selected drugs and drug combinations were evaluated in cell death and proliferation assays. Imaging and image-based quantifications were performed under 3D setup. PDOs were set up for *in vivo* drug testing in immunodeficient NOD/Shi-scid/IL-2Rgnull (NOG) mice.

Summary: A set of HGSC PDOs of different longitudinal, prospective, and multiregional samples has been established representing the three evolutionary states of HGSC: evolving, maintaining and adaptive state. They are ready to be used as rational and effective models for studying drug interventions. Supportively, results of preclinical studies with PI3K inhibitor Alpelisib matched the published patient responses. Tumor evolutionary analysis based on data of longitudinal, prospective, and multiregional collected samples suggest further targetable pathways that can mediate chemotherapy resistance and pinpoint potential targets for drug intervention.

Conclusion: Inhibition of these pathways with simultaneous targeting of other cellular functions, such as lysosomal-mediated cell death, may be highly effective alternative treatment option. 3D imaging and efficient image analysis are necessary tools to understand tumor organoid biology and drug responses to assist development and pre-clinical evaluation of new treatments. This study is a part of the DECIDER project (https://www.deciderproject.eu/, NCT04846933).

#4250 Adherent and spheroid cell models of patient-derived xenograft for drug development and translational research.

Lars Winkler, Joshua Alcaniz, Maria Stecklum, Wolfgang Walther, Jens Hoffmann

Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany

Introduction: The development of new drugs in cancer therapy comprises toxicity and efficacy tests with increasing complexity. First and foremost, in vitro experiments are performed with well-established cancer cell lines, which are subsequently validated in animal experiments as prerequisite for clinical trials. Until a few years ago, there were gaps in the complexity chain between in vitro and in vivo experiments. Ethical considerations have led to use of systems like organ on a chip or mini-organ 3D in vitro models. In cancer research, cell cultures or organoids are generated from patient tumor material. However, these cultures only reflect the tumor of one patient, which is why panels of patient tumors should be used to evaluate the effectiveness of drugs on different patients. In vivo panel screens of patient derived xenografts (PDX) mouse models need high numbers of animals and takes several months. A pre-screen with in vitro models generated from in vivo PDX tissues allows large scale and faster pre-screens complementing in vivo systems for more focused in vivo analyses.
Methods: Currently we have a pool of more than 600 established PDX models of 21 tumor entities. From this pool, cancer tissues of glioblastoma, mesothelioma, gastric, head/neck, lung and breast cancer were processed in single cell suspensions and cultured under defined conditions to obtain adherent cells or spheroids. The generated PDX in vitro cultures were analyzed for cellular impurities, cancer stem cell content and perpetuation of *in vivo* PDX characteristics. FACS analyses for tumor specific markers, chemo sensitivity assays and growth characteristics of the PDX derived cell lines (especially for glioblastoma) were analyzed.
Results: From PDX tissues used, 90% grew as adherent and/or spheroid PDX derived in vitro cultures, in which mouse cells were entirely depleted. A high percentage of these cultures showed enriched cancer stem cell features and stem cell marker expression. Tumor marker expression and standard drug sensitivity data correlate to the in vivo PDX and derived in vitro cell culture models. RNAseq data were used to predict drug sensitivities in silico for untested drugs and drug combinations on our newly established PDX derived glioblastoma cell lines. Initial screens with predicted candidates were performed. Promising conditions were successfully repeated in corresponding animal PDX models.
Conclusion: The newly developed technology for establishment if in vitro cell cultures from PDX efficiently generates stably growing cell lines possessing all key features of the original PDX. These cell lines can be used for initial pre-screens to optimize and improve selection of pharmacologically active drugs or drug combinations before initiating in vivo PDX studies.

#4251 Establishment of hormone-dependent endometrial tumoroids in a conditioned-medium free, serum-free medium.

C. Yankaskas, B. Balhouse, C. Paul, P. Shahi Thakuri, S. Salen, M. Kennedy, M. Dallas, D. Kuninger;
Thermo Fisher Scientific, Frederick, MD

Tumoroids, also known as cancer organoids, are self-assembled three-dimensional cultures of patient-derived tumor cells. Compared to traditional 2D cancer cell lines, tumoroids better maintain key characteristics of the original tumor including the genotype and transcriptome, which lead to better *in vitro* modeling of clinically relevant functional responses such as drug sensitivity. An under-studied aspect of tumoroid cultures has been their ability to recapitulate dependence on hormone signaling *in vitro*, with some reports indicating hormone dependence is lost over time in culture. To investigate this, we utilized Gibco™ OncoPro™ Tumoroid Culture Medium and defined tissue-specific supplements, FGF10 and beta-estradiol, that when added to the medium enabled the derivation of endometrial tumoroids from tumor resections. Derivation of tumoroid lines compatible with long-term growth depended on a variety of factors, including tissue quality and time from resection to culture initiation. Each of the 15 samples processed formed tumoroids when initially seeded into culture. 11/15 samples reformed tumoroids through multiple passages (typically 1-2 weeks per passage) over 1-3 months in culture. 7/15 samples met our high criteria for stable tumoroid line growth of >5 passages and reaching >5 cumulative population doublings (from initial number of cells seeded post-resection) in culture. Next-generation sequencing of the established tumoroids and the uncultured tumor material demonstrated a high degree of correlation (pearson's r>0.9) of genomic mutations in a targeted panel; few differentially expressed genes were detected beyond down-regulation of immune-related genes, presumably because the medium is optimized for outgrowth of cancer epithelial cells, and immune cells do not persist during long-term culture. Endometrial tumoroids were capable of growing embedded in basement membrane extract (BME) or in suspension with dilute BME added and could be cryopreserved and recovered. Endometrial tumoroids retained gene expression levels (both presence and absence) of estrogen receptor and progesterone receptor for up to the 20 passages tested *in vitro*. A subset of the models was tested and showed increased growth rates in response to increased concentrations of beta-estradiol. Of those tested, 2/3 tumoroid cultures stopped growing within 1-2 weeks after removal of beta-estradiol from the medium, demonstrating dependence on this hormone for growth. Maintenance of hormone receptor expression and dependency should enable *in vitro* studies to understand the signaling mechanisms and potential ways to modulate them in the context of cancer. Overall, this method provides a toolset for studying endometrial cancer, particularly hormone dependency, and may be more broadly applicable to other gynecological or hormone dependent cancers.

#4252 Evaluation of NXI-101 in non-small cell lung cancer (NSCLC) using patient-derived organotypic tumor spheroids (PDOTS): Targeting a novel tumorigenic pathway.

J. Vail[1], H. Maeng[2], J. Jang[2], K. Boo[2], J.-I. Youn[2], A. Martin[1], A. Goldman[3], K. Yoon[2], **M. A. Perricone**[1];
[1]Xsphera Biosciences, Inc., Boston, MA, [2]NEX-I, Seoul, Korea, Republic of, [3]Harvard Medical School, Boston, MA

ONCOKINE-1 (OK-1), a soluble protein that is released by tumor cells, is implicated in the resistance of immunotherapy. Here we evaluated the efficacy of NXI-101, a monoclonal antibody that binds and neutralizes OK-1, in a model of patient-derived organotypic tumor spheroids (PDOTS) derived from non-small cell lung carcinoma (NSCLC) patients. NSCLC PDOTS were treated with NXI-101 and the effects of the drug were evaluated on day 3 post-treatment. Cytotoxicity was measured by Hoechst/Propidium Iodide staining and quantified by measuring the area-weighted percentage of cell death. Significant cytotoxicity was observed in 2 out of 10 patient tumors (20%) as a monotherapy and 4 out of 10 (40%) when used in combination with atezolizumab. The therapeutic response for both treatments was positively correlated ($p<0.05$) with the level of OK-1 expression, determined by immunohistochemistry using tissue sections taken on the day of tumor specimen collection. NXI-101 alone and in combination with atezolizumab had immunomodulatory effects that were associated with cytotoxic response. For example, transcriptomic analysis, Nanostring IO 360 Panel, indicated that the drug treatments resulted in the inhibition of TGF-β pathways and stimulated a number of immune pathways in 3 of the 4 responsive PDOTS. These pathways include interferon-α, JAK-STAT, and dendritic cell activation markers. We also observed evidence of activation of these same pathways in 2 of the 6 non-responsive PDOTS. These data support the prospects of NXI-101 as a first-in-class therapeutic for the treatment of NSCLC when used alone or in combination with an immune checkpoint inhibitor. Moreover, the findings highlight the PDOTS platform's substantial value in capturing patient-specific tumor response variability and providing robust support for the mechanistic evaluation of cancer therapeutics.

#4253 High expression of specific gene profiles in organoids from African American pancreatic cancer tumors.

B. D. Lyn-Cook[1], F. Nouri Emamzaden[2], B. Word[2], G. Hammons[2];
[1]FDA-NCTR (National Center for Toxicological Research), Jefferson, AR, [2]National Center for Toxicological Research, Jefferson, AR

Pancreatic cancer remains one of the leading causes of cancer-related deaths in the United States with limited therapies for advanced stages of this disease. African Americans have the highest morbidity and mortality rates of pancreatic cancer compared to other racial groups. Many factors are known to contribute to this disparity such as, socioeconomic and lifestyle factors. One of the major factors contributing to this disparity is the lack of African Americans with pancreatic cancer in clinical trials or genomic databases. In order to gain insight into the biology or genetic differences that may exist in signals driving the aggressiveness of this cancer in this population more studies are needed. Innovative *in vitro* models are needed to investigate possible differences in molecular changes that may exist in African Americans. Studies have shown that organoids developed from metastatic and primary tumors can give sights into genetic and epigenetic changes detected in several type of cancers. Using a Human Pancreatic Adenocarcinoma TagMan Array 96 (Applied Biosystems), which contained 76 genes known to be expressed in pancreatic cancer, pancreatic organoids from African American metastatic tumors revealed high expression levels of specific genes. Usually K-ras is highly expressed in pancreatic tumors but it was not significantly expressed in the organoids from African Americans metastatic tumors. However, preliminary results from organoids, compared to pancreatic cancer cell line spheroids, showed significantly increased gene expression of HSP90AA1 (13-fold), MMP1(36-fold), BRACA2 (20-fold), MDM2 (19-fold), RB1 (14-fold), Rel (12-fold), STAT1 (15-fold), STAT5B (5-fold), and TGFBR1 (1- fold). High expression of HSP90AA1 is related to poor prognosis, constitutively expression of STAT5B confers gemcitabine chemoresistance and promote invasiveness, and mutations in BRCA2 can increase pancreatic cancer risk. Further studies are being done to validate these findings in African American pancreatic tumors and to ascertain their relevance to the metastatic progression phenotype.

#4254 Genetically engineered human lung organoid models for lung cancer evolution study.

S. Moon, R. Kim, D. Lee, K. Park, W. Lee, S. Lee, Y. Park, J. Kim;
Genomic Medicine Institute, Medical Research Center, Seoul National University, Seoul, Korea, Republic of

Initial cellular events in a transitional period from normal to cancer cells, such as transcriptomic or epigenetic dynamics, are poorly understood. Observing these is more challenging than in cancer progression, especially for humans. Mapping this phenomenon in early cancer evolution is crucial, as we can identify targetable molecules to inhibit cancer development at the precancerous stage. Immortalized human cancer cell lines hardly capture these appropriately as they have lost usual cellular characteristics. Normal organoids harbor stem cells and their differentiated cells, reflecting the epithelial physiology of tissues, and are more suitable models for cancer evolution studies. To establish a human cancer development model in vitro, we genetically engineered normal human airway organoids derived from adult stem cells into small cell lung cancer (SCLC). We used CRISPR-Cas9 systems to induce non-homologous end-joining in both *TP53* and *RB1*, the most frequently mutated genes of SCLC. First, we knocked out *TP53* of the airway organoids, selected by Nutlin-3a, an MDM2 antagonist, for 3-4 weeks, demonstrating 88-89% editing efficiencies calculated from Sanger sequencing results. Most mutations were one base pair deletion or insertion, which induced frameshift mutation in *TP53*. They did not show a significant difference from wild-type organoids morphologically at bright-field microscopy. Subsequently, we targeted *RB*1 on *TP53*$^{-/-}$ airway organoids to induce SCLC. We used Palbociclib, a CDK4/6 inhibitor, to enrich the mutated cells. They had 67.1% efficiency, and 20.4% had a 7-base pair deletion mutation. In the initial period, they seemed to have similar shapes to *TP53*$^{-/-}$ organoids. Unexpectedly and interestingly, however, we noticed more rapidly proliferating and disorganized organoids disrupting their original round shapes appeared in 4-5 weeks. The cells were indiscriminately piled up on the airway organoids' apical and basolateral surfaces, indicating their malignant traits. Their chaotic proliferation represented the rapidly progressing clinical feature of SCLC with a median survival of 7-16 months with treatment. This is the first work constructing the SCLC development model from the normal human airway organoid. By sequentially single-cell sequencing this organoid model changing to tumorous condition, we can capture the multi-omics landscape during the initial evolution of SCLC.

#4255 A systematic framework for efficient generation of expandable patient-derived 3D sarcoma models.

Introduction: Sarcomas are rare connective tissue tumors with over 100 described subtypes. High heterogeneity within and among sarcoma sub-entities and low incidence contribute to poor therapeutic success. Patient-derived 3D models (PDMs), i.e. organoids and spheroids, closely recapitulate features of the original tumor, e.g. cell-to-cell interaction, differentiation potential and heterogeneity. However, PDMs are rarely available or even lacking for most sarcoma sub-entities, constituting a major hurdle for sarcoma precision oncology and research. Here, we present a highly efficient and systematic framework to generate long-term 3D models for distinct sarcoma subtypes, which we developed within the HEROES-AYA consortium.

Methods: Tumors were received directly after surgery and processed within 24 hours. After enzymatic dissociation, cell clumps were seeded in 384-well plates with and without Matrigel. Each tumor was cultivated on an array of 140 distinct culture conditions, differing in contribution and concentration of pathway inhibitors and activators. Organoid and spheroid growth was assessed over time via imaging and AI-based algorithms to identify best-growing conditions.

Results: Initially, we combined Ewing sarcoma (EwS) secreted factors and potentially relevant cytokines to generate a matrix of 140 diverse media, named Media Test Plate (MTP). The MTP was tested on five EwS tumors, allowing the identification of optimal culture conditions with 100% efficiency. When transplanted in NSG mice, the established PDMs showed tumorigenicity potential and Ewing sarcoma-specific CD99 marker expression. The MTP was then tested on four synovial sarcomas (SyS) and five myxoid liposarcomas with a 75% and 50% success rate, respectively. The optimal media, as identified by MTP, allowed the cultivation of one EwS and one SyS out of two, respectively, even with limited cell count. Additional PDMs generated include one undifferentiated, one alveolar soft tissue and one spindle cell sarcoma. Established cultures were characterized by Ki67 positivity, ranging from 40% to 70%, and expression of sarcoma subtype-specific markers. EwS models resulted 100% CD99 positive, while TLE1 positivity in SyS models was ≈90%. DNA and RNA sequencing of PDMs will show whether they resemble the genetic and transcriptional features of the original tumors. Conclusions: We here present a novel systematic protocol to generate organoids and spheroids from different sarcoma subtypes. To date, no such systematic protocol is available for sarcoma models generation. Our success rate is comparable to the one of intestinal and pancreatic organoids and exceeds those of 2D and PDX sarcoma cultures, which is ≈20%. Current work aims to adapt the MTP to a broad range of sarcoma subtypes, including rare entities. The efficient generation of expandable PDMs from a wide range of sarcomas will further fuel basic and translational research.

#4256 Autologous organoids and T cell co-cultures as a powerful personalized platform for immunotherapy development.

C. Beaurivage[1], B. Sridharan[2], S. Mucuk[1], K. Nadwodny[2], D. Poore[2], A. Schepers[1], F. Pourfarzad[1], **S. F. Boj**[1];
[1]HUB Organoids B.V., Utrecht, Netherlands, [2]GlaxoSmithKline, Collegeville, PA

Recent advances in cancer immunotherapy have had a positive impact on the life expectancy of patients for an extensive range of clinical indications. With new treatment strategies and druggable targets being identified at an increasing pace, the number of patients eligible for cancer immunotherapy is expected to expand steadily. However, promising therapeutic developments face hurdles in translating preclinical findings into therapy since conventional 2D cancer models hold low clinical predictive value. We developed an innovative alternative, building on the discovery that adult stem cells proliferate and organize into three-dimensional organotypic structures when they are embedded into extracellular matrix. Patient-derived organoids are generated from normal and malignant tissues and stored as high-quality biobanks that yield highly reproducible results. HUB Organoids® recapitulate complex characteristics of the parental tissue, including molecular heterogeneity, as well as morphological and functional traits. Since cancer progression and response to immunotherapy are governed by immune cell interactions in the tumor microenvironment, we developed an assay in which colorectal (CRC) and non-small cell lung cancer (NSCLC) tumor organoids are co-cultured with paired tumor infiltrating lymphocytes (TIL) that are simultaneously expanded as a source of tumor reactive cells. Paired resources allow for the screening of immune-modulatory therapies under physiologic conditions, not depending on peptide-pulsing and alloreactivity. We quantify tumor organoid killing and TILs reactivity by combining imaging-based analysis of apoptotic cells with flow cytometry to measure cytokine release by cytotoxic TILs. Here, we show that our system is robust and reproducible with an establishment rate of 75%, allowing for expansion of TILs that preserve T cell receptor repertoires. First line expansion of both PDO and TIL components can be used to effectively build coculture models and probe the tumor and immune components, respectively. Our system offers a powerful tool for the development and validation of cancer immunotherapy and can help to stratify cancer patients for susceptibility to various types of immunotherapies. We certify that the research use of each of the HBS marked above was conducted according to the expectations of each institution.

#4257 A novel 3D co-culture platform for patient-specific immune-oncology treatment.

T. Light, **S. Kamali**, M. Gilardi, A. Andar, K. Abarca-Heidemann, M. Mancini;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

Lung cancer is the leading cause of global cancer-related mortality resulting in ~1.8 million deaths. annually. Over the past decade, the contribution of tumor microenvironment (TME) in lung cancer progression has been highly appreciated and provided significant improvements of survival outcomes for patients. That includes the complexity of the tumor immune microenvironment (TIME) playing a critical role in cancer progression. However, drug resistance usually arises and there is an urgent need for novel immune cell-based therapies. 3D tumor cell structures that recapitulate the architecture and functionality of the original tumor have revolutionized the understanding of disease mechanisms and testing potential therapeutics. However, there are certain drawbacks that need to be overcome. For example, these models mainly consist of only the epithelial compartment and lack signals from the microenvironment. Recent advances with engineering co-culture systems with immune cells at Champions Oncology help to emulate cell-cell and immune cell infiltration. We have successfully established a biobank of TumorGraft3D (CTG3Ds) derived from non-small cell lung cancer (NSCLC) patient-derived xenografts as well as their autologous and allogeneic immune cells (TILs, PBMCs) to establish a proprietary co-culture platform to investigate disease mechanisms and test potential therapeutics. In brief, surgical resections from patients were used to generate patient-derived xenografts organoids, and matched immune cells were expanded using standard rapid expansion protocol. The combination of a comprehensive staining system and high-content imaging as an endpoint allowed for 3D confocal analysis and deep evaluation of cancer-immune cellular interaction at the single cell level. Our pipeline of image analysis not only differentiates cancer-immune cell spatial distribution and cellular death but also allows for the evaluation of tumor infiltration and drug cytotoxicity. The characterization of the platform showed proliferation of the cancer cells and functional immune profiling by flow cytometry. The molecular profile of the organoids composing the platform showed a tight overlap with the original tumor highlighting the clinical relevance of the model. In addition, this novel co-culture platform has been tested with several NSCLC models to test the efficacy of various therapeutics such as immune-checkpoint inhibitors (ICIs) in reproducible, cost-effective, and patient-specific manner. In summary, Champion's novel co-culture platform allows screening of novel immune targeting agents to determine impacts tumor cytotoxicity. Furthermore, our lung cancer tumorGraft3D platform serves as a powerful tool to facilitate the practice of precision medicine by investigating a variety of therapeutic modalities, alone or in combination, to identify patient-specific treatment strategies.

#4258 An innovative PDX and patient-derived 3D platform for improved translatability of new medical entities.

S. Kamali, S. Cairo, F.-J. Chou, T. Light, M. Gilardi, B. Walling, C. Baer, H.-W. Tsai, A. Andar, K. Abarca-Heidemann, M. Mancini;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

The preclinical platform landscape in oncology has radically changed in the last 15 years, mainly due to an increased ability to generate patient-derived models. Multiple 3D tumor cell cultures methods, either from established cell lines or from primary cultures, have been developed to assess the activity of therapeutic agents in vitro. These methods are strongly influenced by the experimental conditions, such as cell culture conditions, the presence of 3D supports like Matrigel, and the experimental design of the assay, such as the choice of the dose and the duration of the assay. The ability of these methods to predict drug efficacy in the patient relies not only in the optimization of the experimental settings, but also on the representativeness of the patient population, and on the prevention of model drifts due to clonal selection and/or tumor cell adaptation to culture conditions with passages. In this project, we aimed to develop an innovative 3D cell model platform that addresses all these experimental challenges. To do so, we took advantage of our low passage Tumorgraft platform, a bank of more than 1500 patient-derived xenografts (PDXs) well characterized at molecular and pharmacological level and highly representative of the patient population, to generate the Tumorgraft3D platform. We derived TumorGraft3D models from low passage PDXs, by using proprietary, indication-specific culture conditions. By keeping these models at low passage, we were able to avoid clonal drifts. Moreover, the use of indication specific media allowed the preservation of patient's and PDX's tumor histology, molecular traits at genetic, gene expression and proteomic level, and displayed proliferation rates that recapitulate those observed in the parental PDXs. So far, we have successfully developed over 100 models from breast, ovarian, prostate, NSCLC, colorectal and gastric indications, with success rates up to 90%. Ex-vivo testing of standard of care highlighted different response profiles in accordance with the molecular feature of these models. The tumor dissociation process and culture conditions optimized with PDXs were also used for the development of 3D cultures derived from patients' samples. These data demonstrated that our 3D platform can integrate the complementarity of our PDX and patient-derived 3D platform, which lies in the possibility of evaluating test agent activity in the repeatable and reproducible setting provided by the patient-derived 3D models, as well as in models directly derived from patients with more heterogeneous and indication-specific establishment success rate, and throughput dependent on the amount of primary tumor material.

#4259 A novel human model of lung squamous cell carcinoma to deconvolve the cell-intrinsic effects of key dysregulated pathways.

J. Ogden[1], R. Sellers[1], A. Oojageer[1], S. Sahoo[1], A. Chaturvedi[2], **C. Lopez-Garcia**[1];
[1]Cancer Research UK Manchester Institute (Alderley Park), Manchester, United Kingdom, [2]The Christie NHS Foundation Trust, Manchester, United Kingdom

Tractable, patient relevant models are needed to investigate the essential components of normal cell transformation. We developed a unique in vitro model of early lung squamous cell carcinoma (LUSC) genetic alterations and driver pathway dysregulation using genetically modified primary human bronchial basal cells (hBCs) from three independent donors. The co-operation of ubiquitous and early LUSC alterations (TP53 and CDKN2A loss) and commonly deregulated pathways including squamous differentiation (SOX2), PI3K signaling (PTEN) and the oxidative stress response (KEAP1) was investigated using a combinatorial approach, culminating in eight unique hBC mutants harboring cumulative pathway alterations in a $TP53^{-/-}$/$CDKN2A^{-/-}$ background. Phenotypes indicative of mutant hBC transformation were investigated using proliferation assays, organotypic cultures and anchorage independent growth assays. Organotypic cultures revealed LUSC pathway alterations to drive dramatic changes in airway histology, ranging from a normal epithelium to severe dysplasia. Furthermore, these analyses confirmed the role of SOX2-overexpression in initiating transformation by inducing squamous cell commitment and anchorage independent growth. We also identified a co-operation of SOX2-overexpression with the oxidative stress response and PI3K pathways to drive more advanced lesions in-vivo and in-vitro. Importantly, we were able to map changes in the expression of immunomodulatory factors with the pathway dysregulation. We demonstrated that this strategy constitute an alternative and patient-relevant system to model LUSC and identify genotype-phenotype correlations of clinical relevance.

TUMOR BIOLOGY: The Extracellular Matrix in Cancer

#4262 AI-driven analysis of collagen characteristics in the tumor immune microenvironment predicts immune checkpoint inhibitors treatment responsiveness in gastric cancer.

M. Kim[1], E. Redekop[2], Y. Choi[1], S. Lee[3], J.-H. Cheong[4], Y. Aoki[5], K. Shitara[5], T. Hwang[1];
[1]Mayo Clinic, Jacksonville, FL, [2]University of California, Los Angeles, CA, [3]The Catholic University of Korea, Seoul, Korea, Republic of, [4]Yonsei University College of Medicine, Seoul, Korea, Republic of, [5]National Cancer Center Hospital East, Kashiwa, Japan

Background: Recent studies indicate a correlation between increased stromal composition in tumors and resistance to immune checkpoint inhibitors (ICIs) across various cancer types. Specifically, the extracellular matrix (ECM) within the stromal compartment significantly influence the tumor microenvironment, affecting cancer cell proliferation and immune cell recruitment. However, identifying and quantifying the ECM at the collagen fiber level in whole slide images (WSIs) is challenging due to its inherent heterogeneity and complexity. In this work, we utilized statistical analysis and a deep learning (DL)-based approach to identify and assess collagen in the ECM, examining its characteristics in relation to the ICIs treatment response in gastric cancer.
Methods: We analyzed 116 WSIs of hematoxylin and eosin (H&E) stained slides before ICIs treatment from three institutions. Responders were defined as those with a complete response or partial response (N=18); those with stable disease (SD) (N=34) or progressive disease (PD) (N=64) were considered non-responders (N=98). For non-responders, post-treatment H&E slides were available for 21 patients; SD (N=5) and PD (N=16). We applied a DL-based second harmonic generation (SHG) synthesis algorithm to tumor regions identified by a tumor detection model. We then calculated various collagen properties, including volume, fiber orientation and alignment, waviness, straightness, and fiber thickness, based on collagen fiber centerlines extracted from the generated SHG images. An attention-based multiple instance learning (ABMIL) model was trained to automatically predict the treatment response solely based on collagen features. The dataset of 116 pre-treatment slides was divided into training and validation subsets using stratified 3-fold cross-validation. The area under the curve (AUC) was used to assess the performance of the trained models.
Results: Collagen fiber features were significantly associated with ICIs response. Notably, ICIs responders have a decrease in collagen waviness and fiber orientation variation (p-value<0.05, by Mann-Whitney U test). Among non-responders, the PD group showed a statistical decrease in waviness after treatment (p-value<0.05, by Mann-Whitney U test). The ABMIL model achieved a mean AUC score of 0.823, with a standard deviation of 0.023.
Conclusion: This study provides a comprehensive analysis of collagen in the ECM, and its properties in relation to gastric cancer ICIs response within Tumor Immune Microenvironment. We also developed a model using collagen features and demonstrated high accuracy in predicting treatment response.

#4263 Prostate cancer cell-derived small extracellular vesicles regulate monocyte migration via STEAP4 and promote a monocyte transitional state.

N. M. Naranjo[1], A. Testa[1], S. K. Yadav[1], U. P. Naik[1], L. Yu[1], W. K. Kelly[1], Q. Liu[2], J. Ding[2], H. Yang[1], H. Tang[2], C. E. Verrillo[1], C. D. Hooper[1], L. R. Languino[1]; [1]Thomas Jefferson University, Philadelphia, PA, [2]The Wistar Institute, Philadelphia, PA

Our group has previously shown that prostate cancer (PrCa)-derived small extracellular vesicles (sEVs) are powerful cell communication mediators as they carry an array of proteins that have the ability to change recipient cell functions. Here, we describe a novel pathway of cancer cell-monocyte communication mediated by sEVs. Since sEVs carry cargoes that alter recipient cell phenotypes, we analyzed via proteomic analysis sEVs released from PC3 PrCa cells. Using CRISPR Cas9 methods, we downregulated IFIT3 (Interferon-induced proteins with tetratricopeptide repeats-3, member of the interferon-stimulated gene family) in PC3 PrCa cell (IFIT3KO). We then isolated sEVs from PC3 or IFIT3KO cells by using differential ultracentrifugation followed by iodixanol density gradient. Our proteomic analysis of IFIT3KO sEVs compared to PC3 sEVs shows that IFIT3 downregulation results in a significant upregulation of a metalloreductase, STEAP4 (six-transmembrane-epithelial antigen of the prostate 4), which is increased in PrCa cells and promotes PrCa cell proliferation and survival. STEAP4 is also known to promote an anti-inflammatory response in monocytes and macrophages. We then, investigated whether PrCa sEVs enriched in STEAP4 have a causal effect on monocyte functions and phenotype by using adhesion and migration assays as well as flow cytometry. Our results show that while all PrCa sEVs stimulate the adhesion of healthy donor or non-metastatic PrCa patient monocytes, only PrCa sEVs expressing STEAP4 increase their migration. In parallel, we provide evidence that all PrCa sEVs affect some of the M2 (CD163 or CD204) and M1 (CD80 or HLA DR) polarization markers analyzed in healthy donor monocytes. We show that there is a transitional state induced by PrCa sEVs in healthy donor monocytes, which occurs in a STEAP4-independent manner. This state mimics the non-metastatic PrCa patient monocyte phenotype. In conclusion, we describe a unique pathway whereby PrCa cell sEVs expressing STEAP4 promote monocyte migration with partial changes to their polarization.

#4264 The TWEAK-Fn14-NF-kB signaling axis enhances expression of integrin AVB3 in a post-chemotherapy tumor microenvironment.

O. Lujano Olazaba, M. Robinson, C. Gallo, M. Shammas, K. Shelby, L. Cruz, S. F. Gilbert, C. D. House;
San Diego State University, San Diego, CA

High grade serous ovarian cancer (HGSOC) patients initially respond to chemotherapy but a majority relapse with chemoresistant disease. Research supports the notion that tumor-initiating cells (TICs), a subpopulation of drug resistant stem-like tumor cells, are responsible for facilitating relapse and therapies targeting these fecund cells may prolong remission. The tumor microenvironment (TME) plays a crucial role in therapy resistance, and tumor relapse. Cytotoxic chemotherapies have been shown to modify the stroma of the TME which may favor the survival of TICs displaying specific adhesion proteins. We and others have shown that NF-kB transcription factors RelA and RelB respond to signals from the ovarian TME to promote proliferation, chemoresistance, and survival. Our results further show that RelA and RelB regulate expression of specific integrins. Recently we found that TNF-like inducer of apoptosis (TWEAK), a cytokine involved in tissue repair, and its only known receptor Fn14, are enriched following chemotherapy, leading to enhanced chemoresistance and survival of TICs. TWEAK also induces expression of specific integrins in ovarian TICs. Therefore, we hypothesize that NF-kB mediated integrin expression enables adhesion and survival of TICs to a chemotherapy modified extracellular matrix (ECM) to facilitate tumor repopulation and relapse. Using magnetic activated cell sorting (MACS) for CD117+ TICs, we found that a significant majority are enriched for integrin AVB3. Supporting a role for TWEAK-Fn14-NF-kB in mediating integrin expression we further show that integrin AVB3, but not AVB5 or A5B1, was significantly increased in CD117+ TICs in the presence of TWEAK and was dependent on Fn14 as demonstrated through knockdown experiments. RNA-sequencing analysis of tumor cells grown in spheroid conditions with RelA or RelB shRNA knockdown relative to control, show ITGAV is dependent on RelA while ITGB3 expression is dependent on RelB. Taken together, our findings suggest CD117+ TICs have enhanced expression of AVB3 and is further induced by TWEAK mediated NF-kB activity for adaptation to a stressful post-chemotherapy environment. Ongoing in vitro and in vivo studies are investigating the therapeutic benefit of targeting AVB3 or TWEAK in CD117+ TICs for prevention of adhesion and tumor repopulation following chemotherapy. These studies will uncover interactions between TICs and ECM through their unique expression of integrins and clarifies the role of NF-kB transcription factors RelA and RelB in regulating TIC survival in the post-chemotherapy TME.

#4265 ZEB1-regulated hyaluronan network in the lung tumor microenvironment.

S. Lee[1], J. Park[1], E. Kim[1], S. Cho[1], S. Park[2], J. Kurie[3], Y.-H. Ahn[1];
[1]Ewha Womans University, Seoul, Korea, Republic of, [2]Deargen, Inc., Daejeon, Korea, Republic of, [3]University of Texas MD Anderson Cancer Center, Houston, TX

In the tumor microenvironment, hyaluronan surrounds neighboring cells as one of the major components of the extracellular matrix and stimulates the epithelial-mesenchymal transition (EMT) of various epithelial cancer cells. However, the mechanism of how the hyaluronic network is formed by cancer cells and regulates cancer progression and metastasis has not been known in detail. Therefore, we investigated the role of the hyaluronan network built-up by cancer cells in regulating cancer progression and metastasis in the tumor microenvironment. Our study demonstrated that ZEB1, an EMT-inducing transcription factor, reconstructs the hyaluronan network to induce the expression of ITIH2, a hyaluronan-binding protein, and hyaluronic acid synthase-2 (HAS2). ZEB1 was also shown to control the isoform switching of CD44, a hyaluronan receptor. ITIH2 knockdown and HAS inhibition reduced the formation of hyaluronan cables and inhibited cancer cell migration and invasion. In addition, the treatment of a specific ITIH2 inhibitor identified through deep learning-based screening suppressed the formation of hyaluronan cables, cell migration, and metastasis. These findings suggest that targeting the hyaluronan network could be a novel strategy for suppressing lung cancer progression and metastasis in the tumor microenvironment.

#4266 Evaluation of integrin alpha v beta 5 as a novel target for non-small cell lung cancer via tumor intrinsic and host immune regulation.

B. P. Kahangi[1], W. P. Crosson[1], J.-A. Lee[1], C. Dumitras[1], T. Zhang[1], R. Salehi-Rad[2], L. M. Tran[2], M. Palazzolo[1], D. Conklin[2], S. M. Dubinett[2], B. Liu[2];

Lung cancer is the leading cause of cancer related deaths worldwide, with the most prevalent subtype being non-small cell lung cancer (NSCLC). As only a subset of patients exhibits durable clinical responses to current treatments, including targeted therapy and immunotherapy, new treatment options are needed. Integrins (ITGs) are a diverse class of heterodimeric, transmembrane receptors that bind extracellularly to the extracellular matrix (ECM) and intracellularly to the cytoskeleton to integrate signals bi-directionally between the extracellular environment and cell interior. One of 18 α subunits is paired with one of 6 β subunits to create the 24 known αβ ITGs in mammals. ITGs are expressed at low levels in normal tissue and can be upregulated in cancer cells in response to stress signals in the tumor microenvironment (TME). Altered expression of ITGs is associated with enhanced cell proliferation, metastasis, and immune evasion. Targeting of the diverse ITG family members by inhibitors not specific to individual isoforms has obscured understanding of potentially distinct functions of each heterodimer. Through data mining of a genome wide CRISPR screening publicly available at the DepMap portal, we have identified a novel cancer dependency to ITG αvβ5 in approximately 40% of NSCLC cell lines. Using small molecule ITG αv inhibitors, we have mirrored sensitivity of NSCLC cell lines to their ITG αvβ5 CRISPR scores, suggesting that these inhibitors function specifically through ITG αvβ5 in cell lines. RNA sequencing analysis following αvβ5 inhibition in human NSCLC cell lines revealed downregulation of YAP and E2F1 target genes with alterations in gene ontologies associated with cell cycling and cell death in sensitive, but not resistant, lines. This is consistent with the known function of YAP driving gene transcription promoting cell proliferation and survival, and of E2F1 being implicated in regulating the proliferation and self-renewal of cancer stem cell (CSC). Additional changes to immune processes, specifically perturbations to interferon (IFN) pathways, were identified in response to ITG αvβ5 inhibition, suggesting that ITG αvβ5 may play a role in host anti-tumor immune responses. Pharmacological inhibition of ITG αvβ5 also led to a reduction of tumor growth in NSCLC murine models accompanied with increased CD8 T cell activation. These findings support ITG αvβ5 as a unique target of cancer dependency in NSCLC whose inhibition promotes anti-tumor responses through both tumor intrinsic and host immune regulatory mechanisms.

#4267 Inflammation mediated expression of integrin αvβ3 potentiates KRAS driven PDAC oncogenesis.

R. M. Shepard, A. D. Campos, Z. M. Ortega, H. I. Wettersten, T. Von Schalscha, S. M. Weis, D. A. Cheresh;
University of California San Diego - UCSD, San Diego, CA

Understanding how pancreatic epithelial cells respond to inflammation and why some become tumorigenic and aggressive could identify new methods of early detection and novel therapeutic targets to control disease progression. Here, we leveraged an in vivo model in which mice with pancreas-specific expression of mutant Kras progress from pre-malignant intraepithelial neoplasias (PanINs) to pancreatic ductal adenocarcinoma (PDAC) following caerulein-induced chronic pancreatitis. During the transition from PanINs to PDAC, we observe two classes of neoplastic lesions: classically-described PanIN tubular structures that are highly organized and previously uncharacterized atypical highly disorganized lesions that are marked by robust integrin αvβ3 expression, observations which are consistent with human pancreatitis and PDAC. In vitro, we report that immune-, stroma-, and tumor cell-derived inflammatory cytokines induce β3 expression in a STAT3-dependent manner leading to increased integrin αvβ3. Considering that we previously established αvβ3 as a driver of cancer cell stress tolerance, drug resistance, and a stem-like phenotype, the acquisition of αvβ3 during chronic inflammation may promote tumorigenesis. Indeed, using the spontaneous tumor mouse model and xenograft models of human PDAC, we find that cells with an inability to upregulate β3 during tumor initiation fail to form tumors. These findings implicate integrin αvβ3 as a critical driver of inflammation-mediated pancreatic tumorigenesis.

#4268 Engineered hydrogel elucidates contributions of matrix mechanics to pathobiology of adenocarcinoma and identify matrix-activated therapeutic targets.

R. Cruz-Acuna[1], S. W. Kariuki[1], K. Sugiura[1], S. Karaiskos[1], E. M. Plaster[2], C. Loebel[2], G. Efe[1], T. Karakasheva[3], J. T. Gabre[1], J. Hu[1], J. A. Burdick[4], A. K. Rustgi[1];

[1]Columbia University Irving Medical Center, New York, NY, [2]University of Michigan, Ann Arbor, MI, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]University of Colorado, Boulder, CO

Dysregulation of the extracellular matrix (ECM) properties disturbs tissue homeostasis and contributes to pathological conditions, such as cancer. Recent studies have demonstrated that ECM stiffening is associated with metaplasia-dysplasia-adenocarcinoma sequence in the esophagus. This underscores a compelling need to develop a physiologically-relevant 3D culture model to enable the study of the independent contribution of matrix stiffness to the initiation and progression of esophageal adenocarcinoma (EAC). Such a model will then serve as a platform for pre-clinical drug screening in the context of matrix properties. In this context, we have engineered a hyaluronic acid-based 3D hydrogel platform that supports the growth and differentiation of patient-derived Barrett's esophagus (BE) organoids, a precursor to EAC, as well as patient-derived EAC organoids. The engineered biomaterial 3D platform allows control over matrix stiffness to better recapitulate the mechanically dynamic esophageal cancer microenvironment and help identify therapeutic targets in EAC.Our data demonstrates that BE and EAC organoid density, growth and proliferation can be controlled by matrix stiffness. RNA sequencing data show that increased matrix stiffness promotes changes in the transcriptional profiles of BE and EAC organoids, revealing enrichment of pathways associated with tumorigenesis and disease progression. Furthermore, we demonstrate through molecular and functional assays that increased matrix stiffness endows stem-like properties to the EAC organoids via Yap-Sox9 mechano-activation. Finally, targeted therapy studies in our in vitro and in vivo engineered environments revealed that Yap inhibition regressed the effects of increased matrix stiffness in EAC organoids. In summary, our data suggest that matrix mechanics have a significant role in activation of EAC-associated signaling pathways in patient-derived BE and EAC organoids. We also demonstrate that the engineered hydrogel serves as a platform to identify potential therapeutic targets to disrupt the contribution of pro-tumorigenic matrix mechanics in EAC. Together, these studies establish an engineered patient-derived organoid culture platform that can be used to elucidate underlying matrix-mediated mechanisms of the metaplasia-dysplasia-adenocarcinoma sequence and inform the development of novel therapeutics that target ECM stiffness in EAC. FUNDING SOURCES: NCI P01CA098101, U54 CA163004 and NIDDK K01 DK133620.

#4269 Effect of PAX3-FOXO1 fusion gene on cell-extracellular matrix interaction of Rhabdomyosarcoma.

Chandra Kaladhar Vemula, Ivan Chavez, Anthony Chronopoulos, Jinseok Park

Hematology and Oncology, Children's Hospital of Los Angeles Foundation, Los Angeles, CA

Background Rhabdomyosarcoma (RMS) is the most common childhood soft tissue sarcoma, categorized by two subtypes, fusion protein-positive (FPRMS) and negative (FNRMS), based on the existence of PAX3-FOXO1 fusion gene (P3F). Different features between the two subtypes could guide the use of distinct treatment approaches. We discovered that FNRMS exhibited enrichment of gene sets related to cell-extracellular matrix (ECM) interaction than FPRMS. ECM, providing physical support as a scaffold, regulates cancer development. We hypothesize that a distinct molecular feature, P3F, may cause the difference in cell-ECM interaction between FPRMS and FNRMS.

Methods To confirm the higher cell-ECM interaction of FNRMS vs. FPRMS, we used confocal reflection microscopy (CRM), enabling us to monitor the fibrous structures of ECM. We generated the spheroids with FNRMS and FPRMS cell lines by hanging drop method and embedded them into collagen type I. Then, we assessed orientation and dynamic changes in the structure of collagen fibers surrounding spheroids. Also, we analyze the transcriptome of FPRMS cells with P3F knockdown to confirm if P3F regulates cell-ECM interaction negatively via RNA seq. Additionally, we examined ECM surrounding spheroids of P3F knockdown FPRMS cells if P3F modulates fibrous structures of ECM, indicating cell-ECM interaction.

Results We showed that collagen fibers are oriented more perpendicular to the FNRMS spheroid surface, indicating the strong pulling and pushing effect of cells. However, fibers surrounding FPRMS spheroids showed parallel alignment to their surfaces, reflecting passively pushed by the spheroids. Additionally, fibers near FNRMS spheroids showed greater displacement than those near FNRMS spheroids, which suggests stronger cell-ECM interaction in FNRMS than in FPRMS. Furthermore, P3F knockdown FPRMS cells exhibited significant enrichment of gene sets related to cell-ECM interaction. Their CRM results showed that collagen fiber orientation was significantly perpendicular to the surfaces of spheroids of P3F knockdown FPRMS cells than those of control cells. P3F knockdown cell spheroids also displayed enhanced displacement of ECM fibers than control cells. These results suggest that P3F suppresses cell-ECM interaction, consistent with higher cell-ECM interaction of FNRMS than FPRMS.

Conclusions The PAX3-FOXO1 gene may regulate cell-ECM interaction negatively, causing distinct features between FPRMS and FNRMS, which is crucial for various cellular functions and suggest different treatment between the two RMS subtypes.

#4270 Differential expression of the αVβ3 integrin affects small extracellular vesicle cargo and promotes small extracellular vesicle pro-tumorigenic activity *in vivo* via its downstream effector, NgR2.

C. E. Verrillo, F. Quaglia, N. Naranjo, A. Testa, L. R. Languino;
Thomas Jefferson University, Philadelphia, PA

It is known that small extracellular vesicles (sEVs) are released from cancer cells and contribute to cancer progression via crosstalk with recipient cells. These sEVs are being investigated as powerful biomarkers and possible therapeutic agents for prostate cancer (PrCa), which remains the leading cause of cancer death among men in the United States. We have previously reported that sEVs expressing the αVβ3 integrin, a protein upregulated in aggressive neuroendocrine prostate cancer (NEPrCa), contribute to neuroendocrine differentiation (NED) in recipient cells. sEVs used in this study were isolated by iodixanol density gradient and characterized by nanoparticle tracking analysis, immunoblotting, and single vesicle analysis. Our proteomic profile of sEVs containing αVβ3, when compared to control sEVs, shows a downregulation of typical effectors involved in apoptosis and necrosis, and an upregulation of tumor cell survival factors. This subset also contains an αVβ3 downstream effector, NgR2, a member of the Nogo receptor family and a novel marker for NEPrCa. We have previously shown that NgR2 promotes NED and cell motility, and upregulates RhoA, a protein associated with aggressive phenotypes of PrCa. In this study, we show that the expression of NgR2 increases tumor growth *in vivo*. We also show that the downregulation of NgR2 inhibits tumor growth and NED. Furthermore, we report that sEVs containing αVβ3 are loaded with higher amounts of NgR2 as compared to sEVs that do not express αVβ3. Mechanistically, we demonstrate that sEVs containing NgR2 do not affect the sEV marker profile, but, when injected *in vivo* intratumorally, they promote tumor growth and induce NED. We confirm that the transfer of NgR2 into recipient cells is sufficient to promote tumor growth and show that NgR2 mimics the effect of sEVs containing αVβ3 since it displays increased growth of NgR2 transfectants *in vivo,* as compared to control cells. Overall, our results describe a new mechanism mediated by sEVs containing αVβ3 and NgR2 that promotes cancer progression.

#4271 The ITGA2 (CD49b) collagen receptor excludes the $CD8^+$ T cell infiltration in pancreatic ductal adenocarcinoma.

Ibrahim Ragab Eissa, Eric D. Abston, Darshini Kuruppu, Yongtao Wang, Guoliang Qiao, Motaz Qadan, Michael Lanuti, Kenneth K. Tanabe

Massachusetts General Hospital /Harvard Medical School, Boston, MA

BACKGROUND: Pancreatic ductal adenocarcinoma cancer (PDAC) is characterized by an enriched extracellular matrix and limited T cell infiltration, which poses challenges for immunotherapy. The significant accumulation of collagen type I (COL1) in PDAC tumor microenvironment raises questions about its functional role in PDAC progression and its interactions with the cellular compartments. **OBJECTIVE**: The objective of this study was to investigate whether the collagen receptors expressed by cancer cells modulate the anti-tumor activity of $CD8^+$ tumor-infiltrated lymphocytes ($CD8^+$ TILs).**METHODS**: Collagen receptor expression patterns in PDAC were examined using flow cytometry, western blot, multiplex immunofluorescence, RNA seq, and scRNA seq databases in KPC and treatment-naïve PDAC that were resected from patients. The KPC cell line, known as Hy15549, was established from KPC mouse model (Ptf1-Cre; LSL-KRAS-G12D; Trp53 Lox/+). Using CRISPR-Cas9, we conducted targeted deletions for either ITGA2(CD49b) or ITGB1(CD29), as well as generating double knockouts for both CD49b and CD29. Growth of these cell lines implanted into the flanks of immunocompetent, immunodeficient mice was measured, as well as after $CD8^+$ T cell depletion in immunocompetent mice. We analyzed TILs using FACs. We used multiplex immunofluorescence to analyze tumors microenvironment including collagen fiber alignment. Downstream signaling pathways were assessed using RNA seq and western blot. **RESULTS:** CD49b is highly expressed specifically in PDAC cancer cells, as assessed in both KPC cell flank tumors and resected human PDAC. Using adhesion assay, we found that CD49b specifically binds to Col1 rather than ColIV. $KPC^{CD29b\ KO}$ exhibited a complete loss of adhesion to both Col1 and ColIV. Tumor growth of the $KPC^{CD49b\ KO}$, $KPC^{CD29\ KO}$, $KPC^{CD49b\ CD29\ KO}$ was observed to be significantly slower than KPC^{WT} despite identical in vitro growth kinetics. Knockout of CD49b in tumors promoted intratumoral infiltration of $CD8^+$ T cells and significantly impeded tumor growth. Tumor growth by $KPC^{CD49bKO}$ was rescued by depletion of $CD8^+$ T cells. In contrast to observations in immune-competent mice, $KPC^{CD49bKO}$ tumor growth was similar to KPC^{wt} in immunodeficient nude mice. Analysis of downstream signaling in $KPC^{CD49bKO}$ tumors revealed a decrease of FAK as well as pFAk expression pathway. The proteomic profiling of $KPC^{CD49bKO}$ revealed an increase of CXCL10 chemokine. Moreover, In the absence of CD49b, the orientation of collagen fiber alignment appeared more scattered, with thinner fibers. This altered alignment could potentially contribute to immune cell infiltration.**Conclusion:**These findings reveal a previously unreported function of CD49b in PDAC cancer progression and the immune response within the TME. Together, our study reveals a mechanism underlying immune exclusion and suggests a novel immunotherapeutic target in PDAC.

#4272 Disruption of hyaluronan metabolism alters glioma cell proliferation by ligand dependent and independent mechanisms.

E. R. Neves, J. Mueller, A. Anand, K. Selting, H. Xu, R. Remy, B. Harley, **S. Pedron-Haba**;
University of Illinois Urbana-Champaign, Urbana, IL

Hyaluronan (HA) is the main constituent of the brain extracellular matrix and is an essential component of the glioblastoma (GBM) tumor microenvironment. The biosynthesis and catabolism of hyaluronan has multiple roles in tissue architecture and cell signaling. Dysregulation of these mechanisms is crucial in pathological processes such as cancer, inflammation or tissue remodeling. The role of HA is believed to be strongly dependent on its size (molecular weight), location, and cell receptor density and activity. HA is produced intracellularly by HA synthases (HAS1-3) and can also be catabolized endogenously by hyaluronidases (HYAL1-3).The fabrication of controlled microenvironments provided by three dimensional (3D) models helps to elucidate the role of HA signaling in GBM tumors. We exploit here the advantages of these models to understand the role of hyaluronan in the local behavior of GBM after radiation therapy and selected targeted inhibitors. We have established engineered brain tumor biomaterials based on functionalized hydrogels to monitor the response of patient-derived xenograft cell populations with different molecular signatures in combination with microfluidic devices. We have analyzed shifts in metabolism, hyaluronan secretion, as well as hyaluronan synthetic enzymes (HAS) and hyaluronidases (HYAL) activity in an array of patient derived GBM cells. We reveal that endogenous HA plays a role in mitochondrial respiration and cell proliferation in a tumor subtype dependent manner. We also show that HA fragments can enhance tumor metabolism and growth through ligand dependent and independent mechanisms. We provide bioengineered platforms and strategies to predict and stratify tumors in order to achieve more efficient combinatorial treatments targeting endogenous hyaluronan production. This work emphasizes the potential of these preclinical models to predict and accelerate cancer treatments, more relevant in malignancies with limited treatment options.

#4273 Genetically engineered mesenchymal stromal cells degrade hyaluronic acid to disrupt the ECM and enhance cancer therapy outcomes.

A. T. Browne, M. Clements, W. Ju, R. Kaplan;
National Institutes of Health (NIH), Bethesda, MD

The extracellular matrix (ECM) is a vital component of cancer pathophysiology. However, little is known about how to modulate the ECM for therapeutic benefit effectively. Hyaluronic acid (HA) is a polysaccharide component of the ECM with increased deposition during tissue injury or inflammation. HA in the tumor microenvironment (TME) has been linked to aggressive cancer progression. We have found enhanced ECM remodeling behavior linked to pre-metastatic niche formation and metastatic progression. To remodel this ECM-enriched microenvironment, we developed HA-targeting genetically engineered mesenchymal stromal cells (GEMesys) expressing hyaluronidase (Hyal), the enzyme responsible for HA degradation. We examined the impact of Hyal-GEMesys in osteosarcoma (F42010), rhabdomyosarcoma (M-3-9M), and pancreatic cancer (Panc02) syngeneic murine models. Hyal-GEMesys delivered to tumor-bearing mice homed to primary tumor sites and successfully degraded HA in the TME. The degradation of HA also resulted in a significant remodeling of collagen. T cells in Hyal-GEMesy treated tumors display an activated CD4+CD44+ phenotype with a reduction of LAG3+PD1+ exhaustion markers. Additionally, Hyal-GEMesy treatment results in a significant decrease in hypoxic regions within tumors and reorganization of the tumor vasculature to a more normalized phenotype, marked by diminished CD31 expression. Hyal-GEMesy treatment reduces tumor volumes in osteosarcoma, rhabdomyosarcoma, and pancreatic cancer models and enhances chemotherapeutic efficacy. These findings suggest that reorganizing the tumor ECM with Hyal-GEMesys holds the potential to dismantle the protective stroma of the tumor, which often shields malignant cells from therapeutic reach, and combining anti-cancer and anti-stroma agents can enhance anti-tumor efficacy and patient outcomes.

#4274 Unraveling collagen signatures in cancer-associated fibroblasts: A biomarker-driven approach.

A. Hettich, N. I. Nissen, M. A. Karsdal, **N. Willumsen**;
Nordic Bioscience, Herlev, Denmark

Background: The tumor microenvironment (TME) plays a crucial role in driving tumor development. Among the constituents of the tumor stroma, cancer-associated fibroblasts (CAFs) are a significant component. CAFs are actively involved in tumor progression by modulating the architecture of the TME through increased deposition of various collagens resulting in tumor fibrosis. Several studies have shown that CAFs have heterogeneity within, and between, individual tissues. TGF-β is thought to be the main driver of tumor fibrosis, however, the field lacks a characterization of the specific collagen deposition of CAFs from different tissues. In this study, we investigated the fibrotic activity of CAFs from various tissues by measuring the production of three specific collagen peptides in vitro by use of non-invasive clinically validated biomarkers.
Methods: Primary human CAFs from pancreas (pCAF), colon (cCAF), breast (bCAF) and lung (lCAF) were cultured over a 12-day period in ficoll-based media under both unstimulated conditions and TGF-β stimulation. Additionally, cells were subjected to treatment with the ALK5/TGF-β1 receptor kinase inhibitor (ALK5i). The assessment of collagen I (PRO-C1), collagen III (PRO-C3), and collagen VI (PRO-C6) formation was conducted in the cell supernatant at day 3, day 6, day 9, and day 12 using competitive enzyme-linked immunosorbent assay (ELISA).
Results: For lCAFs, cCAFs, and pCAFs, the addition of TGF-β led to a notable elevation in the levels of PRO-C1, PRO-C3, and PRO-C6 within the supernatant. Conversely, in the case of bCAFs, stimulation with TGF-β did not elicit remarkable alterations in the levels of PRO-C1 and PRO-C3 compared to unstimulated cells. Notably, bCAFs exhibit elevated intrinsic activity (high PRO-C3) even in the absence of TGF-β stimulation whereas lCAFs and cCAFs exhibited relatively low level of PRO-C3. Additionally, across all different CAFs, the introduction of ALK5 inhibitor (ALK5i) to the culture medium resulted in a considerable reduction in PRO-C1, PRO-C3, and PRO-C6 levels, returning them to the baseline of the unstimulated control or even lower. Distinct collagen formation patterns were observed among the various CAFs. CAFs derived from breast cancer exhibited the highest release of PRO-C1 and PRO-C3, while CAFs isolated from colon cancer displayed the highest levels of PRO-C6.
Conclusion: These findings underscore the heterogeneity in collagen production among different CAFs, providing valuable insights into the extracellular matrix dynamics within distinct tumor microenvironments. Moreover, non-invasive biomarkers demonstrate the capability to differentiate between different CAF subtypes. Lastly, our model proves to be a valuable tool for anti-fibrotic drug screening, as evidenced by the consistent suppression of TGF-β1 signaling and reduced levels of PRO-C1, PRO-C3, and PRO-C6 upon treatment with ALK5i across all cases.

#4275 Targeting tumor extracellular matrix to improve response to therapy.

O. M. T. Pearce;
Queen Mary University of London, London, United Kingdom

Introduction. Building on our previous findings that tumor extracellular matrix (ECM) composition associates with immune cell phenotype (Pearce et al, Cancer Disco, 2018), and ECM can directly educate tumor-associated immune phenotypes (Puttock et al, Nat Commun, 2023), we present here the identification of specific ECM components that associate with tumor immune phenotype, and discuss our approach to target these components as a way to improve anti-tumor immunity and immunotherapy response.

Methods. We use a combination of transcriptomics, proteomics, glycomics, and spatial tissue analysis to identify correlations between ECM composition and the immune landscape in breast and ovarian cancers. Correlations are tested within a decellularized tumor model made from patient samples which allow immune cell movement, interaction with ECM, and tumor killing to be measured in real-time.

Results. Through our analysis pipeline we have identified a specific ECM molecule that appears to regulate the spatial location of tumor infiltrating CD8 T-cell populations via post-translational modifications that are present on the molecule. Deletion of this molecule in injectable orthotopic murine models dramatically alters the immune landscape within the tumor. Within an in vitro decellularized tumor tissue model the *in situ* deletion of the ECM molecule drives tumors into an inflamed phenotype which is more responsive to cell-based cancer therapy.

Conclusions. Tumor ECM can direct immunity in two ways. These are educating or stimulating immune cells to develop specific phenotypes that tend to be immunosuppressive, and secondly directing the movement of cells within the tissue. These immunosupressive effects can be overcome through small modifications to ECM structure, indicating therapeutics that make subtle changes to ECM composition may be used in combination with current cell-based therapies to improve tumor response.

#4277 CREB-ROCK driven extracellular matrix remodeling exasperates pancreatic cancer progression.

S. Jinka, S. Mehra, V. Krishnamoorthy, A. Bianchi, K. Rajkumar, A. Adams, H. Amirian, S. Singh, E. W. Box III, E. Dickey, N. L. Alberto, B. Yuguang, J. Datta, N. Merchant, N. Nagathihalli;
University of Miami, Miami, FL

Background: Pancreatic Ductal Adenocarcinoma (PDAC) is characterized by a heightened oncogenic mutational burden, an immunosuppressive tumor microenvironment, and a dense desmoplastic stroma. During the tumor progression from *in situ* carcinoma to intraductal neoplasia, cancer cells manage to evade the stromal compartment and infiltrate into the ducts. This invasive tumor progression is often associated with the overexpression of extracellular matrix (ECM) modulating genes. Despite this correlation, there are currently no effective and specific inhibitors of ECM-altering pathways. By understanding the signaling mechanism, the ECM remodeling pathways may be intercepted to prevent invasive tumor progression. This study aims to elucidate the role of cAMP-response element binding protein 1 (CREB1) and its downstream effectors in regulating PDAC ECM remodeling.
Methods: The Cancer Genome Atlas (TCGA) was quired for *CREB1* expression and other ECM modulators in PDAC patients. *In vitro*, CRISPR/CAS9-based genomic editing was utilized to knockout CREB1 in the murine KPC cell line, on which RNA-seq analysis was performed. To investigate the effects of CREB in PDAC progression, a novel conditional CREB1 knockout ($CREB^{fl/fl}$) was created in LSL-$Kras^{G12D/+}$; $Trp53^{R172H/+}$; $Pdx1^{Cre/+}$ (KPC) mice ($KPCC^{-/-}$). Tumors were extracted and histologically evaluated. Immunoblotting and staining were conducted on both *in vitro and in vivo* samples. Chromatin immunoprecipitation sequencing (ChIP-seq) and qPCR were performed on the KPC $CREB^{KO}$. Eukaryotic Promoter Database (EPD) and ENCODE databases were explored to evaluate the transcriptional role of CREB in regulating ECM genes.
Results: Patient PDAC samples data from TCGA revealed elevated levels of *CREB1, ROCK1,* and *ROCK2* compared to normal pancreatic tissues. When comparing high *CREB* expression to low *CREB* expression, upregulation of several ECM genes was noted, including *ROCK1* and *ROCK2* in patients with high *CREB* expression. In $CREB^{KO}$, RNA-seq analysis revealed the downregulation of key ECM genes, including *Mmp3, Mmp10, Lama3,* and *Fn1* compared to CREB wildtype. In our novel murine conditional knockout model, a substantial reduction in fibrosis was observed. In both *in vitro* and *in vivo*, immunoblot and staining demonstrated a marked reduction in the expression of ECM remodeling proteins upon CREB deletion. Through ChIP-seq, the direct involvement of CREB1 in the transcriptional regulation of *Rock1* and *Rock2* was established. EPD and ENCODE were utilized to confirm and validate our CREB regulation experimental findings.
Conclusion: These findings demonstrate the role of CREB in PDAC progression, which may provide a potential target to intercept ECM remodeling via inhibition of the CREB-ROCK axis to suppress PDAC tumor progression and invasion.

#4278 Role of WNK1 in extracellular matrix modification in breast cancer.

P. Suman, S. Kakkat, S. S. Patil, V. Ramirez, E. A. Turbat-Herrera, S. Singh, C. Sarkar, D. Chakroborty;
University of South Alabama, Mobile, AL

Introduction: Breast cancer (BCa) is the most common cancer and the second leading cause of cancer related deaths in women in the United States. Metastatic dissemination of cancer cells remains the leading cause of mortality in BCa. Therefore, determination of the mechanisms that promote metastasis is important for development of new therapeutic strategies. The extracellular matrix (ECM), which is the main non-cellular component of the tumor microenvironment (TME), plays an important role in BCa progression and metastasis. The cancer-associated fibroblasts (CAFs) are the principal cell types that together with BCa cells drive the modification of ECM during cancer development. Lysine deficient receptor protein kinase 1 (WNK1), a widely expressed serine threonine kinase that regulates blood pressure and electrolyte balance in the body, and is highly overexpressed in BCa microenvironment. The aim of the present study was to investigate the role of WNK1 in modification of ECM in BCa.

Methods: The clinical relevance of WNK1 overexpression in BCa was determined by immunohistochemically staining human BCa sections, analyzing data from publicly available databases and creating orthotopic mouse models of BCa using 4T1 mouse BCa cells followed by treatment of the tumor bearing mice with WNK1 inhibitors, WNK-IN-11 and WNK463 (10 mg/kg , oral for 10 days). *In vitro* assays were conducted using 4T1 cells and mouse embryonic fibroblasts (MEFs) to determine the regulatory role of WNK1 on cancer cells and fibroblasts.

Results and Conclusion: Our results indicated that WNK1 is strongly expressed in BCa cells and fibroblasts, the two most abundant cell types in the BCa microenvironment. Furthermore, WNK1 expression strongly correlated with expressions of matrix regulatory and cross-linking genes. Our results demonstrated that WNK1 inhibitors significantly reduced orthotopic 4T1 growth and metastasis. WNK1 inhibition also significantly inhibited collagen deposition in tumor tissues, which is a negative prognostic indicator in BCa. *In vitro* proliferation and migration assays using 4T1 cells and MEFs identified that WNK1 inhibitors (1-100nM) can significantly inhibit the proliferation and migration of 4T1 cells and MEFs. Results from co-culture studies with 4T1 cells and MEFs further indicated that WNK1 inhibition in MEFs could significantly reduce the invasive properties of 4T1 cells. Taken together, our results suggest that blocking the actions of WNK1 in BCa may be a promising therapeutic approach.

#4280 Regulatory T cells contribute to tumor cell dissemination by extracellular matrix remodeling.

A. Garcia-Santillan, J. Y. Lichtenberg, H. Shen, M. G. Dozmorov, A. L. Olex, P. Y. Hwang, **P. D. Bos**;
Virginia Commonwealth University, Richmond, VA

Regulatory T (Treg) cells function to enforce peripheral tolerance and are potent suppressors of tumor immunity. In breast cancer, we have shown that Treg cells promote tumor growth by favoring alternative activation of macrophages via suppression of IFN-γ. The tumor-associated extracellular matrix (ECM) is a key regulator of metastatic dissemination and is emerging as a critical regulator of tumor immunity. However, the reciprocal effects of the immune system on the ECM remain elusive. Using murine *in vivo*, *ex vivo* and bioengineering models we describe Treg cell-dependent changes in the tumor ECM that facilitate tumor cell movement and metastatic dissemination. Further, Treg cell-dependent matrisome signatures correlate with survival in human breast cancer samples. This work underscores a previously unrecognized role of Treg cells on the ECM that facilitates metastasis and is consistent with tissue Treg cell emergent function as critical regulators of tissue repair and cancer.

#4281 BMP signaling impaired telocytes-Foxl1+disrupt the extracellular matrix network enabling the development of colitis-associated cancer.

V. Reyes Nicolas, A. B. Alfonso, J. Raisch, F. M. Boisvert, M.-A. Lauzon, N. Perreault;
Universite de Sherbrooke, Sherbrooke, QC, Canada

The relationship between colon stem cells (SCs), its surrounding niche microenvironment like the extracellular matrix (ECM) and the mesenchymal niche cells is complex and dynamic. ECM proteins are not only a scaffolding system for SCs, but their biophysical properties also contribute to localizing signals and creating gradients leading to the SCs homeostasis. Foxl1+-Telocytes (TC^{FoxL1+}) are mesenchymal niche cells implicated in cell-cell communication and the production of BMP ligands. Upon chronic inflammation, mice lacking BMP signaling in TC^{FoxL1+} (*BmpR1a*$^{\Delta FoxL1+}$), developed colonic tumors with microenvironment exhibiting abnormal TC^{FoxL1+} structure, increased BMP expression and myofibroblastic-like cancer-associated fibroblasts (myCAF) subpopulation. Yet, how the TC^{FoxL1+} influences SCs niche ECM proteins during tumorigenesis is less understood. We aimed to investigate how the loss of BMP signaling in TC^{FoxL1+} affects ECM network impacting the niche microenvironment promoting the development of CAC. DSS-based chronic inflammatory challenge in mutant and control mice, quantitative-MS-based strategy was performed to determine the proteome of the transformed regions solely in epithelial-mesenchymal tissue following colon deconstruction. Expression of the proteins of interest were validated by Western Blots or immunostainings. Quantitative analysis of collagen network was assessed using phyton pipeline U-net in Sirius red-stained colon analyzed under polarized light. Differential significant expression of 798 proteins, with 342 upregulated and 456 downregulated, were found in the tumors of mutant mice compared to controls. Mfap5 involved in CAF activation was the highest upregulated protein. We found upregulated, laminin subunits α4 and β2, decorin, lumican as well as transgelin (myCAF marker), which are proteins known for contributing to the stiffening of the ECM during colorectal cancer. Adamdec1 which prevents aberrant ECM accumulation and thrombospodin-1, an ECM glycoprotein whose low levels have been related to tumor growth, were both found to be downregulated. Data extracted from Python's U-Net pipeline demonstrated that tumors, in mutant mice, exhibited higher frequencies of straighter collagen fibers compared to wavier fibers in controls. Collagen fiber distribution was shown to present an even angle distribution in controls whereas *BmpR1a*$^{\Delta FoxL1+}$ mice presented a preferential orientation. These results suggest that defective TC^{FoxL1+} commits the surrounding niche microenvironment, especially its ECM, toward the development and progression of CAC.

#4282 Crosstalk between the immune system and the extracellular matrix in the context of melanoma and aging.

E. I. Harper, Y. Chhabra, A. Carey, M. Ramos Rocha, L. Huser, V. Wang, A. Dixit, A. Weeraratna;
Johns Hopkins University, Baltimore, MD

Aging is an independent prognostic factor for the diagnosis of melanoma. The extracellular matrix of the skin has well-documented changes with age, such as the loss of HAPLN1, which can lead to differential metastasis in aged individuals. The aged microenvironment can contribute to the phenotype switch, where aged individuals have smaller primary tumors but more metastases, i.e., going instead of growing. The extracellular matrix (ECM) has been shown to modulate the immune response either through direct binding of ECM proteins or through mechanotransduction, but it is unclear how aging affects this crosstalk. Our hypothesis is that the ECM can modulate immune response to melanoma and affect response to immune checkpoint blockade (ICB) therapy. Melanoma cells cultured on cell derived matrices (CDMs) from young and aged human fibroblasts show differential levels of expression of PD-L1, a ligand that binds to PD-1 on T cells to induce T cell exhaustion. Antibodies targeting PD-1/PD-L1 are one of the main ICB treatments available to melanoma. We are also investigating T cell motility on young and aged CDMs, as well as correlating T cell infiltration in murine tumors with ECM signatures as identified by second harmonic generation microscopy. Therefore, we have compiled evidence that aging affects the crosstalk between the extracellular matrix and the immune system, providing a new horizon for therapeutic improvement of response in older patients.

#4283 NAMPT-enriched small extracellular vesicle promotes liver cancer via activation of SLC27A4-mediated glycolysis.

L. Yeung, T. Ng, J. Yam;
University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pok Fu Lam, China

Introduction: Tumor-derived small extracellular vesicles (sEV) act as a major mediator of the tumor microenvironment (TME) and are reported to regulate various metabolic pathways.
Methods: Small extracellular vesicles (sEV) were collected from normal human hepatocyte and metastatic HCC cell lines using differential ultracentrifugation. Mass Spectrometry proteomic analysis was employed to identify NAMPT to be enriched in metastatic HCC-sEV. The glycolytic effect of NAMPT-sEV was analyzed by seahorse glycolytic assay.
Result: Mass spectrometry protein analysis revealed nicotinamide phosphoribosyl transferase (NAMPT) to be upregulated in metastatic HCC-sEV. NAMPT is a rate-limiting enzyme essential for maintaining cellular level of nicotinamide dinucleotide (NAD+). However, the underlying pathway of sEV-NAMPT-induced metabolic consequence in HCC remains largely unknown. This study elucidated sEV-NAMPT's carcinogenic role by establishing NAMPT-knockdown (NAMPT-KD) stable clone in metastatic HCC cell lines, which significantly hampered the promoting effect of HCC-sEV in glycolysis. sEV-mediated *in vitro* and *in vivo* tumor growth was also inhibited. Through sEV treatment, we found that sEV-NAMPT significantly elevate SLC27A4 in both transcription and protein level of recipient cells. Mechanistically, it is demonstrated that SLC27A4 expression was enhanced by NF-κB transcription factor, which is activated upon binding of sEV-NAMPT to toll-like receptor 4 (TLR4). SLC27A4 mainly function as a long-chain fatty acid transporter or acyl-CoA synthetase. Lipidomic and metabolomic analysis unveiled SLC27A4 to be positively correlated with intracellular triacylglycerol (TG) and dihydroxyacetone phosphate (DHAP) level. Elevation of TG aggravates lipolysis by hepatic lipase and promotes conversion of glycerol-3-P to DHAP, which is an intermediate metabolite that transit between lipid metabolism and glycolysis. This study uncovers a regulatory axis of sEV-NAMPT-mediated SLC27A4 in glycolysis, apart from conventional fatty acid-related metabolisms. Clinically, we explored the therapeutic potential of targeting sEV-NAMPT by inhibitor FK866. Treatment of NAMPT-inhibitor significantly hampered tumor growth in various HCC *in vivo* models, which suggested an alternative therapeutic strategy for HCC.
Conclusion: NAMPT is enriched in metastatic HCC sEV. sEV-NAMPT regulates the promoting effect of HCC-sEV in glycolysis and oncogenesis. SLC27A4 function as the downstream target that promotes HCC progression via glycolysis. NAMPT inhibitor FK866 are proven to reduce *in vitro* and *in vivo* tumorigenic ability of metastatic HCC-sEV, which may serve as potential HCC treatment option.

#4284 Macrophage reprogramming and immune suppression through extracellular vesicles loaded eIF4A1in ovarian cancer.

S. Mittal, I. Pulikkal Kadamberi, S. Kumar, J. George, M. singh, A. Geethadevi, P. Chaluvally-Raghavan, S. Pradeep;
Medical College of Wisconsin, Wauwatosa, WI

Background- In ovarian carcinoma (OvCa), macrophages are reprogrammed toward pro-tumorigenic phenotypes, including releasing anti-inflammatory cytokines and expressing immunosuppressive molecules. However, how these macrophages acquire their phenotype remains largely unexplored. To understand the mechanism driving pro-tumorigenic phenotype in macrophages, we studied the role of tumor cell-derived extracellular vesicles (EVs) in the cross-talk with macrophages in OvCa. We found that EVs from ovarian cancer cells contain eukaryotic translation initiation factor 4A1 (eIF4A1). eIF4A1 containing EVs from ovarian cells enhanced macrophage translational activity and PD-L1 expression. However, the detailed mechanism that explains how eIF4A1-packaged EVs induce immunosuppressive phenotype in macrophages is necessary to develop novel immunotherapy strategies for advanced OvCa treatment.

Methods- We performed SUnSET assay (surface sensing of translation) to determine whether eIF4E-EVs affect global translation in macrophages. SILAC (Stable isotope labeling by amino acids) based mass spectrometry was used to identify the downstream targets of eIF4A1 in macrophages. We isolated murine peritoneal macrophages from naïve C57BL/6 female mice and co-cultured the macrophages with EVs derived from ovarian cancer cell lines. The expression of PD-L1, CD206, interleukin-6 (IL-6), and other inflammatory cytokines on EVs treated macrophages was evaluated using flow cytometry and a cytokine array kit. Further, we created a Rab27aKO ovarian cancer in vivo model to study the effect of eIF4A1 packaged EVs on the immune suppressive ability of macrophages and tumor progression.

Results- Our study shows that tumor cells employ EVs to deliver eIF4A1 to the tumor microenvironment, facilitating the release of cytokines such as IL-6 and the expression of PD-L1 on macrophages and supporting tumor growth. In addition, our data shows that eIF4A1-EVs enhance protein synthesis in macrophages. Our data show that in the Rab27aKO ovarian cancer in vivo mouse model, intravenous injection of eIF4A1-packaged EVs increased the tumor burden, metastasis, and ascites accumulation as compared to PBS control. eIF4A1-EVs treatment increased the infiltration of tumor-associated macrophages (TAM) in ascites. We also found increased expression of PD-L1 and CD206 on TAM isolated from ascites

#4285 Tumor-on-chip co-culture system: A comprehensive tool in personalized medicine to study cancer progression.

S. Kamali, M. Gilardi, B. Walling, A. Andar, K. Abarca-Heidemann, M. Mancini;
Champions Oncology, Inc. (Hackensack, NJ), Hackensack, NJ

As a part of the rapidly advancing organ-on-chip field of research, tumor-on-chip technology (TOC) has emerged as a promising co-culture system to mimic the mechanical and biochemical properties of the tumor microenvironment. This includes factors such as oxygen and nutrient gradients, extracellular matrix stiffness, and cell-cell interactions. Depending on the complexity of system, TOCs are miniature tumor models in a microfluidic chip allowing researchers to gain a better understanding and controlled cancer environment to effectively test potential drug treatments and study immune cell co-cultures. Champions'TumorGraft3D (CTG3D), established from patient-derived xenografts, is the essential component used to recapitulate tumor microenvironment in the TOC platform which provides an even more powerful tool to gain more insight on the efficacy of various therapeutics. Here, we demonstrate the value in combining microfluidic devices with well characterized CTG3D models at Champions Oncology focused on indications including colorectal, breast, gastric and lung cancer. In brief, we optimized cell seeding conditions in both top (seeded with CTG3Ds) and bottom (seeded with endothelial cells) channels to develop TOCs interfacing epithelial-endothelial cells. These established systems may be applied as a baseline for introducing additional cell types such as autologous tumor-infiltrating lymphocytes (TILs) and studying their effect in the presence and absence of additional treatments. With an initial focus on colorectal cancer, we successfully developed TOC epithelial-endothelial interface using CTG3Ds originated from patients with various clinical backgrounds. We measured the permeability as an initial read-out to prove that although tumor cells do not inherently form a tight barrier, they can still form a non-leaky barrier with distinct organoid-like structures. Next, we extended our study to additional indications featuring unique characteristics and proved the feasibility of applying TOCs as a preclinical tool regardless of the tissue-of-origin. In all cases, the endothelial cells formed mature microvascular structures and to confirm the consistency of formed epithelial-endothelial interface among the replicates of each experimental group, we did Luminex studies to prove high consistency in secreted proteins. Regarding the functionality of TOCs, we investigated the effect of relevant test agents to each indication and showed that that the combination of DRAQ7 dye and high-content imaging may be a reliable read-out to detect the response and viability of cancer cells pre- and post-treatment. In summary, our established tumor-on-chip system proves to be a robust and powerful tool for studying the effect of microenvironmental factors in drug testing and immune cells in cancer progression.

#4286 Proteolytic degradation of BIGH3 can be quantified non-invasively in serum with biomarker potential for patients with non-small cell lung cancer.

R. S. Pedersen, M. Karsdal, N. Willumsen;
Nordic Bioscience, Herlev, Denmark

Introduction: Transforming growth factor beta induced protein ig-h3 (BIGH3/TGFBI) is expressed widely by multiple cell types, including macrophages and fibroblasts, and is participating in various biological processes including adhesion, migration, angiogenesis and wound healing. BIGH3 is known to bind multiple collagens and are often embedded in the matrix where it seems to function as a linker between ECM and cell surfaces. The increased proteolytic activity found in non-small cell lung cancer (NSCLC) may degrade BIGH3 that affect this interaction as well as generate small peptide fragments that can serve as novel non-invasive biomarker targets if released to circulation. The aim of this study is to develop a tool to quantify degraded BIGH3 non-invasively and explore its potential as a biomarker in NSCLC.

Methods: An ELISA, named nordicBIGH3M-N targeting a cleaved fragment of BIGH3 was developed to reflect BIGH3 degradation and enable serological quantification. We incubated recombinant BIGH3 with and without collagenase to confirm that nordicBIGH3M-N only measured degraded BIGH3. In addition, we generated matrixes from normal fibroblasts and cancer associated fibroblasts (CAFs) grown with or without tgf-b. These matrixes were cleaved with collagenase to confirm that NordicBIGH3M-N could be generated from degradation of matrix. nordicBIGH3M-N was also measured in serum from 39 patients with NSCLC (18 patients with adenocarcinoma and 21 patients with squamous cell carcinoma) and 35 healthy controls. BIGH3M-N levels in serum from patients with the two subtypes of NSCLC and healthy controls was compared using Dunn’s multiple comparison test and area under receiver operation characteristic curves (AUROC).

Results: BIGH3M-N was only detectable after incubating recombinant BIGH3 and fibroblasts matrices with collagenase. A 7-fold increase of BIGH3M-N levels was seen between the collagenase degraded matrix from tgf-b treated fibroblasts compared to the degraded matrix from untreated fibroblasts. No difference in BIGH3M-N levels was observed between degraded matrix from tgf-b treated or untreated CAFs. BIGH3M-N was significantly elevated in patients with squamous cell carcinoma compared to healthy controls ($p = 0.006$, AUROC = 0.73) and patients with adenocarcinoma ($p = 0.022$, AUROC = 0.78). However, there was no significant difference between BIGH3M-N levels in serum from patients with adenocarcinoma and healthy controls ($p>0.99$, AUROC = 0.51).

Conclusion: Degradation of BIGH3 can be reflected by non-invasive quantification of the cleaved fragment of BIGH3, BIGH3M-N, in serum. BIGH3M-N is a promising biomarker in NSCLC with potential for discriminating between subtypes. Moreover, BIGH3M-N is connected to fibroblast matrix biology so the optimal use for this biomarker might be in combination with other ECM biomarkers.

#4287 Serological quantification of fibroblast activation protein (FAP) cleaved type III collagen: A biomarker for FAP activity.

R. S. Pedersen, M. Karsdal, N. Willumsen;
Nordic Bioscience, Herlev, Denmark

Introduction: Fibroblast activation protein (FAP) has unique proteolytic activity with very low expression in healthy tissues, while being upregulated in diseased tissues including many types of cancer for example non-small cell lung cancer (NSCLC). The disease specific expression and unique proteolytic activity have made FAP an interesting protein to be utilized for drug targeting purposes. Therefore, it is important to identify the patients with FAP activity. The aim of the study was to develop a tool to non-invasively quantify FAP activity and investigate its potential as a biomarker for patients with NSCLC.
Methods: We developed an ELISA (named C3F), with monoclonal antibodies raised against a FAP generated fragment of type III collagen that was identified by MS, to quantify FAP-mediated cleavage of type III collagen in serum to reflect proteolytic activity of FAP. We confirmed that the biomarker reflects proteolytic activity of FAP by incubating type III collagen with or without FAP and measured C3F. In addition, we confirmed elevated FAP expression in NSCLC (adenocarcinoma and squamous cell carcinoma) compared to healthy tissue and correlation between FAP and COL3A1 expression using data from The Cancer Genome Atlas (TCGA). The comparisons between FAP expression in healthy and cancer tissue was done using one-way ANOVA and correlation between FAP and COL3A1 was done using Spearman correlation. Lastly, C3F was measured in serum samples from patients with NSCLC (n = 109) and healthy controls (n = 42) and the two groups was compared using Mann Whitney test and area under receiver operating characteristic curves (AUROCs).
Results: A C3F signal only appeared after type III collagen incubation with FAP, supporting that C3F reflects FAP proteolytic activity. C3F was significantly elevated in serum from patients with NSCLC compared to healthy controls ($p < 0.0001$, AUROC = 0.78). In support, FAP expression (TCGA) was significantly elevated in NSCLC tissue compared to normal lung tissue ($p < 0.0001$) and FAP expression correlated with expression of COL3A1 (persons $r = 0.83$).
Conclusion: The FAP-cleavage mediated type III collagen fragment C3F reflects FAP activity and can be quantified non-invasively in serum. In this study we show C3F as promising diagnostic biomarker in NSCLC, however as the biomarker reflects FAP activity the optimal use is more is potentially as a predicter of treatment response from FAP-based drug delivery systems.

TUMOR BIOLOGY: Tumor Evolution Models and Technologies
Poster Session

#4291 Bai1 inhibition promotes ferroptosis of breast cancer cells to prevent tumor growth in human xenograft tumor models.

F. K. Noubissi[1], O. Odubanjo[1], H.-C. Huang[1], B. Ogle[2], P. Tchounwou[3];
[1]Jackson State University, Jackson, MS, [2]University Of Minnesota-Twin Cities, Minneapolis, MN, [3]Morgan State University, Baltimore, MD

The adhesion G-protein coupled- receptor 1 ADGRB1/Bai1 was identified as a phosphatidylserine receptor that cooperates with ELMO/Dock180/Rac to promote maximal engulfment of apoptotic cells. This function of Bai1 was also shown to promote myoblasts fusion. Cell-cell fusion has been demonstrated to occur in normal physiological functions as well as in diseases. Studies have shown in cancer that cell-cell fusion increases tumor heterogeneity, drug resistance, and metastasis as hybrids acquire new properties that allow them to migrate and proliferate at new sites. Activation of ELMO-Dock signaling pathway has been associated with breast cancer metastasis. Moreover, ELMO1 has been identified as a modifier of breast cancer risk for BRCA mutation carriers. Rac1 was also shown to be overexpressed in proliferative breast disease, preinvasive and invasive breast carcinoma as well as lymph node metastases. Our recent studies showed that breast cancer cell fusion with bone marrow-derived mesenchymal stem cells was modulated by hypoxic conditions and promoted by apoptosis. Our hypothesis is that hypoxia stress induced apoptosis activates the phosphatidylserine receptor Bai1, and it signals through the ELMO/DOCK180/Rac to promote breast cancer cell fusion-driven tumor heterogeneity and metastasis. In this study, we determined the ability of Bai1 depleted breast cancer cells to induce tumor growth in immunocompromised mice. We used Bai1 sgRNA to inhibit Bai1 expression in the breast cancer cell MDA-MB-231. These cells ($1x\ 10^6$) together with bone marrow-derived mesenchymal stem cells (MSCs) ($1x\ 10^6$) were injected into the fat pad of the breast of 15 NOD SCID female mice. Control mice (15) received the same cells with no inhibition of Bai1. The mice were monitored for eight weeks. We found that Bai1 inhibition significantly reduced tumor growth in these mice in the course of time ($P<0.05$). The average tumor weight was also significantly reduced when Bai1 was inhibited ($P<0.001$). RNA sequencing of tumors generated from these mice revealed a significant increase in the expression of genes driving ferroptosis and a reduction in critical oncogenes in the experiment group compared to the control group. These findings will be helpful in the development of new classes of drugs effective in breast cancer treatment.

#4292 Unraveling the interplay of aging, smoking, and mutation-driven clonal expansions in lung cancer evolution: A multifaceted approach.

A. N. Briggs, J. DeGregori;
University of Colorado Anschutz Medical Campus, Aurora, CO

Despite the well-established link between tobacco use and lung cancer, military personnel face additional risks due to heightened smoking rates and exposure to various environmental contaminants. Aging further amplifies susceptibility to lung cancer, contributing to elevated incidence rates among Veterans compared to non-Veterans. Our studies aim to elucidate the intricate relationship between aging, smoking, and mutation-driven clonal expansions in lung tissue, examining their impact on lung function and cancer evolution. Using cell culture and mouse models, we introduce mutations identified in human lung tissue into airway epithelial cells. Using CRISPR, base editing, and genetically engineered mouse models, we assess the effects on barrier function, cell differentiation, and gene expression. Ultimately, we are investigating the interaction between induced mutations, aging, and smoking, exploring how mutation-driven clonal expansions contribute to lung dysfunction and pre-malignant phenotypes, potentially forming a feedforward loop. This research addresses critical gaps in understanding the complex interplay of aging, smoking, and mutation-driven clonal expansions in lung cancer evolution. Findings have the potential to unveil novel insights into the development of lung dysfunction and malignancy, paving the way for safe and accessible interventions to reduce cancer risk and enhance lung health.

#4293 Chromosomal instability causes epigenetic aberrations in cancer.

Chromosomal instability and changes in the epigenome are defining features in most metastatic cancers. Our research links chromosomal missegregation, their containment in micronuclei, and subsequent rupture of the micronuclear envelope to histone post-translational modification aberrations. This relationship was across all tested human and murine cancer cell lines, as well as non-transformed cells. Furthermore, we discovered that the observed changes in histone PTMs were caused by either micronuclear rupture or the persistence of histone PTM status during cell division. Moreover, we revealed substantial chromatin accessibility differences in micronuclei. Notably, there is a distinct bias in chromatin accessibility between promoter regions compared to distal and intergenic regions of the genome, which aligned well with observed changes in histone modifications. The induction of chromosomal instability leads to widespread, heterogeneous, and heritable abnormalities in the epigenetic landscape of cancer cells. Therefore, on top of genomic copy number changes, chromosomal instability causes epigenetic reprogramming, which adds another layer to cancer heterogeneity.

#4294 The emerging role of deubiquitinase enzymes in lung cancer plasticity.

Juntae Kwon[1], Jinmin Zhang[2], Boram Mok[1], Samuel Allsup[2], Cecil Han[1]

[1]Department of Oncology, Georgetown University School of Medicine, Washington, DC, [2]Department of Biochemistry and Molecular & Cellular Biology, Georgetown University School of Medicine, Washington, DC

Lung cancer is characterized by a high degree of genetic and molecular heterogeneity. Lineage plasticity has emerged as a source of intratumoral heterogeneity and drug resistance, resulting in poor prognosis and treatment failure. The molecular mechanisms driving lung cancer plasticity remain unclear. Ubiquitin-Specific Peptidase 13 (USP13), a deubiquitinating enzyme, is one of the most amplified genes in lung squamous cell carcinoma (LUSC). We developed a USP13 knock-in overexpressing mouse model in *Kras*$^{LSL\text{-}G12D/+}$; *Trp53*$^{fl/fl}$ (KP) background (KPU mice). USP13 overexpression resulted in aggressive tumorigenesis and a shortened survival in *Kras*/*Trp53*-driven lung cancer. Notably, while KP mice developed lung adenocarcinoma (LUAD), KPU mice developed LUSC and LUAD. LUSC in KPU mice faithfully recapitulated the key pathohistological, molecular features, and cellular pathways of human LUSC. Bulk RNA-sequencing analysis showed that KPU tumors were heterogeneous and enriched in lineage reprogramming pathways including basal cell signaling, stem cell pluripotency, and epithelial-mesenchymal transition (EMT). Using cell-type-restricted adenoviral Cre to target cells expressing surfactant protein C (SPC) or club cell antigen 10 (CC10), we identified bronchiolar secretory club cells as the predominant cell origin of LUSC. USP13 altered the levels of lineage transcription factors such as TTF-1 and SOX2 in club cells during early tumorigenesis. Altered expression of these factors reinforced the fate of CC10+ club cells to squamous carcinoma development rather than adenocarcinoma. In addition, USP13 directly acted on the K48-linked ubiquitination of c-Myc and increased its protein stability, contributing to the elevation of squamous gene expression (SOX2, CK5, P40) in the primary mouse and advanced human lung cancer cells. These results suggest that USP13 promotes lineage plasticity in club cells during the early stage of cancer development and drives reprogramming into LUSC. We also found a potential functional association between USP13 and EMT pathway. Notably, irrespective of cell origin, USP13 overexpression enhanced EMT marker expression including N-cadherin, SNAI1, and ZEB1 in lung cancer cells, promoting cell migration and invasion. USP13 increased tumorigenic and metastatic abilities of lung cancer cells in 3D organoid culture and syngeneic mouse models. Collectively, our research highlights the pivotal significance of USP13 in unleashing lineage plasticity during lung cancer progression, suggesting the potential role of deubiquitinase enzymes in regulating lineage plasticity, which may lead to novel therapeutics for treating lung cancer.

#4295 Apoptotic DNase DFFB-induced DNA damage within cancer persister cells underlies acquired resistance to targeted therapies across multiple tumor types.

A. F. Williams[1], D. A. G. Gervasio[1], C. E. Turkal[1], A. E. Stuhlfire[1], M. X. Wang[1], B. E. Mauch[1], A. H. Nguyen[1], M. H. Paw[1], M. Hairani[1], C. P. Lathrop[1], S. H. Harris[1], J. L. Page[2], M. J. Hangauer[1];

[1]UC San Diego, La Jolla, CA, [2]Salk Institute for Biological Studies, La Jolla, CA

Cancer acquired drug resistance contributes to a large proportion of patient deaths. A major obstacle to the development of effective therapies which prevent resistance is our lack of understanding of the relevant fundamental molecular adaptive processes. Here we report the discovery that tumor cells rely upon sublethal engagement of apoptotic death machinery and apoptotic DNase DFFB to acquire resistance to targeted therapies in multiple tumor types in cell culture and in vivo. We found that while DFFB wild type tumor cells readily acquire resistance to targeted therapies by escaping from the quiescent “persister” state into proliferating resistant cells, persister cells lacking functional DFFB remain indefinitely in a quiescent state on treatment. Mechanistically, we found that DFFB, which is activated by apoptotic caspases in surviving cancer persister cells, induces persistent DNA damage which promotes resistance through acquired mutations and nongenetic resistance through suppression of growth-arresting interferon signaling. During drug treatment acute interferon induction arises from sublethal mitochondrial outer membrane permeabilization and cytoplasmic exposure of mitochondrial nucleic acids which activate pattern recognition receptors. However, during longer treatments we found that DFFB knockout persister cells exhibit strikingly elevated levels of STAT1 and STAT2 and interferon stimulated gene sets. This interferon signaling is growth arresting because treatment of DFFB knockout persister cells with a JAK1/2 inhibitor rescues their ability to regrow. Furthermore, in DFFB wild type persister cells we found that DFFB-dependent DNA damage activates stress response transcription factor ATF3 which blocks the transcriptional activation of interferon stimulated genes following initial interferon induction. This is consistent with prior data in other contexts demonstrating that ATF3 is induced by DNA damage and that ATF3 directly binds to promoters of multiple interferon genes repressing their expression. These findings reveal that DFFB activation in persister cells prevents chronic interferon signaling and enables escape into proliferating drug resistant tumor cells. Therefore, DFFB-mediated interferon suppression represents a novel mechanism that is fundamental to acquired drug resistance. In addition, high expression of DFFB and ATF3 correlates with worse overall survival in a pan-cancer analysis and DFFB knockout mice develop normally indicating DFFB is a nonessential gene in normal tissue. Therefore, we propose that DFFB is a promising therapeutic target to prevent acquired resistance to targeted therapy.

#4296 Investigating metabolic sensitivity and organization of renal cell carcinoma: To enhance effective therapies and patient survival.

M. Patankar[1], J. Albeck[1], S. Gulati[2];

[1]University of California Davis, Davis, CA, [2]UC Davis Comprehensive Cancer Center, Sacramento, CA

Background: Renal cell carcinoma (RCC) is the 6th most common cancer in men and the 9th most common in women in the United States. RCC tissues are metabolically dysfunctional, often resulting from loss of von-Hippel Lindau (VHL) and consequent upregulation of hypoxia-inducible factor (HIF1/2). HIF1a is a transcription factor that upregulates glycolytic gene expression. Current therapies, including immune checkpoint inhibitors and tyrosine kinase inhibitors, have shown improvements in the outcomes of RCC patients, however, there are no biomarkers clinically available to predict the efficacy of these drugs. While genomic data and transcriptomic signatures have been investigated, they are not used in clinical practice due to lack of prospective validation. Understanding additional pathways pertaining to metabolic features of RCC, is critical. Our bulk gene expression analysis of primary RCC samples from TCGA-KIRC show a predominance of genes expressing mitochondrial ribosomal proteins and electron transport chain in tumors that relapsed early after nephrectomy, warranting further validation.

Aim: We aim to investigate changes in metabolic adaptation in RCC cells from kidney cancer cell lines (VHL mutant) and primary cells from human-matched primary and metastatic kidney cancer sites. Using a novel biosensor-based technique developed in the Albeck lab, we aim to identify the dependence of live RCC cells on specific metabolic pathways and test the effect of standard-of-care (SOC) pathway inhibitors such as tyrosine kinase, HIF pathway, metabolic pathway inhibitors impacting tumorigenicity.

Methods: To examine functional metabolic behavior in single cells, we generated immortalized cell lines (MCF10A, 184A1, FL83B and HBE-1) stably transfected with biosensors for the activity of AKT, glycolysis, mTOR and AMPK pathway. Data from Live-cells treated with metabolic inhibitors were collected and analyzed using our MATLAB-based pipeline. We have extended the analysis to RCC cell lines (786-O cell lines) and primary cells collected from nephrectomy specimens and matched metastatic biopsy samples, using current SOC pathway inhibitors (including sorafenib, sunitinib, belzutifan) and investigational metabolic drugs (metformin, IACS-010759, niclosamide).

Results & Conclusion: Our preliminary results show an association of high OX-PHOS with primary tumors from early relapse after nephrectomy than the relapsed late tumors. Our biosensor single cell data show that even genetically homogeneous cell populations can vary in their usage of OXPHOS and glycolysis to supply ATP for cell growth. Tumor gene expression profile coupled with biosensor data, will address mechanism behind this metabolic shift in RCC tumors in primary cells isolated from primary and metastatic sites. Our research will improve tumor prognosis and allow designing therapeutic trials.

#4297 Interrogating metabolic heterogeneity and cooperation in lung cancer collective cell invasion.

I. E. Robinson[1], V. Matsuk[2], M. Shanmugam[2], J. K. Mouw[2], A. I. Marcus[2];

[1]Georgia Institute of Technology/Emory Winship Cancer Institute, Atlanta, GA, [2]Emory Winship Cancer Institute, Atlanta, GA

Tumor heterogeneity contributes to tumor progression and a variable response to treatment. We have previously shown that tumor heterogeneity - including metabolic, transcriptional and mutational - underlies non-small cell lung cancer (NSCLC) collective invasion. Using stable subpopulations derived with our Spatiotemporal Cellular and Genomic Analysis (SaGA) technique, we found that two distinct subpopulations of the H1299 NSCLC line cooperate during collective tumor invasion *in vitro*; while H1299 pack leaders are heavily dependent on oxidative phosphorylation, H1299 pack followers are more reliant on glycolysis. To further dissect how intratumoral heterogeneity enables cancer progression to metastasis, we incorporate high resolution imaging, stable fluorescent labeling, gene editing, and *in vitro* tumor invasion models to interrogate mechanisms of metabolic cooperation between heterogeneous NSCLC subpopulations. We hypothesize that cooperation and communication between these distinct metabolic subpopulation drives metastatic tumor progression. To determine mechanisms of metabolic cooperativity between subpopulations, we stably transduced our subpopulations to fluorescently label either the mitochondria (through TOM20 labeling) or a key enzyme in glycolysis (through glucose 6-phosphate isomerase GPI labeling), cultured labeled subpopulations with unlabeled subpopulations, and observed metabolic changes and exchange via time-lapse, fluorescence microscopy and flow cytometry in 2D culture conditions. Next steps include visualizing the metabolic cooperation that occurs in conditions mimicking the tumor microenvironment (i.e., 3D invasion assays) using super-resolution microscopy. Taken together, we have developed a method of temporally visualizing metabolic exchange with high spatial resolution between NSCLC subpopulations to investigate the underlying mechanisms enabling successful cell invasion in a variety of tumor microenvironments. Thus far, we have discovered multiple broad mechanisms of exchange including tunneling nanotubes and extracellular vesicles, both of which are inducible with certain stressors common to the tumor microenvironment.

#4298 Predicting tumor evolution from digital histology using AI.

C. E. Spencer[1], A. Camara[2], A. Riou[2], L. Au[1], J. I. Lopez[3], Z. Tippu[1], C. Maussion[2], K. Ho[1], A. Strange[1], E. Nye[1], V. Birault[1], L. Van-praet[2], K. Edmonds[4], E. Carlyle[1], S. Hazell[4], S. Rudman[5], J. Larkin[1], S. Turajlic[1];

[1]The Francis Crick Institute, London, United Kingdom, [2]Owkin, Paris, France, [3]Biocruces Bizkaia Health Research, Biaritz, Spain, [4]The Royal Marsden Hospital, London, United Kingdom, [5]Guys and St Thomas' Hospital NHS Trust, London, United Kingdom

Diverse clinical presentations of clear cell renal cell carcinoma (ccRCC) confound clinical decision making, leading to over and undertreatment. Clonal evolution of ccRCC proceeds through distinct trajectories characterised by differing levels of genomic intratumoral heterogeneity (gITH) and chromosomal complexity (weighted genomic instability index, wGII). However, accurate evaluation of these indices requires multiregional profiling of fresh tumour; cost prohibitive and logistically challenging in the clinical setting. Clinical histopathology workflows routinely capture multiple tumour areas enabling the use artificial intelligence (AI) to predict tumour evolutionary features directly from clinical grade H&E whole slide image (WSIs). ccRCC displays profound genetic and histological ITH but the link between these entities remains unclear. We leverage the TRACERx Renal cohort, comprising 1485 WSIs from 81 tumours to predict WGII and gITH and to gain insights into the relationship between genetic and histological ITH. Critically, each WSI is associated with a wGII and gITH label derived from a closely linked fresh tumour sample. For both prediction tasks, we extracted meaningful features for each WSI using self-supervised representation learning “MoCo”. Since high wGII confers poor prognosis we focussed on predicting binary stratification label of high wGII or low wGII (relative to the cohort median). First we predicted wGII as a continuous variable using a supervised multiple instance learning regression model trained on the MoCo features, and then classified the predicted wGII into “high” or “low” achieving 0.80 AUROC. To predict gITH we postulated that the degree of gITH would correlate with histological ITH. Using an unsupervised clustering of refined MoCo features we defined 24 histological clusters. The number of computationally derived histological clusters within a single tumour positively correlated with gITH (pearson’s 0.56). We used the number of clusters to classify WSIs into prognostic binary groups of high or low gITH (relative to the cohort median) achieving an AUROC of 0.80. To understand the biological relationship between histological and genetic ITH we pathologically characterised the histological clusters: a pathologist annotated WSIs with tumour architecture and cytomorphology. Image tiles were associated with the annotations using spatial coordinates, illuminating phenotypic traits of different evolutionary trajectories and providing an interpretability framework for our AI pipelines. Since the tumour evolutionary course dictates disease progression tempo, applying evolutionary classification in clinic can fundamentally improve patient care. Here, for the first time, we provide a framework to translate fundamental evolutionary principles underpinning tumour biology and clinical progression into a prognostic computational pathology biomarker possible to clinically implement.

#4299 A lineage-specific role of oncogenic protein kinase Cι in lung adenocarcinoma.

D. T. Nguyen, N. Yin, C. R. Weems, L. Jamieson, K. Meneses, Y. Liu, N. R. Murray, A. P. Fields;
Mayo Clinic Florida, Jacksonville, FL

Lung adenocarcinoma (LUAD), the most prevalent subtype of lung cancer, can arise from two different cell populations: alveolar type 2 (AT2) cells and bronchiolar club cells. By utilizing genomic data from the cancer genome atlas program, human LUAD cell lines, and the well-characterized *LSL-Kras*^{G12D}/*Trp53*$^{-/-}$ (*KP*) mouse model, we demonstrated that tumors arising from club cells are much more aggressive and follow a different trajectory of tumorigenesis when compared to those arising from AT2 cells. Intriguingly, our data strongly suggest that expression and signaling activity of protein kinase C iota (PKCι) can profoundly affect the cell of origin and oncogenic signaling pathways employed by resultant tumors. Specifically, *KP*-mediated transformation of club cells appears to be dependent on PKCι-ELF3-NOTCH3 and PKCι-YAP1 signaling axes, while AT2 cell malignancy is dependent on the PKCι-independent WNT signaling. In addition, club-cell-origin tumors exhibit an enrichment of cancer stem cells and increased infiltration of immunosuppressive myeloid cells in comparison to AT2-cell-origin tumors. This results in accelerated progression and increased likelihood of metastasis by LUAD tumors that originate from club cells. Taken together, our results indicate that PKCι expression and signaling activity can profoundly influence the cells of origin, tumor trajectories, and therapeutic vulnerabilities of LUAD tumors.

#4300 Large-scale, low-cost, and accurate measurement of cancer evolutionary dynamics from clinical patient samples.

C. Gabbutt[1], M. Duran-Ferrer[2], H. Grant[1], D. Mallo[3], F. Nadeu[2], J. Househam[1], N. Villamor[2], O. Krali[4], J. Nordlund[4], T. Zenz[5], E. Campo[2], A. Lopez-Guillermo[2], J. Fitzgibbon[6], C. P. Barnes[7], D. Shibata[8], J. I. Martin-Subero[2], **T. A. Graham[1]**;

[1]Institute of Cancer Research, London, United Kingdom, [2]Fundacio de Recerca Clinic Barcelona-Institut d'Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain, [3]Arizona State University, Tempe, AZ, [4]Uppsala University, Uppsala, Sweden, [5]University Hospital and University of Zurich, Zurich, Switzerland, [6]Barts Cancer Institute, London, United Kingdom, [7]University College London, London, United Kingdom, [8]University of Southern California, Los Angeles, CA

Introduction: Cancer is a dynamic evolutionary process; thus, the evolutionary history of a cancer should strongly influence its future trajectory and so the clinical outcome of patients. However, accurately assessing an individual cancer's evolutionary history in a scalable and clinically relevant manner is currently an open problem. To address this, we introduce a novel methodology (EVOFLUx) to quantitively infer the history of a cancer from single time-point bulk samples using inexpensive, standard methylation arrays.

Description of Methodology: We recently identified fluctuating CpGs (fCpGs), which are CpGs that neutrally and stochastically change methylation state over time in individual cells, uniquely barcoding cells and thus enabling high temporal-resolution lineage tracing approaches. In a bulk population of cancer cells, the distribution of fCpG methylation is determined by the evolution of the population and thus encode a cancer's past clonal dynamics. Here, we have developed a general computational approach to model how the patterns of fCpGs vary according to the evolutionary history of a growing cancer, and a Bayesian inference method to infer these parameters from data.

Results We applied EVOFLUx to quantify the evolutionary dynamics of 1,976 lymphoid cancers, finding that the tumor growth rates, malignancy age and epimutation rates varied by orders of magnitude across disease types.

In addition, EVOFLUx allowed us to test for the presence of ongoing subclonal selection and validated our inference with matched whole exome sequencing data. Alongside characterizing the evolutionary dynamics within single bulk samples, fCpGs also allow for the inference of the phylogenetic relationships between longitudinal samples, which we validated with whole genome sequencing.

Within cancer types, more aggressive subtypes typically had elevated growth rates. In our clinically annotated cohort of chronic lymphocytic leukemia (CLL) samples, we found that patient-specific evolutionary dynamics are strongly associated with outcome.

Conclusions: Hence, we present a powerful new method that uses widely available, low-cost bulk DNA methylation data to precisely measures cancer evolutionary dynamics in patient samples with clinical implications.

#4301 Increasing the therapeutic vulnerability of heterogenous cell phenotypes within prostate cancer.

A. I. Paxson[1], L. H. Chang[2], K. D. Marr[1], J. M. C. Gard[1], C. S. Nelson[1], A. Kapoor[2], W. L. Harryman[1], J. J. Marugan[2], M. J. Henderson[2], T. W. Sanchez[2], A. E. Cress[1];

[1]University of Arizona, Tucson, AZ, [2]National Institutes of Health, Rockville, MD

Phenotype heterogeneity is a hallmark of prostate adenocarcinoma and is a major source of recurrent disease. We tested pre-clinical therapies to eradicate phenotypically distinct cell populations derived from the parental DU145^{WT} prostate cancer cell line. The derived cell lines are called DU145^{AA}, DU145^{J7}, and DU145^{G6}. The DU145^{AA} variant is a non-aggressive cell population while the DU145^{J7} and DU145^{G6} are aggressive phenotypes that invade through muscle and metastasize to bone. Flow cytometry analysis documented the phenotypic plasticity of the DU145 cell variants since DU145 aggressive lines expressed 1.3-fold increases in matrix metalloprotease 14 surface expression and a 2-fold increase in tri-methyl Histone H3 at lysine 27 as compared to the DU145^{WT} parent line. The DU145^{AA} non-aggressive line expressed an epithelial cell-cell lineage phenotype with up to 2-fold increases in E-cadherin, claudin 4, claudin 7, and a unique cytokeratin 6A expression and a 2-fold loss of Zinc finger E-box-binding homeobox 1, EVL, and Kindlin 2. A collaboration with the National Center for Advancing Translational Science (NCATS) resulted in the identification of pharmacological agents active in eradicating DU145^{J7} and DU145^{G6} cells as compared to the DU145^{WT} population. The agents were selected from a quantitative high-throughput screen of 10,677 combined investigative and approved anti-cancer agents using the Cell Titer-Glo Luminescent Cell Viability assay. We independently validated 31 compounds from the assay that have 2-fold, or greater, differences in concentration to inhibit 50% cell growth (IC_{50}) between the wild-type and aggressive variants of DU145 cells. The top 10 hits were tested for the efficacy of different combinations to eradicate defined admixtures of aggressive and non-aggressive phenotypes, including the DU145^{AA} cells, to model tumor heterogeneity. Tested compounds with differential sensitivity between aggressive and non-aggressive cells were those inhibiting histone deacetylase (vorinostat, fimepinostat, and pracinostat), proteasomes (bortezomib, delanzomib, ixazomib), topoisomerases (gimatecan and daunorubicin), and other compounds identified independently by us targeting nicotinamide phosphoribosyl transferase (FK866) and DNA (bleomycin). Using admixtures of tumor cell phenotypes, we determined optimal combinations of compounds that would selectively eradicate the sub-populations. The results suggest that determination of phenotypes within tumor populations may eliminate the heterogenous tumor and prevent recurrent disease. Funding was provided by the University of Arizona Cancer Center (NCI-P30 CA23074 and NCI-R01 CA159406) and by the Partnership in Native American Cancer Prevention at the University of Arizona (U54CA143924) and Northern Arizona University (U54CA143925). Collaborators at NCATS were supported by the intramural research program.

#4302 ONECUT2 activates diverse resistance drivers of androgen receptor-independent heterogeneity in prostate cancer.

C. Qian[1], Q. Yang[1], M. Rotinen[2], R. Huang[3], H. Kim[1], B. Gallent[1], Y. Yan[1], R. M. Cadaneanu[3], B. Zhang[3], S. Kaochar[4], S. J. Freedland[1], E. M. Posadas[1], L. Ellis[5], D. Di Vizio[1], C. Morrissey[6], P. S. Nelson[7], L. Brady[7], R. Murali[1], M. J. Campbell[1], W. Yang[8], B. S. Knudsen[9], E. A. Mostaghel[10], H. Ye[1], I. P. Garraway[3], S. You[1], M. R. Freeman[1];

[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Public University of Navarre, Pamplona, Spain, [3]UCLA, Los Angeles, CA, [4]Baylor College of Medicine, Houston, TX, [5]National Cancer Institute, Bethesda, MD, [6]University of Washington, Seattle, WA, [7]Fred Hutchinson Cancer Center, Seattle, WA, [8]Stony Brook University, New York, NY, [9]University of Utah, Salt Lake City, UT, [10]U.S. Department of Veterans Affairs Puget Sound Health Care System, Seattle, WA

Androgen receptor- (AR-) indifference is a mechanism of resistance to hormonal therapy in prostate cancer (PC). Here we demonstrate that ONECUT2 (OC2) activates resistance through multiple drivers associated with adenocarcinoma, stem-like and neuroendocrine (NE) variants. Direct OC2 targets include the glucocorticoid receptor (GR) and the NE splicing factor *SRRM4*, which are key drivers of lineage plasticity. Thus, OC2, despite its previously described NEPC driver function, can indirectly activate a portion of the AR cistrome through epigenetic activation of GR. Mechanisms by which OC2 regulates gene expression include promoter binding, enhancement of genome-wide chromatin accessibility, and super-enhancer reprogramming. Pharmacologic inhibition of OC2 suppresses lineage plasticity reprogramming induced by the AR signaling inhibitor enzalutamide. These results demonstrate that OC2 activation promotes a range of drug resistance mechanisms associated with treatment-emergent lineage variation in PC and support enhanced efforts to therapeutically target OC2 as a means of suppressing treatment-resistant disease.

#4303 Enrichment of nonadherent prostate cancer stem cell populations using simulated microgravity bioreactor.

K. Khazaw, S. Unlu, A. M. Dwead, B. Cinar;
Clark Atlanta University, Atlanta Georgia, GA

Prostate cancer is the most prevalent and the leading cause of cancer-related death among men, particularly African Americans. The cellular and molecular mechanisms contributing to this deadly disease remain largely unknown. As such, there are no effective strategies to treat metastatic cancer and improve patient outcomes. Anchorage-independent growth of circulating prostate tumor cell clusters is essential for developing cancer metastasis. However, there is no model system to study the molecular and functional characteristics of prostate tumor cell clusters reminiscent of the bloodstream in a laboratory setting. In addressing this need, we have established nonadherent LNCaP cell clusters, LN-G2 and LN-G3, under androgen-depleted growth conditions in a simulated microgravity bioreactor called Slow Turning Lateral Vessel (STLV). Our quantitative PCR analysis repeatedly demonstrated that LN-G2 and LN-G3 cell populations expressed high levels of the well-characterized CD44 and CXCR4 cancer stem cell maker, respectively, compared to the LNCaP parental. In addition, our functional analysis indicates that, unlike the LNCaP cell, LN-G2 and LN-G3 cells showed superior clonogenic and growth behaviors in response to androgen depletion and enzalutamide-treatment under adherent monolayer and nonadherent conditions. These observations suggest that cancer stem cell-like cell clusters that survived under microgravitational stress confer distinctive molecular and functional properties associated with superior survival and contribute to castration-resistant prostate cancer. Furthermore, the STLV bioreactor could help enrich cancer stem cell populations and enhance our understanding of the underlying mechanisms of lethal cancer, which may lead to novel therapeutics to improve patient outcomes.

#4304 Chromosome 3 dosage-loss informs on the unique biology underlying ultra high-risk uveal melanoma.

J. L. Rose[1], S. Srinivasan[1], M. He[1], R. Minelli[1], C.-Y. Liu[1], C. Terranova[1], J. Gay[1], J. R. Daniele[1], L. Dmitriy[1], M. Peoples[1], M. Soeung[1], V. Ramamoorthy[1], P. Shah[1], S. Soni[1], C. Bristow[1], F. Wang[1], A. Lopez[1], C. Deckard III[1], B. Meyers[1], L. Perelli[1], K. Wani[1], N. Feng[1], C. P. Vellano[1], J. Marszalek[1], A. J. Lazar[1], A. Futreal[1], G. F. Draetta[1], S. E. Woodman[1], T. Heffernan[1], G. Genovese[1], A. Carugo[2], V. Giuliani[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]IRBM, Rome, Italy

Uveal melanoma (UM) is a rare and lethal tumor characterized by mutually exclusive activating mutations in *GNAQ* and *GNA11*, secondary mutations in *EIF1AX*, *SF3B1* and *BAP1*, and a late-stage chromosome 3 copy-number (CN) loss event. Importantly, chromosome 3 CN loss is associated with BAP1 loss-of-function (LOF) and corresponds with tumor metastasis and poor patient prognosis. Understanding the biology underlying this chromosome 3 CN loss event is critical to informing on metastatic UM. To this end, we leveraged CRISPR-based centromere targeting to engineer multiple clones exhibiting chromosome 3 CN loss. We determined that dosage-loss of chromosome 3 was sufficient to develop multiple isogenic clones exhibiting genomic features of “ultra high-risk” UM, independent of BAP1 LOF. Leveraging this isogenic system, we evaluated *in vitro* and *in vivo* profiling, demonstrating site-specific liver metastasis only in orthotopic HR tumors, along with a significantly increased fitness in the liver. Next, we sought to inform on differential signaling pathways and therapeutic sensitivity between LR and HR models. Characterization of established UM oncogenic pathways identified a clear disengagement from classical MAPK and non-canonical Hippo signaling in the HR clones. These findings also correlate with a significant decrease in sensitivity to MEK and FAK inhibitors. In addition, we observed a PKC isoform swap from PKCε and PKCδ to PKCα, a feature observed in late-stage UM patient tumors. Interestingly, we also observed an increase in the expression of PRAME and NBS1 in HR models, both markers for poor prognosis in patients. Genome-anchored transcriptomic analysis also captured distinct profiles between the LR and HR clones, highlighting a significant increase in MYC associated targets upon chromosome 3 dosage-loss. This increase in MYC signaling coincides with site-specific 8q amplifications across the HR clones, implicating MYC as a core fitness driver in high-risk UM and a potential contributor to poor patient prognosis in monosomy 3 patients. Leveraging engineered models of chromosome 3 CN loss, and the subsequent induction of “ultra high-risk” UM, provides a unique opportunity to inform on the underlying biology of UM evolution and potential therapeutic strategies.

#4305 Analysis of tumor heterogeneity in syngeneic models; CT26.WT colon carcinoma and 4T1-Luc2-1A4 breast carcinoma in female BALB/cAnNHsd mice.

J. Snider, D. Germain, L. Kucharczyk, A. Zaitouna, S. Barnes, D. Draper, S. Wise;
Laboratory Corporation of America, Ann Arbor, MI

Cancer is a complex disease that involves both malignant cells and the surrounding microenvironment. The tumor microenvironment (TME) is comprised of various components, including cancer-associated fibroblasts, immune cells, blood vessels, and extracellular matrix elements, all of which interact with cancer cells. It is increasingly recognized that the components of the TME are a critical determinant of therapeutic response and resistance, and as such targeting the TME has emerged as a promising strategy in cancer therapy.

Syngeneic models are necessary to study the TME, and more specifically the tumor infiltrating immune cell populations, as these models allow us to monitor various aspects of the immune response. Another important aspect to consider is tumor heterogeneity, which can cause issues during analysis due to immune cell populations not being evenly distributed throughout the tumor. The decision of whether to analyze whole tumors or halved tumors when monitoring changes in immune cell populations is an important consideration. When considering multiple endpoints from a single tumor sample, halved tumors are oftentimes considered as we remain mindful of the 3Rs (replacement, reduction and refinement) in animal research. As such, it is important to understand the effects of splitting samples and how it can affect the data that is generated.

To determine the effects of analyzing whole and halved tumor samples on immune cell subsets, studies were designed to subcutaneously implant either CT26.WT or 4T1-Luc2-1A4 cells into female BALB/cAnNHsd mice and harvest tumor samples after the completion of treatment. Mice were treated with isotype control (Clone MPC-11) or anti-mCTLA-4 (Clone 9D9). At the time of sample collection, tumors were kept whole intact or halved and analyzed via flow cytometry to quantify lymphoid and myeloid immune cell subsets within tumor samples.

The data revealed differences in immune cell subset populations for both isotype vs. anti-CTLA-4 treated tumors and whole vs. halved tumors. Changes in the lymphoid cell compartment were observed for whole vs. halved tumors of ± ~25-100% and ± ~0-40% for isotype treated and of ± ~0-30% and ± ~25-2600% for anti-CTLA-4 treated CT26.WT or 4T1-Luc2-1A4 tumors, respectively. Changes in the myeloid cell compartment of ± ~5-45% and ± ~10-65% for isotype treated and of ± ~15-100% and ± ~0-70% for anti-CTLA-4 treated CT26.WT or 4T1-Luc2-1A4 tumors, respectively, were also observed. Additionally, differences were observed between the two tumor halves, not just between whole and halved tumors.

Taken together, the data support that splitting tumor samples can negatively impact the analysis of the immune cell populations. Tumors can be split if required to perform multiple analyses, however, this should be done with caution, as it can result in trend differences and increases variability within the dataset.

#4306 Label-free melanoma phenotype classification using AI-based morphological profiling.

Evelyn Lattmann[1], **Andreja Jovic**[2], Julie Kim[2], Aizhan Tastanova[1], Tiffine Pham[2], Christian Corona[2], Kiran Saini[2], Zhouyang Lian[2], Senzeyu Zhang[2], Ryan Carelli[2], Kevin B. Jacobs[2], Manisha Ray[2], Vivian Lu[2], Stephane C. Boutet[2], Mahyar Salek[2], Maddison Masaeli[2], Mitchell P. Levesque[1]

[1]Dermatology, University Hospital Zurich, University of Zurich, Schlieren, Switzerland,[2]Deepcell Inc., Menlo Park, CA

Melanoma plasticity and heterogeneity contribute to therapeutic resistance and mortality, and the ability of melanoma cells to switch from melanocytic to mesenchymal phenotypes results in increased invasion and metastasis. Investigating the role of these phenotypic states has been challenging due to limited marker availability for each cell state. High-parameter molecular methods such as RNAseq have produced more descriptive gene signatures of phenotypic states, but these methods are cell-destructive, labor-intensive, expensive, and can take days to weeks to obtain a readout. Different morphologies have been observed for melanocytic and mesenchymal phenotypic states in culture, thus we hypothesized that morphology could provide an orthogonal method to define and study phenotypes. We utilized the Deepcell platform to develop a classifier to predict the phenotype of melanoma cells as melanocytic or mesenchymal based on morphology alone. This method is free of labels and utilizes viable cells, overcoming the technical and practical limitations of traditional, marker-based methods.

We used 20 patient-derived cell lines with known melanocytic or mesenchymal transcription scores to develop the 'Melanoma Phenotype Classifier' to phenotype melanoma cells based on morphology alone. A classifier accuracy of **>88%** was achieved, and morphological analysis of the images revealed distinct morphotypes for each phenotype, highlighting distinct morphological differences. To further link phenotypic state with multi-dimensional morphological profiles, we performed genetic and chemical perturbations known to shift the phenotypic state. The Melanoma Phenotype Classifier successfully predicted shifts in phenotypes driven by these perturbations. These results further demonstrate how phenotype is linked to distinct morphological changes that are detectable by artificial intelligence. Lastly, we applied the Melanoma Phenotype Classifier to dissociated melanoma biopsies, which revealed phenotypic heterogeneity that was confirmed by single cell RNASeq.

This work establishes a link between cellular morphology and melanoma phenotype and lays the groundwork for the use of morphology as a label-free method of phenotyping viable melanoma cells.

#4307 Quantifying the cell-intrinsic and cell-extrinsic growth effects of cancer-causing mutations *in vivo*.

C. D. McFarland, J. Maltas;
Case Western Reserve University School of Medicine, Cleveland, OH

Adaptive driver phenotypes in cancer must confer either a cell-intrinsic (birth minus death) or cell-extrinsic (field) effect on growth. These effects can be summarized by an r/K logistic growth curve, whereby cell-intrinsic effects manifest as a change in the early, exponential growth constant (*r*) of a tumor population while cell-extrinsic effects alter the long-term 'carrying capacity' (*K*). Previously, we developed a novel genetically-engineered mouse model that tracks tumor growth dynamics with unprecedented precision via Tumor Barcoding, termed TuBa-seq[1]. Here, we quantify the growth trajectories of thousands of *Kras*-driven lung tumors over eight months. Median tumor size is best-described by a Gomp-Ex growth law (i.e. N^{ν}/K where $\nu \to +0$), which also characterizes advanced-stage human tumors[2]. Carrying capacities of individual isogenic tumors varied by over four orders of magnitude, suggesting that microenvironmental heterogeneity profoundly impacts growth dynamics. Our approach further allowed us to track the growth effects of eleven canonical tumor suppressor gene knockouts introduced via multiplexed CRISPR/Cas genome-engineering. All but one of these secondary mutations augmented either the exponential growth rate or the carrying capacity of the tumor. However, only three tumor suppressor losses increased both growth parameters (Rb1, Setd2, and Stk11). Hence, the growth benefits of most cancer-causing mutations are missed when growth is measured only at a single time point. Clinically, we find that *r*-promoting and *K*-promoting mutations interact synergistically to create the most aggressive tumors in human patients (HR = 1.71, P-value < 10^{-10}). Collectively, these results support a universal *r*/*K* framework for tumor growth and progression.

#4308 Same-section spatial multiomic analyses using MICS technology for investigating the dynamics of the tumor microenvironment.

Dongju Park[1], Emily Neil[1], Rebecca C. Hennessey[1], Michael DiBuono[1], Hanna Lafayette[1], Erica Lloyd[1], Hsinyi Lo[1], Julia Femel[2], Alex Makrigiorgos[1], Shaina Lu[1], John Lee[1], Sameh Soliman[1], Dominic Mangiardi[1], Paurush Praveen[2], Fabian Staubach[2], Ryan Hindman[1], Thomas Rothmann[2], Telma Santos[2], Stefan Borbe[2], Hansueli Meyer[1], Tanya Wantenaar[2], Jinling Wang[1], Werner Muller[2], Robert Pinard[1], Andreas Bosio[2]

[1]Miltenyi Biotec, Waltham, MA,[2]Miltenyi Biotec, Bergisch Gladbach, Germany

The recent increase in image-based, spatially-resolved technologies enables researchers to profile the tumor microenvironment (TME) by capturing gene expression profiles within tissue sections. However, a significant limitation of these technologies is the lack of ability to resolve protein and RNA information in the same section, as well as conveniently analyze multimodal data sets. Here, we report a spatial RNA detection method, RNAsky, using Miltenyi Biotec's MACSima™ Platform as an automated, multiomic approach. Our method integrates spatial proteomics and transcriptomics data to provide in-depth profiling with single-cell resolution on the same tissue section. We demonstrate these capabilities by characterizing key immune-oncology markers across normal and diseased tissues using our specialized MACS® iQ View analysis software. MACS iQ View provides fast segmentation and intuitive gating and clustering strategies to simultaneously assess protein and RNA data. We investigated the impact of clustering using protein, RNA, or the combination of both to evaluate the contribution of different information modalities on TME spatial dynamics. This cutting-edge approach will enable the identification of valuable parameters and new cell types, furthering the discovery and development of predictive and prognostic biomarkers.

#4309 Establishment of intratumor heterogeneity using patient derived lung cancer cells.

T. Funazo[1], H. Ozasa[1], T. Tsuji[2], Y. Shima[1], K. Suminaga[1], K. Hashimoto[1], H. Yoshida[1], T. Ogimoto[1], K. Hosoya[1], H. Ajimizu[1], T. Nomizo[1], H. Yoshida[1], T. Hirai[1];

[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan, [2]Graduate School of Medicine, Nagoya University, Nagoya, Japan

Overcoming cancer treatment resistance is a problem that must be solved to improve the prognosis of cancer patients. In recent years, genome analysis has revealed the existence of multiple subgroups with different properties within a single tumor, and intratumor heterogeneity is a cause of treatment resistance. It has also been reported that. However, the mechanism of intratumor heterogeneity remains unclear. Previous research on intratumor heterogeneity has mainly focused on analyzing patient cancer cells, classifying subgroups, and estimating characteristic factors. This method has two drawbacks. One is limitations in including all subgroups as research subjects, and other is lack of verification of whether characteristic factors are actually involved in intratumor heterogeneity in patients. Therefore, it is necessary to use a model of "early intratumor heterogeneity" in which monoclonal cells are divided into subgroups with different properties, and to verify the discovered factors using patient-derived cancer cell lines. In alectinib-resistant cell line (H2228-AR1S) created from monoclonal ALK-positive lung cancer cell line (H2228) by exposing to alectinib *in vitro*, existence of two fractions with different appearances. Using flow cytometry, it was revealed that H2228-AR1S bimodally expresses EpCAM, and the EpCAM-low fraction has high migration ability. In EpCAM-low fraction, epithelial markers were decreased, and mesenchymal markers were increased using immunoblotting. It suggests that EpCAM low subpopulation has undergone epithelial-mesenchymal transition (EMT). Additionally, we established a BRAF-positive lung cancer cell line (KTOR83) collected with consent from patients attending Kyoto University Hospital. Cells after *in vitro* dabrafenib exposure to KTOR83 showed bimodal EpCAM expression, and the EpCAM-low fraction has high migration ability. We established an intratumor heterogeneous model using commercially available cells and a patient-derived lung cancer cell line. Furthermore, we will explore factors common to the two models and examine factors involved in intratumor heterogeneity.

#4310 Impact of drug combination schedules on the evolution of tumor resistance.

M. Stoddard[1], A. Chen[2], **L. Yuan**[1], D. Van Egeren[3], D. Bottino[4], A. Chakravarty[1];
[1]Fractal Therapeutics, Inc., Lexington, MA, [2]Columbia University, Computational Biology, NY, [3]Stanford University, Palo Alto, CA, [4]Takeda Pharmaceuticals, Cambridge, MA

The emergence of drug resistance during treatment is a critical limiting factor for the long-term effectiveness of anticancer therapies. The use of drug combinations limits the emergence of resistance, thereby prolonging their therapeutic utility. The effect of a drug combination is dependent both on the concentration of the individual drugs and the extent of their interaction (synergistic, additive, or antagonistic). Thus, understanding the scheduling implications for efficacy can be valuable for optimizing tumor response and time to resistance for the combination. To examine this more closely, we used a pharmacokinetic/pharmacodynamic (PK/PD) modeling approach, coupling one-compartment PK models of two hypothetical drugs based on set synchronous or asynchronous (offset) schedules with an evolutionary model of tumor clone growth. We simulated four tumor subpopulations representing binary resistance to one or both drugs, using an exponential growth model with growth penalties based on drug concentrations. We used the model to simulate the effects of pairs of antagonistic, synergistic, and additive drugs on the growth of sensitive and resistant populations in a tumor. Final tumor volume and resistant population were used to compare the efficacy of various drug schedules. As expected, the effect of a drug interaction—either synergistic or antagonistic—is greatest when dosing is synchronous, as this results in the greatest simultaneous drug concentration. The effect of a drug interaction is proportional to the sensitive population size, so the effect of drug interactions decreases over time as the sensitive population is eliminated. Intuitively, the final tumor volume decreases as the strength of a synergistic interaction increases until the sensitive population is eliminated. The resistant populations are unaffected by the strength of the interaction for both antagonistic and synergistic combinations. Resistant populations are not affected by interactions between drugs to which they are resistant, so the growth of resistant populations over time is independent of drug interactions. Crucially, for effective drugs—that is, drugs that eliminate the sensitive population—synergy and antagonism converge to additivity as the sensitive population dies out because the remaining resistant populations are not affected by drug interactions. As synergistic and additive drug combinations are equivalent in the long-term, synergy and asynchronous dosing could be used to limit toxicity without sacrificing efficacy. The evolution of resistance also explains why *in vitro* synergy or antagonism may not translate *in vivo*. Taken together, our work provides several unintuitive insights about combination drug scheduling with practical implications for therapeutic design.

#4311 The interplay of SYNCRIP deficiency, APOBEC activity, and extrachromosomal DNA in castration-resistant prostate cancer drug resistance.

X. Li[1], S. Deng[1], C. Wang[1], Y. Wang[2], P. Mu[1];

[1]UT Southwestern Medical Center, Dallas, TX, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background: Prostate cancer, particularly in its castration-resistant form (CRPC), frequently develops resistance to androgen receptor (AR)-targeted therapies. This resistance involves complex factors, including tumor mutational burden and heterogeneity. APOBEC proteins, associated with mutagenesis and DNA damage, are implicated in this process. Our study centers on SYNCRIP, a key regulator of APOBEC activity, and investigates its influence on extrachromosomal DNA (ecDNA) in CRPC. Objective: This research aims to explore how SYNCRIP deficiency leads to increased APOBEC activity, and to examine its possible implications for ecDNA formation and its contribution to drug resistance and tumor heterogeneity in CRPC.

Methods: Genomic and transcriptomic analyses, such as whole exome sequencing and single-cell RNA-seq, were performed on CRPC cell lines and patient-derived samples, with an emphasis on SYNCRIP-deficient models. The study focused on understanding the relationship between elevated APOBEC activity due to SYNCRIP deficiency and potential ecDNA changes, evaluating their effect on AR-targeted drug sensitivity and overall tumor behavior.

Results: SYNCRIP was identified as a critical factor in resistance to AR therapy in both *in vitro* and *in vivo* models. Its deficiency resulted in increased therapy resistance and amplified APOBEC-mediated mutagenesis. Functional CRISPR screening identified eight key drivers of resistance in SYNCRIP-deficient tumors. Single-cell RNA sequencing revealed APOBEC-driven mutagenesis as a key factor in promoting intratumoral heterogeneity and resistance. Notably, in SYNCRIP-deficient CRPC samples, increased APOBEC activity and significant DNA damage were observed, prompting an investigation into a possible correlation between resistance and ecDNA presence.

Conclusion: The study uncovers a significant link between SYNCRIP deficiency and increased APOBEC activity in CRPC. While it also hints at a potential connection with ecDNA alterations, further research is necessary to establish this relationship firmly. This interplay contributes to the complexity of drug resistance in CRPC, highlighting the need for novel therapeutic targets. The dynamics among SYNCRIP, APOBEC activity, and ecDNA offer valuable insights into the molecular underpinnings of therapy resistance in prostate cancer, suggesting new directions for treatment strategies.

#4312 KRAS oncogenic activation in *Gramd2*$^{\pm}$ AT1 cells form lung adenocarcinoma with distinct transcriptomic and tumor microenvironment signatures.

Minxiao Yang[1], Jonathan Castillo[1], Edgar Gonzalez[2], Chunli Yan[3], Evanthia Roussos torres[2], Zea Borok[4], Crystal Marconett[1]

[1]Department of Translational Genomics, USC - University of Southern California, Los Angeles, CA,[2]Department of Medicine, USC - University of Southern California, Los Angeles, CA,[3]USC - University of Southern California, Los Angeles, CA,[4]Department of Medicine, University of California, San Diego, San Diego, CA

Lung adenocarcinoma (LUAD) is the most prevalent subtype of lung cancer and presents with a high degree of biological heterogeneity and distinct clinical outcomes. The current paradigm of LUAD etiology recognizes alveolar epithelial type II (AT2) cells as the primary cell of origin, while the role of AT1 cells in LUAD oncogenesis remains relatively unknown. Here, we examined transformation via activation of the oncogenic KRAS^{G12D} mutation in a Gram-domain containing 2 (*Gramd2*)$^{\pm}$ AT1 cell lineage tracing model system, which resulted in multifocal LUAD, primarily of papillary histology. Spatial transcriptomic sequencing revealed significant differences of transcriptomic signatures and signaling activities between *Gramd2*$^{\pm}$ AT1 cell-derived and *Sftpc*$^{\pm}$ AT2 cell-derived LUAD. Single-cell RNA sequencing of macrodissected LUAD lesions demonstrated heterogeneous cell composition of the tumor microenvironment (TME), with *Gramd2*$^{\pm}$ AT1 cell-derived LUAD fostering a proinflammatory, immunoreactive TME and *Sftpc*$^{\pm}$ AT2-derived LUAD presenting with an immunosuppressive TME. Collectively, our study suggests that cell of origin for LUAD is associated with histologic subtype, transcriptomic aberrations, and immune cell composition within LUAD that may influence response to therapy.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Autophagy and Other Forms of Cell Death
Poster Session

#4316 Investigation the role of DDI2 in autophagy.
N. Hosseini, H. A. Byers, S. K. Radhakrishnan;
Virginia Commonwealth University, Richmond, VA

Background: The ubiquitin-proteasome system (UPS) and autophagy-lysosomal pathway (ALP) are critical intracellular protein degradation pathways. In response to proteasome dysfunction, cells initiate compensatory autophagy to manage proteotoxic stress, which impacts cancer therapy efficacy. Despite current insights, the exact molecular mechanisms underlying the induction of autophagy due to impaired proteasome function remain unclear. The transcription factor nuclear factor erythroid-2-related factor 1 (NRF1) is the master regulator of proteasome subunit genes, which is activated by the protease DNA damage inducible 1 homolog 2 (DDI2) upon proteasome inhibition. DDI2 also acts as an ubiquitin shuttling factor, and its depletion causes the accumulation of highly ubiquitinated proteins, resulting in increased sensitivity to proteasome inhibition in cancer cells. However, cancer cells might trigger compensatory autophagy in response to DDI2 depletion to degrade ubiquitinated protein aggregates. Here, we demonstrated that DDI2 depletion plays a role in autophagy induction.
Methods: A panel of cell lines of different origins (EW16 and ES1 human Ewing sarcoma, MIA PaCa-2 human pancreatic cancer, and NIH-3T3 murine fibroblasts) either control or DDI2-deficient were examined for autophagy activity following treatment with the autophagy inhibitor chloroquine (CQ). Through total proteome analysis, we identified an increase in cellular communication network factor 1 (CCN1) protein levels in DDI2-depleted cells, which plays a role in autophagy induction. To determine whether CCN1 is required and sufficient to induce autophagy, we applied small interfering RNA (siRNA), and viral constructs to knockdown and overexpress CCN1.
Results: The autophagic flux measurements in four different DDI2-deficient cell lines revealed elevated LC3B-II protein levels, a known autophagy marker, following CQ treatment compared to their control. Western blotting analysis confirmed increased CCN1 protein levels in the same cell lines. The autophagy induction observed in DDI2-deficient cells was diminished by CCN1-siRNA, demonstrating that CCN1 may be required for autophagy induction. Furthermore, overexpressing CCN1 in wild-type cells resulted in increased LC3B-II protein levels, indicating that CCN1 alone is sufficient to induce autophagy.
Conclusion: Targeting autophagy is a promising therapeutic strategy to improve the effects of anti-cancer therapies. We demonstrated that upon depletion of ubiquitin shuttle factor DDI2, secretory protein CCN1 accumulates leading to the subsequent induction of autophagy. These findings improve our understanding of the molecular basis governing DDI2's role in crosstalk between protein degradation pathways. Targeting DDI2 in combination with autophagy inhibition could further potentiate these drugs as anti-cancer therapies.

#4317 The role of autophagy in triple negative breast cancer.

S. Gamal[1], **N. A. El-Nikhely**[1], H. Nematallah[2], H. M. Saeed[1];
[1]Alexandria University, Alexandria, Egypt, [2]Damanhour University, Damanhour, Egypt

Breast cancer (BC) remains a global health concern, being the most common cancer amongst women in the world, and the second-leading cause of cancer related death. Triple-negative breast cancer (TNBC) represents a challenging frontier in oncology, characterized by its aggressiveness and its unique molecular profile devoid of the known receptors. Its elusiveness lies in the inherent heterogeneity within its subtypes, contributing to diverse clinical behaviours and treatment responses. TNBC has also shown elevated basal autophagy level as a pro-survival mechanism to make up for the increased nutrients demand mandated by the high K-RAS signalling. To tackle such tumour, we chose an autophagy blocker in addition to multi-kinase inhibitor. The combination index calculated for the proposed drugs has shown promising results in reduction of cell viability more than each drug separately. Selectivity index proved the safety of our doses on normal fibroblast cells in contrast to two breast cancer cell lines (MDA-MB 231 & MCF7). To further complement the findings, cell cycle arrest was witnessed at S phase which lead to apoptosis seen by flowcytometry and other expression analysis studies. Finally, Imaging studies and expression analysis on protein level have documented the apoptotic effects rendered by autophagy inhibition.Research endeavours continue to unravel the intricate landscape of TNBC, seeking novel avenues for targeted treatments, immunotherapies, and personalized medicine, aiming to transform the paradigm of care for those affected by this enigmatic form of breast cancer. As evident from the results, our combination has also managed to reduce the cells migration effectively which reflects that it can be initiated with aggressive metastatic tumours like TNBC.

#4318 CD24 enhances cisplatin resistance in ovarian cancer by suppressing autophagy.

Y.-L. Chen, T.-M. Hong, Y.-Y. Wen;
National Cheng Kung University, Tainan, Taiwan

Ovarian cancer is one of the most common gynecological cancers with the highest mortality rate. Most patients are diagnosed with advanced disease and will relapse due to chemoresistance. CD24, a highly glycosylated GPI-anchored membrane protein. Recent studies have shown that CD24 expression is significantly up-regulated in ovarian cancer and is associated with chemotherapy resistance, and CD24 also plays an inhibitory role in tumor immunity by binding to Siglec-10 on macrophages. However, the molecular mechanisms of how CD24 affects chemotherapy resistance in ovarian cancer remain unclear. In this study, we used shRNAs to knockdown CD24 and explore the impact and mechanism of CD24 on the chemotherapy resistance of ovarian cancer cells. The results showed that knockdown of CD24 in ovarian cancer cells SKOV3 and TOV21G significantly reduced cell proliferation and arrested the cell cycle in S phase. Knockdown of CD24 also significantly increased the sensitivity of ovarian cancer cells to cisplatin but had no effect on paclitaxol treatment. Further experiments showed that knockdown of CD24 increased cisplatin sensitivity by promoting autophagy-induced cell death. In addition, Gene Set Enrichment Analysis (GSEA) was used to analyze the correlation between the expression of CD24 and its biological functions in the TCGA ovarian cancer dataset. The results showed that CD24 is mostly correlated to cell proliferation and autophagy-related pathways in ovarian cancers. Further mouse xenograft tumor transplantation experiments also confirmed that knockdown of CD24 reduced tumor size and increased sensitivity to cisplatin treatment by increasing cell autophagy. Taken together, these results indicate that CD24 regulates cell growth and chemoresistance in ovarian cancer cells and that inhibition of CD24 may be helpful in the treatment of ovarian cancer.

#4319 HSF1 inhibition induces pancreatic ductal adenocarcinoma autophagy through JNK.

S. Ghai[1], A. Young[2], K.-H. Su[1];
[1]The University of Toledo College of Medicine and Life Sciences, Toledo, OH, [2]Lake Erie College of Osteopathic Medicin, Erie, PA

Background: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related mortality, with a 5-year survival rate of 12%. Chemoresistance due to autophagy, a natural process of proteotoxic stress response, is the most common chemotherapy challenge for pancreatic cancer. Autophagy, which maintains cellular homeostasis by removing damaged or unnecessary proteins and organelles, is a self-degradation process regulated by the mammalian target of rapamycin complex (mTORC1). Excessive levels of autophagy can be detrimental and lead to cell death. Nevertheless, this dual function of autophagy in regulating pancreatic cancer remains poorly understood. It has been reported that heat shock factor 1 (HSF1), a critical pro-oncogenic transcription factor in the proteotoxic stress response, inhibits c-Jun N-terminal kinase 1/2 (JNK1/2) signaling pathway to maintain mTORC1 activity and control cell size. HSF1 is highly expressed in pancreatic tumors, and inhibition of HSF1 via small molecules enhances the chemotherapy drug effect on PDAC programmed cell death. However, the PDAC autophagy response in HSF1 inhibition is currently not fully understood. Objective: The objective of this study is to investigate the molecular mechanism of HSF1 inhibition in PDAC autophagy.
Methods and Results: In human PDAC cells, Western blotting analysis revealed that HSF1 inhibition via small molecular including CCT361814/NXP800, an HSF1 inhibitor in phase I clinical trials, increased autophagy marker microtubule-associated protein 1A/1B-light chain 3 (LC3) lipidation and decreased expression of phosphorylation of HSF1 at Ser326 and total HSF1 protein, conversely using HSF1 overexpression model reversed this effect. Inhibition of autophagy via 3-methyladenine reversed HSF1 inhibition-induced autophagy. Results from transmission electron microscopy and GFP-LC3 reporter revealed that HSF1 inhibition induced autophagosome formation and accumulation. Furthermore, HSF1 inhibition induced phosphorylation of JNK1/2 at Thr183/Tyr185 and decreased mTORC1 activity, while knockdown JNK1/2 diminished HSF1 inhibition-induced LC3 lipidation. The combination of chemotherapy drugs with HSF1 inhibitors decreased PDAC cell viability. Additionally, blocking autophagy increased HSF1 inhibition-induced apoptosis.
Conclusions: In conclusion, JNK1/2 is involved in HSF1 inhibition-induced PDAC autophagy, targeting autophagy could unveil a novel treatment strategy for pancreatic cancer through targeted HSF1 inhibition.

#4320 Interrogation of autophagy inhibition in anaplastic large cell lymphoma (ALCL).

K. L. Buelow[1], S. Celano[2], G. Poole[2], K. Martin[2], J. MacKeigan[2], D. J. Hoogstra[3];

[1]Corewell Health, Grand Rapids, MI, [2]Michigan State University, Grand Rapids, MI, [3]Helen DeVos Children's Hospital at Corewell Health, Grand Rapids, MI

The objectives of this study are to evaluate if anaplastic lymphoma kinase (ALK) inhibition activates autophagy in ALK+ ALCL cells and to determine if that activation can be mitigated using autophagy inhibition. ALCL is an aggressive T-cell non-Hodgkin lymphoma that often presents as advanced stage disease. With the addition of crizotinib or brentuximab vedotin to the ALCL99 chemotherapy backbone, the recently reported Children's Oncology Group ANHL12P1 study demonstrated a 2-year event-free survival for ALCL patients of 79%. Thus, even with multi-agent chemotherapy combined with targeted therapy, improved therapeutic efficacy is needed. Autophagy is activated when mTORC1 is inhibited, and as ALK signaling is known to promote mTORC1 activity, ALK inhibition is hypothesized to activate autophagy. If present, ALK inhibitor-induced autophagy activation would represent a novel therapeutic opportunity targetable with emerging autophagy inhibitors. An ALK+ ALCL cell line, Karpas 299, was treated with drug combinations for 3 hours, lysates prepared, and proteins separated by molecular weight using standard procedures. ALK inhibitor target engagement was assessed by western blot using phospho-ALK^{Y1604} intensity in 9-point dose response curves. Target engagement of autophagy inhibition (ULK-101 directed against ULK1/2 and hydroxychloroquine (HCQ) targeting the lysosome) was assessed by western blot using phospho-ATG14^{S29} and LC3B-II intensity in 6-point dose response curves. Cell viability was evaluated using a luminescent CellTiter-Glo assay. Karpas299 cells resistant to crizotinib at 50nM (KCrizR50) were generated by gradually increasing crizotinib concentration in the media until cells grew at a rate similar to parental cells. Crizotinib, ceritinib, and lorlatinib all effectively inhibit ALK phosphorylation in Karpas 299 cells with low nanomolar potency. ULK-101 effectively inhibited pATG14^{S29} at 5 μM and HCQ effectively inhibited autophagic flux, as evidenced by increased LC3B-II intensity, at 20 μM. When treated with the lowest ALK inhibitor dose needed to achieve complete pALK inhibition (IC_{99}), pATG14 intensity increased representing increased autophagic activity. When combined with ALK inhibition, ULK-101 effectively decreased pATG14^{S29}, blocking the ALK inhibitor-induced autophagy activation. Decreased viability in Karpas 299 cells was observed after crizotinib, ceritinib and lorlatinib treatments with nanomolar potency. KCrizR50 cells had a potency higher than parental Karpas 299 cells for all three ALK inhibitors. ALK inhibition activates autophagy in ALCL cells and autophagy activation is effectively mitigated through concurrent autophagy inhibition. ALK inhibitor resistance in Karpas 299 cells will be further evaluated to determine whether autophagy contributes to the resistant phenotype.

#4321 The oncogenic DMTF1β splice variant promotes autophagy-dependent cancer cell motility.

M. P. Tschan, J. Xu, A. M. Bill;
University of Bern, Bern, Switzerland

The oncogenic isoform DMTF1β, which is generated by alternative splicing of the DMTF1 tumor suppressor gene is associated with increased cell proliferation and tumorigenesis. Despite these correlative findings little is known about the DMTF1β mechanism of action. In order to decipher the oncogenic DMTF1β signaling pathway, we performed RNA sequencing of DMTF1β depleted prostate cancer cells and analyzed the DMTF1β-specific protein interactome in these cells. Interestingly, autophagy-related pathways belonged to the most downregulated networks in DMTF1β knockdown cells. Moreover, we found that predominantly DMTF1β, but not a protein lacking the β-specific domain interacts with the key autophagy ULK1-ATG13 protein complex. These interactions were confirmed by co-immunoprecipitation and proximity ligation assays. Importantly, DMTF1β binding to ULK1 stabilized this key autophagy protein. Accordingly, knocking down DMTF1β significantly lowered autophagic flux in breast and prostate cancer cells as assessed by LC3-dependent and independent autophagy assays. Since published data show an important role for autophagy in migration and invasion of cancer cells, we next investigated whether DMTF1β is regulating these cellular processes. Indeed, DMTF1β depleted breast and prostate cancer cells displayed significantly decreased wound closure, trans-well invasion and metastatic foci formation in a zebra fish xenograft model. Importantly, pharmacological inhibition of ULK1 kinase activity or knocking down ULK1 reversed DMTF1β-mediated cancer cell migration. In agreement, decreased cell motility in DMTF1β knockdown cancer cells could be rescued by ectopic expression of the VPS34 complex member Beclin-1. In summary, we identified a novel DMTF1β-ULK1 signaling pathway that activates aberrant cancer cell migration most probably by increasing basal cell autophagy. Targeting autophagy using ULK1 inhibitors may represent a promising strategy to lower metastatic activity of tumor cells.

#4322 Inhibition of ULK and KRAS^{G12C} control tumor growth in preclinical models of lung cancer.

P. Ghazi[1], K. O'Toole[1], S. Boggaram[1], M. Scherzer[1], M. Bogdan[2], B. Smith[2], D. Flynn[2], C. Kinsey[1], M. McMahon[1];
[1]University of Utah, Salt Lake City, UT, [2]Deciphera Pharmaceuticals, Waltham, MA

Approximately 30% of lung cancers are driven by mutationally activated KRAS. The recent FDA approval of sotorasib, a direct pharmacological inhibitor of KRASG12C, marks a critical milestone in the treatment of this important subset of lung cancer. However, a major obstacle in treating lung cancer is resistance to current therapeutic treatments. In response to cellular stresses such as RAS pathway-targeted therapeutics, RAS-mutated cancer cells have been demonstrated to increase autophagy, an intracellular recycling pathway. However, the mechanism(s) underlying treatment-induced autophagy is not well understood. Here, we demonstrate that KRASG12C-driven lung cancer cells increase autophagy in response to treatment with sotorasib. Currently, the only therapeutics in clinical use to inhibit autophagy are lysosomal inhibitors (hydroxy)chloroquine. High concentrations of these compounds are needed to achieve modest inhibition of autophagy, suggesting that the potency of these compounds may limit clinical responses. ULK kinases are serine/threonine kinases that are necessary for the initiation of autophagy. DCC-3116 is a potent inhibitor of the ULK1/2 protein kinases, master regulators of autophagy. Treatment with sotorasib and DCC-3116 led to superior anti-tumor effects in preclinical models of lung cancer. Additionally, about 30% of lung cancer patients with KRAS mutations also have deletions or inactivating mutations in LKB1, a protein involved in the regulation of nutrient sensing and autophagy. In other KRAS-driven cancers, the LKB1-AMPK-ULK1 signaling axis is a proposed mechanism as to how autophagic flux increases following KRAS pathway inhibition. However, our preliminary data demonstrates that LKB1 is dispensable for sotorasib-induced autophagy, suggesting the mechanism(s) of autophagy induction in KRASG12C-driven lung cancer may be different from those detected in other KRAS mutated cancers. Consequently, we have generated genetically engineered mouse models (GEMMs) of KRASG12C-driven lung cancer in which LKB1 is silenced to further investigate the role of LKB1 in the autophagy response of KRASG12C-driven lung cancers to pathway-targeted blockade of oncogenic KRAS signaling. We have treated KRASG12C-driven GEMMs with sotorasib and/or DCC-3116 to test the sensitivity of lung tumors to these treatment options.

#4323 Deletion of the lipid kinase PIKfyve in Kras-driven pancreatic genetically engineered mouse model.

S. N. Yee, X. Jiang, C. Cheng, A. Korkaya, R. Mannan, R. Mehra, Y. Qiao, A. M. Chinnaiyan;
University of Michigan Medical School, Ann Arbor, MI

Background: Pancreatic ductal adenocarcinoma (PDAC) accounts for 95% of all pancreatic cancers and, as one of the most lethal cancers, has a five-year survival rate of approximately 6%. Autophagic processes have been reportedly elevated in PDAC; thus, the inhibition of autophagy leads to decreased tumor growth. Autophagic processes are catabolic mechanisms that recycle cellular components. Cells in stressful conditions, such as starvation, have elevated autophagy to redistribute energy to sustain cell survival; however, this can also lead to cell death when attempts to maintain cell viability fail. In addition, autophagy is known to promote immune evasion by tumors and cancer progression and appears to be required for the optimal development of PDAC. The lipid kinase PIKfyve converts phosphatidylinositol-3-phosphate to phosphatidylinositol 3,5-bisphosphate and is required in the late stage of the autophagic pathway. Blocking PIKfyve disrupts autophagic processes. However, the role of PIKfyve in PDAC development has not been fully understood. We investigated the role of PIKfyve in the progression of PDAC using a genetically engineered mouse model. Given the poor clinical outcomes of pharmacological inhibition of autophagy by chloroquine, we have evaluated the PIKfyve inhibitor ESK981 in the context of PDAC progression.
Methods: The pancreatic-specific deletion of PIKfyve was established on a Kras G12D, Tp53 R172H, and p48 Cre (KPC) or Kras G12D and p48 Cre (KC) background. The ratio of pancreatic mass to body weight was monitored at various time points. Histopathology evaluations were conducted based on hematoxylin and eosin staining and immunohistochemistry of cytokeratin 19 staining. Pharmacological inhibition of PIKfyve was performed on KPC mice using ESK981 monotherapy. Four weeks after vehicle or ESK981 treatment, pancreatic tissues were collected intact and weighed. Histopathology evaluations were performed to evaluate the lesion.
Conclusion: We demonstrated that the deletion of PIKfyve in pancreatic tissue significantly reduces the pancreatic mass weight compared to the PIKfyve wildtype counterpart and is coupled with less pancreatic intraepithelial neoplasia (PanIN) and PDAC development in KPC and KC mice. Compared to the vehicle treatment, pharmacological inhibition of PIKfyve by ESK981 on KPC mice resulted in a significant increase in the percentage of normal pancreatic tissue and reduced pancreatic lesion development.

#4324 IL6ST increases sorafenib-resistance in hepatocellular carcinoma by regulating BECN1-mediated mitophagic cell death.

H. Ma, **Y.-S. Roh**;
Chungbuk National University, Cheong-Ju, Korea, Republic of

Introduction: Sorafenib resistance is often seen in patients with late-stage hepatocellular carcinoma (HCC) and it is a serious concern for the treatment of these patients. Lethal mitophagy plays an important role in anti-tumorigenic mechanisms by inducing mitochondrial dysfunction and mitophagic cell death. Sorafenib resistance is associated with the activation of IL6ST signaling, inhibiting mitochondrial quality. However, how lethal mitophagy regulates sorafenib resistance through IL6ST and mitochondrial dysfunction in HCC is not fully understood.
Experimental procedures: Hepatocyte-specific TAK1 deleted (TAK1ΔHep) and TAK1/ IL6STΔHep were used for in vivo study. Histology, immunoblots, qPCR, microscopy, FACS, and seahorse bioanalyzer were used for analyzing liver and tumor tissues and Hep3B cells.
Results: We identified that sorafenib suppressed IL6ST signaling and that IL6ST signaling was activated in sorafenib-resistant HCC. The number and maximum size of spontaneous HCC in 9-month-old TAK1ΔHep mice were decreased when hepatocyte IL6ST was additionally deleted. Expression of pro-carcinogenic H-19, c-SRC, and MDM2 was increased in 1-month-old TAK1/IL6STΔHep mice compared to TAK1ΔHep mice. An additional IL6ST deletion induced decreases in mitochondrial membrane potential and glycolysis, suggesting that IL6ST protects against mitochondrial dysfunction. Interestingly, IL6ST deletion increases PRKN and BECN1 interaction and translocation to normal mitochondria and subsequent degradation, hereafter referred to as lethal mitophagy. Furthermore, inhibition of BECN1 restores IL6ST deletion-induced lethal mitophagy in HCC, suggesting that IL6ST-mediated lethal mitophagy is dependent on BECN1. Mechanistically, IL6ST inhibited BECN1-lethal mitophagy through STAT3(S705) phosphorylation independently of mTORC1 activation. Notably, enhanced BECN1 through a combination of sorafenib and inhibition of IL6ST increased mitophagic cell death, reducing sorafenib resistance and tumor growth. In addition, enhanced lethal mitophagy through inhibition of GP130 effectively killed sorafenib-resistant HCCs by silencing sorafenib resistance. We further defined the relationship between IL6ST, BECN1, and PRKN expression and sorafenib resistance in terms of HCC patients, RNA sequencing datasets.
Conclusion: These results provide the importance of IL6ST in the development of sorafenib resistance and could be an innovative treatment strategy for sorafenib-resistant patients by regulating the IL6ST/STAT3/BECN1 axis-regulated lethal mitophagy.

#4325 CX-4945 (Silmitasertib) induces cell death through impairment of lysosomal utilization in *KRAS* mutant cholangiocarcinoma cell lines.

C. Kim[1], D. Lee[1], M. Han[2], S. Lee[3], K.-p. Kim[1], C. Yoo[1];
[1]Asan Medical Center, Seoul, Korea, Republic of, [2]University of Ulsan College of Medicine, Seoul, Korea, Republic of, [3]University of Ulsan Digestive Diseases Research Center, Seoul, Korea, Republic of

Purpose: Macropinocytosis is a non-selective endocytosis that uptakes extracellular substances such as nutrients and macromolecules into the cells. In *KRAS*-driven cancer such as pancreatic ductal adenocarcinoma, the macropinocytosis and following lysosomal utilization are enhanced to overcome metabolic stress. In this study, we investigated the role of CK2 in micropinocytosis and the following metabolic process in the *KRAS* mutant CCA cell line.
Materials and Methods: The BSA uptake indicating micropinocytosis was performed by flow cytometry using the HuCCT1, cholangiocarcinoma cell line harboring *KRAS* mutation. To validate macropinosome, the Rab7 and LAMP2 were labeled and analyzed via immunocytochemistry and Western blot. The CX-4945, CK2 inhibitor, was used to investigate the role of CK2 in micropinocytosis and following lysosomal metabolism.
Results: The HuCCT1, a *KRAS* mutant CCA cell line, showed micropinocytosis. Although CX-4945, a CK2 inhibitor, induced morphological changes accompanied by accumulation of intracellular vacuoles and cell death rate, the level of micropinocytosis was not changed. The vacuoles accumulated in the cell were identified as late macropinosomes representing Rab7 before fusion with lysosomes. In addition, the CX-4945 suppressed LAMP2 expression following inhibition of the Akt-mTOR signaling pathway which interrupts mature macropinosome and lysosomal metabolic utilization.
Conclusion: These results support the utilization of micropinocytosis as an energy source even in CCA cell line harboring *KRAS* mutation. The inhibition of CK2, the regulator of macropinosome maturation, by CX-4945, alters lysosome dependent metabolism and leads to cell death in *KRAS* mutant CCA cell lines.

#4326 CDK7/CDK9 mediates transcriptional regulation to prime cancer cell paraptosis.

L.-C. Chang[1], S.-K. Chiang[2], S.-E. Chen[2];

[1]China Medical University Hospital, Taiwan, Taichung, Taiwan, [2]National Chung Hsing University, Taiwan, Taichung, Taiwan

The mechanisms underlying progression in cell paraptosis are largely unknown. CPYPP, cyclosporin A, and curcumin incited cytoplasmic vacuolization and induced paraptosis in breast cancer cells. The paraptotic program evolved with reactive oxygen species (ROS) provocation and overactivation of proteostatic dynamics to elicit transcriptional regulation involved in redox homeostasis and proteostasis. Pharmacological and genetic approaches suggested that cyclin-dependent kinase (CDK) 7/9 drives paraptotic progression in a reciprocally-dependent manner with heat shock proteins (HSPs). Proteostatic stress as accumulated cysteine-thiols, HSPs, ubiquitin-proteasome system, endoplasmic reticulum stress, and unfolding protein response, as well as ROS provocation primarily within the nucleus enforced CDK7/CDK9-Rpb1 (RNAPII subunit B1) activation by potentiating its interaction with HSPs and protein kinase R (PKR) in a forward loop to amplify the transcriptional regulation and thereby exacerbate proteotoxicity leading to overt paraptosis. Xenograft mouse with OECM-1 cells further confirmed the paraptotic induction against tumor growth. A novel regulatory paradigm that activation of CDK7/CDK9-Rpb1 by nuclear proteostatic stress mediates transcriptional regulation to prime cancer cell paraptosis therefore was concluded.

#4327 Development of bioluminescent biosensors to monitor the interaction betweenGSDMD and caspase-1 in living cells.

T. Kelly;
Queen's University, Kingston, ON, Canada

Gasdermin D (GSDMD) is the key executioner of pyroptosis, an inflammatory form of programmed cell death implicated in various inflammation-driven diseases, including cancer, heart failure and strokes. The interaction between GSDMD and caspase-1 (CASP1) orchestrates the critical pathway of GSDMD-mediated pyroptosis. During pyroptosis, pyroptosis stimuli activate CASP1, which subsequently binds to and cleave GSDMD between GSDMD's N- and C-terminal domains. The free N-terminal domains oligomerize and translocate to the cell membrane, forming pores and releasing proinflammatory cytokines and causing cellular lysis. Key interaction sites have been identified for GSDMD recognition and engagement by CASP1; therefore, blocking functionally significant residues presents a new therapeutic strategy for inhibiting CASP1-induced GSDMD cleavage and pyroptosis. Currently, there is no small molecule capable of specifically disrupting the GSDMD and CASP1 interaction. In response, the ongoing pursuit of identifying potential inhibitors is a driving force for developing a biosensor capable of monitoring this interaction and their roles in downstream pyroptotic effects. In this study, we utilized the NanoLuc Binary Technology (NanoBiT) to construct several bioluminescent biosensors comprising two NanoLuc luciferase enzyme fragments (LgBiT and SmBiT) fused to GSDMD and CASP1, respectively, in various combinations. Further validation of these biosensors by luciferase assays in living cells identified a GSDMD-CASP1 biosensor with highest luciferase activity. This newly developed biosensor paves the way for high-throughput screens to identify novel small molecule inhibitors disrupting the GSDMD-CASP1 interplay. These small molecule inhibitors will effectively impede GSDMD-mediated pyroptosis, holding promise for novel therapies of various human diseases.

#4328 Erlotinib suppresses autophagy in colorectal cancer.

A. Siegman[1], A. Shaykevich[1], I. Silverman[1], S. Goel[2], R. Maitra[1];
[1]Yeshiva University, New York, NY, [2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Introduction: Oncogenic *KRAS* mutation is prevalent in approximately 45% of colorectal cancer (CRC) patients. Limited targeted therapies are available to inhibit the detrimental effects of *KRAS* mutation primarily pertaining to its unique structural intricacies. Erlotinib is an EGFR inhibitor which inducing autophagy in lung cancer cells. In this study, we followed the effects of Erlotinib treatment in mutant and wild-type colorectal cancer (CRC) cells. We report that Erlotinib exhibits selectivity between mutated *KRAS* and wild type, significantly modulating the expression of autophagy proteins ATG5, ULK1, Beclin1, and LC3A.
Methodology: The 2 cell lines used in this study were HCT116 (*KRAS* mutant) and Hke3 (*KRAS* wild type). These cells were treated with Erlotinib for 24 hours and 48 hours, A cell viability assay was performed and subsequently followed by protein extraction. The expression of autophagy proteins ATG5, ULK1, Beclin1, and LC3A was determined. The TCGA COAD-READ patient dataset was utilized using GEPIA 2 software. A correlation was found between the autophagy proteins and the *KRAS* gene expression.
Results: The cell viability assays showed that there was significantly more cell death in *KRAS* wild-type cells compared with *KRAS* mutant at time points ranging from 24 to 48 hours ($p = 0.036$). The experiment also showed that treatment of Erlotinib with concentrations of 20 uM, 35 uM, and 50 uM and significant down regulatory fold changes ($p < 0.05$). Both *KRAS* mutated and wild-type cells treated with Erlotinib expressed significant downregulation of ATG5, ULK1, Beclin1, and LC3A proteins at 48 hours ($p < 0.05$). The 20 uM treatment demonstrated a significance of $p < 0.05$ for all proteins. The 20 uM treatment resulted in fold changes of the *KRAS* mutated cells for ATG5, ULK1, Beclin1, and LC3A to be 1.42, 1.42, 1.81, and 2.09 respectively. A strong *KRAS* correlation was found with ATG5, ULK1, Beclin1, and LC3A using COAD & READ tumor and COAD & READ normal ($R > 0.75$, $p < 0.05$).
Conclusion: This study highlights the effects of Erlotinib as a treatment for *KRAS* mutated CRC. Our results confirmed that Erlotinib had the opposite effect on CRC cells in relation to the expression of the autophagy proteins when compared to lung cancer cells. There were distinct effects of Erlotinib between *KRAS* wild-type and mutant cells in both cell viability and the expression of autophagy-related proteins. In both *KRAS* cell types, there was significant downregulation of autophagy proteins, however, the *KRAS* wild type had significantly more downregulation than the *KRAS* mutant. This data suggests that there is a relationship between *KRAS* mutation and the expression of the autophagy proteins. Our analysis of the patient datasets confirmed the strong correlation between *KRAS* mutation and the expression of autophagy proteins. These findings emphasize the need to explore further how Erlotinib can be augmented into the current treatment regimen as a benefit to CRC patients.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Characterization of Mutational Processes and Drivers in Cancer Development and Evolution Poster Session

#4331 Machine learning-based classification of tissue origin of cancer using methylation profiles.

Marco A. De Velasco, Kazuko Sskai, Seiichiro Mitani, Yurie Kura, Shuji Minamoto, Takahiro Haeno, Hidetoshi Hayashi, Kazuto Nishio

Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Cancer of unknown primary (CUP) is a malignancy with poor prognosis and an unknown primary site and histologically unknown metastasis. Most patients receive empiric chemotherapy including platinum-taxane therapies but experience short survival times. Patients with poor prognosis CUP could benefit from optimizing drug therapy based on primary organ estimation. We constructed and evaluated an ensemble learning model to accurately determine the primary organ using methylation profiles of tumor tissues. Methylation data from 890 samples representing 10 types of cancer from TCGA were analyzed. After data preprocessing, we extracted the top 10,000 CpGs sites based on ANOVA and Gain Ratio or 100 CpG sites from a Gradient Boosting classifier. Performance was evaluated using several machine learning models. Unsupervised analysis was carried out to determine the relationships between the CpG sites selected by Gradient Boosting. Methylation profiling by ANOVA and Gain Ratio yielded favorable performance when using various machine learning models. Using gradient boosting as a feature selector reduced the number of CpG sites by 100-fold without compromising model performance. The training and validation sets showed favorable results for the classification of primary organs with ensemble models. In validation, classification accuracy was 91.2%, 93.5%, 89.7%, and 87.7% for Extreme Gradient Boosting, CatBoost, Random Forest, and Gradient Boosting, respectively. Further profiling of the selected methylation regions was correlated with cancer types and even revealed subgroups within breast and lung cancers. Gradient Boosting as a feature selector for DNA methylation profiling was highly effective in accurately determining tissue origin. Our study has outlined an approach whereby we used an embedded machine learning algorithm to identify a select set of informative features from complex high-dimension data to train and predict cancer type.

#4332 Isoform-level transcriptome-wide analyses identify extensive genetic mechanisms for breast cancer risk undetectable on the gene-level.

A. Bhattacharya[1], Y.-H. Chang[2], B. Pasaniuc[2], S. Lindstroem[3],

[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of California, Los Angeles, Los Angeles, CA, [3]University of Washington, Seattle, WA

Genome-wide association studies (GWAS) have identified over 170 genetic variants associated with breast cancer risk. Integrative methods, like colocalization and transcriptome-wide association studies (TWAS), can identify potential biological mediators for genetic associations but, to date, have only contextualized a fraction of GWAS loci. This reduced discovery is due to an overreliance on reference transcriptomic panels of total gene expression, which ignore widespread alternative splicing that gives rise to multiple transcript-isoforms of the same gene with differing effects on tumorigenesis and progression. However, integrating highly correlated transcript-isoforms with phenotypic associations from genome-wide association studies (GWAS) requires methodological innovations.Here, we first introduce isoTWAS, a multivariate, machine learning method to integrate genetics, isoform-level expression, and phenotypic associations in a step-wise testing framework, and present its advantages over traditional gene-level methods.We then apply isoTWAS to multiomic data from non-cancerous breast samples from the Genotype-Tissue Expression Project (GTEx) and breast cancer risk GWAS summary statistics from the Breast Cancer Association Consortium. In total, we generated strong predictive models for 70,816 isoforms across 12,103 genes and estimated isoform associations for overall and subtype-specific breast cancer risk. We observed 570 associated isoforms across 384 unique genes (compared to 141 associated genes out of 14,613 genes tested in a gene-level TWAS with the same GWAS) at FDR and FWER-corrected P < 0.05. Critically, isoTWAS prioritized isoform associations within 1 Megabase of 66 independent GWAS-significant loci compared to 22 from gene-level TWAS. Of these isoforms within 1 Megabase of a GWAS locus, 19 associated isoforms had a significantly associated risk variant within the gene body. Of note, we find a negative association between the *ESR1* isoform ENST00000488573 and overall breast cancer risk ($P = 3.35 \times 10^{-9}$). Previous studies using breast tissue have not prioritized *ESR1* expression as a potential mediator, despite strong SNP associations at this locus. We are currently updating transcriptomic annotations using long-read RNA-sequencing data to improve the precision and specificity of GTEx isoform-level quantifications. We will then expand our isoTWAS analysis to other related tissues (connective, adipose, and immune-related tissues) to identify causal susceptibility transcripts for overall and subtype-specific risk. Our study underscores the wealth of information remaining in bulk RNA-seq datasets that sophisticated methods like isoTWAS can leverage to identify genetic risk mechanisms for breast cancer that is missed with traditional gene-centric measurements and methods.

#4333 Identification of glucose-6-phosphate dehydrogenase dependency in IDH1 mutant glioma cells using functional genomics.

K. M. Paras, P. Patel, P. Choi, W. R. Wilson, T.-W. Lee, S. M. F. Jamieson, **D. C. Singleton**;
University of Auckland, Auckland, New Zealand

Astrocytoma and oligodendroglioma are most commonly initiated by missense mutations at the arginine 132 codon of isocitrate dehydrogenase 1 (*IDH1*). Biochemically the mutant IDH1 protein acquires neomorphic activity: reductive NADPH-dependent catalysis of α-ketoglutarate (αKG) to (*R*)-2-hydroxyglutarate [(*R*)-2-HG]. (*R*)-2-HG interferes with the function of αKG-dependent epigenetic modifiers, resulting in extensive epigenetic remodeling that impairs cellular differentiation and promotes gliomagenesis. Strategies for selectively targeting *IDH1*-mutant cells offer promise for improved treatment over the standard modalities of surgery, chemotherapy and radiotherapy.

Whole-genome CRISPR/Cas9 knockout screens were conducted to identify gene dependencies in isogenic *IDH1*-mutant and wild-type (WT) U-87 MG cells. Cells were transduced with the Brunello single guide RNA (sgRNA) library, grown for 21 days, then sgRNA distributions were assessed by amplicon sequencing. Gene dependencies were identified using CRISPRcleanR and BAGELR pipelines. We discovered that glucose-6-phosphate dehydrogenase (G6PD), a pentose phosphate pathway (PPP) enzyme, was needed for viability of *IDH1*-mutant cells, but was dispensable for U-87 MG WT cells. The PPP is the main producer of cytosolic NADPH that is required for de novo lipogenesis, maintenance of antioxidants and production of (*R*)-2-HG by mutant IDH1. Previous reports demonstrated that *IDH1*-mutant cells increase PPP flux to support these processes.

We have validated this dependency using G6PDi-1, a cell-active inhibitor of G6PD. Growth inhibition (IC_{50}) assays demonstrated that *IDH1*-mutant U-87 MG cells were threefold more sensitive to G6PDi-1 with IC_{50} of 23 μM and enhanced cell death (increased propidium iodide uptake), compared with WT U-87 MG cells with IC_{50} of 67 μM. *G6PD* knockout was then conducted to further validate this dependency. Nucleofection of *IDH1* WT U-87 MG cells with *G6PD* multi guide RNA-Cas9 ribonucleoproteins resulted in highly efficient knockout of *G6PD* at day 5 (99-100%), which was maintained at day 21 (96-98%). In contrast, efficient *G6PD* knockout in *IDH1*-mutant U-87 MG cells at day 5 (98-100%) was lost following 21 days culture (0-5%), indicating death of almost all edited cells within the culture. Finally, Kaplan-Meier analysis of *IDH1*-mutant patients in the TCGA lower grade glioma dataset demonstrated that higher *G6PD* expression correlated with worse median overall survival (7.3 versus 9.5 years; log-rank p=0.01), but was not prognostic in the *IDH1* WT TCGA glioblastoma multiforme dataset.

These findings demonstrate that a cell line model of *IDH1*-mutant glioma is highly dependent on *G6PD* for survival. This observation builds on the recognized importance of the PPP in the metabolic biology of *IDH1*-mutant malignancy by establishing G6PD as a targetable dependency in this disease.

#4334 Insight into the structure of breakage fusion bridge events and chromothripsis in cancer cell lines using long-read sequencing.

I. Rodriguez[1], N. Rossi[1], A. Kesus[2], Y. Xie[1], T. Ahmad[2], A. Bryant[2], H. Lou[3], J. Godinez Paredes[1], R. Milano[1], M. Kolmogorov[2], S. Tulsyan[1], J. Bess[1], V. Mukhina[4], D. Gaykalova[4], L. Malik[5], K. J. Billingsley[5], C. Blauwendraat[5], L. Mirabello[1], M. Dean[1];

[1]National Cancer Institute, National Institute of Health, Rockville, MD, [2]National Cancer Institute, National Institute of Health, Bethesda, MD, [3]Frederick National Laboratory for Cancer Research, National Cancer Institute, Frederick, MD, [4]University of Maryland School of Medical Center, Baltimore, MD, [5]National Institute on Aging, National Institute of Health, Bethesda, MD

Cervical cancer is caused by human papillomavirus (HPV) infection and is the most common cause of cancer death in low-resource countries. We characterized 18 cervical and 4 head and neck cancer cell lines using long-read DNA and RNA sequencing and identified the HPV types, HPV integration sites, and cancer driver mutations. This cell line panel represents the major molecular subtypes of cervical cancer. Structural variation analysis revealed recurrent chromosomal alteration and telomeric deletions associated with DNA inversions resulting from breakage-fusion-bridge (BFB) cycles. BFB is a common mechanism of chromosomal alteration in cancer that has not been studied using long-read sequencing. Analysis of the inversion sites revealed staggered ends consistent with exonuclease deletion of the DNA after breakage. Some BFB events are complex, involving interchromosomal or intrachromosomal insertions or rearrangements. In total, there were three different types of BFB events: Type I, II, and III. Type I BFB events have staggered ends but no additional insertion at the fusion site. Type II BFB events have an insertion of DNA from another chromosome at the junction, and Type III has an insertion of sequences from the same chromosome as the BFB. BFB cycles are thought to resolve with the addition of a telomere. However, a search for telomeric sequences did not identify any on chromosomes impacted by BFB. In many cancers, BFB events co-occur with chromothripsis; however, in our cervical cancers, only 1 out of 13 had chromosomal shattering near the BFB event, indicating that the mechanism of chromosome rearrangement may be different in cervical cancers. Five cell lines have a Chr11q BFB event, with YAP1/BIRC2/BIRC3 gene amplification. Analysis of 911 publicly available cervical cancer exomes showed that YAP1 amplification is associated with a 10-year earlier age of diagnosis of cervical cancer (x2, p<0.0001) and is three times more common in African Americans (x2=12, p=0.003). Therefore, cervical cancer patients with YAP1/BIRC2/BIRC3 amplification, especially those of African American ancestry, might benefit from anti-YAP1/BIRC2/BIRC3 therapies. Our panel provides models for all the major HPV types and subtypes of cervical cancer that will aid in developing new therapeutic approaches. In summary, we uncovered novel insights into the mechanisms and consequences of BFB cycles in cervical cancer using long-read sequencing. We are expanding long-read sequencing to other cancer cell lines to gain knowledge of events associated with BFB.

#4335 High-resolution characterization of age-specific cell type composition changes and signaling events in HPV-negative HNSCC tumors.

L. Kroehling[1], A. Spinella[1], M. Kukuruzinska[2], X. Varelas[1], S. Monti[1];
[1]Boston Univ. School of Medicine, Boston, MA, [2]Boston Univ. School of Dental Medicine, Boston, MA

This study is aimed at testing the hypothesis that increased patient age fosters conditions that are favorable for head and neck squamous cell carcinomas (HNSCC) of the oral cavity development. There is a well-documented increase in cancer incidence with age observed across diverse cancer types, where elderly patients exhibit diminished survival outcomes compared to their younger counterparts. While the convergence of aging and cancer hallmarks offers valuable insights, further work is needed to elucidate the age-specific mechanisms influencing HNSCC, beyond the shared characteristics of these biological processes.

To this end, we have assembled a high-quality human single-cell RNA-sequencing HNSCC atlas profiling more than 230,000 cells across more than 50 patients with ages ranging between 18 and 89, which provides a resource to investigate age-associated changes in the disease heterogeneity. For this library, we integrated six publicly available single-cell RNAseq datasets from 54 HPV-negative patients to create the atlas. Cells were clustered, classified, characterized by gene set enrichment analysis, both in the epithelial cell compartment and in the tumor microenvironment (TME). Differential cell type proportion analysis was performed to identify cell types enriched in young (<49 years) or old (>70 years) patients. Cell-cell communication analysis was performed to identify signaling events occurring between different populations, and how these and specific ligand-receptor pairs differed in patients of different ages. CNV analyses were performed to identify cancer subclones and assess level of variation across tumors. Interestingly, we identified distinct cell populations and signaling events that associate with age, and we were able to compare, validate and recapitulate these observations in the 4MOSC1 OSCC isograft tumor model in old and young mice. Additional notable findings include a differential enrichment for cytotoxic CD8 T cells over dysfunctional CD8 T cells in young patients when compared to old, suggesting younger patients have a more effective immune TME. We also found an enrichment for cancer-associated fibroblast populations in old patients (myCAFs) that send collagen signals to malignant epithelial cells, a result we have recapitulated using the 4MOSC1 model, and hypothesize may play a role in ECM stiffening, EMT, and metastasis. Further analyses are ongoing, and we plan to validate the hypotheses generated, specifically the presence of differential abundance of specific cell populations, and age-specific ligand-receptor signaling events that lead to tumor growth.

#4336 Homologous recombination repair deficiency, and not recurrence, determines mutational burden and clonal dynamics in high grade serous ovarian cancer.

M. A. Diaz[1], N. Gull[1], P.-C. Peng[1], K. Lawrenson[1], B. J. Rimel[1], J. Lester[2], B. Karlan[2], S. A. Gayther[1], M. R. Jones[1];
[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of California, Los Angeles, Los Angeles, CA

High grade serous ovarian cancer (HGSOC) is the most lethal gynecologic malignancy, killing more than 9,000 women each year in the United States. Nearly 80% of patients with HGSOC will experience recurrence within 5 years, but little is known about the mechanisms that drive this process. Up to 60% of the genome in an HGSOC tumor is impacted by structural variant mutations and pronounced intratumoral heterogeneity. Intratumor heterogeneity is believed to be a key feature of recurrence and therapy resistance with some evidence indicating diverse and complex mechanisms of the seeding of metastatic sites and recurrent tumors. We included 35 HGSOC patients for whom paired chemo-naive and chemoresistant tumors as well as germline DNA was available. Whole genome sequencing was used to identify somatic single nucleotide variants (SNV) insertion/deletion variants (indels), and structural variants (SVs) in each tumor. The number of somatic SVs and indels was higher in tumors with homologous recombination repair deficiency (HRD; P=0.000252 SVs, P=0.00385 Indel) but was not affected by recurrent status (P=0.826 SV, P=0.145 SNV/indel). Clonal composition and dynamics were measured using SNVs/indels as tumors progressed from chemo-naïve primary samples to recurrent chemo-resistant tumors. Surprisingly, few changes were observed in clonal abundance and complexity through progression. When this analysis was repeated with SVs homologous recombination repair proficient tumors tend to be polyclonal while HRD tumors tend to be monoclonal. Five *denovo* structural variant signatures were identified in our cohort and led to three distinct structural variant classes tumors defined by deletion, tumors defined by duplication, and tumors defined by copy number neutral changes (inversions, translocations and balanced complex events). Patients with tumors defined by deletions and copy number neutral changes carry pathogenic SVs correlating with reduced survival (P=0.00023), while DNA gains are less subject to pathogenic alterations. Each class displayed distinct regions of the chromosome that was frequently affected by large scale SV events (>5Mb), which was also observed in the HRP/HRD status. Although no regions were notably altered across recurrence, GO analysis revealed that recurrent tumors have a significantly reduced immune response, which was not seen in the primary tumors. Within a subset of tumors, we are plan to utilize Oxford Nanopore Technologies ultra long read sequencing which will allow for confirmation of SVs observed in the WGS as well as identification of more complex events that cannot be deciphered using WGS techniques.

#4337 Illuminating the complex rearrangement landscape of sarcoma.

S. Waise[1], T. Lesluyes[1], J. Demeulemeester[2], M. Tarabichi[3], A. Flanagan[4], N. Pillay[4], P. Van Loo[5];
[1]The Francis Crick Institute, London, United Kingdom, [2]KU Leuven, Leuven, Belgium, [3]Universite Libre de Bruxelles, Brussels, Belgium, [4]University College London, London, United Kingdom, [5]MD Anderson Cancer Center, Houston, TX

Structural rearrangements and in particular, gene fusions, are key mutational processes in bone and soft tissue tumors, used for both disease classification and as biomarkers. However, the mutational processes and rearrangement processes underlying many of these events remain poorly characterized. Recent data indicate that sarcomas show particularly high frequencies of complex rearrangement events, including patterns which do not fit those of known mutational mechanisms. As the largest whole genome sequencing (WGS) cohort of sarcomas to date, the Genomics England (GE) 100,000 Genomes project represents a unique dataset in which to profile these events.

Structural variants (SVs) were identified in whole genome sequencing data for 978 samples from the Genomics England 100,000 Genomes Project using an optimized approach based on 5 specialized SV callers. SVs identified by at least 2 callers were filtered to retain only those which passed the quality filter, and to remove variants present in either matched germline samples or >1% of a panel of normal variants. Chromothriptic events, extrachromosomal DNA (ecDNA) and genes enriched for SVs were identified using established algorithms.

The prevalence of SVs varies across sarcoma, in keeping with previous reports, with particularly high rates observed in myxofibrosarcoma and liposarcoma. As described previously, liposarcomas showed the highest rates of chromothripsis. We have examined some tumor types at higher granularity than previously available, demonstrating directly that the rates of complex rearrangement events vary across subtypes. For example, chromothriptic events are identified in 100% of well-differentiated liposarcomas, but less than 10% of myxoid liposarcomas. Similarly, the presence of ecDNA varies by tumor type, with the novel observation of particularly high rates in angiosarcoma. Using these data, we have catalogued the rearrangement patterns generating canonical gene fusions in fusion-driven soft tissue tumor types.

Despite more recent advances in histological classification, survival for patients with sarcoma has remained largely unchanged for 40 years. Characterization of the mutational processes underlying these rearrangements will shed light on the pathogenesis of these tumors.

#4338 A pan-cancer single-cell analysis of intratumoral copy number diversity and evolution.

H. Ye[1], T. McDonald[2], E. Sei[1], D. Conterno Minussi[1], M. Hu[1], C. Tang[1], J. Wang[1], K. Wang[1], A. Casasent[1], H. Chen[1], F. Michor[2], N. Navin[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Harvard University, Boston, MA

Aneuploidy is a hallmark of human cancers and studies have shown that cancer patients harbor many differences in their copy number aberrations (CNAs) reflecting interpatient heterogeneity (IPH). While IPH has been studied extensively, the intratumoral heterogeneity (ITH) of CNAs within a tumor remains understudied. Here, we conducted a pan-cancer analysis of 94 human tumor samples at single cell genomic resolution, representing seven major cancer types: bladder, breast, colon, glioblastoma, kidney, lung, and ovary. In total, 62,646 aneuploid cells were analyzed by single cell copy number profiling and bulk exome sequencing was performed. In most cancer types, increased subclonal diversity was associated with higher CNA burden, whole genome doubling (WGD) events, and *TP53* mutations. In all tumors, our data show that cancer cells share a clonal set of truncal CNAs or mutations, suggesting these tumors evolved from a single ancestral cell. In 18/94 cases we identified subclonal WGD events, which resulted in a higher number of copy number losses after tetraploidization. Macro-spatial sampling showed that increased clonal diversity also correlated with increased spatial geographical diversity. We found that many cancers evolved CNAs in short punctuated bursts of evolution, and that this was not restricted to a specific cancer type. Collectively, these data show that copy number ITH is universally associated with molecular features across these human cancer types.

#4339 Chromatin landscapes of colorectal cancer development and cfDNA fragmentation.

N. A. Vulpescu[1], Z. H. Foda[1], P. H. A. Wisse[2], J. E. Medina[3], V. Adleff[1], R. J. A. Fijneman[2], R. B. Scharpf[1], G. A. Meijer[2], B. Carvalho[2], V. E. Velculescu[1]; [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Netherlands Cancer Institute, Amsterdam, Netherlands, [3]Delfi Diagnostics, Baltimore, MD

Introduction: The stepwise progression of colorectal cancer from healthy epithelium, to premalignant adenoma, to cancer is accompanied by genome-wide epigenetic reprogramming. However, current analyses of these processes have been hampered by complex mixtures of cells in normal, adenoma and cancer tissue samples, as well as absence of suitable adenoma model systems. Cultured colorectal organoids, comprised of pure epithelial cells, could enable insights on the epigenetic changes leading to progression from healthy tissue to cancer.

Methods: Using 43 patient-derived colorectal organoids derived from healthy, adenoma, and cancer tissues, we examined the chromatin landscape of tumor progression using transposase accessible chromatin analyses with next generation sequencing. We defined a consensus set of nucleosome depleted regions for each disease stage and used principal component analyses to identify peaks that contributed the most variation across the collection of organoids. Consensus regions were linked to genes they overlapped, and intergenic consensus regions were linked to the nearest gene within 1 Mbp. Subsequently, we performed a gene set enrichment analysis to assess pathways affected by differential chromatin accessibility. To identify the transcription factor drivers of regulatory reprogramming, the DNA sequences within the consensus peaks were analyzed for enrichment of characteristic binding motifs. We analyzed regions of consensus peaks for fragmentation characteristics in the circulating cell-free DNA (cfDNA) of 250 healthy individuals and 51 patients with stage IV colorectal cancer.

Results: Across all organoid samples, we identified >35 million nucleosome depleted regions that we coalesced into a consensus set of 61,755 regions. We excluded 13,040 regions that had low variation across the organoid tissues, leaving 48,715 regions that could potentially define tissue-specific signatures of chromatin accessibility. As 78% of these regions could be linked to genes, we assessed whether these signatures identify known pathways involved in colorectal cancer. We identified unique signatures of healthy tissues, adenomas, and cancers comprising genes of known and novel pathways, including those involved in WNT, hippo, and RAS signaling. We found that changes in chromatin accessibility can be detected in circulating cfDNA profiles and were associated with independent circulating tumor DNA abundance by droplet digital PCR ($R=0.78$, $p<0.0001$).

Conclusions: These analyses highlight important targets of chromatin remodeling in colorectal tumorigenesis and provide an avenue for evaluating these through genome-wide analyses of cfDNA fragmentation.

#4340 Profiling the evolutionary history of giant cancer cells in sarcomas: Hopeful monsters or an evolutionary dead end?.

A. Bowes[1], T. Lesluyes[1], S. Waise[2], A. Verfaillie[3], A. Flanagan[4], J. Demeulemeester[5], M. Tarabichi[6], N. Pillay[7], P. Van Loo[8],
[1]The Francis Crick Institute, London, United Kingdom, [2]Cancer Sciences, University of Southampton, Southampton, United Kingdom, [3]Genomics Core, UZ / KU Leuven, Belgium, Belgium, [4]Genetics and Cell Biology of Sarcoma, UCL Cancer Institute, London, United Kingdom, [5]VIB Centre for Cancer Biology, Leuven, Belgium, Belgium, [6]Institute for Interdisciplinary Research, Universite Libre de Bruxelles, Brussels, Belgium, United Kingdom, [7]Sarcoma Biology and Genomics Group, UCL Cancer Institute, London, United Kingdom, [8]The University of Texas MD Anderson Cancer Centre, Houston, United Kingdom

Background: As tumors evolve, they accumulate somatic mutations that serve as an archeological record of their evolutionary past. Undifferentiated pleomorphic sarcomas (USARCs) are malignant soft tissue tumors that often contain scattered giant cancer cells, or potential 'hopeful monster cells', histologically. As USARCs frequently undergo whole genome doubling (WGD) and chromothripsis (Steele *et al*, 2019), both mutational events are likely to contribute to the formation of giant cancer cells, which frequently display atypical nuclear features such as polyploidy, micronuclei and extrachromosomal DNA. Giant cancer cells are also a common histological finding in other sarcoma types, such as dedifferentiated liposarcomas.
Aims: This study aims to leverage single cell sequencing approaches to determine the evolutionary history and genomic landscape of giant cancer cells in sarcomas.
Methods: 112 giant cancer cells identified in 8 USARCs, 1 dedifferentiated liposarcoma (DDLPS) and 1 myxofibrosarcoma by histology (i.e. nuclear size and shape, as well as multi-nucleation) were isolated via laser capture microdissection thereby retaining important spatial and morphological information. Once isolated, single cell DNA was extracted and amplified using the Ampli1 whole genome amplification (WGA) kit and underwent WGS. DNA was also estimated at a single cell level in one USARC using FACS. Once sorted into different ploidy populations, single nuclei also underwent WGS. Allele specific copy number aberrations (CNAs) were inferred in all single cells. Bulk tumour and normal WGS was also performed.
Results: LCM isolated giant cancer cells exhibited extreme sub-clonal heterogeneity with some demonstrating *de novo* chromothripsis events that was not present in bulk WGS. FACS analysis and copy number inference of single cancer cells in one USARC also revealed the presence of three ploidy populations, including a haploid, a near diploid and a WGD population. Single cell WGS and copy number profiling demonstrated that following near genome scale haploidisation, multiple haploid cells underwent successive rounds of WGD.
Conclusions: Chromothripsis and WGD emerges as major contributors to intra-tumor heterogeneity in sarcoma giant cancer cells. Single cell LCM and WGS revealed that some giant cancer cells contained *de novo* chromothripsis events that were not observed in bulk WGS. Multiple sub-clonal WGD events also permitted one USARC to continue to explore its fitness landscape contributing to ongoing tumor heterogeneity and lethality.

#4341 Non canonical mitochondrial hotspot mutations in cancer.

S. Boscenco[1], J. Tait-Mulder[2], M. Kim[1], C. Tang[1], M. Zucker[1], T. Park[1], W. Wei[3], P. F. Chinnery[3], P. A. Gammage[2], E. Reznik[1];
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Cancer Research UK Beatson Institute, Glasgow, United Kingdom, [3]Medical Research Council Mitochondrial Biology Unit, Cambridge, United Kingdom

The vast majority of recurrent somatic mutations arising in tumors affect protein-coding genes in the nuclear genome. Here, through population-scale analysis of 15,619 whole tumor genomes, we report the discovery of highly recurrent mutations affecting both the small (12S, *MT - RNR1*) and large (16S, *MT - RNR2*) RNA subunits of the mitoribosome. In total, we identified 70 recurrent, hotspot mutations affecting either subunit of the mitoribosome. Compared to non-hotspot positions, rRNA hotspots preferentially affect positions participating in Watson-Crick base pairing, and tend to arise at positions under strong purifying selection in the germline. Consistent with their putative selection, hotspot rRNA alleles arose at higher heteroplasmy than silent mutations under neutral selection. Transcriptional and metabolomic profiling of the m.1227G>A *MT - RNR1* hotspot revealed a heteroplasmic dosage-dependent shift in energy generation towards glycolysis. Mutations disrupting the mitoribosome therefore represent a novel class of functional mutations under positive selection in cancer genomes.

#4342 Breast cancer multi-omic single cell profiling identifies key progressive disease markers.

H. Russell, M. Rao, G. Duclos, R. Aguilar, N. Barkas, M. Callahan, O. Chaudhary, P. Gathungu, C. Rands, V. Shankarappa, D. Stetson, A. Rotem, M. Scaltriti, B. Dougherty;
AstraZeneca US, Waltham, MA

Breast cancer is one of the most diagnosed cancers and has a complex tumor microenvironment (TME). Breast tumors are subtyped by receptor expression, and all have a high degree of cellular heterogeneity. We analyzed tumors from 8 individuals with early-stage breast cancer. The patients had either triple negative breast (TNBC) or an estrogen receptor (ER) positive cancer. The tumors and normal adjacent tissue were profiled by single-nuclei gene expression (GEX) and ATAC data using the 10X multi-ome methodology. Gene set analysis identified specific epithelial clusters associated with the estrogen early/late response, epithelial mesenchymal transition, and several key cytokine pathways. From those epithelial cells, a subset highly proliferative in nature emerged. It consists of both ER positive and TNBC tumor types enriched for specific DNA transcriptional motifs including those for stem cell (Yamanaka) factors and other cellular proliferation motifs. GEX proliferation markers such as MKi-67 were also highly expressed. Overlaying GEX and ATAC data, it was possible to filter the numerous differentially expressed genes and peaks into a subset of genes specific to progressive breast cancer within the proliferative cluster. Those genes included ESRP1, POP4, CCNE1, and AAMDC all of which are associated with progressive breast cancer. To further elucidate the complexity of the TME, we examined clusters of fibroblasts from our dataset. A difference in cancer associated fibroblast marker gene expression was related to the level of ER expression expressed in the tumor epithelium. In general, ER-low tumor fibroblasts had higher expression of immune cancer associated fibroblasts (iCAFs) markers while ER-positive and TNBC tumors had greater expression of extracellular matrix associated markers (emCAFs). Specific clusters were enriched for emCAFs and iCAFs representing another critical part of the TME. In conclusion, using a multi-modal single-cell approach to the TME allowed the identification of an aggressive cluster of epithelial cells marked by genes for cellular proliferation and noted therapeutic targets while also characterizing other critical TME components especially, CAFs.

#4343 Revealing ovarian cancer copy number variation in single cells.

Y. Jin[1], R. Bassiouni[1], L. D. Gibbs[2], J. Qian[2], S. Rotimi[2], M. G. Webb[1], S. Rajpara[2], D. W. Craig[1], L. D. Roman[2], J. D. Carpten[1];
[1]Beckman Research Institute of The City of Hope, Duarte, CA, [2]University of Southern California, Los Angeles, CA

The mortality rate associated with ovarian cancer (OvCa) is disproportionately high in comparison to its incidence rate. This is partly due to the heterogeneous nature of the disease, which reduces treatment efficacy and contributes to high rates of relapse and chemotherapy resistance. Most OvCa are epithelial in origin and can be classified into four main subtypes: serous, mucinous, endometrioid, and clear cell. Of these, high grade serous ovarian cancer (HGSOC) is the deadliest. Epithelial ovarian carcinomas (EOC) typically exhibit widespread chromosomal and arm-level copy number abnormalities across most of the genome; in HGSOC, focal amplifications and microdeletions are especially prevalent and indicative of high genomic instability. To understand the heterogeneity of aneuploidy in EOC and HGSOC, we performed shallow single-cell whole genome sequencing on four EOC samples: two HGSOC, one clear cell, and one mixed clear cell and endometrioid. All samples were late stage and treatment naïve, and one sample had a known *BRCA2* mutation. Sequencing data was processed by two complementary methods to call copy number alterations. First, we used the Cell Ranger DNA pipeline (10x Genomics) to align cell-identified sequencing reads to human reference genome GRCh38 for coverage-based copy number estimation. Resulting copy number calls were cleaned up for mappability, quality, and noisiness. Each sample was then subject to clustering and subclustering analysis using maximum likelihood genetic clustering algorithms. All samples exhibited a high level of aneuploidy, including characteristic alterations known to be associated with EOC. Two tumors contained readily distinguishable clonal populations, and all samples contained main tumor clones that could be further divided by unique subclonal characteristics. Evidence of polyploidy was also seen in all four specimens, with some tumor clusters exhibiting triploid and tetraploid baselines. In parallel, sequencing data was analyzed by the Copy-number Haplotype Inference in Single-cell by Evolutionary Links (CHISEL) algorithm. CHISEL utilizes both binned read depth ratio and B-allele frequency data to determine allele- and haplotype-specific copy numbers in single cells. Results from CHISEL confirmed the copy number calls from Cell Ranger DNA, and revealed widespread loss of heterozygosity in all samples. These findings were corroborated with allele-specific copy number data derived from matched tumor-normal whole exome sequencing. Furthermore, CHISEL detected polyploidy in one-third of the tumor cells with no preference for the A or B alleles. Overall, our findings highlight that the known heterogeneity of ovarian cancer extends to the level of aneuploidy and CNAs, shedding light on factors which pose significant barriers to effective personalized medicine implementation.

#4344 Comprehensive analysis of LINE-1 transposable elements in colorectal cancer.

R. de Wit[1], S. Lakbir[2], C. Buranelli[2], G. A. Meijer[3], S. Abeln[4], R. J. A. Fijneman[3];

[1]Dept. Information and Computing Sciences and Dept. Biology, Utrecht University, Utrecht, Netherlands, [2]Dept. Computer Science, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, [3]Netherlands Cancer Institute, Amsterdam, Netherlands, [4]Utrecht University, Utrecht; VU Bioinformatics Group, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

Background: Colorectal cancer (CRC) is the third most frequent cancer worldwide, and approximately a third of patients die from the disease. There is therefore an urgent need to better understand CRC biology. A particular feature in (colorectal) cancer is the activation of LINE-1 (L1) retrotransposons: DNA fragments which propagate to other places in the genome through an RNA intermediate. Per genome, about 100-150 genomic L1 copies are still retrotransposition-competent, but repressed in most somatic tissues. Their role in tumor development is currently unknown. Recently, the PCAWG consortium characterized the landscape of somatic L1 retrotranspositions in a series of primary cancers of different origin, and identified 124 recurrently active L1 source regions. However, only a limited number of these concerned CRC.

Aim: This study aims to perform a comprehensive analysis of L1 activity in a large cohort of metastatic colorectal cancer.

Methods: To this end, we retrieved data from the Hartwig Medical Foundation, comprising deep (106x) whole genome sequencing (WGS) data from metastatic CRC (n=745), to compare to breast (n=888) and lung cancer samples (n=640). We determined L1 activity as the number of somatic L1 insertions reported by the HMF DNA analysis pipeline and used the activity of each of the 124 L1 sources as previously reported by the PCAWG consortium.

Results: 99% of mCRC samples (n=741) displayed at least 1 somatic L1 retrotransposition, with at least 10 retrotranspositions in 89% of samples. L1 retrotransposition is more prevalent in mCRC than in metastatic lung and breast cancer, in which only 40% and 20% had at least 10 retrotranspositions per sample, respectively. Each cancer type showed a unique profile of active L1 sources. We did not observe a clear preference of L1 insertions for a single genomic region. However, in CRC, the gene most frequently affected in an *exon* was APC (n=13), an important tumor-suppressor gene. An analysis of somatic SNVs and SVs confirmed an association of mutations in some known L1 regulators such as TP53 with increased L1 activity, whereas mutations in others showed no change in the number of somatic retrotranspositions.

Conclusions: We conclude that somatic L1 retrotranspositions are highly prevalent in metastatic colorectal cancer. Presence of L1 insertions in APC suggests retrotranspositions start very early in CRC development and prompts further investigation into earlier CRC stages.

#4345 Evaluation of the prevalence and impact of molecular variation in the three-prime repair exonuclease 1 TREX1 across mammalian species and in human malignancies.

M. M. Konate, M. Shekfeh, J. Krushkal;
National Cancer Inst - Shady Grove Campus, Rockville, MD

The three-prime repair exonuclease 1, TREX1, degrades cytosolic DNA to prevent aberrant immune activation. Inactivation of TREX1 results in DNA accumulation in the cytosol and subsequent induction of the cGAS-STING DNA sensing pathway, downstream interferon-mediated innate immune signaling, and inflammation. Correspondingly, germline pathogenic mutational defects in the TREX1 gene lead to hereditary autoimmune and autoinflammatory disorders. While TREX1 mutations are also reported in some tumors, their consequences in cancer remain poorly understood. To assess the functional importance of amino acid residues in TREX1, we analyzed protein sequences of the functional TREX1 isoform, TREX1b, from 168 mammalian species. We also conducted a survey of genomic variant databases COSMIC, ClinVar, TCGA, LOVD, Decipher, and gnomAD for disease-associated TREX1 mutations. Finally, we modeled TREX1 mutations occurring in human tumors to evaluate predicted impact on protein stability and function using structure-based approaches FoldX and INPS-3D, and compared results to available predictions from AlphaMissense and COSMIC-3D. In the Cancer Genome Atlas (TCGA), 16 out of 32 cancer histologies have tumor samples bearing protein-altering TREX1 variants, with bladder cancer and melanoma having the highest frequency of TREX1 variants at 2.7% of tumor samples. Moreover, all 32 cancer types have some samples with loss of one or both copies of TREX1; frequencies of heterozygous loss range from 0.6% (thymoma) to 86% (kidney clear cell and lung squamous cell carcinomas). We also observed TREX1 copy gain with lower frequency than instances of copy loss, but also occurring in 31 out of 32 studies. Multiple tumors have a combination of a TREX1 protein sequence variant and copy number gain or loss, suggesting that their potential interplay may increase functional impact of TREX1 variants. Out of 15 cancer-associated TREX1 variants, 5 (33%) were predicted to be pathogenic by AlphaMissense. For FoldX and INPS-3D mutagenesis modeling, we used the published experimental 3D crystal structure of the wild type (WT) human TREX1 (PDB: 7TQQ). The changes in Gibbs free energy of folding ΔΔG between WT and mutant predicted by FoldX and INPS-3D both correlated strongly with the AlphaMissense pathogenic probability scores (Pearson r=0.69 and 0.73, respectively). We will discuss implications of TREX1 variation and conservation across mammalian species and potential effects of germline TREX1 variants in hereditary autoimmune and autoinflammatory disorders and on somatic and germline TREX1 variants in human cancer cells and tumor samples.

*The first two authors contributed equally.

#4346 Deciphering the landscape of extrachromosomal DNA in gastric cancer and its potential impact on cancer dynamics.

D. Seol[1], S. Kang[2], S. Kim[2], J. Lee[1], M. Yoo[1], D. Hwang[1], S. Kang[1], C. Bang[1], Y. Park[1], S.-H. Ahn[1], H.-H. Kim[1], H. Kim[2], Y.-S. Suh[1];
[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [2]Sungkyunkwan University, Suwon, Korea, Republic of

Extrachromosomal DNA (ecDNA) drives substantial copy number increases in focal regions harboring oncogenes and its non-Mendelian inheritance during mitosis contributes to cancer heterogeneity and a poor prognosis across multiple cancer types. However, the prevalence and function of ecDNA in gastric cancer (GC) are still largely unknown. Here, we profiled ecDNA by whole-genome sequencing analysis from 76 GC patients and explored its functional attributes through whole-transcriptome sequencing from the same tissues. Focal somatic copy number amplification (fSCNA) was detected in 27 patients (35.5%), of which 17 (22.4%) had at least one circular form of focal amplification (ecDNA$^{\pm}$/fSCNA$^{\pm}$). Most of the patients carrying one or more ecDNA were classified as TCGA-CIN subtype (n=12; CIN: chromosomal instability). The fSCNA hotspots were observed at 17q12 and 19q12, where *ERBB2* and *CCNE1* are located, respectively. Amplifications at both loci occurred in seven patients and were formed into ecDNA in four and two patients, respectively. The ecDNA amplicons carried more oncogenes with significantly higher copy numbers than other amplicons (one-tailed Mann-Whitney *U* test, p=3.9e-03), and 44.4% (12 of 27) of ecDNA amplicons regions were overlapped with tandem duplication or chromothripsis, known causes of ecDNA formation. Oncogenes such as *ERBB2* and *MIEN1*, residing on ecDNA, exhibited significantly increased expression compared to matched normal tissue as well as patients with the corresponding genes located on their chromosome only, suggesting that the ecDNA-induced copy number increases contribute to elevated expression levels. On the other hand, *MYC* showed higher expression in the ecDNA$^{\pm}$/fSCNA$^{\pm}$ group, irrespective of its fSCNA status ($padj$=0.028 and 4.24e-06 against the ecDNA^{-}/fSCNA$^{\pm}$ and ecDNA^{-}/fSCNA^{-} group, respectively). We further explored gene clusters that were associated with the ecDNA$^{\pm}$/fSCNA$^{\pm}$ group using weighted gene co-expression network (WGCNA) analysis. One module was distinct from ecDNA^{-} patients, consisting of genes associated with the “protein processing in endoplasmic reticulum” and “spliceosome” pathways, inferring that transcription and translation are more active in ecDNA$^{\pm}$ patients. Moreover, the overall survival analysis of 76 GC patients revealed that ecDNA$^{\pm}$/fSCNA$^{\pm}$ patients were significantly associated with poor prognosis (log-rank test, p=0.014). In conclusion, ecDNA may be a main source of high expression of oncogenes that influence GC development, and subsequently upregulated global transcription activity will make GC more aggressive.

#4347 Cell-type specific transcriptional regulation of APOBEC3A in cancers.

D. Yesudhas, B. Lone, K. Butler, A. Chakraborty, A. Banday;
NIH-NCI, Bethesda, MD

APOBEC3s (A-H) are a family of seven cytosine deaminases that inactivate viruses as part of the innate immune response. However, APOBEC3A and APOBEC3B have been found to mediate mutagenesis in tumor genomes by deaminating ssDNA that transiently arise during transcription and DNA replication. The mechanisms that trigger these enzymes to generate high mutation burdens in some cancers and affect disease progression and clinical outcomes are largely unknown. Here, we explored cell-type-specific transcriptional regulation of APOBEC3s using single-nucleus/cell RNA-seq (sn/scRNA-seq) data (>100 samples and >300,000 cells) from four tumor types - bladder, lung, breast, and kidney - that display different levels of APOBEC-induced mutation burden. Our analyses revealed that among seven members of the APOBEC3 family, *APOBEC3A* is expressed in a cell-type-specific manner. The expression was predominant in KRT13 and CDH12 epithelial cell-types and inflamed macrophages. The APOBEC3A+ epithelial cell populations were abundant in the bladder, moderate in the lung and breast, and nearly absent in the kidney tumors. *APOBEC3A* expression correlated with interferon and pro-inflammatory signaling in KRT13+ cells. Transcription factors ELF3 and ATF3 were significantly upregulated in APOBEC3A+ KRT13 cells. Pseudotime analysis of sn/scRNA-seq data revealed that *APOBEC3A* cells are in epithelial-mesenchymal transition. Finally, several gene markers defining APOBEC3A+ KRT13 cell types were identified. Ongoing analyses include investigations into clinical correlates, cell-type-specific mutation burdens, and validation through *in vitro* functional approaches. Our results propose that *APOBEC3A* is turned on in specific epithelial cell types by multiple signaling pathways during tumorigenesis, thereby driving tumor heterogeneity, particularly in high mutation-burden cancers.

#4348 *TP53*-regulome and *TP53*-effectome are frequently altered in Epstein-Barr virus-associated nasopharyngeal cancer.

T. Law[1], Y.-K. Ng[1], J. Wen[1], J.-H. Ng[2], M. Wong[2], P. Tse[2], V. Lui[1];
[1]Augusta University, Augusta, GA, [2]University of California San Diego, La Jolla, CA

Dysregulation of p53 signaling is central to oncogenesis. As revealed by the Cancer Genome Atlas (TCGA), mutation of tumor suppressor *TP53* is the most frequent single somatic event found across human cancers. In Epstein-Barr Virus (EBV)-associated nasopharyngeal cancer (NPC), an aggressive head and neck cancer prevalent in Southeast Asia, our recent study showed that only 9% cases harbored *TP53* mutation. Studies in NPC demonstrated that EBV infection alone was not sufficient to attenuate p53 signaling in EBV(+)NPC cells. As p53 signaling and function are intricately regulated by multiple pathway components, aberrations of the p53 regulatory network may also off-set p53 signaling, thus facilitating EBV(+)NPC tumorigenesis. Here, we hypothesized that in addition to *TP53* aberrations, *TP53*-regulome (genes direct regulate *TP53* expression and function), and *TP53*-effectome (genes responsible for executing biological functions of p53 signaling in cells) may also be genomically altered in NPC during oncogenesis. Here, we assembled the most updated *TP53*-regulome/-effectome genelists, including newly identified p53 regulatory components, to enable characterization of *TP53*-regulatory network in EBV(+)NPC patient tumors. Among the subclasses of *TP53*-regulome, mutations of genes regulating p53 acetylation and ubiquitination were significantly co-occurred, while *TP53*-effectome genes involved in p53-mediated DNA repair and p53 metabolism were co-mutated with statistical significance, for instance. Analysis of the 111 whole-exome sequenced EBV(+)NPC samples first demonstrated that 40.5% and 26.1% was affected by *TP53*-regulome and *TP53*-effectome mutations respectively, while only 9.0% cases carried *TP53* mutation. In total, 55% of EBV(+)NPC harbored p53-related somatic mutations, which may implicate a wider *TP53*-associated genomic defect for NPC tumorigenesis. Among the 10 cases of *TP53*-mutated EBV(+)NPC, 5 of them co-harbored *TP53*-regulome mutations while 5 cases co-harbored *TP53*-effectome mutations. Subsequent in-depth allele frequency analysis revealed that in 4 out of 7 *TP53*, *TP53*-regulome and *TP53*-effectome co-mutated cases, the allele frequencies of *TP53*-regulome or *TP53*-effectome mutant genes were higher than that of *TP53*, implicating likely earlier events of these genetic defects than *TP53* mutation during NPC tumorigenesis. In conclusion, p53 regulatory network mutations are far more frequent than *TP53* mutations in this virally associated HNC, and functional study of such a wide array of p53-network mutations on p53 signaling in NPC tumorigenesis are warranted.
Acknowledgments: VWYL is supported by the Start-up Fund from the Georgia Cancer Center, USA.

#4349 Characterization of a centrosome loss-induced tumorigenic signature in prostate epithelial cells.

J. Yang, D. de Oliveira Pessoa, J. M. Ryniawec, E. Loertscher, A. E. Cress, M. Padi, G. C. Rogers;
University of Arizona, Tucson, AZ

Prostate cancer (PCa) stands as the second leading cause of cancer death in American men, with overtreatment being common given the difficulty in distinguishing between indolent and aggressive cases. Unlike many cancers, PCa lacks hallmark mutations in key oncogenes and tumor-suppressor genes. Instead, PCa exhibit extensive genomic rearrangements and chromosomal instability (CIN). CIN occurs during PCa progression, producing ETS gene family fusions, PTEN loss and androgen receptor amplification. Importantly, the mechanism underlying CIN in PCa remains unclear.

Previously, we found that cell within early-grade human primary prostate adenocarcinomas (PRAD) frequently lack centrosomes, and this frequency correlates with tumor grade. We demonstrated that transient removal of centrosomes within non-tumorigenic human prostate epithelial cells (hPrEC) induces CIN and was, strikingly, sufficient to transform subpopulations of cells capable of producing xenograft tumors in mice. To unravel the molecular mechanisms underlying this path to tumorigenesis, we isolated DNA and RNA from parental hPrECs, clonal lines subjected to transient centrosome loss, and xenograft tumor cells and performed whole genome sequencing (WGS) and bulk RNA-seq. This allowed us to characterize the genomic profiles induced by centrosome loss and to identify an associated mutational signature.

We used MUTECT2 to identify single nucleotide variants. Kataegis loci were observed on multiple chromosomes in all transient centrosome removal samples. Copy number variations were also detected in these samples using FACETS and SEQUENZA. Next, we extracted the copy number (CN) signature with SigProfiler and Sigminer, comparing it to COSMIC CN signatures and WGS data from PRAD patients. Our results revealed that the transient centrosome loss signature bears similarity to CN signatures associated with chromothripsis, loss of heterozygosity, and homologous recombination repair deficiency. Patients with PRAD displaying the centrosome loss CN signature had a poorer prognosis. Additionally, our CN analysis discovered that centrosome loss induced mosaic loss of chromosome Y in our samples. To detect structural variations, we employed DELLY, MANTA, SVABA, revealing a high occurrence of both non-clustered and clustered translocations in transient centrosome loss samples. These translocations were validated in our RNA-seq data using STAR-Fusion. Ongoing analyses include inferring CNV from PCa scRNA-seq data, and determining cell populations with the centrosome loss CN-signature and their associated transcriptome features.

This work unveils a comprehensive genomic profile stemming from centrosome loss and demonstrates its role in driving oncogenesis in PCa. These findings have the potential to establish centrosome loss as a hallmark in PCa stratification, and lead to a significant advancement in prostate tumor treatment.

#4350 Characterization of PUF60 splicing activity that is essential for the survival of triple negative breast cancer.

A. Tankka, T. Gomberg, C. Zhou, V. Pham, G. Yeo;
University of California San Diego - UCSD, La Jolla, CA

Alternative splicing driven by RNA-binding proteins (RBPs) plays a significant role in TNBC, however, pharmacological modulators of core spliceosomal proteins can disrupt early stages of spliceosome assembly and lead to toxic effects in normal tissues, limiting their utility as safe therapeutics. Here, we used *in vivo* CRISPR-Cas9 screening to evaluate RBP dependencies in TNBC and identified 17 splicing regulatory candidates that are essential in TNBC but dispensable for normal cell growth and survival. Within this cohort, the alternative splicing factor, PUF60, was the most significantly upregulated candidate in patient TNBC tumors. We found that depletion of PUF60 induced apoptosis in human TNBC cell lines and impeded xenografted tumor growth *in vivo* while upregulation of PUF60 expression increased TNBC cellular proliferation. Although PUF60 has been shown to also bind DNA and influence transcription, TNBC cells constructed with a previously characterized mutation (L140P) required for 3' splice site recognition displayed significantly decreased cellular proliferation compared to cells containing wild type PUF60. Integrated eCLIP and KD RNA-sequencing revealed that PUF60 selectively regulates the splicing of mRNAs in TNBC that contribute to essential processes including DNA repair, replication and cell cycle progression. RNA-seq following L140P-mediated inhibition of 3' ss recognition revealed a cohort of splicing events within genes enriched for similar processes following knockdown of endogenous PUF60 including cell cycle and histone modification. Altogether, our study highlights a critical role for PUF60-mediated splicing in the maintenance of genomic integrity in TNBC as well as the therapeutic potential of identifying and targeting splicing effector RBPs only responsible for TNBC survival.

#4351 Differential dependency mapping of chimeric RNAs across cancer reveals a new landscape of functional fusion transcripts.

S. Lalani, S. Gadh, J. Elfman, S. Singh, H. Li;
University of Virginia, Charlottesville, VA

Chimeric RNAs are RNA transcripts containing sequences originating from multiple distinct genetic loci and can form through a variety of mechanisms such as DNA rearrangement, cis-splicing of adjacent genes, or RNA trans-splicing. Chimeras have long been known to be a hallmark of cancer and due to their unique properties are promising targets for precision medicine. Appropriately, fusion proteins transcribed from chimeras such as *BCR-ABL1* and *TPM3-NTRK1* have been shown to be effective targets. Due to these past successes, there exists an opportunity to identify new chimeras as therapeutic targets. While modern chimera prediction software allows for the fast and accurate identification of chimeric RNAs from RNA sequencing data, investigations separating therapeutically relevant transcripts from “transcriptional noise” remain lacking. In this study we performed an *in-silico* functional screen of chimeras across cell lines representing a wide variety of cancers. We used state-of-the-art chimeric RNA prediction software to create a database of chimeric RNAs across 1017 cell lines from The Cancer Cell Line Encyclopedia. For each chimera we assessed factors such as frequency, recurrence, breakpoint coordinates, frame, and coding potential. To identify specific functional transcripts, we integrated publicly available shRNA knockdown data with our predictions and developed an in-silico functional analysis pipeline comparing differential knockdown effects between chimera and corresponding parental transcripts. For each transcript we assessed the average fold change of chimera-mapping probes, a function score defined as the difference between the fold change of chimera-mapping and parent-specific probes, and a p-value assessing the confidence of our functional score. From our initial screen of 127,819 transcripts, we identified 1088 high-confidence functional chimeras. We successfully identified nearly all known functional chimeras screened including *PAX3-FOXO1*, *EWSR1-FLI1*, and *TCF3-PBX1*. We also identified previously unknown chimeras that that we predict have a function in cell growth and proliferation. Overall, the results of our study reveal a new landscape of functionally relevant chimeric transcripts in cancer. Follow-up studies can further investigate these transcripts to determine their potential as therapeutic targets.

#4352 A high rate of episomal HPV16 is present in head and neck squamous cell carcinoma tumors by long-read whole genome sequencing.

Sonam Tulsyan[1], Vera Mukhina[2], Isabel Rodriguez[1], Subhendu R. Choudhury[2], Erin Allor[2], Kyle Hatte[3], Michael Dean[1], Daria A. Gaykalova[4]

[1]Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]University of Maryland School of Medicine, Institute for Genome Sciences, Baltimore, MD,[3]Department of Otorhinolaryngology-Head and Neck Surgery, Marlene & Stewart Greenebaum Comprehensive Cancer Center, University of Maryland Medical Center, Baltimore, MD,[4]Department of Oncology, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD

Persistent Human Papillomavirus (HPV) infection causes an increased risk of Head and Neck Squamous Cell Carcinoma (HNSCC). However, a comprehensive understanding of the intricate molecular events within virus-positive tumors remains a critical knowledge gap. Therefore, we used long-read sequencing to study the intricacies of HPV integration events within the genomic landscape of HPV+ HNSCC tumors. A total of 16 tissue biopsies, including 10 tumors and 6 matched adjacent normal tissues from histopathologically confirmed HNSCC subjects were sequenced by LSK114 chemistry of Oxford Nanopore Technology with an average coverage of 30X and 10X, respectively. The predicted mitochondrial haplotype from Mitomaster confirmed that the tumor/normal pair was from the same individual. The HPV integration status was determined by aligning fastq_pass files at the Cancer Genomics Cloud and viewing the breakpoints in the Integrated Genome Viewer. HPV lineage and sub-lineage classification was determined using ClustalOmega. We detected HPV16 in 8/10 tumors, with sublineages A1 and A2 accounting for 38% (3/8) and D3 for 25% (2/8). One tumor sample had a very low HPV load with only one HPV16 sequence read and low detection by PCR. Interestingly, we found that 5/8 HPV positive tumors had episomal HPV16 with different states. So, two tumors had intact HPV episomes, two more had either a small deletion or an insertion in the episomal HPV, and the last one had a rearranged episomal multimer (Table 1). The remaining three tumors had integrated HPV16: one with type 1 integrations at 11q12.13 and two others with type 2 integrations at chr1q42.12 and chr14q21.1. Our results indicate that episomal HPV16 is more prevalent than integrated HPV16 in primary HPV+ HNSCC samples. These findings provide new insights into the molecular mechanisms and consequences of HPV infection in HNSCC. Table 1: HPV characterization in HNSCC studied tissue biopsies.

Patient ID	Race	HPV status	HPV sublineages	Predicted Haplotype	HPV pattern
#PID_1	Caucasian	HPV16 +	A2	T2b (T2b)	Type 2 Integration (chr1q42.12)
#PID_2	-	HPV-	-	I1a (I1a1b)	-
#PID_3	Caucasian	HPV16 +	A1	H1q (H1q)	Episomal (rearranged multimer)
PID_4	African American	HPV16 +	A1	-	Episomal (deletion of 636bp from 4892 to 5528)
#PID_5	-	HPV16 +	A2	H1 (H1+16189)	Type 1 Integration (complex chr11q12.13)
*#PID_6	Caucasian	HPV16 +	-	T2b (T2b)	-
PID_7	Caucasian	HPV16 +	D3	-	Episomal
#PID_8	African American	HPV16 +	D3	L1c (L1c3a)	Type 2 Integration (chr14q21.1)
PID_9	African American	HPV16 +	A2	-	Episomal (insertion of 257bp from 7310-7567)
PID_10	Caucasian	HPV16 +	A1	-	Episomal

*Very weakly HPV16 positive; #Tumor-normal pair

#4354 Long noncoding RNA DUXAP10 serves as a putative driver of carcinogenic transformation in anaplastic thyroid cancer.

N. R. DeSouza, M. Carnazza, D. Quaranto, T. Jarboe, K. Kopec, R. Suriano, K. Nielsen, A. Moscatello, H. Islam, J. Geliebter, R. K. Tiwari;
New York Medical College, Valhalla, NY

Anaplastic Thyroid Cancer (ATC) is the most aggressive thyroid cancer subset, with a <4% five-year survival rate. ATC is completely refractory to traditional therapy and newer immunotherapeutic options. Unlike other lethal cancers, ATC has a low mutational burden, warranting the need for a comprehensive study of differential gene expression patterns. Transcriptomic regulators known as long non-coding RNAs (lncRNA) have been described as pivotal orchestrators of gene expression and drivers of carcinogenic patterns. Thus, we present the role of novel lncRNAs in shaping the ATC genotype and phenotype. Publicly available ATC vs. normal thyroid tissue transcriptomic datasets (Gene Expression Omnibus; GSE33630, GSE85457) were investigated to identify genomic transcripts that are differentially expressed in ATC samples using GEO2R. Bioinformatic analysis identified Double Homeobox A Pseudogene 10 (DUXAP10), as a highly upregulated lncRNA in ATC patient tissue samples in both databases (40-fold and 20-fold). Gene Expression Profiling Interactive Analysis statistically correlated high DUXAP10 expression with decreased survival in thyroid cancer patients. DUXAP10 expression was similarly upregulated in ATC cell line, T238, compared to immortalized “normal” thyroid epithelial cell line, Nthy-ori-3-1. Our T238-CRISPRi knockdown model of DUXAP10 was evaluated in vitro to assess consequences of overexpression. CRISPRi knockdown of DUXAP10 in T238 significantly reduced its migratory capabilities by 50%, invasion index by 30%, clonogenicity by 70%, cell viability by 67%, 60%, and 50% at 24, 48, and 72 hours, respectively, proliferation by 28%, 45%, and 36% at 24, 48, and 72 hours, respectively, and global transcription rate by 65%. Further, our DUXAP10-CRISPRi knockdown exhibited a downregulation of N-Cadherin and mediators of beta-catenin signaling- confirming a role in regulatory cross-talk of central carcinogenic pathways. We are currently evaluating proteins and miRNAs bound to and “sponged” by DUXAP10 in vitro utilizing RNA-centric methodology. These data reveal the novelty of DUXAP10, and that its over-expression may increase the negative consequences of ATC metastasis. Thus, we have identified DUXAP10 as a putative determinant for ATC diagnosis, prognosis, and therapeutic targeting.

#4355 Characterizing HRD in ovarian cancer: Insights from copy number signatures.

A. Hawari[1], A. Tapinos[1], C. J. H. Kramer[2], A. J. Gruber[3], R. Houlston[4], J. Brenton[1], **D. Wedge**[1],
[1]University of Manchester, Manchester, United Kingdom, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Konstanz, Konstanz, Germany, [4]The Institute of Cancer Research, London, United Kingdom

Copy number changes are defining features in ovarian cancers. Two distinct methods by Steele et al. and Drews et al., published back-to-back in 2022, detail features and categories of copy number signatures. However, these methods have not been benchmarked for ovarian cancer. Mutational signatures are pivotal in understanding cancer biology and serve as predictive and prognostic biomarkers. This study aims to examine the landscape of copy number signatures to characterize the diversity of Homologous Recombination (HR) impairment within ovarian cancer. While assessing Homologous Recombination Deficiency (HRD) is crucial for targeted treatments, current HRD tests lack clarity. Using signature extraction tools SigProfilerExtractor and CINSignature, we analyzed whole-genome sequencing data (mean depth 100x) from 416 ovarian cases from Genomics England (GeL), employing both copy number signature methods. Among the signatures extracted, HRD signature CN17 from Steele et al. methodology was identified in 37% of the samples and primarily found in the high-grade serous ovarian cancer (HGSOC) subtype (77%). Additionally, higher exposure levels (median of 0.4 in n=154 compared to median of 0.29 in n=416) of Drews et al. methodology's most complex HRD signature, CX3, was detected in samples exhibiting CN17 activity. This ongoing exploration of the copy number signatures landscape works towards identifying the spectrum of HR impairment, aiming to benchmark these two methods for a standardized diagnostic tool. This study contributes to our understanding of the mutational landscape of ovarian cancer and its potential implications for prevention and personalized treatment strategies.

#4356 An isoform-resolution transcriptomic atlas of colorectal cancer from long-read single-cell sequencing.

Z. Li[1], B. Zhang[1], **J. Chan**[2], H. Tabatabaeian[2], Q. Tong[2], X. Chew[2], X. Fan[2], C. Chan[2], P. Driguez[1], F. Cheong[2], S. Wang[3], B. Siew[4], I.-W. Tan[3], K.-Y. Lee[3], B. Lieske[3], W.-K. Cheong[3], D. Kappei[2], K.-K. Tan[3], X. Gao[1], Y. Tay[2];

[1]King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, [2]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore, [3]National University Health System, Singapore, Singapore, [4]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Colorectal cancer (CRC), a complex and molecularly heterogenous disease that lacks robust predictive markers and targeted therapies, is the second leading cause of cancer death worldwide. In recent years, technological advances in short-read single-cell RNA sequencing (scRNA-seq) have been instrumental in deciphering tumor cell heterogeneities. However, most studies have focused on gene-level expression quantification without considering alterations in transcript structures arising from widespread alternative end processing and/or splicing which are frequently dysregulated in cancer. Here, we combined short- and long-read scRNA-seq of CRC patient samples to build the first isoform-resolution CRC transcriptomic atlas. We identified 394 dysregulated transcript structures in tumor epithelial cells, including 299 derived from the coupling of multiple alternative splicing events. Additionally, we characterized genes and isoforms associated with different colon epithelial lineages and tumor cell subpopulations exhibiting varying levels of stemness and differentiation, as well as their distinct prognostic implications. Finally, we built an algorithm by integrating mass spectrometry data and novel peptides derived from predicted open reading frames of recurrent tumor-specific transcripts to curate a panel of recurring neoepitopes. Overall, this study unveils the transcriptomic landscape of CRC and may drive the identification of neoantigens based on full-length transcriptomic atlases to aid future development of more universal neoantigen-based cancer vaccines.

#4357 Examining the role of end-stage kidney as a potential intermediate stage in the development of renal cell carcinomas; understanding the pathogenesis allowing for early detection.

M. Wan[1], V. Castillo[1], R. Saleeb[2],
[1]University of Toronto, Toronto, ON, Canada, [2]St. Michael Hospital, Toronto, ON, Canada

Introduction: Clear cell renal cell carcinoma (CCRCC) and papillary renal cell carcinoma (PRCC) are both thought to arise from the renal proximal tubules. End stage renal disease (ESRD) patients have an increased incidence of developing PRCC and CCRCC. Some studies showed a progenitor cell population that is inherently present in renal tubules, and is significantly increased after renal injury. The studies have also illustrated similarities between these progenitor cells and PRCC & CCRCC; hypothesizing that they are the cell of origin of these tumors. This trend was not observed in other renal cell carcinomas such as chromophobe renal cell carcinoma (chRCC). This study aims to further examine the possible role of ESRD in the development of PRCC and CCRCC to understand this initial step of renal cell carcinoma pathogenesis.

Methods: A cohort of n = 39 PRCC, 25 CCRCC, 63 normal, 10 end-stage and 18 chRCC cases were selected. RNA sequencing was performed and differential-gene-expression analysis was conducted between normal, ESRD and tumor using DESeq2 software. Pathway analysis was performed using GSEA. Genes from oncogenic pathways that have been studied to be involved in renal cancer development were selected to perform consensus clustering analysis on Genepattern.

Results: Oncogenic and developmental pathways enriched in ESRD are consistently overlapping with that of CCRCC and PRCC tumors. 50% of end-stage developmental pathways are found in both CCRCC and PRCC but only 4.5% in chRCC. 62.4% and 46.4% of end-stage oncogenic pathways are found in CCRCC and PRCC respectively but only 16% in chRCC. Clustering analysis showed ESRD cases clustered together with CCRCC and PRCC groups and not with chRCC. Overall, the ESRD cases exhibited a gene expression profile more closely resembling that of CCRCC and PRCC than chRCC.

Conclusion: Our findings support the hypothesis that ESRD provides a favorable environment for tumor growth promoting pathogenesis of both PRCC and CCRCC. The enrichment of the same developmental pathways in both ESRD and the tumors suggests that the progenitor cell population in the renal tubules, mentioned above, could be the origin of both PRCC and CCRCC lesions. Further analysis would allow the uncovering of the pathways that lead to tumor progression from these cells of origin, and can be used to determine biomarkers for early detection of CCRCC and PRCC. This is of particular benefit for those with increased risk as the ESRD patients.

#4358 Genomic profiling of residual kidney structures in dialysis patients.

Kosuke Ieiri[1], Nobuyuki Kakiuchi[2], Tomonori Hirano[3], Koichi Watanabe[3], Hirona Maeda[3], Hiroko Tanaka[4], Satoru Miyano[4], Dai Takamatsu[1], Takashi Matsumoto[1], Keisuke Monji[1], Masaki Shiota[1], Junichi Inokuchi[1], Hideki Makishima[3], Masatoshi Eto[1], Seishi Ogawa[3]

[1]Kyushu Univ. Graduate School of Medical Sci., Fukuoka, Japan,[2]The Hakubi Center for Advanced Research, Kyoto University, Kyoto, Japan,[3]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[4]Department of Integrated Analytics, M&D Data Science Center, Tokyo Medical and Dental University, Tokyo, Japan

Background: Chronic kidney disease is frequently associated with persistent inflammation, which results in fibrosis in the stroma, a reduced number of renal tubules, the formation of multiple cystic lesions, ultimately terminating in renal failure and hemodialysis. The high incidence of renal cell carcinoma (RCC) in hemodialysis patients suggests a relationship between tissue remodeling by chronic inflammation and carcinogenesis. However, little is known about the genetic background of cancer development from remaining tubules and cystic lesions in hemodialysis patients.

Methods: We enrolled 5 patients under hemodialysis who were accompanied by acquired cystic kidney disease and who underwent total nephrectomy for renal cancer. Surgical specimens were fixed with alcohol-based solution and paraffin-embedded, and after H&E staining, subjected to laser capture microdissection (LCM) to collect remaining tubules and cysts containing approximately 200 cells. DNA was extracted and analyzed for somatic mutations and copy number alteration by whole-exome sequencing.

Results: In total, we collected 161 LCM samples, including 118 from proximal tubules, 17 from collecting ducts, and 26 from cysts. The median variant allele frequencies of detected mutations were 0.237 in proximal tubules, 0.133 in collecting duct, and 0.381 in cysts, indicating larger clonal expansion in proximal tubules and cysts than in collecting ducts. Proximal tubules and cysts contained recurrent mutations in *FAT1* (11% and 8%, respectively), *STAG2* (5% and 8%), and *PTEN* (3% and 4%), whereas no recurrent driver mutations were identified in collecting ducts. In copy number analysis, 26% of proximal tubules, 35% of collecting ducts, and 80% of cysts had copy number alterations. Of note, samples from cysts had more copy number alterations compared to remaining tubules (on average, 2.3 vs. 1.1). Proximal tubules had recurrent copy number gains of chromosomes 3, 7, 10, 18, and 20, and loss of chromosome 22 and samples from collecting ducts showed gains of chromosome 7 and loss of chromosome 18. In cysts, gains of chromosomes 2, 3, 7, 10, 12, and 16 and loss of chromosomes 15, 16, 21, and 22 were frequently observed. Copy number profile in cysts was similar to that of papillary RCC and acquired cystic disease-associated RCC.

Conclusion: In the end-stage cystic kidney, both proximal tubules and cysts exhibited an enrichment of driver mutations commonly found in papillary RCC and RCC with acquired cystic disease, reflecting the fact that the incidence of these two types of RCC increases as the duration of dialysis becomes longer. In addition, clear cell RCC drivers, such as *VHL* mutation and loss of chromosome 3, were not observed, possibly explaining the rare occurrence of clear cell RCC in hemodialysis patients. Since cysts had more frequent copy number alterations than remaining tubules, cysts in the end-stage kidney might be precursor lesions of RCC.

#4360 Integrative analysis of multiplex interphase FISH copy number with whole exome sequencing identifies tumor evolution in Stage II colon cancer.

S. Yaghoubi[1], K. Heselmeyer-Haddad[1], I. Archilla[2], C. Parra[3], D. Wangsa[4], G. Castellano[3], J. Zhu[1], D. Yaghoubi[5], S. Lahoz[3], V. Pablo-Fontecha3[6], D. Hirsch[7], W.-D. Chen[1], T. Ried[1], M. Cuatrecasas[8], P. S. Meltzer[1], J. Camps[3];

Colon cancer ranks as the second leading cause of cancer-related death worldwide. Although standard therapies are highly effective in stage II lymph-node negative colon cancers, about 10-15% of these patients show disease relapse within the next 5-year period after intended curative surgery. Extensive prior research has highlighted the role of intratumor heterogeneity, arising from genomic instability, as a leading contributor to metastasis in colon cancer. In the current study, we pioneered the integration of Multiplex Interphase FISH (miFISH) and Whole Exome Sequencing (WES) data aiming to depict intratumor heterogeneity and delineate the landscape of genetic aberrations that underlie the early metastatic potential in stage II colon cancer patients. To this aim, we have showcased the genome-wide copy-number alterations and single nucleotide mutations derived from WES analysis of samples obtained from primary stage II colon tumors and their patient-matched liver metastases of nine patients using multi-region sampling. miFISH was employed for the concurrent quantification of copy-numbers for nine genes relevant to colon cancer and a centromeric control probe in intact tumor nuclei derived from archival patient material allowing us to establish ploidy baselines and gain and loss patterns for the genes analyzed. Our study was revealing of several copy number alterations, such as gains of chromosomes 1q, 7, 8q, 13q and 20, and losses affecting chromosomes 17p and 18, which were confirmed by miFISH. Based on our SNV data, most frequently mutated genes were *APC, TP53, KRAS*. We were able to show several mutations in genes belonging to specific pathways most commonly altered in colorectal cancer, such as *APC*, *TCF7L2*, *AXIN2*, *FBXW7* in WNT signaling, *SMAD4* in TGF-ß signaling, *PIK3CA* and *PTEN* in PI3K signaling and *KRAS* in RTK-RAS signaling pathways. In nearly all cases, subclones that led to metastasis were already present in the primary cancer, indicating a direct progression from the primary to metastatic disease. However, the divergence from the primary tumor to metastasis enabled us to uncover several potential genetic aberrations present in the metastasis but not observed in the primary tumor. Moreover, in one of our cases, despite harboring *APC* and *TP53* mutations in both the primary and metastatic tumor, unique mutations for these genes along with several distinct mutations in the metastasis were identified. These observations suggest that the metastasis might not be related to the primary tumor analyzed and may have arisen from an independent lesion. In conclusion, applying miFISH and WES to decipher the mutational and copy number landscape in metastatic stage II colon cancer provided comprehensive insights into the complex and heterogenous nature of primary colon cancer and the clonal evolution leading to subsequent liver metastases.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Deregulated Signaling in Tumor Development and Progression
Poster Session

#4364 Molecular insight of non-canonical Gsk3β-Gli-AR axis: Therapeutic implications of truncated-Gli3 in castration-resistant prostate cancer.

J. B. Kaushal[1], P. Raut[1], S. Seshacharyulu[1], Z. W. Alsafwani[1], G. Sharma[1], A. M. Khan[1], S. Halder[1], S. Rachagani[2], S. K. Batra[1], J. A. Siddiqui[1];
[1]University of Nebraska Medical Center, Omaha, NE, [2]University of Missouri, Missouri, CA

The aberrant activation of the hedgehog (Hh) signaling pathway causes the progression of therapy-resistant castration-resistant prostate cancer (CRPC). In this study, we aimed to unravel the biological significance of Gli-family proteins and their functional involvement of Gsk3β-mediated regulatory mechanism(s) in CRPC. We have discovered a novel function of the truncated form of Gli (t-Gli3) in advancing CRPC. This was accomplished through *in silico* analysis, *in vitro* experiments, PCa patient clinical data, and *in vivo* PCa MYC overexpression mouse models. Our investigation into the Gli3 regulation, typically influenced by receptor-mediated ciliary localization, uncovered a Smo-independent mechanism. Surprisingly, despite the lack of a transactivation domain in t-Gli3, we found a specific requirement for an androgen receptor variant 7 (AR-V7) for its action, as evidenced by co-immunoprecipitation and chromatin immunoprecipitation assays. Mechanistically, Gsk3β activation leads to the t-Gli3 generation, and inhibition of Gsk3β supported the accumulation of full-length Gli3 through a non-canonical mechanism. Knockdown of Gsk3β (Gsk3β KD) reduces CRPC cell proliferation in *2-D* and *3-D* culture models, inhibiting key proliferative signaling pathways and inducing apoptosis via mitochondrial fragmentation. These findings were supported using an orthotropic PCa mouse model. RNA-seq analysis also showed upregulated phenotype enrichment of the apoptosis, P53, and glycolysis pathway genes in 22Rv1Gsk3β KD cells. Compared to scramble, a lower OCR/mitochondrial respiratory rate is evident in 22Rv1Gsk3β KD cells. Next, our exploration of potential therapies for PCa showed that individually targeting Smo or Gli1 is insufficient to inhibit cell viability. Interestingly, we uncovered that solely targeting Gli3 was sufficient to inhibit the growth of CRPC cells. In conclusion, our study provides the significance of Gli-family proteins and novel insights into the interplay of Gsk3β, t-Gli3, and AR, offering therapeutic implications in CRPC.

#4365 Mechanistic effects of N361 glycosylation in epidermal growth factor receptor protein.

D. Lam, A. N. Liberchuk, B. Arroyo, A. L. Wolfe;
Hunter College, New York, NY

Glycosylation is a tightly regulated post-translational modification where structured sugar groups are added to protein amino acid backbones, most commonly on asparagine for N-glycosylation. The glycosylation-regulating metabolic enzyme uridine diphosphate-glucose pyrophosphorylase 2 (UGP2) is required in oncogene-transformed cancer cells, but not in normal cells. UGP2 heavily regulates glycosylation of epidermal growth factor receptor (EGFR) at asparagine 361 (N361), a key site near the ligand binding domain. EGFR is a transmembrane tyrosine kinase receptor that promotes cell proliferation via growth cascades. Mutations and amplifications in EGFR account for a significant fraction of non-small cell lung carcinomas and breast adenocarcinoma, with L858R being the most common oncogenic hotspot. Other glycosylation sites on EGFR have been implicated in ligand binding, dimerization, and phosphorylation of downstream targets. Molecular dynamic simulations suggested that N361 may be important for dimerization or ligand binding. However, the functional relevance of how glycosylation of EGFR at N361 impacts EGFR protein and cellular behaviors remains unclear. To determine the functional relevance of glycosylation at N361, we created glycosylation-defective EGFR N361A mutant, with or without an additional oncogenic EGFR L858R mutant. We expressed these constructs in MCF10A and 293T cells, which do not have pre-existing activation of this pathway. Immunofluorescence and flow cytometry showed that the mutants were each well expressed at the cell membrane. Proximity ligation assays measuring dimerization of EGFR in cells showed that EGFR N361A greatly increased dimerization relative to wildtype controls. Loss of glycosylation of EGFR N361 impacted cell viability when grown in dose courses of its high affinity ligand EGF or lower affinity ligand amphiregulin. Furthermore, EGFR N361A desensitized cells expressing the oncogenic EGFR L858R to inhibitors targeting the extracellular domain, possibly because the mutation alters the antibody binding interface. N361A sensitized EGFR L858R to inhibitors targeting the cytoplasmic domain of EGFR. These findings help us understand the intricate relationship between EGFR and N-glycosylation, reinforcing the critical functional relevance of post-translational modifications on oncogenes.

#4366 Loss of *EP300* triggers IL-1α signaling and subsequent activation of the IL-6/JAK/STAT3 axis to drive oncogenesis in bladder cancer.

J. A. Rodrigues, J. Luo, A. R. Sabel, Z. Chen, X. Tang, F. Kuo, H. Al-Ahmadie, K. Kim, E. Pietzak, G. Iyer, D. B. Solit, S. P. Gao;
Memorial Sloan Kettering Cancer Center, New York, NY

Bladder Cancer (BLCA) is the sixth most common cancer in the United States with 81,180 new cases and 17,100 deaths in 2022. Next Generation Sequencing of BLCA has revealed an enrichment of alterations in genes classified as chromatin modifiers compared to other solid tumors. Among these is *EP300*, the gene encoding the p300 histone acetyltransferase, which is mutated in ~12% of BLCA with the majority putative loss of function frameshift and nonsense mutations. To investigate the biological role of *EP300* loss-of-function in BLCA pathogenesis, we generated isogenic *EP300* null RT112 bladder cancer cells using a 2-step CRISPR knockout (KO) and knockin strategy. *EP300* KO cells demonstrated increased proliferation, anchorage independent cell growth, tumor formation in mice, and enhanced invasive potential. To investigate the mechanism(s) whereby *EP300* loss-of-function enhances oncogenicity, we performed an unbiased Tandem Tag Mass Spectrometry (TMT MS) screen to identify pathways dysregulated in *EP300* KO versus parental cells. *EP300* loss-of-function was found to induce IL-6/JAK/STAT3 signaling via upregulated expression of IL-1α, a canonical pro-inflammatory cytokine. Knock down of *IL1A* gene expression was sufficient to downregulate STAT3 activation in *EP300* KO cells, whereas ectopic stimulation using IL-1α increased STAT3 activation in parental RT112 cells, suggesting that IL-1α was the predominant upstream activator of JAK/STAT3 signaling in our model. Pharmacological inhibition of downstream targets of IL-1α signaling such as IRAK1/4 were also able to inhibit STAT3 signaling in *EP300* KO cells in a dose and time dependent manner. Further investigations indicated that activated IL-1α signaling not only drove transcriptional upregulation of IL-6 but also the production of soluble IL-6R, activating IL-6 trans signaling. Finally, to elucidate how IL-1α upregulation is triggered by *EP300* loss-of-function, we performed immunoprecipitation and immunofluorescence assays, which revealed that IL-1α binds directly to p300. Additionally, ectopic p300 expression in *EP300* KO clones dramatically reduced IL-1α protein expression, indicating that p300 acts as a negative regulator of IL-1α in a bladder cancer context. In summary, *EP300* loss-of-function relieves p300's transcriptional and/or physical-tethering inhibition on IL-1α signaling, subsequently activating the IL-6/JAK/STAT3 pathway to drive oncogenesis in BLCA.

#4367 PTEN/AKT signal promotes cholangiocyte fate in liver tumorigenesis by inducing SOX9 overexpression and crosstalk with Notch activation.

Q. Tang, J. Chen, N. Zeng, L. He, S. Chopra, D. Alhousari, P. Nguyen, G. Zhang, B. L. Stiles;
USC - University of Southern California, Los Angeles, CA

Cholangiocarcinoma (CCA) is the second most dominant primary liver malignancy next to hepatocellular carcinoma (HCC), and among the most mortal among human cancers. The PI3K/AKT signaling pathway was considered a permissive signal for the development of CCA. To explore how the PI3K/AKT signal contributes to CCA development, we deleted *Pten*, the lipid phosphatase that negatively regulates the PI3K/AKT signal in the liver. The Lv-PTEN (*PtenloxP/loxP*; Alb-Cre^{+}) mice developed a mixed HCC and CCA tumor phenotype with all mice developing CCA by 12-month age. Treatment of Lv-PTEN mice with DDC at 3 months to obstruct the bile duct leads to an earlier CCA oncogenesis. Deletion of *Akt2* in the Lv-PTEN mice (Lv-DM, *Akt2*$^{loxP/loxP}$; *PtenloxP/loxP*; Alb-Cre^{+}) significantly attenuates tumor development. Compared with the Lv-PTEN mice, loss of AKT2 in Lv-DM mice robustly and significantly reduced the expression of SOX9, a cholangiocyte gene. This data suggests that the AKT signal may permit a cholangiocyte fate by inducing SOX9 expression. Supporting the role of PTEN/AKT in permitting a cholangiocyte fate, SOX9 expression is also induced in the livers of mice where *Pten* deletion is targeted to the hepatocytes via injection of AAV8-TGB-Cre (Hp-PTEN, *PtenloxP/loxP*; *R26RYFP*; AAV8-TBG-Cre). Similar to the Lv-PTEN mice, treatment with DDC induced early onset of CCA development in the Hp-PTEN mice. We next explore Notch signal for its crosstalk with PTEN loss that permits CCA development. Notch signal is robustly induced in the tumors of the Lv-PTEN mice and induced with DDC treatment in both Lv-PTEN and Hp-PTEN livers. We showed that exposure to Jag1 ligand-coated extracellular matrix or expression of NICD also induced the expression of SOX9 while DAPT time-dependently attenuated the expression of SOX9. In the Hp-Pten mice treated with DDC, inhibiting the Notch pathway with DAPT attenuated ductal reaction and led to downregulation of SOX9 in the Lv-PTEN livers, suggesting a positive regulatory role of Notch on SOX9. These data support that Notch activation regulates SOX9 and collaborates with PTEN loss to drive cholangiocyte fate and CCA development.

#4368 USP36 SUMOylates EXOSC10 and Las1L to promotes their function in rRNA processing.

M. Dai, Y. Li, Y. Yang, X.-X. Sun;
OHSU, Portland, OR

Eukaryotic ribosome biogenesis is a highly regulated multistep process to generate ribosomes, including transcription of pre-ribosomal RNA, rRNA processing, ribosome subunit assembly and export. Dysregulation of ribosome biogenesis is associated with various human diseases, including ribosomopathies and cancer. Therefore, it is crucial to understand how ribosome biogenesis is regulated during normal cell homeostasis and how it is deregulated in human diseases. Here, we report that the ubiquitin-specific protease USP36 acts as a novel SUMO ligase to promote nucleolar protein SUMOylation. Using affinity purification, we found that USP36 associates with a large number of nucleolar and ribosome biogenesis-related proteins, including all 10 components of the nucleolar RNA exosome complex, EXOSC1 to EXOSC10, as well as the Las1L-Nol9 endonuclease-kinase complex. We showed that USP36 interacts with the RNA exosome through EXOSC10 and SUMOylates ECOSC10 at Lys 583. Mutating K583 impaired the binding of EXOSC10 to pre-rRNAs and the K583R mutant failed to rescue the defects in rRNA processing and cell growth inhibition caused by knockdown of endogenous EXOSC10. Likewise, USP36 interacts with the Las1L-Nol9 complex and promotes Las1L SUMOylation at K565. In addition, USP36 deubiquitinates Las1L and Nol9 and regulates their protein stability. Mutating K565 does not affect the levels of Las1L and the formation of the Las1L-Nol9 endonuclease-kinase complex. However, induced expression of a K565R mutant of Las1L failed to rescue the defects in rRNA processing and cell growth inhibition caused by knockdown of endogenous Las1L. Together, these results suggest that USP36 plays an important role in regulating ribosome biogenesis by post-translationally regulating the function of RNA exosome and Las1L-Nol9 complexes.

#4369 CYP3A5 promotes aggressive and therapeutically resistant prostate cancer by modulating AR and Wnt signaling: Implications for racially disparate clinical outcomes.

J. McLean[1], A. P. Singh[2], E. Oh[1], **R. Mitra**[3];
[1]University of Nevada Las Vegas, Las Vegas, NV, [2]University of South Alabama, Mobile, AL, [3]Roseman Univ. of Health Sciences, Las Vegas, NV

Prostate cancer (PC) is the second leading cause of cancer-related death in American men, which disproportionately affects Black/African American (AA) men. The androgen receptor (AR) signaling plays a pivotal role in PC development and is a primary target for intervention in patients with advanced disease. Aberrant activation of AR is also suggested to play a significant role in castration-resistant prostate cancer (CRPC). Despite advancements in anti-androgen therapies with new targeting agents, such as enzalutamide, metastatic CRPC (mCRPC) remains incurable. CYP3A5, a monooxygenase expressed in the prostate, liver and intestine, is involved in drug metabolism and steroid biosynthesis. We earlier reported that intratumoral CYP3A5 activated AR signaling by facilitating its nuclear translocation of AR. More notably, we found a higher CYP3A5 expression in AAs, attributed to the *1 CYP3A5 variant, as compared to non-Hispanic White Americans (NHWA) possessing the *3 variant. Analysis of RNA-seq data using patient tumor samples revealed that elevated CYP3A5 in AA PC patients was associated with Wnt-β catenin signaling activation via TCF4 overexpression. Here, we investigated the role of CYP3A5 in enzalutamide resistance and Wnt signaling by generating enzalutamide-resistant PC cell lines of NHWA (low CYP3A5-LNCaP) and AA-origin (high CYP3A5-MDAPCa2b). RT-qPCR assay was used to examine the changes in AR and CYP3A5 expression between the parental and the enzalutamide-resistant cell lines. The data show heightened CYP3A5 expression in enzalutamide-resistant cells of AA origin (MDAPCa2b/EnzR) but not of NHWA origin (LNCaP/EnzR). Interestingly, MDAPCa2b/EnzR exhibited no change in AR levels whereas it was increased in LNCaP/EnzR cells relative to parental lines. A loss of function assay was performed for siRNA-mediated silencing of CYP3A5 to study its effect on Wnt signaling. RNA sequencing results show that CYP3A5 inhibition in MDAPCa2b downregulated Wnt pathway genes (Wnt5A, Wnt10B, Wnt11, Fzd2, and Dvl3). These observations align with our previous RNA seq results using patient samples where we observed upregulated Wnt-β catenin signaling in high CYP3A5 expressing patient tumor samples. Western analysis post-CYP3A5 inhibition in LNCaP and MDAPCa2b cells revealed upregulated Axin and downregulated LRP6 and Dvl-3, signifying CYP3A5's regulation of the canonical Wnt-β catenin pathway. Additionally, MDAPCa2b saw downregulated Wnt 5A and Wnt 10B, known to influence the Wnt non-canonical pathway. Altogether, our data suggest that *1 CYP3A5 variant in AAs likely contributes to aggressive behavior and therapeutic resistance of PC and serves as a molecular determinant of disparate clinical outcomes.

#4370 Functional characterisation of a novel mutation in PRKCA, a major driver of chordoid gliomas.

C. Bellamy[1], H. Tovell[2], F. Dingli[3], D. Loew[3], S. Liva[4], S. Schwaighofer[5], E. Stefan[5], A. Newton[2], M. Sanson[6], F. Bielle[6];
[1]Paris Brain Institute (ICM), Paris, France, [2]Department of Pharmacology, University of California, San Diego, La Jolla, CA, [3]CurieCoreTech Mass Spectrometry Proteomics, Institut Curie, PSL Research University, Paris, France, [4]Inserm, U900, Institute Curie, Paris, France, [5]Institute of Molecular Biology and CMBI, University of Innsbruck. Tyrolean Cancer Research Institute (TKFI), Innsbruck, Austria, [6]Sorbonne Universite, Inserm, CNRS, UMR S 1127, Paris Brain Institute - Institut du Cerveau (ICM), AP-HP, Hopitaux Universitaires La Pitie Salpetriere - Charles Foix, Service de Neurologie 2-Mazarin, Paris, France

Chordoid gliomas (ChG) are a rare low-grade brain tumor, believed to be derived from tanycytes. An analysis by the team identified a novel mutation present in all ChGs: *PRKCA* p.D463H. This mutation involves a D463H substitution at the kinase domain of the Protein kinase C alpha (PKCα), it is not found in any other cancer, and represents the hallmark of ChG. The aim of the project is to identify novel and biologically relevant $PKC\alpha_{D463H}$ signaling pathways, which will demonstrate the involvement and the role of this mutated kinase in cellular functions implicated in the development of ChGs. The D463H mutation affects a critical residue of the kinase domain of PKCα, suggesting that such a change modifies substrate affinity. Following the purification of $PKC\alpha_{D463H}$, we have shown its inactivation via *in vitro* kinase assays and peptide array. *In cellulo* fret-based activity reporter assays have shown that $PKC\alpha_{D463H}$ has a dominant negative effect over $PKC\alpha_{WT}$. Through co-immunoprecipitation we have shown that the mutant protein can bind the WT form and also colocalizes in the cell. Our results also show that the mutation affects the tertiary structure of the protein, resulting in a more open, unstable protein compared to the WT. Phosphoproteomic analysis of HEK cells overexpressing $PKC\alpha_{D463H}$ show a decrease of phosphorylation specifically on proteins involved with cell-cell adhesion, including functionally relevant phosphosites. This is in line with our Co-IP mass spectrometry data which shows a decrease in interaction of $PKC\alpha_{D463H}$ with proteins involved in cell junctions. The cell of origin, tanycytes, are highly specialized cells that contain important cell-cell junctions and therefore their perturbation could be a potential route of tumorigenesis. By understanding these changes integrated with our snRNAseq and bulk RNAseq of ChGs, and exploration in cellular models, we hope to elucidate the mechanism by which the mutation leads to the development of Chordoid Glioma.

#4371 ERBB4 heterodimers appear to drive *BRAF*WT melanoma cell lines.

V. Dwivedi, L. M. Lucas, J. Davis, K. O'Daniel, R. H. Cooke, J. N. Woggerman, E. N. Wilson, M. N. Ingrao, D. J. Riese II;
Auburn University, Auburn, AL

Purpose of The Study: To determine whether heterodimerization of ERBB4 with EGFR or ERBB2 drives the proliferation of *BRAF* WT melanoma cell lines.
Introduction: Metastatic melanomas that possess wild-type (WT) *BRAF* alleles are just as aggressive as melanomas that harbor gain-of-function (e.g., V600E) *BRAF* alleles. Moreover, no targets for effective chemotherapeutic intervention (other than immune checkpoint inhibitors) have been identified for these tumors. Thus, our goal is to identify candidate targets for therapeutic intervention in *BRAF* WT melanomas. ERBB4 (HER4) is a receptor tyrosine kinase that is closely related to the epidermal growth factor receptor (EGFR/ERBB1/HER1), ERBB2 (Neu/HER2), and ERBB3 (HER3). We have previously demonstrated that *ERBB4* is both sufficient and necessary for the proliferation of *BRAF* WT melanoma cell lines. However, the constitutively homodimerized *ERBB4* Q646C mutant inhibits the proliferation of *BRAF* WT melanoma cell lines. We have also previously demonstrated that ERBB4-EGFR and ERBB4-ERBB2 heterodimers stimulate proliferation and other oncogenic phenotypes in a variety of tumor model systems. Hence, here we test the hypothesis that ERBB4-EGFR or ERBB4-ERBB2 heterodimers drive *BRAF* WT melanomas.
Experimental Approach: We are testing whether wild-type *EGFR* or *ERBB2* alleles stimulate the proliferation of four different human *BRAF* WT melanoma cell lines. We are testing whether the dominant-negative *EGFR* (K721A) or *ERBB2* (K753A) mutant alleles inhibit the proliferation of these cell lines. Likewise, we are testing whether *EGFR* or *ERBB2* shRNAs inhibit the proliferation of these cell lines. Finally, we are testing whether *EGFR* or *ERBB2* enables *ERBB4* mutant alleles found in *BRAF* WT melanoma samples to drive greater levels of proliferation in 32D cells than wild-type *ERBB4*.
Unpublished Results: Wild-type *ERBB2* causes a significant increase in the proliferation of the MEL-JUSO and IPC-298 *BRAF* WT female melanoma cell lines. The *ERBB2* dominant-negative allele causes a significant decrease in the proliferation of these cell lines. Finally, preliminary data suggest that the *EGFR* and *ERBB2* dominant-negative alleles inhibit the proliferation of the MeWo *BRAF* WT male melanoma cell line.
Preliminary Conclusions: Our data suggest that ERBB2-ERBB4 heterodimers drive two female *BRAF* WT melanoma cell lines, whereas ERBB2-ERBB4 and EGFR-ERBB4 heterodimers drive a male *BRAF* WT melanoma cell line. Thus, we predict that FDA-approved ERBB2 inhibitors (and in some cases, EGFR inhibitors) may be effective in *ERBB4*-dependent, *BRAF* WT melanomas. Moreover, ERBB4 heterodimerization with ERBB2 or EGFR may account for the gender disparities observed in *BRAF* WT melanomas.

#4372 Epithelial-to-mesenchymal transition-driven secretory program underlies vulnerabilities in lung cancer.

K. L. Fulp, O. E. Obaleye, G.-Y. Xiao;
University of Kentucky, Lexington, KY

Epithelial-to-mesenchymal transition (EMT) is a driving force behind lung adenocarcinoma (LUAD) progression. Although substantial evidence has been attained in the involvement of EMT and its regulatory mechanisms in cancer, few effective EMT-targeted therapies have been available in the clinic thus far. It is urgent to develop new therapeutic strategies for improving patient outcomes. We have identified RAB6A as a master regulator of EMT-driven secretory trafficking, which coordinates cancer cell invasion and immunosuppression in LUAD. We found that RAB6A expression was associated with a poor prognosis in LUAD patients and that RAB6A inhibition in our LUAD models reversed resistance to immune checkpoint inhibition with PD-L1 blockade, an emerging clinical problem. Thus, RAB6A machinery is a therapeutic target of interest in EMT-driven cancers. Screening approaches to identify selective RAB inhibitors are in their infancy, a challenge that can be overcome only by obtaining insights into the regulation of RAB6A. RAB6A is a small GTPase whose activity is controlled by guanine nucleotide exchange factors (GEFs) like RIC1 and RGP1, and GTPase activating proteins (GAPs) like RABGAP1, as well as other effector proteins. While these GEFs, GAPs, and effectors are all known regulators of RAB6A function and are frequently amplified in different cancer types, their specific functions in cancer progression are still unknown. To establish the causal relationship between these proteins and EMT-driven LUAD progression, we utilize human and murine LUAD cell lines that have been characterized with respect to EMT status. Our findings here show that the intervention of RAB6A activity via depletion of these regulators impairs the recruitment of RAB6A to the Golgi. We demonstrate that knocking down the GEFs, RIC1 and RGP1, significantly decreases invasion while having negligible effects on the migrative and proliferative abilities of these cells. RABGAP1 depletion, on the other hand, reduces cell proliferation but has no effects on the migration and invasion of the cells. Consistent with these results, inactivation of RAB6A abolishes the EMT-dependent pro-metastatic secretion. Mechanistically, the EMT activator, ZEB1, upregulates RGP1 via silencing miR-148a that targets this GEF to activate RAB6A. These findings elucidate the regulatory mechanisms underlying the EMT-driven secretory program, providing a foundation for therapeutic intervention to prevent the progression of LUAD.

#4373 Molecular interactions of human receptor tyrosine kinase oncogenic fusions.

G. Dashi, M. Varjosalo;
University of Helsinki, Helsinki, Finland

Oncogenic fusions (OFs) play a critical role in cancer development. Despite the exponential increase in identifications, only a small number have been extensively characterized functionally. In this study, we are focused on receptor tyrosine kinase OFs (RTK-OFs) prevalent in aggressive cancers. Our primary objective is to elucidate the underlying molecular mechanisms of 182 in-frame RTK-OFs identified in The Cancer Genome Atlas.

An automated high-throughput PCR technique will be used to clone individual gene fusions using the sequences obtained from RNA-Seq data sourced from the TCGA dataset. These clones will be used to establish an RTK-OF-expressing isogenic cell line library. Multiple Approaches Combined (MAC)-tag workflow combining Affinity Purification (AP) and proximity biotin-dependent (BioID) purification within a single construct will be used. Subsequent high-throughput EvoSep One Liquid Chromatography coupled to ultra-fast TimsTOF Pro 2 Mass Spectrometry sample processing enables sensitive and robust analysis. These methods enable the capture of stable protein complexes and transient interactors associated with RTK-OFs. In our proof of concept study, we have identified four in-frame variants of FGFR3::TACC3 oncogenic fusions.FGFR3, part of the fibroblast growth factor (FGF) RTK family, activates cellular proliferation and growth through FGF binding and receptor dimerization. In FGFR3-TACC3 OFs, diverse isoforms are observed, with prevalent rearrangements linking FGFR3 exon 17 to various TACC3 exons. TACC3 is vital for mitotic microtubule organization and stabilizes kinetochore fibers and the mitotic spindle through its conserved C-terminal coiled-coil domain (TACC domain). TACC3 contributes to the fusion with varying sizes of the C-terminal coiled-coil domain which all constitutively activate the FGFR3 tyrosine kinase. In our studies, we show that FGFR3::TACC3 variants have a different localization to their wild-type counterparts. While FGFR3 and TACC3 are found in the cytoplasm all the OF variants strongly localize around the nucleus. Our identified high-confidence interactors represent a comprehensive FGFR3::TACC3 interaction network and reveal central pathways and key interactors related to microtubule assembly and possible deregulation of the cell cycle.

The resultant data from these advanced technologies enable the construction of comprehensive interaction networks, shedding light on critical signaling pathways and subnetworks relevant to RTK-OFs. Further in-depth analysis of 182 RTK-OFs may uncover actionable pathways and druggable interactors within these networks. Our multi-faceted research strategy holds significant promise for advancing targeted drug discovery, ultimately contributing to improved cancer treatment strategies.

#4374 PP2A-B56α in nutrient scavenging: Tipping the balance from macropinocytosis to cell death in pancreatic cancer..

G. Baral, C. M. Pfeffer, I. Doraivel, S. N. Filippelli, B. L. Allen-Petersen;
Purdue University, West Lafayette, IN

Pancreatic Ductal Adenocarcinoma (PDAC) is the fourth leading cause of cancer related deaths in the US, with the lowest five-year survival rate of all major cancers. Nutrients in the PDAC microenvironment are commonly depleted, with the vital amino acid glutamine among the most deficient metabolites. To circumvent this deprivation, PDAC cells initiate KRAS dependent macropinocytosis, an actin-driven nutrient scavenging pathway. Macropinosomes fuse with lysosomes in a process mediated by the kinase PIKfyve. It allows cells to replenish the nutrients required for survival. As glutamine is essential for PDAC cell survival, therapeutic inhibition of macropinocytosis represents a novel strategy to suppress nutrient acquisition and drive cell death.

Protein phosphatase 2A (PP2A) is a heterotrimeric Serine/Threonine phosphatase known to inhibit downstream targets of the KRAS signaling cascade and is implicated in macropinocytosis regulation. PP2A holoenzyme comprises of A, B and C subunits, where the regulatory B subunit provides substrate specificity to the enzyme. Using high molecular weight TMR-Dextran, we demonstrate that overexpression of PP2A-B56α subunit or pharmacological activation by DT061 promotes macropinosome accumulation in cells. Macropinosome accumulation was caused by the inability of macropinosomes to fuse with lysosomes, leading to cell death. The cell death caused by DT061 was significantly rescued when treated with a Rac family inhibitor. To understand if B56α regulates the process of macropinosome-lysosome fusion, we performed co-immunoprecipitation and established the interaction of B56α with PIKfyve. Further, pharmacological PIKfyve inhibition with Apilimod phenocopies DT061 induced vesicle accumulation in cells, suggesting that B56α likely inhibits PIKfyve to promote aberrant macropinocytosis.

Prevention of lysosomal fusion will impact nutrient uptake through macropinocytosis. Our metabolomics study confirmed the deprivation of glutamine with activation of PP2A-B56α. This regulation can be therapeutically leveraged to metabolically stress cells with a combination of DT061 and glutamine transport inhibitor V-9302. Combination drug treatment was found to be synergistic in a panel of PDAC cells. Together, these findings indicate that activation of PP2A in late stage PDAC promotes aberrant macropinocytosis by preventing lysosomal fusion through PIKfyve regulation and establishes a novel role of PP2A-B56α in nutrient scavenging and cell death. These pathways can be further exploited to identify potential combination therapeutics in PDAC.

#4375 ALPPL2 is involved in MAPK signal pathway of pancreatic cancer.

K. Gong, B. Hamid, K. W. Castro, M. S. McDermott, F. Epstein, K. Chau, C. Hu, J. Zhang, M. Lu, B. G. Hoffstrom, **N. A. O'Brien**, D. J. Slamon;
UCLA - University of California Los Angeles, Los Angeles, CA

Background: Alkaline phosphatase placental-like 2 (ALPPL2) is a member of the alkaline phosphatase family. ALPPL2 is currently being investigated as a novel therapeutic target due to its cancer-specific expression. However, our knowledge of ALPPL2 biological function in cancer is limited. Here we describe an interaction between ALPPL2 and MAPK signaling pathway in pancreatic cancer.
Materials and Methods: ALPPL2 mRNA expression in a panel of 27 pancreatic cell lines was determined by RNAseq. Protein expression and phosphorylation were measured by Western blot. ALPPL2 or ALPP were overexpressed in pancreas cell lines through a Lentiviral packaging system. MEK inhibitor (trametinib) activity was assessed in the same panel of cell lines using a 6-day cell proliferation assay on a Synentec Cellavista imaging system. MEK inhibitor resistant cell lines were developed by culturing cells in increasing concentrations of MEK162.
Results: We hypothesized that pancreatic cancer cells with high ALPPL2 expression may be less sensitive to MEK inhibition. Our study from a panel of 27 pancreatic cancer cell lines showed that there was no correlation between ALPPL2 expression and response to trametinib. Western blot showed that the level of phospho-ERK was reduced in PANC1 and HPAC cells at 6 hours after trametinib treatment. Signaling rebounded at 24 and 48 hours, though it remained below baseline. Surprisingly, ALPPL2 expression increased at 24 and 48 hours after trametinib treatment, however, the mRNA of ALPPL2 and ALPP was down-regulated in three pancreatic cancer cell lines conditioned to be MEK inhibitor resistant. To understand the role of ALPPL2 in the MAPK signaling pathway in response to MEK inhibition, ALPPL2 and ALPP were overexpressed in 2 pancreatic cancer cell lines: YAPC and PSN-1 whose ALPPL2 and ALPP were undetected by Western blot prior to transfection. Overexpression of ALPPL2 or ALPP in YAPC cells resulted in more ERK phosphorylation with no change in total ERK, it also resulted in increased total and phospho-S6, and decreased phospho-STAT3 with no change in total STAT3. The amount of total and phospho-ERK were not changed in PSN-1 with overexpression of ALPPL2 or ALPP, however, it did result in increased total and phospho-S6, decreased phospho-STAT3. Interestingly, the expression of ALPPL2 and ALPP in YAPC cells with ALPPL2 or ALPP overexpression was increased at 48 hours after trametinib treatment.
Discussion: To our knowledge, this is the first study to report that ALPPL2 interacts with the MAPK signaling pathway in pancreatic cancer cells. The activated MAPK signaling pathway appears to control ALPPL2 expression. The MAPK signaling pathway may regulate ALPPL2 expression through transcription and protein metabolism. We have also shown that ALPPL2 expression can activate MAPK signaling pathway. Our findings that ALPPL2 expression can be increased after trametinib treatment provide further rationale for targeting ALPPL2 in cancer.

#4376 The pseudokinase PTK7 is a negative regulator of EPHA2 in colorectal cancer.

J.-P. Borg, C. Dessaux, L. Camoin, S. Audebert, E. Baudelet, A. Daulat;
Centre de Recherche en Cancerologie de Marseille (CRCM), Marseille, France

Colorectal cancer (CRC) remains a major public health issue. Identification of biomarkers predicting high risk of recurrence and discovery of novel targets for therapy are urgently needed[1]. The cell surface receptor PTK7 is a poorly described evolutionary conserved member of the receptor tyrosine kinase superfamily that was first identified in human colon carcinoma and melanoma[2-3]. Accumulated data highlighted the implication of PTK7 in diverse cancer-related signaling pathways[4-6] and, despite the lack of kinase activity, anti-PTK7 inhibitors are currently in development at preclinical and clinical stages[7-9]. The dual aim of this project is to increase the basic knowledge about PTK7 and to evaluate its role in CRC in order to propose in the future novel therapeutics directed against PTK7. With the aim to discover novel PTK7 associated pathways, we used a proximity biotinylation strategy coupled to mass spectrometry in CRC cells. Among the partners identified, we found that the pseudokinase PTK7 interacts with the active receptor tyrosine kinase EphrinA2 (EPHA2). Similarly to PTK7, EPHA2 expression correlates with poor prognosis in CRC[10]. In this work, we also demonstrate that PTK7 acts as a negative regulator of EPHA2 activation through the promotion of distinct oligomeric protein complexes and the modulation of EPHA2 phosphorylation. We also shed in light on the role of PTK7 in EPHA2 K63-linked ubiquitination and its subsequent endosomal sorting and lysosomal degradation.

#4377 AT rich interaction domain 5a promotes gastrointestinal tumorigenesis by regulating YAP and STAT3 pathways.

K. Taniguchi, K. Hamada, S. Tanaka, H. Kurosu, I. Kawakita, K. Kumagai, K. Nakazono, S. Iwasaki, S. Tanaka;
Hokkaido University, Sapporo, Japan

Background: Chronic inflammation and an inflammatory cytokine, interleukin(IL)-6, play important roles in gastrointestinal tumorigenesis and metastasis. Recently, autocrine IL-6 has been reported to promote cancer development and progression in gastrointestinal cancer. However, it is still unknown how IL-6 level is regulated in gastrointestinal cancer cells. RNA-binding proteins (RBPs) are known to be one of the regulatory mechanisms of cytokine production, including IL-6, especially in immune cells. AT rich interaction domain 5a (Arid5a), one of the RBPs, has been reported to bind to *IL6* 3'UTR and regulates its stability and expression. Therefore, we aimed to elucidate the role of Arid5a in gastrointestinal cancer, especially gastric and colon cancer.
Methods: Human gastric and colon cancer cell lines were used in this study. Arid5a knocked-down gastric and colon cancer cells were generated with lentiviral transduction of shRNAs targeting Arid5a and their phenotypes were investigated by several assays including MTT, apoptosis and sphere formation assays. Bulk RNA-seq analysis was performed using Arid5a knocked-down gastric and colon cancer cells.
Results: In both human gastric and colon cancer cell lines, Arid5a knockdown suppressed cancer cell proliferation and spheroid formation, and increased apoptosis. Unexpectedly, IL6 mRNA expression was not correlated with Arid5a expression level. We found that Arid5a knockdown suppresses the activation of YAP and STAT3 by western blot analysis. We identified several new Arid5a target genes by bulk RNA-seq analysis.
Conclusion: Arid5a plays an important role in the regulation of cancer cell proliferation, apoptosis and stemness in human gastric and colon cancer cells, perhaps independently of IL-6. Arid5a regulates YAP and STAT3 pathways by unknown mechanisms. We are now investigating how Arid5a regulates YAP and STAT3 pathways by focusing new Arid5a target genes.

#4378 Identification of novel TXNIP-dependent antitumor pathways in breast cancer.

J. Singh, B. Sah, R. Clarke, L. Liu;
The Hormel Institute, University of Minnesota, Austin, MN

Thioredoxin-interacting protein (TXNIP) plays a critical role in glucose metabolism and redox signaling. TXNIP has recently emerged as a potent tumor suppressor in various cancer models. In previous studies, we found TXNIP was activated by UNC0642, an inhibitor of histone methyltransferase, in MDA-MB-231 breast cancer cells. TXNIP activation was coupled with significant suppression of cell proliferation and tumor growth. In contrast, TXNIP knockdown increased MDA-MB-231 cell proliferation and in tumor growth and metastasis in vivo. TXNIP-reconstitution in TXNIP-deficient HCC1954 cells reduced cell proliferation and migration coupled with increased reactive oxygen species production. TXNIP-reconstitution also significantly decreased mitochondrial respiration, mitochondrial membrane potential and glycolysis in HCC1954 cells. To understand the mechanisms underlying TXNIP's antitumor activity, we performed co-immunoprecipitation and proteomic analyses to uncover TXNIP-interacting proteins. We identified calpastatin (CAST) as a novel TXNIP-interacting protein in breast cancer cells. CAST is an endogenous inhibitor of calpains, a family of calcium-activated cysteine proteases. Intriguingly, CAST association with TXNIP was readily detectable in TXNIP-low, but not in TXNIP-high breast cancer cells. The disassociation of CAST from TXNIP in TXNIP-high cells might allow CAST to inhibit calpain activity to augment TXNIP's antitumor function. Through RNAseq analysis, we identified a positive correlation between TXNIP expression and IL-24 activation in various breast cancer cells, which were also confirmed by western blotting. IL-24 has emerged as an important cancer therapy target because of its role in promoting cancer-specific apoptosis. Our data also demonstrated that TXNIP upregulated the level of IL-24 and downregulated STAT-3. Moreover, TXNIP exerts multifaceted effects on BC development through the IL24-STAT3 signaling axis, deepening our understanding of its complex role in the disease. Taken together, these studies identified novel TNXIP-dependent pathways and their potential new mechanisms in breast cancer pathogenesis with significant clinical implications.

#4379 RING1, a novel E3 ubiquitin ligase for CIP2A, negatively regulates smoking-induced lung tumorigenesis.

I.-h. Jeong[1], C.-W. Peter Lee[1], H. Lim[2], S. Park[2], J. Hyun[2];
[1]Asan Medical Center, Seoul, Korea, Republic of, [2]Korea Research Institute of Chemical Technology, Daejeon, Korea, Republic of

Lung cancer is the second incidence rate of all new cancer diagnoses and the leading cause of cancer-related deaths globally. To develop novel diagnostic and therapeutic targets for lung cancer, there are emerging needs for molecular biological research on the occurrence and progression. Among the targets, CIP2A has been studied for promoting various cancer types, but detailed underlying mechanisms are needed to be further investigated. In this study, it was verified that CIP2A is overexpressed in lung cancer tissues, particularly amongst those with a smoking history, compared to adjacent normal tissues. CIP2A knockdown in lung cancer cells efficiently reduced cell proliferation and migration capacity. Through the mass spectrometry analysis on A549 cells overexpressing CIP2A, RING1 was identified as a candidate for E3 ligase of CIP2A. The interaction of the two proteins and ubiquitin chain regulation by RING1 was verified by immunoprecipitation. RING1 knockdown enhanced proliferation and migration of lung cancer cells, and these effects result from the upregulation of CIP2A and its downstream molecules, c-Myc and cyclin B1. To further study a trigger for RING1 expression changes in lung tumorigenesis, cigarette smoke extract (CSE) was applied for the following experiments. CSE treatment depleted RING1 mRNA, including protein expression. Decreased RING1 level led to upregulation of CIP2A and c-MYC. Collectively, these results reveal novel roles of the RING1 and CIP2A in lung cancer progression caused by smoking and propose a potential biomarker candidate for the therapeutic and diagnostic targets.

#4380 Role of kindlin-2 in prostate cancer progression and metastasis.

L. El Khalki[1], W. Wang[2], N. A. Yousaf Zai[1], J. Szpendyk[2], E. Pluskota[3], K. Bialkowska[3], E. F. Plow[3], L. R. Languino[4], D. C. Altieri[5], K. Sossey-Alaoui[1]; [1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]Metrohealth System, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH, [4]Thomas Jefferson University, Philadelphia, PA, [5]The Wistar Institute, Philadelphia, PA

Prostate cancer (PC) is the leading type of cancer in men accounting for more than 25% of all newly reported cancer cases and remains the second leading cause of cancer-related deaths in men in USA in 2023. The success of early treatments has resulted in a 98% 5-year survival rate for early-stage PC. However, resistance to androgen ablation can lead to metastatic castration-resistant prostate cancer (mCRPC), with a significant drop in the survival rate to ~30%. The metastatic cascade involves changes in adhesive, metabolic and signaling properties of PC cells, allowing them to survive, proliferate and thrive in their new microenvironment. Kindlin-2 (K2), a cytoskeletal adapter protein, is highly expressed in cancer, including PC cells and tumors, contributing to their tumorigenic properties. The present study focuses on three K2 functions relevant to PC metastasis: 1)Reduction in K2 levels, achieved through CRISPR/Cas9, profoundly affected the tumorigenic properties of PC cell lines LNCaP (androgen dependent), DU145, and PC3 (both androgen independent), influencing colony formation, invasion, and adhesion to integrin ligands. While reduction in K2 was observed, K1 and K3 levels in these cell lines was not altered by K2KO. 2)The E3 ubiquitin ligase, Parkin, known for its role in Parkinson's disease, has emerged as a tumor suppressor inhibiting various cancer hallmarks. Our recently published studies showed that Parkin induces ubiquitination of specific lysines in K2, leading to the hypothesis that Parkin acts as a tumor suppressor by targeting K2 for degradation. Stable over-expression of Parkin inhibited adhesion to fibrinogen (Fg), while loss of function Parkin mutants failed to do so, supporting a role of Parkin in K2 turnover and its impact on mitochondrial dynamics. We are currently investigating the effect of K2-lysines mutants as well as loss of function Parkin mutants on the progression and metastasis of PC tumors in vivo.3)K2's established function is the regulation of integrin activation, affecting adhesion receptors' transition from low to high affinity/avidity states. The K2-integrin axis is pivotal for understanding oncogenic responses, and its role in the prostate microenvironment in PC progression and metastasis is under exploration using our newly established K2-floxed mouse. The K2-floxed mice are currently being crossed with mice harboring prostate-epithelial specific cre under control of the probasin (Pbsn) promoter. These animal studies will shed light on K2's contribution to PC development and progression in vivo, providing insights into its role in the prostate microenvironment. To sum up, this study emphasizes the crucial role of K2 in the tumorigenic properties of PC cells and tumors. By incorporating CRISPR/Cas9 and innovative mouse models, the study seeks to shed the lights on the mechanisms through which K2 contributes to PC development and progression.

#4381 Role of Kindlin-2 in the regulation of integrins and TBR1 signaling in TNBC.

N. A. Yousaf Zai, L. El Khalki, W. Wang, J. Szpendyk, K. Sossey-Alaoui;
Case Western Reserve University School of Medicine, Cleveland, OH

Background: Kindlins are a small gene family of FERM domain-containing adaptor proteins that function as essential drivers of integrin activation. Kindlin-2 (K2) is the most widely expressed member of the Kindlin family; its homozygous deletion in mice is embryonically lethal, K2 expression is also dysregulated in several human cancers, including the breast. We established K2 as a major driver of TNBC tumors progression and metastasis through the regulation of several hallmarks of cancer. A well-established pathway whereby K2 regulates TNBC oncogenic behavior is through the regulation of integrin inside-out signaling by directly binding to the cytoplasmic tail of integrin β subunit. Interestingly, our recent studies found K2 to play a major role in activating the TGF-β-mediated regulation of the CSF1/EGF signaling through macrophage polarization to the M2 tumorigenic state and their increased tumor infiltration, as well as inhibiting tumor infiltration of cytotoxic lymphocytes, therefore, driving tumor immune evasion. Here we present novel findings involving K2 in the stabilization of the β1-Integrin:TβRI complexes by establishing a physical bridge that links β1-Integrin to TβRI. Loss of K2 results in the degradation of this protein complex and therefore, the inhibition of the oncogenic pathways downstream of these two major regulators of several hallmarks of cancer.
Methods: We applied a combination of in vitro assays; CRISPR/Cas9 gene editing, cell migration, 3D tumor-sphere, solid binding, co-immunoprecipitation, cell adhesion and spreading, as well as western blot and flow cytometry analyses with MDA-MB-231 and 4T1 TNBC cell lines. We also used preclinical in vivo mouse models of TNBC tumor progression and metastasis to support or investigations.
Results: We found that the K2/β1-Integrin direct interaction is mediated through the C-terminal F3 domain of K2, while the K2/TβRI direct interaction is mediated through the F2 domain of K2. Disruption of this bridge, via CRISPR/Cas9-mediated knockout of K2, leads to β1-Integrin and TβRI degradation, and inhibition of the oncogenic pathways downstream of both β1-Integrin and TβRI, and inhibited tumor growth and metastasis in levels comparable to loss of expression of either β1-Integrin and TβRI. Treatment of the K2-deficent cells with the proteasome inhibitor MG-132 restored expression of both β1-Integrin and TβRI, confirming that K2 is required for the stabilization of the β1-integrin/TβR1 complexes at the protein level. Rescue of K2 expression in the K2-KO cells restored their oncogenic activities both in vitro and in vivo.
Conclusion: We identified K2 to play a novel and major in the stabilization of the β1-integrin/TβR1 complexes and the regulation of their downstream oncogenic signaling. These studies have a significant translational impact as they may identify new therapeutically targeted pathways that are desperately needed for the treatment of TNBC tumors.

#4382 PKC-ι/ζ signaling is crucial for apoptosis/pyroptosis inhibition and invasiveness of glioblastoma cells through upregulation of β-catenin, PDK1/Akt1 and Smad cascades via 14-3-3.

L. Lajmi[1], W. S. Ratnayake[1], K. M. Khalid[1], S. Breedy[1], A. Todman[1], T. Smalley[2], C. A. Apostolatos[1], R. Hill[1], M. Acevedo-Duncan[1];
[1]University of South Florida, Tampa, FL, [2]Moffitt Cancer Center, Tampa, FL

Glioblastoma (GB) is an aggressive form of brain cancer derived from astrocytes. Poor predictability of patient outcomes has limited the development of current therapeutic treatments of GB mainly due to the development of drug resistance. Comparative over-expression of atypical protein kinase C-iota and zeta (aPKC-ι/ζ) in GB cells and tissue samples were previously reported. This study establishes the downstream effects of PKC-ι/ζ attenuation on key cellular signaling which governs apoptosis, pyroptosis, survival, proliferation and epithelial-mesenchymal transition (EMT). Our data suggested that aPKC knockdown of expression induces apoptosis and works as an antecedent of pyroptosis. Data also suggested that involvement of Akt1 and PDK1 in aPKC maturation process weakened due to aPKC attenuation. aPKC attenuation downregulated Ras/Erk1 and canonical β-catenin pathways which resulted in reduced transcriptional activities of Stat3, c-Myc, c-Jun and β-catenin. In addition SNAIL1, SLUG, and PRRX1 were diminished that have been known to stimulate EMT. Proteins 14-3-3 and Smad2/3 acted as molecular adaptors between these pathways. A PKC-ι specific inhibitor 5-amino-1-(2,3-dihydroxy-4-(hydroxymethyl)cyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S) and a PKC-ζ specific inhibitor 8-hydroxy-1,3,6-naphthalenetrisulfonic acid (ζ-Stat) were used to conduct *in-vivo* experiments using mouse models. Intravenous and oral administration of ICA-1S resulted in the reduction of tumor growth by approximately 30% in athymic nude mice for U-87 xenografts. Taken together, these results suggest that not only do aPKCs play a central role in GB progression, invasiveness, and cell survival, but that effective therapeutics can be developed to specifically target oncogenic aPKCs.

#4383 Atypical protein kinases C-ζ and ι-inhibitors impede the growth of malignant gastric cancer cells.

Abiral Hasib Shourav, Mahfuza Marzan, Khandker Mohammad Khalid, Wishrawana Sarathi Ratnayake, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

Currently, the global data on gastric cancer demonstrate that it is the fifth most common type of cancer and as far as cancer-related death is concerned, it is the third most common type. The high mortality of gastric cancer can be attributed to the fact that it is mostly diagnosed when the disease has progressed to the advanced stage. While the bacterium *Helicobacter pylori* is known to be the most common cause of gastric cancer, other notable risk factors also include high salt intake, age and diets lacking in fruits and vegetables. Demographic data have revealed that the regions of East Asia, Eastern Europe and South America are notable hotspots of this type of cancer. Endoscopic resection is considered as the major treatment procedure for early detected gastric cancer while those diagnosed in later stages are treated with surgeries such as D2 lymphadenectomy. Previously, the Atypical Protein Kinases C (aPKCs) - ζ and ι - have been documented to play significant roles in elevated cell proliferation in various cancer types. Here, we employed two inhibitors, ICA-1S (5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide and ζ-stat (8-hydroxy-1,3,6- naphthalenetrisulfonic acid), that specifically inhibit aPKC-ι and-ζ respectively on a gastric cancer cell line (i.e., AGS) to observe their effects on cell proliferation. In separate trials, AGS cells were treated with ICA-1S and ζ-stat for 72 hours (about 3 days). An assortment of drug concentrations for each of the inhibitors were tried and the analysis of the cell count demonstrated that the cell proliferation decreases were statistically significant for both drugs in all concentrations. In case of ICA-1S, the highest decrease in cell proliferation was observed at 20 μM ($p < 0.0001$), whereas in case of ζ-stat, the highest decrease was observed at 10 μM ($p < 0.0001$). Our previous research have revealed that these aPKC inhibitors downregulate the aPKCs-ι and-ζ and interfere with established cancer pathways to cause cell deaths. Based on that and the results from the preliminary data on this project, it can be hypothesized that these two aPKC inhibitors have the potential to lead to Gastric Cancer cell deaths, which could potentially open a new door for Gastric Cancer therapeutics. Henceforth, the Western Blot analysis of AGS cells treated with ζ-stat have demonstrated the downregulation of the aPKC-ζ protein. Likewise, a downregulation of the apoptosis-related markers, Survivin and Caspase-3, was also illustrated in ζ-stat treated cells. Current, investigations include how these aPKC inhibitors, ICA-1S and ζ-stat, play into some of the well-established gastric cancer pathways to lead to cell deaths with techniques such as Western Blot analysis, Immunoprecipitation Assays and Flow cytometry.

#4384 Differential epitope tagging of oncogenic GNAQ mutants produces distinct effects on downstream signaling of GNAQ.

C. Jagadan Ushakumari[1], A. Manglik[2], B. Bastian[1], X. Chen[1];

[1]UCSF - Helen Diller Family Comprehensive Cancer Center, San Francisco, CA, [2]UCSF - School of Pharmacy, San Francisco, CA

GNAQ Q209P and Q209L are common driver mutations in uveal melanoma, leading to constitutive activation of downstream signaling of GNAQ. It is not fully understood whether the two GNAQ mutants have similar effects on downstream signaling pathways. Due to lack of available specific GNAQ antibody, epitope tagging is a well-established tool for protein interaction studies using mass spectrometry. Several studies used an epitope tag inserted into an internal region or the c-terminus of GNAQ to study its function. However, the functional consequences of these modalities on effector engagement are not fully elucidated. Here, we engineered both GNAQ wild-type and GNAQ mutants (Q209L and Q209P) without epitope tag as well as three different commonly used tagging modalities. A 3xflag tag of 22 amino acids was inserted after residue 122 of GNAQ. A MYC/DDK tag consisting of 18 amino acids was incorporated before the stop codon of GNAQ. An internal Glu-Glu epitope tag (EE tag) of 6 amino acids was introduced internally by mutating residues AYLPTQ(171-176) of GNAQ to EYMPTE. To assess the impact of the different modalities on the function of GNAQ mutants, we introduced them into 293FT cells and examined the known oncogenic signaling outputs downstream of GNAQ: MAPK, PKC and FAK signaling. We found that all three tags of both $GNAQ^{Q209L}$ and $GNAQ^{Q209P}$ activated MAPK signaling at similar levels as the corresponding untagged GNAQ mutants as evidenced by increases of pERK and pp90RSK level compared to GNAQ wild-type controls. By contrast, both $GNAQ^{Q209L}$ and $GNAQ^{Q209P}$ tagged with MYC/DDK induced lower p-PKD (a readout of PKC) and p-FAK (a readout of FAK activation) compared to EE-tagged or untagged, suggesting that MYC/DDK tag fused to the c-terminus of GNAQ affects specific effectors downstream of GNAQ. Furthermore, $GNAQ^{Q209P}$ with the 3xflag tag induced lower levels of p-PKD and p-FAK than 3xflag tagged $GNAQ^{Q209L}$ did, indicating that $GNAQ^{Q209P}$ may have a different three-dimensional conformation compared to $GNAQ^{Q209L}$ with different downstream effectors engagement. Moreover, the GNAQ/11 inhibitor YM-254890 inhibited phosphorylation of ERK, PKD, FAK in a concentration dependent manner in 293FT cells transfected with GNAQ mutants tagged with MYC/DDK but had no effect on MAPK, PKC and FAK signaling in cells expressing EE-tagged GNAQ mutants. These data suggest that EE tag has no effect on the function of GNAQ , but interferes
with YM-254890 binding. Our findings highlight unappreciated consequences of epitope-tagging of the oncogene GNAQ that are relevant for studies on the interactome of mutant GNAQ and drug response.

#4385 ZCCHC3 and Efp are prognostic factors for triple-negative breast cancer and potentially modulate cell division-related pathway.

A. Fujimoto[1], K. Ikeda[1], T. Takeiwa[2], K. Kinowaki[3], T. Ogura[3], H. Kawabata[3], A. Osaki[1], K. Horie[1], S. Inoue[2];
[1]Saitama Medical University, Saitama, Japan, [2]Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, [3]Toranomon Hospital, Tokyo, Japan

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer with poor prognosis and limited therapeutic strategies, lacking expression of estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2. We previously demonstrated that estrogen responsive finger protein (Efp)/TRIM25 functions as a ubiquitin ligase that degrades cell cycle checkpoint 14-3-3 sigma and promotes cell growth of ER-positive breast cancer [Urano et al., Nature 417:871-875, 2002]. In TNBC cells, we further showed that Efp regulates cell cycle-related gene expression and promotes cell proliferation [Sato et al., Biochem Biophys Res Commun 624:81-88, 2022]. Efp also exerts a distinct function to activate cellular RNA sensors such as RIG-I (retinoic acid inducible gene I), which plays a role in the innate immunity [Gack et al., Nature 446:916-920, 2007]. Another immune-related gene zinc finger CCHC domain-containing protein 3 (ZCCHC3) was recently suggested as Efp interactor, although its pathological relevance in breast cancer remains elusive. We here aimed to clarify the role of ZCCHC3 in TNBC. Immunohistochemical analysis of TNBC tissues from over 100 Japanese patients showed that a positive ZCCHC3 immunoreactivity (IR) was significantly associated with shorter disease-free survival (DFS) and positively correlated with Efp IR. Notably, patients with both ZCCHC3 and Efp IR positivity showed much shorter DFS than those with ZCCHC3 positivity alone. Functional analysis of ZCCHC3 by siRNA silencing demonstrated that ZCCHC3 promotes the proliferation, migration, and cell cycle progression of MDA-MB-231 TNBC cells. We established long-term culturable TNBC patient-derived cells (TNBC-PDC) using spheroid culture technique and revealed that the spheroid growth was suppressed by ZCCHC3-specific siRNA treatment. Moreover, ZCCHC3-specific siRNA injection suppressed in vivo tumor growth of MDA-MB-231 cells inoculated in immunodeficient mice. RNA sequencing analysis of ZCCHC3-silenced TNBC cells showed that cell division-related pathway was enriched among downregulated genes, including non-structural maintenance of chromosomes condensin I complex subunit H (NCAPH). NCAPH silencing inhibited the proliferation of TNBC-PDCs and MDA-MB-231 cells. Overall, ZCCHC3 and Efp are potential poor prognostic factors and can be applied to alternative therapeutic options for TNBC.

#4386 Androgen hormone signaling regulates the association between the hippo pathway component YAP1 and RNA binding protein NPM1.

A. M. Dwead[1], M. M. Al-Mathkour[2], B. Cinar[1];
[1]Clark Atlanta University, Atlanta, GA, [2]University of Miami, Miami, FL

Prostate cancer represents a major health concern for men in the United States and globally, disproportionately affecting men of African descent. Despite recent advances, the precise etiology and molecular mechanisms underpinning fatal prostate cancer in humans remain inadequately understood. RNA binding proteins (RBPs) regulate various aspects of RNA biology, and when their regulation is disrupted, they can lead to human diseases, including cancer. However, the comprehensive alterations in RBP-mRNA interactions in prostate cancer have not been explored. In this study, we investigated the dynamics of RBPs and their interactions with polyadenylated mRNA in the castration-sensitive LNCaP and castration-resistant C4-2 prostate cancer cell lines. Using an enhanced RNA interactome capture assay in combination with mass spectrometry, we discovered that LNCaP and C4-2 cells showed distinct RBP-mRNA interaction patterns in steady-state growth conditions and in response to androgen treatment. Additionally, we investigated the interplay between the oncogene Yes-associated protein 1 (YAP1) and the RNA-binding protein nucleophosmin (NPM1). We identified NPM1 as a component of the YAP1 protein complex through mass spectrometry-based proteomics. Our proximity ligation assay demonstrated that androgen signaling could regulate the interaction between YAP1 and NPM1. Also, our GST-pulldown revealed that NPM1 binds to the proline-rich domain of YAP1 in LNCaP cells, while the WW/SH3 domain of YAP1 mediates the interaction with NPM1 in C4-2 cells. Genetic and pharmacological inhibition of NPM1 activity reduced prostate cancer cell growth in culture by modulating cell cycle progression. Furthermore, our computational and immunological analysis of prostate tumor tissues indicated that the upregulation of NPM1 might be associated with the clinical advancement of human prostate cancer. These findings underscore the critical role of the molecular functional connection between YAP1 and RBPs and the global changes in RBP and RNA interaction patterns, in the progression and recurrence of prostate cancer.

#4387 Interplay of Notch1 and Notch3 signaling regulates pancreatic neuroendocrine tumor proliferation.

R. Guenter, W. Chen, Y. Golivi, M. Robledo, C. Adams, R. Jaskula-Sztul, H. Chen, J. Rose;
University of Alabama at Birmingham, Birmingham, AL

Background: The 5-year survival rate for patients with advanced pancreatic neuroendocrine tumors (pNETs) is less than 30%. Notch signaling is a transmembrane receptor pathway with four receptor isoforms and five different ligands. Binding between a receptor and ligand triggers pathway activation and is linked to cellular differentiation, cell fate, proliferation, and viability. Both Notch1 and Notch3 signaling have been shown to be dysregulated in pNETs. Notch3 activation has been shown to repress Notch1 activity in other cancers. We hypothesize that activation of Notch3 can reduce Notch1-mediated proliferation in pNETs.

Methods: Genetic deletion of Notch1 (N1-KO) in a pNET cell line (BON) was achieved using CRISPR/Cas9 to create a compound heterozygous knockout at exon 3. An inducible Notch1 overexpression cell line was generated by stably transfecting BON with a plasmid construct containing the Notch1 active form (N1ICD) under a Tet-On regulator. A constitutively active Notch3 cell line was generated by lentiviral transduction of BON with a plasmid overexpressing the Notch3 active form (N3ICD). Real-time quantitative PCR was used to measure mRNA transcript levels, and western blot was used to measure protein expression. Two-dimensional (2D) viability was measured by MTT assay, and three-dimensional (3D) proliferation was measured by spheroid size.

Results: Genetic knockout of Notch1 (N1-KO) reduced the expression of Notch3 at both mRNA and protein levels. N1-KO had reduced proliferation compared to (WT) BON. Increased cell density (ligand availability) or treatment with valproic acid (known Notch1 inducer) led to increased N3ICD in WT BON but not in N1-KO. Overexpression of N1ICD was associated with increased expression of a known downstream target Hes1, as well as Notch3. In contrast, forced overexpression of N3ICD led to increased Notch1 expression, but not Hes1 when compared to a BON cell line transfected with an empty vector. Functionally, N1-KO and N3ICD overexpression cells both had reduced proliferation in both 2D and 3D cell culture.

Conclusions: The Notch1 and Notch3 receptors produce signaling cascades that regulate growth in pNET cells through distinct mechanisms. Reduction of Notch1 signaling suppresses growth, while the same effect can be achieved with Notch3 overexpression. Thus, specifically upregulating Notch3 may be a strategy to block Notch1-mediated proliferation in pNET cells.

#4388 Tumor-associated RhoA mutants interact with effectors in both GDP- and GTP-bound states.

Y. Lin[1], T. A. Ramelot[2], S. Senyuz[3], A. Gursoy[4], H. Jang[5], R. Nussinov[5], O. Keskin[4], Y. Zheng[1];
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]Koc University, Istanbul, Turkey, [4]Koc Univeristy, Istanbul, Turkey, [5]National Cancer Institute, Frederick, MD

RhoA is the founding member of the Ras-homology (Rho) small GTPase family and is a master regulator for multiple cell functions. Recurrent RhoA mutations have been identified in several human cancers, particularly in leukemia/lymphoma and gastric cancer. Intriguingly, both gain-of-function and loss-of-function mutations of RhoA are present, suggesting that RhoA GTPase may have a more sophisticated role in cancer and requires more rigorous investigations. Here, we have focused on two of the gain-of-function RhoA mutations identified in Adult T cell Leukemia/lymphoma (ATLL) at residue A161 (A161P and A161V) and aim to reveal the underlying mechanistic basis for their function by biochemical and structural analyses. We found that in contrast to conventional gain-of-function RhoA mutants such as $RhoA^{G14V}$ and $RhoA^{Q63L}$ which affect the GTP-hydrolysis activity, $RhoA^{A161P}$ and $RhoA^{A161V}$are both fast-cycling with drastically increased nucleotide dissociation and association rates, but only slightly reduced GTP-hydrolysis activity. We solved the crystal structures of GDP-bound $RhoA^{A161P}$ and $RhoA^{A161V}$ and saw that while $RhoA^{A161P}$ displays impaired solvent-mediated interactions to the bound nucleotide, $RhoA^{A161V}$ has a more exposed nucleotide binding pocket compared to $RhoA^{WT}$ and $RhoA^{A161P}$. Interestingly, $RhoA^{A161P}$ and $RhoA^{A161V}$can interact with effector targets in the GDP-bound states. Further ^{1}H-^{15}N HSQC NMR study provides evidence of the active population in GDP-bound $RhoA^{A161V}$. Molecule dynamics (MD) simulations show that the dynamic properties of RhoA switch regions are affected differently by the two mutations. Thus, $RhoA^{A161V}$ and $RhoA^{A161P}$ are fast-cycling mutants with distinct mechanisms, and both likely endow their GDP-bound state towards an active conformation. These findings provide a better understanding of the oncogenic role of RhoA mutations in cancer and shine light on how changes in RhoA protein dynamic properties caused by mutations may affect its function.

#4389 The role of Rab5 in epithelial growth factor stimulated E-cadherin internalization in spheroid growth of colon cancer cells.

Y.-C. Wang, Y.-C. Ching, H.-C. Chen, C.-P. Cheng, C.-E. Ku, S.-R. Lee, W.-T. Chao;
Tunghai University, Taichung, Taiwan

In epithelial based cancer formation, such as colon cancer, the tumor growth is accompanied with malfunction of cell-cell contact inhibition which is regulated by E-cadherin. However, the dynamics of E-cadherin is complicated, the underlying mechanism in tumor nest growth and collective cell migration is still not clear. Rab5 is the endocytic vesicle protein for the membrane receptor internalization into early endosome. Therefore, this study is to investigate the role of Rab5 in E-cadherin turnover of spheroid formation in colon cancer cells. HT-29 colon cancer cells were used in this study. The cells with less anchorage ability were isolated for spheroid formation. The distribution of Rab5, E-cadherin and focal adhesion kinase were observed by immuno-confocal microscopy. The molecular expressions were analyzed by western blot. HT-29 cells showed well defined epithelial phenotype. In the result of immunostaining, Rab5 was distributed in the cytosol and the cell-cell contacts where it colocalized with E-cadherin. Rab5 was also observed in the cell leading edge, however, not much associated with focal adhesions. When HT-29 cell clusters were stimulated with epidermal growth factor, Rab5 was found abundant in the cell-cell contacts. In cell spheroid that derived from HT-29 cells, Rab5 and E-cadherin co-localization at cell-cell contacts was also increased. Furthermore, when cells were treated with Nocodazole, the tubulin inhibitor blocking tubulin-mediated endocytosis, Rab5 accumulated and colocalized with E-cadherin in the cell leading edge. The results of this study demonstrated Rab5 plays the novel role in E-cadherin turnover upon epidermal growth factor stimulation in the progress of spheroid formation and Rab5 may mediate E-cadherin endocytosis through the cell leading edge.

#4390 IGFBP-6 is induced by progesterone to regulate progesterone receptor expression in breast cancer cells.

F. J. Lariz, P. Botero, K. Houston;
New Mexico State Univ. - Las Cruces, Las Cruces, NM

Insulin-like growth factor binding protein-6 (IGFBP-6) is induced by progesterone (P4) in T-47D breast cancer cells. IGFBP-6 regulates insulin-like growth factor 2 (IGF2) by sequestering it to inhibit receptor binding and extend its extracellular half-life. IGF2 binds to insulin-like growth factor 1 receptor or insulin receptor A to promote breast cancer cell proliferation and survival. Progesterone is an ovarian steroid hormone which has complex roles in breast cancer through the actions of progesterone receptor A and B (PR-A and B). Progesterone antagonizes the actions of estradiol (E2), another steroid hormone which promotes proliferation and survival in breast cancer. T-47D cells treated with both P4 and E2 exhibit significantly reduced proliferation compared to treatment with E2 alone. To better understand the role of IGFBP-6 in progesterone signaling, T-47D cells which over-express IGFBP-6 were treated with P4, E2, or both. Overexpressing cells exhibited stronger antagonism compared to controls when co-treated with P4 and E2. RNA-interference was performed to knockdown IGFBP-6 induction in the presence of P4 and E2. Knockdown of IGFBP-6 in the presence of P4 and E2 decreases the antagonistic effects of P4. Expression of both PR-A and PR-B decreases by about 50% when IGFBP-6 is knocked down. These results indicate that IGFBP-6 increases PR expression in response to P4 stimulation.

#4391 The UBE2F-CRL5^{Asb11}-DIRAS2 axis is an oncogene and tumor suppressor cascade in pancreatic cancer cells.

Y. Sun[1], Y. Chang[1], Q. Che[1], H. Li[2], j. Xu[2], M. Tan[2], X. Xiong[1];
[1]The Second Affiliated Hospital of Zhejiang Univercity School of Medicine, Hangzhou, China, [2]University of Michigan, Ann Arbor, MI

UBE2F is a neddylation E2 that couples with RBX2/SAG E3 to promote CUL-5 neddylation and Cullin-RING ligase-5 (CRL5) activation. Whether and how UBE2F regulates pancreatic tumorigenesis is previously unknown. Here we showed that UBE2F is growth essential for pancreatic cancer cells with KRAS mutant in culture. In *Kras^{G12D}* mouse PDAC model, *Ube2f* deletion suppresses cerulein-induced pancreatitis, and progression of acinar-to-ductal metaplasia (ADM) and pancreatic intraepithelial neoplasia (PanIN). Mechanistically, *Ube2f* deletion inactivates the Mapk-c-Myc signal pathways via blocking ubiquitylation and degradation of Diras2, which is a new substrate of Cul5^{Asb11} E3 ligase. Biologically, DIRAS2 suppresses growth and survival of pancreatic cancer cells with KRAS mutant, and *Diras2* deletion largely rescued the phenotypes induced by *Ube2f* deletion, indicating its causal role. Collectively, Ube2f or Diras2 plays a tumor-promoting or tumor-suppressive role in Kras^{G12D} PDAC model, respectively. The Ube2f-CRL5^{Asb11} axis could serve as a valid target for pancreatic cancer, whereas the levels of UBE2F or DIRAS2 may serve as prognostic biomarkers for PDAC patients.

#4392 Neuropeptide Y system in glioblastoma.

Nouran Abualsaud[1], Jason Tilan[2], Bahauddeen M. Alrfaei[1], Harrison Glor[2], Taylor Polk[2], Ewa Izycka-Swieszewska[3], Joanna Kitlinska[4]

[1]Blood and Cancer Research, King Abdullah International Medical Research Center, Riyadh, Saudi Arabia, [2]Department of Human Science, School of Health, Georgetown University, Washington, DC,[3]Department of Pathology and Neuropathology, Medical University of Gdańsk,, Gdańsk, Poland,[4]Department of Biochemistry and Molecular & Cellular Biology, Georgetown University Medical Center, Washington, DC

Gliomas constitute the most common primary cerebral tumors of the central nervous system (CNS), with glioblastoma (GBM) representing the most aggressive subtype. Neurotransmitters are important players in maintaining physiological processes in CNS and abnormal levels of their expression is pathogenic, leading to different processes, including neoplasia. Neuropeptide Y (NPY) is one of the neurotransmitters that is found to play a pivotal role in several malignancies. NPY, acting via its cognate receptors Y1, Y2 and Y5 (Y1R, Y2R and Y5R), has been shown to stimulate cancer cell proliferation, migration, invasiveness and dissemination, as well as tumor vascularization in various malignancies including neuroblastoma, Ewing sarcoma, colon, breast, prostate and liver cancers. Thus, the goal of this study was to determine if the NPY system is involved in glioma biology. Our immunohistochemistry staining of NPY, Y1R, Y2R, and Y5R in human GBM tissues revealed positive staining for NPY and Y2R in GBM cells. No expression of Y1R and Y5R was detected in GBM neoplastic population. To further elucidate the association between NPY and its receptors with GBM tumor stage and patients' survival, we used the available clinical data from the Cancer Genome Atlas Program (TCGA) database to analyze the gene expression of the NPY system. Y2R expression was increased in high-grade gliomas, while mRNA levels of NPY, Y1R and Y5R inversely correlated with the degree of glioma malignancy. Moreover, high Y2R expression was associated with worse survival in GBM patients. Importantly, endothelial Y2R is also responsible for angiogenic effects of NPY, suggesting its role in GBM vascularization. Altogether, these data suggest the involvement of NPY/Y2R axis in glioma progression toward more aggressive phenotype. Further functional studies are required to determine the role of the Y2R axis in this process.

#4393 Expression levels of T-cell factor-4 variants in hepato-gastrointestinal cancer cells and tissues.

H. Koga[1], Y. Imamura[2], T. Sudo[2], H. Suzuki[1], T. Tanaka[1], T. Sakaue[1], A. Masuda[1], H. Iwamoto[1], T. Nakamura[1], H. Yano[1], T. Kawaguchi[1];
[1]Kurume Univ. School of Medicine, Kurume, Japan, [2]Kurume Univ. Research Center for Innovative Cancer Therapy, Kurume, Japan

Background: We previously identified 14 variants of T-cell factor (TCF)-4, a key transcriptional factor in the canonical Wnt signaling pathway, from human liver cancer cell lines (Exp Cell Res 2011). The functional analysis of the variants demonstrated that the SxxSS motif played crucial roles in high tumorigenicity, resistance to hypoxia (PLoS ONE 2012), and EMT (Liver Int 2013). These findings suggest that expression levels and patterns of TCF-4 variants tightly regulate diverse phenotypes of cancer cells. Currently, we developed a novel RT-PCR system to quantitatively evaluate TCF-4 variant expressions by using the peptide nucleic acid (PNA)-directed PCR clamping method.
Aim: To assess mRNA expression levels of TCF-4 variants in hepato-gastrointestinal cancer cell lines and colon cancer tissues, focusing on TCF-4J and TCF-4K with the presence (K) or absence (J) of the SxxSS motif.
Methods: Thirteen cell lines used in this study were as follows: seven liver cancer; one fetus-derived immortalized hepatocyte; one gastric cancer; two pancreatic cancer; and two colon cancer cell lines. The liver cancer cell lines HAK-1A and HAK-1B are clonally sister cell lines. Sets of three forward primers and four reverse primers were used to generate templates for quantitative PCR (qPCR), and three fluorescence (FAM and Cy5)-tagged primers were applied to detect each variant. Thirty-nine resected human cancer and non-cancerous tissue pairs were used in the IRB-certified study (No. 19192).
Results: All TCF-4 variants except TCF-4M and TCF-4X were specifically and reproducibly detected and quantified. Cancer cells derived from the colon and stomach highly expressed the TCF-4 variants, showing the highest expression in TCF-4J, while cancer cells from the liver and pancreas expressed relatively lower levels. There was no remarkable difference in the expression profile of TCF-4 variants between HAK-1A and HAK-1B. In colon cancer tissues, TCF-4J was significantly more expressed than TCF-4K.
Conclusion: Although the variants had been identified from liver cancer cells, they were universally expressed in cells of other organs. TCF-4J, a variant responsible for aggressive cell phenotype, was prominently found in cancer cells of the digestive tract, where the canonical Wnt signal pathway is known to be constitutively active. A similar variant profile between two liver cancer cell lines with identical clonal origin suggests that the variant pattern in the cells reflects organ-specific traits rather than dynamic phenotypic changes during cancer cell dedifferentiation.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Epigenetics and Cancer Biology
Poster Session

#4397 Alpha-Ketoglutarate is a master regulator of epigenetic reprogramming in pancreatic ductal adenocarcinoma progression.
K. Sherman, J. Cheng, W. Zhou, H. Ji, M. Maeda, A. P. Feinberg;
Johns Hopkins University, Baltimore, MD

Most cases of Pancreatic Ductal Adenocarcinoma (PDAC) are diagnosed after metastasis has occurred, making it crucial to find effective treatments for late-stage disease. Previously, our group found widespread epigenetic reprogramming during PDAC metastasis in the absence of additional driver mutations. These cells develop dependence on glucose metabolism through the oxidative pentose phosphate pathway (oxPPP). Inhibition of oxPPP with 6-aminonicotinamide (6AN) reverses the chromatin changes and restores cells to a less malignant state (McDonald *et al. Nat Gen*, 2017). To identify a clinically actionable mechanism for restoration, we hypothesized that oxPPP dependence leads to downstream metabolic changes that mediate chromatin state. Using untargeted metabolomic analysis, we found that alpha-ketoglutarate (AKG), a cofactor of lysine and histone demethylases, was downregulated by oxPPP inhibition ($p=0.033$) in a patient-derived xenograft lung metastasis cell line, A13Lg. Treatment of cells with 6AN and a cell permeable precursor of AKG largely reversed the chromatin changes seen on a western blot. Given that AKG is mainly produced by glutamine metabolism, we inhibited glutaminolysis with glutamine deprivation (Gln(-)) or the glutamine antagonist JHU083. Both treatments decreased AKG (Gln(-) $p=0.002$, JHU083 $p=0.038$) and prevented cell growth (Gln(-) $p<0.0001$, JHU083 $p=0.0002$). Glutamine-deprived cells showed decreased ability to form colonies ($p=0.004$), and JHU083 treated cells showed impaired migration in a Boyden chamber assay ($p=0.003$). Western blots showed a decrease in H3K27 acetylation, a marker of euchromatin, and an increase in H3K9 and H3K27 methylation, markers of heterochromatin, in response to both treatments. Further, homogenized time-resolved fluorescence (HTRF) assays on glutamine-deprived cells showed that H3K9 di- ($p=0.0016$,) and tri- ($p=0.0003$) methylation was increased. Adding cell permeable AKG to media without glutamine largely negated both the phenotypic and epigenetic changes. Using CUT&RUN against H3K27Ac, we found that acetylation was depleted at promoters involved in tumor cell proliferation, invasion, and migration. Bulk RNA-sequencing also showed decreased expression of genes involved in these pathways. Epigenetic and phenotypic changes were not as apparent after treatment with CB839, a glutaminase 1 inhibitor, suggesting that broad inhibition of glutamine metabolism is necessary for chromatin restoration. Together, these data suggest that decreasing AKG in PDAC distant metastasis cells, through glutamine deprivation or JHU083, leads to chromatin changes that specify less malignant phenotypes, providing a rationale for targeting glutamine metabolism as a therapy for late-stage PDAC. *APF and MM are co-corresponding authors.

#4398 *TET2* accelerates clonal hematopoiesis in an age-dependent manner.

S. Karmakar[1], Y. Liu[1], E. Motakis[1], K. Sengupta[1], T. Roeder[2], K. Mujica[3], J. Trowbridge[3], H. Oguro[2], S. Li[1];
[1]The Jackson Laboratory for Genomic Medicine, West Hartford, CT, [2]University of Connecticut Health Center, Farmington, CT, [3]The Jackson Laboratory, Bar Harbor, ME

Aging is a process of systemic deterioration and the most significant risk factor for cancers. Clonal hematopoiesis (CH) commonly occurs with aging and links to higher mortality, leukemia risk, and cardiovascular diseases. Age-related CH involves the abnormal clonal expansion of hematopoietic stem cells (HSCs) bearing somatic mutations in genes frequently mutated in leukemia, including genes encoding epigenetic regulators, such as the DNA demethylase TET2. While such mutations are known to alter the HSC epigenome, the mechanisms through which these mutations drive HSC self-renewal, myeloid transformation, and inflammatory response remain elusive.

In this study, we hypothesize that aging and CH mutations cooperatively reshape the HSC transcriptomic landscape and enhancing HSC competitive advantage that facilitates clonal expansion. Recently, *TET2*-mutant CH in humans has been strongly associated with epigenetic age acceleration. Using single-cell multi-omic analyses and flow-cytometric phenotyping, we demonstrated, for the first time, that HSC aging processes at transcriptomic, epigenomic, and cellular levels are accelerated by *Tet2* deficiency in mice, in an age-dependent manner. *Tet2*-deficient HSCs increase the HSC aging scores at an older age of greater than or equal to 16 months, but not at a young or mid-age, based on gene expression and chromatin accessibility at a single-cell resolution. This age acceleration was further validated by epigenetic clock analysis of DNA methylation mapping. Moreover, we found that *Tet2* deficiency drives a significant expansion of HSCs, a cellular hallmark of HSC aging, in an age-dependent manner. Specifically, we observed increased expression of *S100a6, Cdk6, Egr1* in *Tet2*-deficient HSCs from older mice, suggesting that *Tet2* deficiency hijacks the HSC expansion strategy during HSC aging by enhanced self-renewal. We also observed that the differentially expressed genes between *Tet2*-deficient older HSCs and control older HSCs are associated with open chromatin accessibility. Many of these genes are enriched in the targets of specific transcription factors (TFs), such as Egr1, Creb1, Stat family and Hoxb8. These target genes play critical roles in inflammatory pathways and HSC functions. In conclusion, our findings reveal that *Tet2* deficiency significantly contributes to the acceleration of HSC aging, and hijacks the HSC expansion strategy (e.g., self-renewal) during HSC aging, which exacerbates age-related clonal hematopoiesis. By elucidating the transcriptomic and epigenomic alterations in *Tet2*-deficient HSCs, our study provides novel insights into how age and somatic mutations collaborate to promote the pathogenesis of age-related hematological diseases. These discoveries not only enhance our understanding of HSC aging mechanisms but also offer potential biomarkers for early detection and targets for therapeutic intervention in age-associated clonal disorders.

#4399 HMGA1 is an epigenetic regulator and plays a critical role in melanoma recurrence.

H. Mou, K. DeRosa, V. Yakovishina, Y. Chen, A. Reynolds, M. Xiao, M. Thomas, M. Herlyn;
The Wistar Institute, Philadelphia, PA

Among various genetic mutation in melanoma, $BRAF^{V600E}$ is one of the key drivers of melanoma initiation and progression and has become the frontline target in clinical trials. Although BRAF/MEK inhibitors show very promising therapeutic outcomes, recurrence or relapse is still a major challenge and its underlying mechanisms are still poorly understood. We hypothesized that survival of recurrent tumors is BRAF independent and relies on epigenetic reprogramming. To test our hypothesis, we used either pharmacological inhibition of BRAF/MEK or CRISPR/Cas9 mediated knockout of BRAF to create cell/tumor models of BRAF-independent survival. Cut&Run sequencing was then used to identify epigenetic alterations regulated by H3K4me3 or H3K27Ac in a genome scale and capture the landscape of epigenetic alterations of BRAF-independent cell survival. Combining regular bulk RNAseq, we narrowed down our top candidates and focused on one of the functionally validated candidates, HMGA1. Interestingly, CRISPR/Cas9 mediated HMGA1 knockout cells show significantly slower growth in both *in vitro* colony formation assays and *in vivo* xenografts assay in BRAF/MEK resistant Patient-Derived-Xenograft (PDX) tumor models resembling melanoma recurrence. Furthermore, we selected CRISPR/Cas9 single knockout cells of HMGA1, which is a pure genetic depletion model, and confirmed the phenotype of impaired tumor growth of HMGA1 knockout cells. We then performed RNAseq and ChIPseq, and identified downstream targets of HMGA1 and elucidated mechanisms by which HMGA1 reprograms epigenetics of recurrence. Utilizing the single knockout cell, we re-introduced HMGA1 in the pure knockout cells, and anticipated that restoration of HMGA1 in pure HMGA1 knockout cells rescues impaired tumor growth and confer cells resistance to BRAF/MEK inhibition. Finally, we subcutaneously injected the HMGA1 single knockout cells into humanized mice and tested whether epigenetic alterations perturb the immune microenvironment and sensitize cells to immunotherapy. In conclusion, this study sheds new lights on how melanoma cells reprogram the epigenome to develop mechanisms of recurrence. Identification of HMGA1 and its upstream or downstream targets provides potential druggable targets of overcoming relapse after BRAF/MEK inhibitor therapy.

#4400 Transcriptional dysregulation of chromosomes localized into the micronucleus.

D. Norkunaite, D. Al-Rawi, S. Bakhoum;
Memorial Sloan Kettering Cancer Center, New York, NY

Chromosomal Instability (CIN) is a characteristic of the most aggressive and drug-resistant cancers. Chromosomally unstable cells form micronuclei (MN), a structure with an unstable nuclear membrane that spontaneously surrounds missegregating chromosomes upon mitotic exit. Several studies have demonstrated that CIN drives drug resistance and metastasis through the karyotypic diversity caused by copy number alterations. Beyond facilitating karyotypic diversity, CIN has recently been demonstrated to cause durable epigenetic alterations including reduction of the activating histone H3K27ac mark in chromosomes localized to micronuclei. This reduction in histone H3K27 acetylation persists after the relocalization of the missegregated chromosome to the primary nucleus (PN). Given the loss of transcription-associated epigenetic modifications, we hypothesized that MN would exhibit transcriptional impairment. Indeed, by using nascent RNA assays and immunofluorescence, we found that chromosomes localized into the MN are less transcriptionally active and exhibit lower levels of active RNA polymerase II (RNAP2). Transcriptional inhibitors targeting RNAP2 largely abrogate MN transcription. Conversely, class-specific histone deacetylase inhibitors (HDACi) cause increased hyperacetylation of the MN relative to the PN, which persists beyond MN reincorporation into the PN. We also hypothesized that transcription in MN depends on the manner of MN biogenesis. Preliminary data shows that MN formed from breakage-fusion-bridge (BFB) events may cause less transcriptionally active MN than ones generated from treatment with the MPS1 inhibitor, reversine. To better understand the mechanisms that regulate transcription in the MN, our ongoing work is focused on an unbiased investigation of the micronuclear transcriptome.

#4401 GATA6 is a novel regulator of gene expression and 3D genome in colorectal cancer.

H. Lyu, X. Chen, Y. Cheng, T. Zhang, P. Wang, J.-y. Wong, J. Wang, L. Stasiak, L. Sun, G. Yang, L. Wang, F. Yue;
Northwestern University - Chicago, Chicago, IL

Colorectal cancer (CRC) is one of the most lethal and prevalent malignancies with elusive molecular causes. While the abnormal activity of transcription factors has been reported as a vital component of cancer progression, the mechanism through which they function remains unclear. Here, through the analysis of primary human CRC tissue data, we identified GATA6 as a CRC specific regulator, whose expression upregulation is potentially associated with promoter hypomethylation. In the human genome, GATA6 showed preferential binding at tumor specific active enhancers. Through both auxin-inducible degron (AID) and CRISPR knockout, we showed that GATA6 depletion severely impaired clonogenicity and proliferation. GATA6 depletion caused the loss of CRC specific open chromatin, suggesting a specific regulatory role of GATA6 in CRC pathogenesis. Interestingly, we also discovered the co-occupancy of GATA6 with CTCF and its direct involvement in promoter enhancer loops, suggesting the possibility that GATA6 mediate transcriptional regulation through 3D genome. The loss of GATA6 led to alterations in E-P chromatin interactions of a panel of oncogenes, accompanied by the oncogene downregulation. Finally, we showed that GATA6 loss is detrimental to the xenograft tumor growth and thereby rescued mice survival. Taken together, we unrevealed a novel mechanism by which GATA6 contributes to CRC.

#4402 A genomic insertion/deletion variant activates immune escape and tumor promoting programs in breast cancer.

P. Betancur, C. DiBenedetto, **D. Acenas**, A. Rodriguez, A. Thach;
UCSF School of Medicine, San Francisco, CA

Purpose: Despite all the knowledge we have concerning cancer cells' immunesuppressive ability, we still don't understand whether the mechanisms upregulatingimmune suppression in cancer cells are patient specific. This information is critical forthe generation of tailored treatments that recruit the immune system for the eradicationof cancer disease. In the past, we showed that super-enhancers, composed of cluster ofenhancers spanning over long genomic regions characterized by having potent generegulatory activity, are critical for the upregulation of immune suppressive genes,including CD47, within the tumor. Recently we found a DNA insertion/deletion variant (8bp in size) within a super-enhancer located between the CD47 and Linc00636 genes,that is present more often in European (53%) than Asian (12%) populations and whichassociates with breast cancer. Moreover, sequence analyses of patient-derived breasttumors (44) and gynecological tumor samples (23) demonstrated a significantassociation of this insert with breast cancer and not with gynecological cancer. Thus, wehypothesize that the insertion variant regulates genes that drive immune escape andbreast cancer specifically in patient populations that carry the insert version.

Methods: To test this, we CRISPR deleted the variant's insertion and CRISPR-VP64induced its activation and quantified its effect on target genes and encoded proteinsusing high throughput RNA sequencing and immunofluorescence flow cytometryanalyses respectively.

Results: CRISPR-VP64 induction of the 8bp insertion confirmed that the insertion issufficient to regulate gene expression of CD47 and of an anti-tumor, long intergenicnon-coding RNA (Linc00636) in breast cancer cells. Furthermore, we observed thatCRISPR deletion of the 8bp insertion increases CD47 levels, while dramaticallyincreasing expression of Linc00636 and reducing the expression of CD44, CXCL14,MUC1 genes involved in invasion and migration. Our work shows that the insertion ofan 8bp is responsible for stabilizing upregulation of CD47 (an immune suppressivesignal), downregulating Linc00636 (a modulator of tumor metastasis), and upregulating,as a result, the expression of cell surface receptors involved in metastasis andtumorigenesis.

Conclusions: Here we found a genomic insert within a super-enhancer that unleashesthe upregulation of Linc00636 and of a program that promotes breast cancer, mostlikely in populations of patients carrying this variant. Our findings are important tounderstand patient specific genomic bifunctional modulators of immune suppressionand tumor progression for the design of more personalized treatments geared towardprecision medicine.

#4403 The crosstalk between the tumor microbiome and epigenomic changes in penile squamous cell carcinoma.

J. Viera-Vera[1], Y. Roque-Reyes[1], D. Santiago-Negron[1], M. Sanchez-Vazquez[1], Y. Ortiz Maldonado[1], G. Borges-Velez[1], J. Figueroa-Diaz[2], C. Rivera-Lopez[2], N. Zacharias Millward[3], M. Marcos-Martinez[2], F. Godoy-Vitorino[2], A. Puras-Baez[2], J. Dutil[1], J. Perez-Santiago[1], M. Martinez-Ferrer[1];

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR, [2]University of Puerto Rico School of Medicine, San Juan, PR, [3]The University of Texas MD Anderson Cancer Center, San Juan, PR

Penile squamous cell carcinoma (PSCC) is approximately three times more prevalent in Puerto Rico when compared to other ethnic groups in the United States. Moreover, the mortality rate for PSCC among Puerto Rican men is significantly higher when compared to the US population. Infection with human papillomavirus (HPV) has been identified as a risk factor for an average of 48% of PSCC cases in Puerto Rico. The molecular etiology of $HPV^{\pm}$ and HPV^{-} PSCC remains poorly understood. To date, the role of the microbiota in the pathogenesis of PSCC is unknown, as there are no studies that characterize the microbiome in association with penile cancer. Furthermore, the role of DNA methylation, which is an epigenetic alteration that can be found in cancer cells that can lead to changes in gene expression and cellular function, is also unknown. Therefore, there is an urgent need to address this knowledge gap. This study aims to analyze the DNA methylation patterns and bacterial communities in HPV-positive and HPV-negative PSCC tissues from Puerto Rican men. DNA was extracted from twenty-one fresh PSCC tissue samples from Puerto Rican patients. HPV status and genotyping were determined using the DNA ELISA kit HPV SPF10 protocol. DNA methylation assay was performed using the Infinium Methylation EPIC v2.0 BeadChip Kit to identify and compare average DNA methylation levels (%) in 7 HPV-positive and 14 HPV-negative penile cancer samples. Microbiota analyses were performed using 16S rRNA genes with the Illumina MiSeq platform. Demultiplexed data was deposited in QIITA for quality control and bioinformatic analyses and downstream analyses were done in R and Qiime2. Our results demonstrated that 45 loci methylation patterns were significantly different between HPV-positive and HPV-negative samples, with an adjusted p-value <0.1 (Benjamini-Hochberg method). Three loci methylation patterns were significantly affected by species diversity and richness. The abundance of Firmicutes, Proteobacteria, Bacteroidetes, Fusobacteria, and Actinobacteria was individually associated with number of affected loci (27, 19, 12, 6, and 3, respectively). We found that HPV status is associated with methylation patterns and microbiome in PSCC in Puerto Rican men. Both changes may be involved in triggering inflammatory responses and oncogenesis. Although many challenges must be overcome to dissect the specific interactions of coinfecting bacteria and methylation patterns during the penile cancer infectious process, our findings demonstrate that microbes may be involved in these cellular processes.

#4404 EZH2 modulates mRNA splicing in chronic myeloid leukemia through the repression of splicing factors and exerts part of its oncogenic function through the regulation of CELF2.

R. Brunmeir, Y. Li, B. Lin, L. Zheng, H. Yang, W. Chng;
Cancer Science Institute of Singapore, Singapore, Singapore

The polycomb protein EZH2 is a commonly deregulated or mutated transcriptional regulator in various cancers. In Chronic Myeloid Leukemia (CML) it has been reported to be upregulated and associated with transcriptional reprograming, rendering CML leukemic stem cells (LSCs) sensitive to EZH2 inhibitor treatment. Mechanistically this seems to be linked to the silencing of apoptotic target genes by EZH2-mediated histone H3 lysine 27 tri-methylation (H3K27me3). We hypothesized that the regulation of apoptotic genes is not the only pathway responsible for its oncogenic function, and that EZH2 might also act as a modulator of the mRNA splicing landscape. To test this, we treated the CML cell line K562 with the EZH2 inhibitors GSK126 and EPZ-6438 and performed RNA-seq followed by splicing analysis. Using two different bioinformatics tools, we detected differential splicing of several hundreds of splicing events. However, differentially spliced genes were not associated with increased EZH2 or H3K27me3 signals, suggesting an indirect mechanism of splicing regulation. Indeed, we found 11 splicing factors transcriptionally upregulated upon EZH2 inhibitor treatment. CELF2 was identified as top candidate to mediate part of the EZH2 inhibitor induced phenotype. Upon overexpression, we observed 1) reduced cell growth, viability, and colony formation of K562 cells, 2) a change in the splicing landscape, significantly overlapping with EZH2 inhibitor induced changes, 3) the downregulation of cMYC signaling, also found upon EZH2 inhibitor treatment. To test if CELF2 is indeed acting as EZH2-regulated tumor suppressor in CML, we extended our study to CML patient samples: we performed RNA-seq followed by splicing and gene expression analysis in seven CML patient-derived CD34+ samples and eight healthy donor-derived CD34+ samples, as well as three CML patient samples transduced with CELF2-containing expression constructs. While we found Celf2 mRNA downregulated in CML derived samples, overexpression led to decreased colony formation and cMYC signaling, validating our findings from K562 cells. We also performed an analysis of CML associated splicing changes and found hundreds of deregulated splicing events, of which a significant portion overlapped with CELF2 overexpression mediated changes, suggesting direct regulation by CELF2. Based on this data we propose a novel role of EZH2, where it exerts part of its oncogenic function in CML through the transcriptional repression of splicing factors, in particular CELF2, leading to splicing deregulation, increased cMYC signaling, and enhanced cell growth and viability. Finally, data from other publicly available EZH2 inhibitor treated cancer models suggests that splicing modulation by EZH2 might not be restricted to CML.

#4406 Single cell multiomic analysis reveals how genomic, epigenomic and transcriptomic events drive progression of multiple myeloma precursor states.

R. Canevarolo, P. Sudalagunta, M. Silva, M. Meads, R. Baz, M. Alsina, K. H. Shain, **A. Siqueira Silva**;
H. Lee Moffitt Cancer Center, Tampa, FL

In this study we have leveraged Moffitt Cancer Center's cohort of over 1,000 bone marrow (BMBX) aspirates from normal donors, MM precursor diseases (MGUS, SMOL), active therapy naïve disease (NDMM), as well as early (post 1-3 lines of therapy, ERMM) and late-relapse (3+ lines of therapy, LRMM) MM patients, characterized clinically, cytogenetically (FISH), genetically (WES), and transcriptomically (RNA-seq).Transcriptomic analysis identified a subset of cancer hallmarks differentially expressed between MGUS and NDMM samples (e.g. cell identity, adhesion and inflammatory signaling, etc.).Dimensionality reduction analysis, followed by unsupervised segmentation, identified clusters of co-expressing genes across this dataset. Enrichment analysis of aforementioned gene clusters, differentially expressed between MGUS and NDMM states, identified a number of putative transcription factors (GATA1/2, SUZ12, RUNX1, SOX2, TP63, NFE2L2, FOXM1 and NANOG), as well as polycomb complex and H3K27me3 as main drivers. Single cell ATAC-seq in 11 BMBX (4 SMOL, 4 NDMM, 1 ERMM, 2 LRMM) and single cell multiomics (simultaneous scATAC-seq/scRNA-seq) in additional 10 BMBX (2 healthy, 3 MGUS, 3 SMOL and 2 NDMM) confirmed that the H3K27me3 putatively regulated gene clusters were the only ones with significant chromatin accessibility changes. Single cell analysis confirmed differential expression and accessibility of cancer hallmarks identified in larger cohort, as well as putative driver TFs. Correlation between TF expression and motif accessibility produced an additional list of pioneer TFs putatively involved in progression from MM precursor states (ZEB1, EBF1, SPI1, PAX5, etc.).Investigation of scMultiomic data demonstrated that NDMM and SMOL samples contain subpopulations of cells in MGUS and normal "states" (cell clusters in scMultiomics UMAP), confirming intra-sample heterogeneity, and that divergence within the multiomic plane occurs in the transition between MGUS and SMOL. Through pseudotime and single cell copy number analysis (epiAneufinder/scATAC-seq and inferCNV/scRNA-seq) we were able to reconstruct how MM FISH cytogenetic abnormalities alter the multiome of these cells, creating aforementioned intra-sample heterogeneity. Despite different initiating events, all samples shared a common biology putatively regulated by epigenetic dysregulation, suggesting polycomb complex hijacking as a therapeutic opportunity for precursor MM.

#4407 Simultaneous spatial epigenomic and transcriptomic analysis of gastric adenocarcinoma reveals regulatory patterns governing tumor and microenvironment architecture at the cellular level.

K. J. Noronha, J. M. Garbarino, D. Massucci, A. R. Tyree, C. Ng;
AtlasXomics, Inc., New Haven, CT

Recent advances in spatial transcriptomics and spatial proteomics have enabled increasingly complex questions on the nature of gene regulation and expression in cellular subtypes in tumor tissue and the tumor microenvironment. However, most spatial omics techniques do not profile the epigenomic landscape responsible for downstream gene expression. Furthermore, current spatial technologies have yet to profile the epigenome and transcriptome simultaneously, and thus it remains a challenge to correlate multi-omics data across sections of extremely heterogenous tumor tissue. Recently, co-profiling of spatial epigenomics and transcriptomics using principles of Deterministic Barcoding in Tissue for spatial omics sequencing (DBiT-seq) has been demonstrated on normal brain tissue. Joint spatial profiling of chromatin states and whole transcriptome in tissue allows for parallel characterization of gene regulation programs across all cell types, while preserving the tissue architecture for greater understanding of the cellular environment. Here we present the first application of spatial ATAC-seq and spatial transcriptomics on the same tissue section to characterize the tumor microenvironment of an invasive gastric adenocarcinoma (GAC) and adjacent normal tissue. GAC is the fifth most common cancer and commonly exhibits mutations in epigenetic modifiers, including ARID1A and MLL1-4. Distinct spatial clusters representing different cell subtypes were identified via both spatial chromatin accessibility and spatial transcriptomics. Spatial ATAC-seq profiling of accessible regulatory elements correlated well with RNA expression of target genes. Spatial patterns of transcription factor motif accessibility also correlated well with the observed transcriptional program of tumor tissue. When compared to adjacent normal tissue, spatial co-profiling of chromatin accessibility and the transcriptome revealed that the epigenetic landscape is significantly altered in tumorigenesis of GAC. Future work will focus on development of co-profiling of histone modifications and the transcriptome to enable the study of another layer of the epigenomic landscape, especially as targeting epigenetic modifiers such as EZH2 has been identified as a potential therapeutic strategy in GACs. Overall, we present a solution to profile multiple layers of gene regulation and expression with spatial context, which can be applied to most tumor types for better understanding of tumorigenesis and the consequences of new targeted therapies.

#4409 *FBXW7* and *BCL9L* altered pathways as hallmarks of early-onset colorectal cancer.

R. Mikaeel[1], D. Bellomo[2], S. Rajpara[3], D. Buckley[3], M. Yagle[2], B. Kerimoglu[2], C. Thorne[2], M. Padi[2], B. Salhia[3], N. A. Ellis[2], X. Llor[4], R. Xicola[4];
[1]Yale Medical of Medicine, New Haven, CT, [2]University of Arizona Cancer Center, Tucson, AZ, [3]University of Southern California, Los Angeles, CA, [4]Yale School of Medicine, New Haven, CT

Background: The incidence of early-onset colorectal cancer (EO-CRC) has been alarmingly increasing, particularly among non-Hispanic Whites (NHWs), resulting in similar rates to ones in African Americans (AAs). Overall, the median age of diagnosis has decreased from 72 to 66 years. The molecular features that could potentially distinguish this phenotype are still not well-established. This study aimed to identify genetic, epigenetic, and transcriptomic factors associated with EO-CRC.

Methods: 510 patients with microsatellite-stable tumors analyzed for somatic mutations, targeting 20 cancer driver genes. We included a cohort of 175 AAs from the Yale New Haven Health System, a previously studied cohort of 51 AAs from the Chicago Colorectal Cancer Consortium, and the publicly available molecular data from TCGA COAD-READ PanCancer cohort (50 AAs and 229 NHWs). We analyzed the transcriptomic and methylation profiles from the Yale cohort using Tempo-Seq™ and Illumina EPIC array, respectively.

Results: Of the 510 patients, 18% were diagnosed with EO-CRC. Using a multiple variant analysis, adjusting for sex, race, tumor location, and stage, EO-CRC patients were less likely to be male (OR = 0.59, 95% CI: 0.37-0.94, p-value = 0.03), their tumors lacked mutations in *APC* (OR = 0.37, 95% CI: 0.22-0.63, p-value = 0.0002), and they were more likely to have mutations in *FBXW7* (OR = 3.1, 95% CI: 1.60-6.00, p-value = 0.0007) and *BCL9L* (OR = 3.1, 95% CI: 1.00-8.72, p-value = 0.04). We compared tumors with and without mutations in *FBXW7* or *BCL9L* in two independently analyses. Combining transcriptomics and methylation data, we identified 10 candidate genes that showed significant gene downregulation with hypermethylation or upregulation with hypomethylation. Among FBXW7 mutant tumors, we found the Cartilage oligomeric matrix protein (COMP) gene was significantly downregulated and hypermethylated. In CRC, COMP has been associated with a crosstalk between the TGF-β pathway and immune cell infiltration. Moreover, inactivation of FBXW7 resulted in the accumulation of phosphorylated TGIF1 molecules and repression of TGFβ-dependent transcription in cancer cell lines. Deficiency of *FBXW7* is a key element in the phosphorylation-dependent ubiquitination and subsequent proteasome degradation of oncoproteins, such as c-MYC, NOTCH, and Cyclin E. Among *BCL9L* mutant tumors, keratin 20 (KRT20), the intermediate filament protein and marker of intestinal differentiation in CRC, was downregulated and hypermethylated. *BCL9L* plays an important role in tumorigenesis induced by aberrant Wnt signaling or aneuploidy tolerance.

Conclusion: Our findings further demonstrate the importance of specific etiologic mechanisms in EO-CRC at the level of somatic alterations, providing new ways to understand the biology of EO-CRC and prospects for the development of targeted therapies.

#4410 The CpG island methylator phenotype is closely associated with prognosis in patients with oral squamous cell carcinomas.

M. Abe[1], S. Yamashita[2], T. Ushijima[3], K. Hoshi[1];
[1]Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Tokyo, Japan, [2]Maebashi Institute of Technology, Maebashi, Japan, [3]Hoshi University, Tokyo, Japan

Few abnormalities are known to be closely associated with prognosis in OSCC cases. In this study, genomic abnormalities of cancer-related genes and epigenomic abnormalities of genes methylation-silenced in OSCCs were analyzed to identify abnormalities associated with prognosis. Thirty-nine OSCC cases and their surgical materials were analyzed for the presence of mutations using next-generation sequencing. Methylation status of promoter CpG islands of five genes was analyzed by methylation-specific PCR. Mutations in CRG, *TP53* and *PIK3CA* were observed in 64.1%, 38.5%, and 33.3%, respectively, of the cases. However, no significant association between mutation status and overall survival (OS) was observed. Aberrant methylation of *CMTM3*, *NKX2-3*, *RBP4*, *EGFLAM*, and *MAP6* were observed in 51.3%, 41.0%, 66.7%, 38.5%, and 41.0%, respectively. Methylation of *NKX2-3*, *EGFLAM*, and *MAP6* were significantly associated with OS in OSCC cases (p=0.006, 0.006, and 0.012, respectively). Cases with methylation of *CMTM3* and *RBP4* showed a trend toward poor prognosis (p=0.052 and 0.059, respectively). Methylation profiles of the five genes indicated the presence of the CpG island methylator phenotype (CIMP), and the CIMP-positive cases showed poor prognosis (HR=20.5, p<0.001). In conclusion, CIMP was closely associated with the prognosis of OSCC cases.

#4411 Enhancing scalability and consistency in clinical multiomics via an optimized fixed cell ATAC-seq method.

D. Alves Winders, R. Graham, X. Mao, I. De Vito, A. O'Hara, L. Turner, H. Latif;
Azenta Life Sciences, South Plainfield, NJ

ATAC-seq has an emerging role in decoding mechanisms of gene regulation, offering valuable insights into pathology and treatment response in disease models. However, clinical adoption of ATAC-seq methods has been limited by logistical hurdles, including time-sensitive processing of fresh samples and compromised viability of cryopreserved cells. These constraints, compounded by changes in open chromatin regions (OCRs) following cryopreservation, introduce unintended bias and pose significant obstacles for the translational impact of ATAC-seq experiments.

Here, we introduce an optimized fixed-cell ATAC-seq approach to overcome these limitations and unlock new sample types for ATAC-seq analyses. Our solution improves and simplifies the workflow from sample collection to clinical deliverable. This method enables ATAC-seq investigation of a diverse range of samples and facilitates the execution of complex experimental designs, including time course studies and high throughput screening.To demonstrate the effectiveness of this method, we compared our optimized fixed-cell method with traditional ATAC-seq preparations in both fresh and cryopreserved GM12878 cells in parallel. Human GM12878 cell line was obtained from Coriell Institute for Medical Research5. Remarkably, we observed consistent genome-wide patterns of OCR enrichment at key regulatory elements across the three sample preparation methods. We observed consistent OCR enrichment across the promoter region of known highly-expressed B-cell genes including *CD48* and *LCP1*, underscoring this assay's ability to detect chromatin changes at key genes in human disease models.

To investigate the potential for multiomic analysis using this method, we prepared RNA-seq libraries from fixed-cell samples in parallel to ATAC-seq. We observed significantly elevated gene expression related to B-cell function and B-cell diseases, demonstrating our method's compatibility with RNA-seq data collection and integration. This optimized fixed-cell ATAC-seq approach offers enhanced scalability and consistency over conventional methods and presents new opportunities for the multiomic analysis of chromatin and transcriptional activity genome-wide from a single sample in both clinical and research settings.

#4412 Defining chromatin alterations in liver cancer at single cell resolution.

Miguel Ramirez[1], Tabea Stephan[2], Daivd Schaeffer[3], Pamela Hoodless[1]

[1]Medical Genetics, University of British Columbia, Vancouver, BC, Canada,[2]University of British Columbia, Vancouver, BC, Canada,[3]Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada

Hepatocellular carcinoma (HCC) is the most common liver cancer and arises from the malignant transformation of hepatocytes. HCC tumors often express genes critical for hepatocyte development but the regulatory mechanisms driving aberrant expression remain unclear. Recent evidence indicates that epigenetic alterations contribute to HCC progression with nearly 50% of cases associated with mutations in chromatin modifiers. Thus, it is imperative to understand how chromatin is altered in HCC and identify the DNA regulatory sequences associated with HCC tumorigenesis. Our study aims to map the chromatin landscape and transcriptome in HCC tumors using a multiomic approach at single cell resolution. Single-cell ATAC- and RNA-seq will be conducted in HCC tumors, matched controls and normal livers to identify regulatory sequences and their target genes critical for HCC tumor progression. We will characterize these regulatory sequences in the context of liver development using genetic manipulation and epigenomic datasets generated from human pluripotent stem cells differentiated to hepatic lineages. Our goal is to elucidate how epigenetic alterations in HCC drive cancer progression and how they relate to a dedifferentiated state.

#4413 Identifying genome-wide histone profiles in patient derived models of AML for predictive biomarker development.

A. Simmons[1], E. Oswald[2], G. Kuales[2], M. Keogh[1], V. U. Kumary[1], E. Brill[1], M. W. Cowles[1], B. Venters[1], **J. B. Schueler**[2];
[1]Epicypher, Durham, NC, [2]Charles River Laboratories, Inc., Freiburg, Germany

Acute myeloid leukemia (AML) is a complex disease with highly individualized treatment plans for patients. Mostly these are based on genetic and phenotypic markers of the disease, but the patient's overall condition is playing a significant role as well. To develop innovative drugs for a broad patient cohort, it is essential to understand the biological implications of these differences and to model them preclinically. In this study, we are assessing the utility of EpiCypher's CUT&Tag-FFPE platform to characterize the epigenome of AML PDX samples. CUT&Tag-FFPE is an epigenome profiling assay that is compatible with Formalin-Fixed Paraffin-Embedded (FFPE) samples, enabling robust genome-wide profiling of histone modifications from limited clinical samples. We derived PDX model LEXFAM 2799 (NPM1 wt; FLT3 wt, t(8;21)) and LEXFAM 2966 (NPM1 mut; FLT3 wt) from treatment naïve patients and established in immunocompromised NSG mice. LEXFAM 2799 is a fast-growing model with passaging times of 33 days, whereas LEXFAM 2966 displays a passaging time of 140 days. We next treated with Standard of Care (SoC) agents Decitabine, Cytarabine and all-trans-retinoic acid (ATRA): LEXF 2966 was highly sensitive towards Decitabine leading to complete remission. Cytarabine induced a partial remission and ATRA had only minor effect on tumor growth. In contrast LEXFAM 2799 was resistant towards treatment with ATRA and showed only partial remission under treatment with Cytarabine or Decitabine. Using the CUT&Tag-FFPE platform we are analyzing FFPE slides from the above mentioned two AML PDX models to investigate differences in the genome-wide histone profile that relate to the different growth behavior as well as sensitivity towards SoC treatment. The goal of these studies is to identify tumor model specific profiles that correlated specifically with the sensitivity towards the hypomethylating agent Decitabine. In addition, we plan to analyze additional untreated as well as treated AML PD models to validate the identified signatures confirming them as predictive biomarkers for sensitivity towards current standard of care and prospectively as well innovative compounds.

#4414 Genome-wide DNA methylation classifier diagnoses pancreatic ductal adenocarcinoma in CUP setting.

Teodor G. Calina[1], Eilis Perez[2], Simon Schallenberg[3], Horst David[3], Erik Knutsen[4], David Capper[2], **Mihnea P. Dragomir**[3]

[1]TGC Ventures UG, Berlin, Germany,[2]Neuropathology, Charite - University Medicine Berlin, Berlin, Germany,[3]Pathology, Charite - University Medicine Berlin, Berlin, Germany,[4]Medical Biology, UiT-The Arctic University of Norway, Tromso, Norway

Introduction: The metastasis of a pancreatic ductal adenocarcinoma (PAAD) is a diagnosis of exclusion and one of the most common causes of cancer of unknown primary (CUP). We have recently developed a genome-wide DNA methylation-based neural network classifier that can accurately differentiate between liver metastasis of a PAAD and intrahepatic cholangiocarcinoma (iCCA) (*PAAD-iCCA-Classifier*). Therefore, the aim of our study was to test whether our *PAAD-iCCA-Classifier* can be extended to be used to correctly diagnose PAAD metastases from other sites in CUP setting.

Methods: For this purpose, we enhanced the anomaly detection layer of the classifier by incorporating ten mimicker carcinomas to be excluded by this layer. We used a validation set 1 (n=3786) including primary PAAD (n=242), PAAD liver metastases (n=20), iCCA (n=151) and 10 other mimicker carcinomas (n=3373) and a validation set 2 (n=26) including primary PAAD from a real-life clinical cohort from an independent institution to validate the classifier. Next, we tested the classifier on 16 PAAD initially considered CUP samples (test set) from different sites: peritoneum, lung, liver, and lymph node. The clinical history and diagnostic imaging of these samples were used to confirm PAAD as the most probable origin. We further performed differentially methylated probes (DMP) and copy number alterations (CNA) analysis of primary PAAD and metastatic PAAD from different locations.

Results: The improved version of the *PAAD-iCCA-Classifier* achieved an accuracy of 98.43% on the validation set 1 and was able to exclude most of the mimicker carcinomas. On validation set 2, the classifier achieved an accuracy of 88.46%. Medical history, imaging and immunohistochemical analysis of the test set samples confirmed the diagnosis of PAAD. The DNA methylation classifier correctly labeled 15/16 PAAD metastatic samples as PAAD (93.75% accuracy). We observed that the classifier performance was negatively affected by a high $CD3^{+}$ immune infiltrate and positively affected by high tumor purity and high proliferation rate. CNA revealed that PAAD liver metastases have a distinct CNA profile characterized by chromosome 6, 9 (*CDKN2A/B*) and 18q (*SMAD4*) deletions. DMP analysis showed that PAAD liver metastases have global hypomethylation of both promoter- and enhancer-associated CpGs compared to primary PAAD and PAAD peritoneal carcinomatosis. Finally, gene ontology analysis revealed that different epithelial-mesenchymal transition pathways are activated in PAAD liver metastases compared to PAAD peritoneal carcinomatosis.

Conclusion: Our tool performs well in classifying metastatic PAAD samples and could be of great clinical use when a PAAD origin is suspected in the case of a CUP. DMP and CNA profiles show that PAAD liver metastases may have a distinct DNA methylation and copy number profile compared to primary and peritoneal carcinomatosis PAAD.

#4415 Utilization of MBD-seq to elucidate differentially methylated regions in cfDNA across healthy and cancer patients.

C. Michelon, B. Egan, **B. Delatte**;
Active Motif, Carlsbad, CA

5-Methylcytosine (5-mC) is the most abundant epigenetic DNA modification in eukaryotes. The presence of 5-mC alters gene expression and genome metabolism, and its deregulation is associated with many human diseases. Cell-free DNA (cfDNA) released from apoptotic cells has recently gained attention, as mutations or epimutations (*e.g.* 5-mC variations) detected in cfDNA were shown to have high diagnostic potential to assess the presence, stage and outcome of several cancers. However, 5-mC detection in cfDNA remains a challenge as input material is often very scarce. MBD-Seq is a method that leverages the ability of Methyl-CpG-binding domain protein 2 (MBD2) to capture and detect highly methylated regions of DNA genome-wide. We evaluated MBD-Seq for the detection of aberrant methylation patterns in cfDNA from healthy and diseased patients. We found MBD-seq on cfDNA to be specific (over 100-fold mC:C detection ratio) and sensitive (5 ng of input cfDNA). Applying MBD-seq to samples from healthy vs colorectal and breast cancer patients showed striking differences in methylation of key tumor-associated genes. Hence, MBD-Seq can elucidate aberrant methylation patterns from cfDNA, highlighting its potential as a diagnostics tool for the detection of cancer.

#4416 Rapid, low-input, targeted NGS workflow for DNA methylation.

Loni Pickle[1], Andrew Hatch[1], Gokhan Yavas[1], Melanie Spears[2], Louis Gasparini[2], Vida Talebian[2], Anna Ying-Wah Lee[2], Mathieu Lariviere[1], Jane Bayani[2], Seth Sadis[3], Jeffrey M. Smith[1]

[1]Thermo Fisher Scientific, Carlsbad, CA,[2]MaRS Centre, Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Thermo Fisher Scientific, Ann Arbor, MI

DNA methylation is a fundamental epigenetic process that regulates human gene expression. In cancer, methylation changes promote proliferation networks and metastasis. Development of biomarkers for methylation will be enabled by flexible, fast, low-input next generation sequencing workflows. We describe the first Ion AmpliSeq™ Methylation targeted panel and protocol on the turn-key Genexus™ Integrated Sequencer as part an ongoing collaboration with Ontario Institute for Cancer Research (OICR) to detect and predict response in early stage breast cancer and improve diagnostics for Black and Asian women. A 2-pool Ion AmpliSeq™ Methylation Panel for Breast Cancer Research was developed as a demonstration of design, workflow, and reporting for targeted, low-input methylation assessment in a multiplex setting across a variety of samples sources including FFPE. The panel contains 327 amplicons and was designed to target both strands and 10ng DNA input into bisulfite conversion was used for controls. A complete workflow begins at bisulfite conversion and progresses through the Genexus™ Integrated Sequencer which combines library construction, template preparation, and sequencing into a single run. The bioinformatics pipeline provides DNA methylation calls on both Watson and Crick strands at single base resolution and methylated:unmethylated ratios for each CpG. The entire end-to-end workflow was completed in 2 days, including a full analysis software solution. The panel was evaluated using 2 control gDNA samples. The first had an expected average methylation state across all CpGs of >98% and the second <5%. An equal mixture of these two samples was also tested. The Methylation Panel for Cancer Research performed well on control samples. The single lane Loading, Total Bases, Final Reads, and Raw Read Accuracy were >92%, >1G, >14 Million, and >90% respectively. The workflow was also demonstrated on research FFPE cancer samples. This Methylation Panel protocol offers a 2-day, end-to-end workflow with high resolution, targeted and quantitative methylation analysis from DNA input as low as 10ng into bisulfite conversion. The option to design custom methylation panels for interrogation of targets of interest without the need for whole genome methylation is now available. <For Research Use Only. Not for use in diagnostic procedures. Early access materials were provided by Thermo Fisher Scientific™ to OICR in support of this abstract, but no other financial support. This study was conducted with the support of the Ontario Institute for Cancer Research through funding provided by the Government of Ontario.

#4417 Development of biochemical screening assays to facilitate drug discovery in RNA m6A modification regulators.

S. F. AbdulSalam, S. Oh, B. P. Lee, J. J. Ferry, J. R. Ries, K. Y. Horiuchi;
Reaction Biology Corporation, Malvern, PA

Over the recent years, knowledge of RNA modifications and their regulation has expanded extensively, providing novel insights and strategies to explore potential therapeutics for pathogenesis of various diseases, including cancer. Several chemical modifications in RNA have been identified so far, among these N^6-methyladenosine (m6A) modification is the most abundant and well-studied epitranscriptomic marker found in mRNA and long noncoding RNA. Abnormal m6A expression is proven to be associated with tumorigenesis, cancer stemness and drug resistance of cancers. Methylation in 6-Adenosin of RNA is a dynamic and reversible process tightly regulated by its writer, m6A methyltransferase complex and erasers, FTO and ALKBH5. m6A methyltransferase complex contains METTL3-METTL14-WTAP as core components. METTL3 is the catalytic component, which is activated by heterodimer formation with METTL14. High METTL3 expression is found in several cancers such as breast, lung, liver, gastric, colorectal, AML and a METTL3 catalytic inhibitor is found to delay AML progression in mouse models. Protein that binds RNA m6A modification to execute it signaling are known as m6A readers. Readers are categorized into three main classes, YTH domain proteins, IGF2 mRNA-binding proteins and heterogeneous nuclear ribonucleoproteins. YTH family readers are found to have oncogenic roles in several cancers including AML, breast, lung, CRC and glioblastoma. Recent studies suggest inhibition of m6A binding of individual YTH family proteins is a promising therapeutic strategy however, potent inhibitors are yet to be identified. This poster summarizes current assays we have developed to facilitate cancer therapeutic discovery in m6A related protein targets. We present development and validation of an assay suitable identify in METTL3 catalytic inhibitors using our proprietary hotspot technology. We also show development of HTRF based biochemical assays for all five YTH family protein YTHDF1-3 and YTHDC1-2, to screen for molecules that disrupt protein-m6A interaction. We further study the selectivity of an FDA approved drug Tegaserod, a reported YTHDF1 inhibitor by a structure based virtual screening, between YTH family proteins.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolomics
Poster Session

#4421 Intracellular cytomatrix actin and the Warburg effect.
T. E. Shaiken;
Baylor College of Medicine, Houston, TX

Introduction: The cytoplasm of living cells is dynamic and the motion arising from fluctuating forces in cells is an active process, rather than being thermally induced. Motor proteins could be the primary causative force of intracellular movement. However, which motor protein is involved in the intracellular dynamics, what process requires fluctuational intracellular activity, and where the energy source comes from is unknown. To address the impact of intracellular motion in cellular processes, we chemically separated the viscous fluid (cytosol) and elastic solid (cytomatrix) phases of cytoplasm. The multiomic analysis was used to dissect the compositional differences between the liquid and solid phases. LC-MS/MS-based proteome analysis was used to identify the composition of the HCT-15 colon cancer cell cytomatrix. The mRNA translation was measured by Ribosome footprinting.
Results: Since the kinesis of the solid phase can trigger liquid phase flux, the composition of the cytomatrix was the primary focus of the study of cytoplasmic motion. The systemic analysis of the cytomatrix constituency allowed the identification of a diverse functional group of proteomes that included cytoskeletal and structural elements of organoids, metabolic enzymes, and normal- and proto-oncogenic signaling pathways. The two-phase system elucidated how diverse chemical reactions can occur simultaneously within the cell cytoplasm. Namely, the immobilization of catalytic complexes on the solid cytomatrix physically segregates biochemical reactants, thereby overcoming spatial impediments and allowing diverse metabolic reactions to coincide. Actomyosin and other actin-binding proteins of cytomatrix were the most abundant and diverse proteome, indicating that the primary machinery driving cytomatrix mobility consists of actomyosin, actin-binding, and actin-regulating proteins of cytomatrix. The cytomatrix dynamics trigger the cytosolic motion that carries substrates to immobilized catalytic complexes of the cytomatrix, thereby increasing product output, which appears to be a more intense process in cancer cells due to genetic and epigenetic aberrations. Under normal physiological conditions, mitochondrial respiration can deliver the energy requirements of cytomatrix micromechanics, but in cancer cells, additional energy of ATP is supplied by the aerobic glycolysis known as the Warburg effect to provide the ATP surplus for actomyosin mechanics.
Conclusion: The intracellular motion is supported through non-muscle actomyosin action of the solid phase (cytomatrix), permitting increased glycolytic pathway activity in tumor cells. This novel concept of cancer links the Warburg effect with the bioenergetics of cytomatrix micromechanics and the dynamics of metabolic processes in tumors. Thus, two of the mysteries in cancer cell biology, how chemical reactions occur in the cytoplasm and energy is generated by tumor cells, have now been linked.

#4422 Metabolic adaptations of glioblastoma in hypoxia is mediated by acox-1.

A. Bhattacharya[1], L. Caflisch[1], H. Balinda[1], A. Lodi[2], M. Zhou[1], M. Li[1], J. Chiou[2], R. Pandey[2], G. R. Sareddy[1], S. Tiziani[2], Y. Chen[1], R. K. Vadlamudi[1], A. J. Brenner[1];

[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]The University of Texas at Austin, Austin, TX

Background: Glioblastoma (GBM) is a recurrent, chemoresistant, malignant brain tumor. Hypoxia is a major factor contributing to resistance in GBM which develops due to aggressive tumor growth and chronic anti-angiogenic therapy. Thus, under limited oxygen supply it is unlikely that the high energy consuming pathways are solely able to provide the energy requirement of GBM cells. Thus, based on our metabolomics data stated below we hypothesize that GBM cells adapt to chronic hypoxia utilizing alternate metabolic pathways such as peroxisomal fatty acid oxidation (FAO). Here we have explored the role of Acyl coenzyme A oxidase (ACOX-1), a rate limiting enzyme for peroxisomal FAO in the metabolic adaptations to hypoxia and as a potential drug target.
Methods: U251 CRISPR dox inducible ACOX1 (KO) cells and patient derived primary GBM were grown under normoxic and hypoxic conditions (2%O2, 5%CO_2, 70% humidity). Metabolic analysis was done using UHPLC-MS and LCMS analysis. RNAseq was done using TopHat2 (genome alignment), HTSeq, and DEseq to study the differential gene expression at cut-off of 2-fold change, and $p<0.05$. GSEA was used to interpret biological pathways. NCr/SCID (Severe Combined Immunodeficiency) mice (n=5) inoculated with U251 ACOX1 knockout cells expressing luciferase were used and treated with anti-angiogenic agent pazopanib at 30 mg/kg, 5 days a week. The U251 luciferase-labeled tumors were imaged starting weekly for tumor volumes using the IVIS (In Vivo Imaging System) Lumina.
Results: In patient derived primary GBM cell lines alterations in metabolites in chronic hypoxia compared to normoxia, such as decrease in citric acid cycle metabolites, increase in glycolytic metabolites, and dysfunctional mitochondrial metabolites. In RNA seq downregulation of genes PCK1, SCD, SREBF1, and PIPOX ($p<1x10^{8}$) involved in PPAR and lipid metabolism pathways in hypoxia versus normoxia were noted. Inhibition of ACOX-1 displayed increased survival in mice administered ($p=6.7E-04$) with pazopanib compared to the U251 parental control group.
Conclusion: There is metabolomic reprogramming in ACOX-1 KO cells channeled predominantly through FAO as seen through the downregulation of genes downstream of the PPAR signaling pathway, mediated through SREBF1 the master regulator of lipid metabolism. Thus, these genes could be future targets for therapy in combination with anti-angiogenic therapies that aggravate hypoxia in GBM.

#4423 Cholesterol and arachidonic acid promote the tumor growth of epithelial ovarian cancer via MAPK signaling pathway.

H. Sakaguchi-Mukaida, K. Hiramatsu, M. Kakuda, S. Nakagawa, T. Kimura, Y. Ueda, T. Kimura;
Osaka University, Suita City, Osaka, Japan

Introduction: Previously, we reported that VLDL promoted cell proliferation of epithelial ovarian cancer (EOC) cells in vitro. In vivo, we also confirmed that High-Fat Diet (HFD) strongly promoted the tumor growth of EOC. These results suggest that lipid molecules in HFD might contribute to cell proliferation of EOC cell. In this study, we performed metabolome analysis and analyzed the metabolomic profile of lipid molecules of HFD fed mouse serum. Finally, we demonstrated that some lipid molecules promoted the cell proliferation of EOC cells in vitro and vivo.
Methods: We obtained the serum of HFD and normal diet (ND) fed mouse (non-tumor bearing) and performed metabolome analysis to identify the lipid molecules which associate with cell proliferation. In addition, we demonstrated that the lipid molecules promoted cell proliferation and activated signaling pathway of EOC cells in vitro. Moreover, we evaluated that the lipid molecules-rich diet promoted the tumor growth of EOC in vivo.
Results: The tumor growth of EOC (EOC cell line; KURAMOCHI and RMG-I) was significantly promoted by HFD compared to ND in vivo ($p < 0.05$, respectively). Metabolome analysis using the serum of HFD and ND fed mouse (non-tumor bearing) detected 210 metabolites, and principal component analysis showed obvious different metabolic profiles of HFD fed mouse serum compared to ND. Partial least squares-discriminant analysis revealed cholesterol and arachidonic acid (AA) as the lipid molecules with high VIP score in the serum of HFD fed mouse. In vitro, cholesterol and AA significantly promoted cell proliferation, respectively ($p < 0.05$) through the activation of MAPK signaling pathway. In vivo, we also confirmed that cholesterol and AA-rich feed promoted the tumor growth of EOC, respectively ($p < 0.05$).
Conclusions: Cholesterol and AA significantly promoted the tumor growth of epithelial ovarian cancer through the activation of MAPK signaling pathway.

#4424 Differential metabolic response of triple-negative and estrogen receptor-positive breast cancer cells to abemaciclib, a CDK4/6 inhibitor.

J. Jiang[1], X. Bao[1], Y. Jiang[1], Y. Yue[1], M. Huettemann[2], **J. Li**[1];
[1]Karmanos Cancer Institute, Detroit, MI, [2]Wayne State University, Detroit, MI

Background: Inhibition of the cell cycle kinases CDK4/6 is the standard-of-care for advanced hormone receptor-positive breast cancer. The clinical efficacy of CDK4/6 inhibitors in triple-negative breast cancer remains uncertain. Mechanisms of sensitivity and resistance are not fully understood. This study comprehensively investigated the metabolic response of triple-negative and estrogen receptor-positive breast cancer cells to abemaciclib (Abe), with the aim of providing metabolic insights for resistance mechanisms.
Methods: MCF-7 (MCF) and MDA-MB-231 (MDA) cells were treated with Abe (0, 100, and 500 nM) for 1, 2, or 7 days. Cell cycle and cell senescence analyses were performed to assess drug effects. Cellular metabolism was investigated using the Seahorse assay, LC-MS/MS based targeted metabolomics, and stable isotope-assisted metabolic flux analyses with [U-^{13}C]glutamine, [1,2-^{13}C]glucose, and [U-^{13}C]glucose as the tracers.
Results: Abe induced cell cycle arrest at G0/G1 in both cell lines, more pronounced in MCF. Dose- and time-dependent cell senescence occurred in both treated cell lines, more pronounced in MDA. The Seahorse assay indicated that energy metabolism (assessed by oxygen consumption rate and extracellular acidification rate) was reduced in both treated cell lines. Targeted metabolomics revealed that post Abe treatment, intracellular lactate significantly decreased in both cell lines; intracellular TCA intermediates significantly decreased in MCF while being unchanged in MDA; intracellular deoxynucleotides decreased in both cell lines, to a lesser extent in MDA; cellular energy levels (assessed as the ratios of ATP/AMP, ATP/ADP, CTP/CMP, CTP/CDP) were significantly lower in MCF while remaining unchanged or increased in MDA; intracellular levels of many amino acids significantly increased in MDA while decreasing in MCF. [U-^{13}C]glutamine flux revealed a significant decrease of intracellular glutamine-derived TCA intermediates in both treated cell lines. [1,2-^{13}C]glucose flux indicated an enhanced oxidate pentose phosphate pathway (PPP) activity and increased de novo syntheses of purine nucleotides (ATP and GTP) in treated MDA (but not MCF). [U-^{13}C]glucose flux suggested that while both cell lines responded to Abe with decreased anaerobic glycolysis (pyruvate converting to lactate), MDA (but not MCF) showed an enhanced capability of utilizing glucose-derived carbon to replenish TCA intermediates and increased amino acid synthesis.
Conclusion: Adaptive cellular metabolism, characterized by enhanced utilization of glucose-derived carbon to replenish TCA intermediates and increased PPP activity, thus promoting biosynthesis of amino acids and purine nucleotides to maintain cellular energy and redox balance, may contribute to the intrinsic resistance of triple-negative breast cancer to CDK4/6 inhibitors.

#4425 Metabolic vulnerabilities of dedifferentiated liposarcoma.

J. O. Brett[1], J. Han[2], C. Kim[3], L. P. Kelley[2], S. Han[2], D. Boone[3], J. Crowley[2], S. Joshi[2], C. P. Raut[4], A. Greka[3], M. C. Haigis[2];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Broad Institute of MIT and Harvard, Cambridge, MA, [4]Brigham and Women's Hospital, Boston, MA

Dedifferentiated liposarcoma (DDLPS) is a rare, life-threatening malignancy in the family of adipocytic sarcomas. DDLPS, which usually arises in the retroperitoneum of middle-aged adults, has a poor prognosis. This is due to the propensity of DDLPS to metastasize and recur locally, combined with a dearth of effective systemic therapies. A longstanding curiosity is that DDLPS has non-lipogenic morphology and no lipid droplets, while its less aggressive sister sarcoma, well-differentiated liposarcoma (WDLPS), resembles benign adipose tissue and contains large lipid droplets. How DDLPS metabolizes lipids and the metabolic vulnerabilities of DDLPS in patients, which may form new therapeutic targets, are unknown. In our project, we investigate the metabolism of DDLPS versus WDLPS using patient samples and cell lines. Snap-frozen tissues from patients were obtained from the Dana-Farber/Harvard Cancer Center specimen bank of DDLPS and WDLPS. We performed metabolomics and lipidomics on these samples. We complemented these results with publicly available transcriptional profiles of separate cohorts of DDLPS, WDLPS, and other cancers. In vitro, we made use of a panel of multiple DDLPS-derived cell lines, WDLPS-derived cells, benign preadipocytes, and benign adipocytes. We measured mitochondrial function and the cellular effects of perturbing various metabolites in screens in culture. Overall, our initial results indicate strong alterations in mitochondrial metabolism in DDLPS in patients. In culture, DDLPS is susceptible to multiple metabolic perturbations related to mitochondrial dysfunction. These metabolic vulnerabilities of DDLPS provide potential therapeutic opportunities. Work is ongoing to optimize the targeting of these vulnerabilities in vivo, elucidate the molecular roles of specific metabolites, and complete a blueprint of DDLPS metabolic weaknesses in patients.

#4426 Targeting MCT1 and PFKFB3 provokes synthetic lethality in small cell lung cancer.

A. H. Prabhu[1], K. Scott[1], P. Stewart[1], D. Grass[1], M. Fernandez[1], D. Ercan[1], J. Koomen[1], T. Bannister[2], C. Rudin[3], G. DeNicola[1], E. Haura[1], J. Cleveland[1]; [1]Moffitt Cancer Center, Tampa, FL, [2]The Herbert Wertheim UF Scripps Institute, Jupiter, FL, [3]Memorial Sloan Kettering Cancer Center, New York, NY

Small cell lung cancer (SCLC) is the third most common lung cancer and is extremely aggressive and highly metastatic. SCLC responds to radiation and standard platinum-based chemotherapy, yet this is invariably followed by relapse and the rapid emergence of lethal chemoresistant disease. Hence, SCLC has been declared a recalcitrant malignancy by NCI, and there is an urgent need to identify new and actionable therapeutic vulnerabilities. Unbiased metabolomic and shotgun and activity-based proteomic analyses of NSCLC and SCLC patient derived tumor tissues, PDX and a panel of cell lines revealed marked upregulation of glycolytic and nucleotide metabolic pathways in SCLC. Further, unbiased screens with metabolic inhibitors revealed selective sensitivity of SCLC cells to the MCT1 lactate transporter inhibitor SR13800 and to the PFKFB3 inhibitor PFK15, and that combined treatment provokes rapid apoptosis. Metabolic, flux and molecular analyses revealed that MCT1 inhibition (MCT1i) or loss in SCLC cells impairs glycolysis and triggers rapid increases in intracellular lactate that then diminish, and this is driven by the induction of lactate dehydrogenase-B (LDH-B) that oxidizes lactate into pyruvate. This is accompanied by a marked shift in the $NAD^{\pm}$ to NADH ratio towards NADH, and increased pyruvate dehydrogenase (PDH) activity and OXPHOS. Further, MCT1 inhibition provoked increases in the Aspartate-Malate and DHAP-SnG3P shuttles, which restored the NAD^{+}/NADH balance in the cytosol. In contrast, treatment of SCLC cells with PFKFB3 inhibitors (PFKFB3i) leads to inhibition of PDH activity, a collapse in OXPHOS and increases in lactate efflux that are due to flux of glucose through pentose phosphate pathway and re-entry into glycolysis via 3-phosphoglygerate (3-PGA). Combined MCT1/PFKFB3 inhibition amplifies metabolic alterations provoked by both MCT1i and PFKFB3i, triggering a collapse in both glycolysis and OXPHOS. Similarly, inhibition or silencing of enzymes that drive the Aspartate-Malate and DHAP-SnG3P shuttles, or inhibition of the mitochondrial pyruvate transporter, provoked metabolic collapse and cell death following inhibition or loss of MCT1. Finally, SCLC xenografts and primary SCLC CDX treated with a combination of SR13800 and PFK15 showed improved survival compared to vehicle or monotherapy treatments. Thus, co-targeting adaptive metabolic circuits provoked by inhibition of MCT1 and PFKFB3 provokes synthetic lethality in SCLC, supporting the notion that inhibition of these metabolic chokepoints will be an effective strategy for treatment of this lethal malignancy.

#4427 Do changes in lipid metabolism link obesity to pancreatic cancer?.

R. Ghosh, D. Ajit, J. Woodworth, D. Fritze, F. G. Cigarroa, G. A. Halff, **A. P. Kumar**;
UT Health Science Center at San Antonio, San Antonio, TX

The near equal incidence and mortality rates of pancreatic cancer, combined with projections that pancreatic cancer will become the second-most common cancer-related deaths by 2050, underscore the need to identify patients with early disease and interrupt this trajectory. Obesity, weight gain and waistline have been implicated in increasing the risk of pancreatic cancer. Although metabolomic analyses of pancreatic cancer patients have established correlations between phospholipids, lysophospholipids with treatment outcomes, the association between metabolites, obesity, and pancreatic cancer remains largely understudied. The objective of this pilot study was to determine differences in serum metabolites in obese and overweight pancreatic cancer patients compared with healthy non-obese subjects. Our long-term goal is to develop serum marker(s) that may be used to prevent advanced pancreatic cancer and thus improve outcomes for these patients. Serum was obtained from healthy subjects (n=11; BMI range from 18-25), overweight (n=9; 25-30) and obese (n=7; >30) pancreatic cancer patients from an IRB approved study. Males (n=12) and females (n=15) were represented in the study. Global metabolic profiles were determined using Ultrahigh performance liquid chromatography-tandem mass spectroscopy. Raw data was extracted, peaks were identified and processed at Metabolon using the Laboratory Information Management System. Comparison between overweight pancreatic cancer patients and healthy controls identified 403 biochemicals (111 upregulated and 292 downregulated; $p < 0.05$) and 93 biochemicals (40 upregulated and 53 downregulated; $0.05<p<0.10$). Comparison of the differences in biochemicals between obese pancreatic cancer patients and healthy controls showed changes in 293 biochemicals (71 upregulated and 222 downregulated; $p <0.05$) and 123 biochemical changes at $0.05<p<0.10$ (42 increased and 81 decreased). 38 ($p <0.05$) and 47 ($0.05<p<0.10$) differential levels of biochemicals were identified when obese and overweight pancreatic cancer patients were compared. Random forest analysis showed that the 30 top ranking biochemicals were involved in lipid metabolism, amino acid metabolism, nucleotide metabolism, peptide, xenobiotics, and carbohydrate metabolism. These data suggest an association between changes in lipid metabolism may be another link between obesity and pancreatic cancer. This project was funded in part by VA-Merit Award (I01 BX003876).

#4428 Integrated multi-omics analysis reveals systemic and localized metabolic disruptions in colorectal cancer.

G. Patti[1], E. Stancliffe[2], A. Richardson[2], A. Mehta[2], M. Gandhi[2], K. Cho[1];
[1]Washington University in St. Louis, St. Louis, MO, [2]Panome Bio, St. Louis, MO

Despite technological advances in molecular medicine over the last 30 years, no single approach has proven to be sufficient to meet the diagnostic needs in cancer care. Here we use a multiomic approach leveraging proteomic, metabolomic, and transcriptomic technologies to study the metabolic shifts that occur during colorectal cancer (CRC) progression. Our integrated analysis identified systemic changes to beta oxidation pathways and localized changes to tyrosine metabolism within the tumor, creating a mechanistic, actionable description of the core CRC metabolic program. We conducted untargeted proteomics and metabolomics profiling on serum samples from CRC patients (n=10) and healthy controls (n=10). Our serum proteomics data is generated through sample enrichment on the Seer Proteograph system followed by LC/MS analysis with the Thermo Orbitrap Astral. Our metabolomics approach employs LC/MS assays for unbiased profiling of the serum metabolome, exposome, and lipidome. We supplemented this discovery work with both targeted serum and tumor-specific approaches including targeted proteomics to quantify select targets, inflammatory profiling with Alamar proteomics, public transcriptomics data from TCGA, and in vitro metabolic flux data. These large and diverse datasets were then integrated through joint pathway analysis and network integration. The global serum proteomics and metabolomics profiles generated show distinct separation between healthy and diseased individuals. Joint pathway analysis of these discovery datasets highlighted enrichment in beta oxidation pathways and tyrosine metabolism, among others. Interestingly, the Alamar inflammatory panel revealed that many of the analytes in the tyrosine metabolism pathway were well correlated with inflammatory status, while the beta oxidation signature had a lower correlation. To determine the relationship of these systemic findings from serum to tumor metabolism itself, we integrated tumor-specific transcriptomics data and found alterations to tyrosine metabolism with differences in tyrosine aminotransferase expression. The beta oxidation related genes, on the other hand, were not concordant with the serum findings. However, our in vitro metabolic flux studies have shown beta oxidation in CRC cells is upregulated to provide additional fuel for oxidative phosphorylation. This result suggests that beta oxidation may not be transcriptionally regulated in the tumor but rather a consequence of organismal metabolic rewiring. The results of this work, which is currently expanding into a larger and more diverse patient population, underscores the power of multiomic profiling for enhancing our understanding of metabolic dysregulation in CRC. Ultimately, a comprehensive model of the molecular alterations in CRC will yield a better understanding of tumor phenotypes and inform better diagnostics and therapies.

#4429 Plasma metabolic profiles in association with subsequent risk of colorectal cancer in the UK Biobank cohort.

F. Yuan, G. Jia, W. Wen, W. Zheng;
Vanderbilt University Medical Center, Nashville, TN

Background: Dysregulation of metabolic processes contributes to colorectal cancer (CRC) etiology. We aimed to comprehensively evaluate the prospective associations between pre-diagnostic metabolic biomarkers and CRC risk in 230,420 UK Biobank participants.
Methods: A total of 249 metabolic biomarkers were measured by nuclear magnetic resonance spectroscopy from baseline plasma samples. Cox proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations of metabolic biomarkers with CRC risk after adjusting for potential confounders. Subgroup analyses were performed by sex and CRC subsites (i.e., proximal colon, distal colon, rectum). We also conducted factor analyses to identify latent factors and examined their associations with CRC risk.
Results: During a median follow-up time of 9.7 years, 2,410 incident primary CRC cases were identified after excluding participants diagnosed with CRC within two years after blood collection. After correcting for multiple testing, 50 metabolic biomarkers, including lipids and lipoproteins, fatty acids, ketone bodies, and inflammation, were significantly associated with incident CRC risk. No statistically significant differences were observed for the biomarker-CRC associations by sex and CRC subsite. In the sensitivity analysis, excluding cholesterol-lowering medication users did not alter the main findings. In factor analyses, we identified a significant association of CRC risk (HR = 1.08; 95% CI = 1.04-1.13; *P*-value = 6.89×10^{-5}) with a metabolite pattern which was positively correlated with triglycerides and inversely correlated with relative concentrations of omega-6 fatty acids and polyunsaturated fatty acids.
Conclusion: We identified multiple metabolic biomarkers and a metabolite pattern associated with CRC risk in a large prospective cohort. These findings suggest lipid metabolism may contribute to carcinogenesis of the colorectum.

#4430 Metabolic reprogramming by ASPSCR1::TFE3 and VCP.

R. Patel[1], A. Pozner[1], K. Dunlap[2], L. Carroll[1], J. Brown[1], G. Ducker[2], K. Jones[1];
[1]Huntsman Cancer Institute, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT

Alveolar soft part sarcoma (ASPS) is a lethal soft tissue malignancy typically incident among adolescents and young adults, distinguished by the t(X;17) ASPSCR1::TFE3 fusion gene (AT3). Conventional chemotherapy has shown limited efficacy against ASPS, necessitating exploration of alternative strategies. Previous investigations have shown the pivotal role of the fusion gene in sarcomagenesis in mice, particularly in lactate-rich environments. This study aims to elucidate the metabolic alterations actuated by the AT3 fusion gene, both in vitro and in vivo. To model in vitro metabolic profiles, ASPS (ASPS-1) and renal cell carcinoma (FU-UR1) cell lines, each expressing AT3, were employed. Utilizing siRNA-mediated gene silencing, AT3 and VCP, a cofactor, were targeted in vitro. Metabolomic profiling through GC-MS analyzed the impact of depletion of AT3 or its transcriptional co-factor, VCP. C13-labeled metabolites were introduced and traced in vitro and in vivo to enhance comprehension of carbon utilization in aerobic respiration. While metabolic activity and O2 consumption differed between cell lines, inhibition of AT3 and VCP led to similar metabolite alterations. Significant changes in amino acid metabolism, notably glutamate, aspartate, and alanine were observed in both cell lines. There was notable diversion of glucose carbon utilization away from typical entry into the tricarboxylic acid (TCA) cycle, with minimal carbon incorporation beyond alpha-ketoglutarate. Despite prior data indicating heightened mitophagy activity in AT3 driven cells, inhibition of lysosomal activity did not yield significant changes in cellular respiration or O2 consumption.

#4431 Steroid hormone metabolites and mammographic breast density in premenopausal women.

K. A. Matthew[1], G. K. Vanapali[1], K. R. Getz[1], M. S. Jeon[1], C. Luo[1], X. Guo[2], J. Luo[1], **A. T. Toriola[1]**;
[1]Washington University School of Medicine in St. Louis, St. Louis,, MO, [2]Vanderbilt Epidemiology Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, TN

Background: Steroid hormones influence breast tissue development and play a role in breast carcinogenesis. Their associations with mammographic breast density (MBD), an established risk factor for breast cancer, are less clear. We, therefore, investigated the associations of steroid hormone metabolites with MBD in premenopausal women.
Methods: Our study population consists of 705 premenopausal women recruited during their annual screening mammogram at the Washington University School of Medicine, St. Louis, MO. We assessed volumetric percent density (VPD), dense volume (DV), and non-dense volume (NDV) using Volpara. We assayed 54 steroid hormone metabolites from fasting blood samples at Metabolon. Linear regression models were used, after adjusting for covariates, to estimate the least square means of VPD, DV, and NDV across tertiles (T) of each metabolite. Sensitivity analysis was performed among the subset of participants with a history of oral contraceptive use (OCP). We used the Benjamini-Hochberg procedure to correct for multiple tests to control the false discovery rate (FDR) at a 5% level.
Results: Five androgen metabolites (androstenediol (3beta,17beta) monosulfate 2, androstenediol (3beta,17beta) disulfate 1, 5alpha-androstan-3alpha,17beta-diol monosulfate 2, 5alpha-androstan-3alpha,17beta-diol disulfate, and 5alpha-androstan-3beta,17beta-diol disulfate) and two corticosteroid metabolites (tetrahydrocortisone glucuronide 5, and cortolone glucuronide 1) were inversely associated with VPD. Androstenediol (3beta,17beta) disulfate 1, and 5alpha-androstan-3alpha,17beta-diol disulfate displayed the strongest associations with VPD. The mean VPD decreased across tertiles of androstenediol (3beta,17beta) disulfate 1 from 9.0% in T1 to 8.5% in T2, and 7.5% in T3 (FDR p-value=0.02). Similarly, the mean VPD decreased from 8.8% in T1 to 8.4% in T2, and 7.6% in T3 of 5alpha-androstan-3alpha,17beta-diol disulfate (FDR p-value=0.03). Progestin steroid metabolites appeared to be positively associated with VPD but only 5alpha-pregnan-3beta,20alpha-diol monosulfate 2 was marginally significant after FDR correction (7.5% in T1, 8.3% in T2, and 8.8% in T3; FDR p-value=0.06). Four metabolites (three corticosteroids and one androgenic steroid) were positively associated with NDV. No metabolite was associated with DV. In sensitivity analysis limited to OCP users, mean VPDs were lower but the directions of associations were similar to those observed in the overall analysis.
Conclusion: We report novel associations of corticosteroids and androgen metabolites with breast density in premenopausal women. Our findings shed important new insights into hormonal biomarkers and MBD.

#4432 Molecular biomarkers of non-Hodgkin lymphomas and subtypes identified by mass spectrometry-based metabolomics.

F. Choueiry, S. Singh, L. Sehgal, **J. Zhu**;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Non-Hodgkin lymphomas (NHLs) constitute a diverse collection of lymphoid neoplasms, each characterized by distinct biological features. Approximately 90% of all lymphomas in the United States stem from B lymphocytes, with the remainder originating from T cells. The therapeutic approach for NHLs hinges on the neoplastic histology and the tumor stage, guiding the determination of whether radiotherapy, chemotherapy, or a combination thereof represents the most effective treatment strategy. Following an indolent phase, 50% of patients experience disease transformation into an aggressive form of lymphoma, leading to rapid deterioration and patient demise. While extensive efforts have been directed towards understanding the genetics of transformation, the contribution of altered tumor metabolism, induced by these genetic lesions, to disease aggressiveness remains unclear. Therefore, there exists an urgent need to better understand the metabolic changes during lymphoma transformation and treatment. Given the metabolic adaptations supporting bioenergetics, biosynthesis, and redox in malignant cells, here in this study we aimed to identify unique metabolic signatures in prominent lymphoma subsets—diffuse large B-cell (DLBCL), mantle cell (MCL), and follicular lymphomas (FL). Employing unbiased mass spectrometry-based metabolomics, we screened sera samples from n=30 patients with lymphoma and n=25 aged and BMI-matched healthy controls for molecular biomarkers that may be indicative of the subtypes. Principal component analysis revealed distinct clustering of the disease and control groups, indicating unique metabolic profiles induced by lymphoma presence. A total of 36 metabolites, including adenine, trans-aconitic acid, and citric acid, were significantly deregulated between groups (FC > 2, FDR $p < 0.05$). Functionally, enriched pathways included tryptophan metabolism and the tricarboxylic cycle (FDR $p < 0.05$), supporting our previous findings that lymphomas rely on oxidative phosphorylation for sustained proliferation. Comparing metabolic profiles of different lymphomas subtypes demonstrated unique clustering, emphasizing the distinct metabolic flexibility of each malignancy. Interestingly, cystine was the primary metabolite driving separation of the groups in our partial least squares discriminant analysis (PLS-DA), with DLBCLs demonstrating the highest abundance of this amino acid. In summary, our research uncovered that there are distinctive metabolic shifts resulting from the transformation of lymphomas. The findings stemming from our unbiased metabolic screening enables a better understanding of the complex metabolic intricacies in lymphomas and paves the way for prominent biomarker detection for improved patient outcomes.

#4433 Secondary electrospray ionization mass spectrometry for volatile analysis of lung cancer.

J. Zhu, F. Choueiry;
The Ohio State University Wexner Medical Ctr., Columbus, OH

Lung cancer remains a leading cause of cancer-related mortality globally, necessitating innovative approaches for early detection and improved understanding of its metabolic landscape and consequences. Secondary Electrospray Ionization Mass Spectrometry (SESI-MS), an innovative analytical technique, has emerged as a powerful tool for the analysis of volatile organic compounds (VOCs) associated with various diseases, from metabolic disorders to bacterial infections. In this proof-of-concept study, we first utilized SESI-MS analyses of four representative lung cancer cells of both non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC) to demonstrate its capability to profile VOCs released by lung cancer cells. The technique allows for real-time, non-invasive analysis of the headspace above cultured cells, enabling the detection of unique VOC signatures associated with different lung cancer subtypes. Meanwhile, SESI-MS also facilitated the discrimination specific cells based on distinct VOC patterns. Furthermore, we also performed cisplatin treatment experiments and observed the metabolic signature shift post drug treatment. These results collectively offered potential applications in early diagnosis and personalized treatment strategies. Next, we continued with in vivo investigations to further extend the utility of SESI-MS in lung cancer research. Animal models, mimicking human lung cancer pathophysiology, have been subjected to SESI-MS analysis to identify volatile biomarkers indicative of tumor development and progression. Several representative cancer drug treatments were performed to the lung cancer mice model, and the drug-induced responses were also monitored via SESI-MS breath analyses. The in vivo SESI-MS approach detected many interesting breath VOC features that could provide valuable insights into the dynamic changes in VOC profiles during various stages of lung cancer, and therefore has the potential to offer a deeper understanding of the disease's metabolic alterations and potential avenues for targeted therapeutic interventions. In conclusion, SESI-MS-based volatile analysis presents a robust and versatile approach for investigating lung cancer, and our ongoing work has the potential to bridge the gap between in vitro and in vivo models for better translational research outcomes. The detection of unique VOC signatures associated with lung cancer cells and tumors holds significant promise for early detection, subtype classification, and monitoring of treatment responses. As technology continues to advance, SESI-MS stands poised to play a pivotal role in transforming the landscape of lung cancer diagnostics and research.

#4434 Cancer cell-derived adrenomedullin downregulates Zeb1 in adipocytes to induce adipolysis and promote breast cancer progression.

L. Cao, X. Chen, Y. Shi, S. Yang;
Nankai University, Tianjin, China

Background: Once breast carcinoma in situ breaks through the basement membrane, it preferentially invades the lipid-rich microenvironment around the mammary gland, which indicates a poor prognosis. However, the detailed mechanisms of this interaction remain elusive. Here, we describe bidirectional communication between breast cancer cells and cancer-associated adipocytes (CAAs). Different from the common hormone-driven mechanism of lipolysis of adipocytes, we found that CAAs perform a unique lipolysis program, and Zeb1 plays an important role in this lipolysis process.

Methods: Fabp4-cre;Zeb1$^{-/-}$ as adipose tissue-specific Zeb1 gene knockout homozygous mice and Fabp4-cre;Zeb1 tg as adipose tissue-specific Zeb1 gene overexpression mice were constructed to study mammary gland development and perform orthotopic tumor transplantation experiments. Tetracycline-induced Zeb1-overexpressing stable cells were constructed from mouse preadipocytes 3T3-L1 to study phenotypes of lipolysis. Single-cell sequencing, targeted lipidomics, and RNA sequencing analysis were used to investigate the interaction between cancer cells and adipocytes. Western blotting and immunohistochemical staining assays were used to detect the expression Zeb1 at the cellular level, in mouse models and in patient tissue samples.

Results: Our results indicated that breast cancer cell-derived adrenomedullin (ADM) significantly down-regulates Zeb1 expression in adipocytes, which drives downstream gene expression of Pnpla2/HSL/SCD1 and induces adipocyte lipolysis into CAA, a process that results in the release of excess palmitoleic acid. Consequently, we proved that palmitoleic acid could replace arachidonic acid (ARA) in the phospholipid sn-2 position of breast cell membrane, which enhances the fluidity and invasiveness of cancer cells. In addition, overexpression of Zeb1 in adipocytes reduces the ability of cancer cells to induce adipolysis and inhibits the malignant progression of cancer cells.

Conclusion: These results indicate that Zeb1 plays a pivotal role as core transcriptional factor in CAA lipolysis. The interaction between breast cancer cells and adipocytes leads to the reprogramming of metabolism within their tumor microenvironment, which may become a new target for breast cancer treatment.

#4435 Taurine metabolism as a marker for pancreatic cancer.

H. Nam[1], W. Lee[2], H. T. Nguyen[1], L. X. Mai[1], S. Kim[2], S. Park[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of

Pancreatic ductal adenocarcinoma (PDAC), known for its aggressive nature and poor prognosis, presents a significantly altered metabolic landscape compared to normal pancreatic tissue, a feature that has been the focus of recent research but remains underexplored in actual pancreatic tissues. In this study, we undertook an untargeted metabolomics analysis to compare the metabolic profiles of PDAC with matched normal tissues, revealing a notable elevation in taurine levels in PDAC. This increase was further validated through immunohistochemistry in separate PDAC and normal tissue samples. To delve deeper, we conducted a comprehensive bioinformatics analysis, integrating transcriptomic and proteomic data, which identified the taurine metabolism pathway as significantly altered, with *ADO* emerging as a pivotal gene in this process. Further investigations, including gene modulation and xenograft models, demonstrated that *ADO* knockdown curtails cancer cell proliferation and tumor growth, potentially impacting the Raf-MEK-ERK signaling pathway. Clinically, the ADO-Taurine axis was found to have substantial prognostic significance, correlating with recurrence rates and survival in PDAC patients. These insights collectively suggest that the ADO-Taurine axis, through its modulation of taurine metabolism, presents as a promising biomarker for PDAC prognosis and a potential avenue for therapeutic development.

#4436 Phenotypic heterogeneity in pancreatic ductal adenocarcinoma revealed by single-cell lipidomics.

M. Trajkovic-Arsic[1], J. Delafiori[2], M. Shahraz[2], C. Munch[3], S. Lueong[3], S. Liffers[3], D. Hellerschmied[4], T. Alexandrov[2], **J. T. Siveke**[1];

[1]German Cancer Consortium (DKTK), partner site Essen/Dusseldorf, a partnership between DKFZ and University Hospital Essen, Essen, Germany, Essen, Germany, [2]European Molecular Biology Laboratory - EMBL, Metabolomics Core Facility, Heidelberg, Germany, Heidelberg, Germany, [3]University Hospital Essen, Bridge Institute of Experimental Tumor Therapy- West German Cancer Center, University of Duisburg-Essen, Essen, Germany, Essen, Germany, [4]Faculty of Biology, Center of Medical Biotechnology, University Duisburg-Essen, Essen, Germany, Essen, Germany

Introduction: The high chemoresistance of pancreatic ductal adenocarcinoma (PDAC) is partly attributed to the phenotypic plasticity and high adaptability of PDAC cells to the challenges of the harsh microenviroment. Phenotypic presentation of the PDAC cell is also determined by the lipid composition of the plasma membrane and lipid species that organize the rigid or more flexible lipid bilayer and determine the cellular mobility and plasticity. Lipids are also important energy and signaling molecules that contribute to the aggressiveness of the cell. Here we focus on differences in lipid profile of PDAC cells in epithelial and mesenchymal cell state using single-cell lipidomics approach (SpaceM).

Methods: Lipid profile of 2D cultures of eight conventional and ten primary patient derived cell lines of different source (patient derived xenograft, ascites, primary tumor, organoid derived) was investigated. Epithelial (E) or mesenchymal (M) cell state was evaluated by gene and protein expression of EMT markers. Matrix-Assisted Laser Desorption/Ionization (MALDI)-imaging MS was used for data acquisition on positive ion mode at 25 µm step size and m/z range of 600-1000. For annotating lipids in MALDI-imaging data, we used the METASPACE cloud software. For constructing single-cell lipidomic profiles we used the SpaceM method. In total, around 150.000 cells were analyzed and 1400 lipid ions detected.

Results: Gene expression analysis suggested prominent metabolism of structural lipids in the conventional epithelial cells. In UMAP analysis of single cell lipidomics data, each cell line, conventional and primary, presented a unique lipid fingerprint with however prominent clustering into the two phenotypes, epithelial and mesenchymal. We detected enrichment of alkyl-acyl phosphatidylcholines, alkyl-acyl phospatidylethanolamines, ceramides and sphingolipids in the epithelial phenotype. Mesenchymal phenotype was enriched for lipids involved in lateral diffusion and low bilayer thickness supporting the increased fluidity of the mesenchymal cell membrane. Furthermore, mesenchymal phenotype was enriched for lipid droplets and energy storing triacylglycerols, also confirmed by histological lipid droplet staining.

Conclusions: Using the single cell lipid information, a successful grouping to epithelial or mesenchymal subtype could be performed regardless of sample source, suggesting a conserved lipid profile typical for the two states. Further detailed investigation of single cell lipidomics data aims to unveil the prominent epithelial-mesenchymal state lipid markers and open a niche for functional investigations of cell-state specific markers and potential cell-state targeting.

#4437 Dysregulated lipid metabolism and high-fat diet influences prostate cancer (PCa) progression.

Saurav Subedi[1], Federico La Manna[1], Katja Ovchinnikova[1], **Wanli Cheng**[1], Eugenio Zoni[1], Nicola Zamboni[2], Bahtiyar Yilmaz[3], George N. Thalmann[4], Marianna Kruithof-de Julio[1]

[1]Department for BioMedical Research, Urology Research Laboratory, University of Bern, Bern, Switzerland,[2]Institute of Molecular Systems Biology, ETH Zurich, Zurich, Switzerland,[3]Department of BioMedical Research, Systems biomedicine of cellular development, University of Bern, Bern, Switzerland,[4]Department of Urology, Inselspital, Bern, Switzerland

Dysregulation of lipid metabolism is observed during the development and progression of various types of cancer including prostate cancer (PCa). Systemic metabolic changes driven by genetic alterations in conjunction with obesity and a high-fat diet have been demonstrated to induce PCa progression. In this study, we aimed to investigate the impact of high- and low-fat diets on the progression and morbidity of prostate cancer, utilizing inducible genetically engineered mouse models (GEMMs) that mimic different grades of prostate cancer. The mice were initially placed on a standard diet until week 6, after which they were randomly assigned to either a low-fat or high-fat diet. At week 8, the Cre recombinase enzyme was activated to induce the desired phenotype in the GEMMs, effectively mimicking the initiation and progression of prostate cancer. The experimental design allowed us to gain insights into the interplay between dysregulated lipid metabolism, diet, and the pathogenesis of prostate cancer. Two groups of mice were taken for the study, with one group being fed a low-fat diet and the other group being fed a high-fat diet. The mice were maintained on their respective diets for a period of 1, 3, and 5 months. At each endpoint, tissue samples were collected. Samples were taken from the prostate, plasma, and liver tissues. These samples were then subjected to various analyses to investigate the changes occurring at the molecular and cellular level. Blood was collected to determine lipidomic content in response to high and low-fat diet and the relation of tumour progression. Finally, faecal samples were collected throughout the duration of the experiment to perform metagenomic studies. The consumption of a high-fat diet significantly increased the body weight of the mice which corresponded to increased liver weight. Furthermore, we identified that the consumption of a high-fat diet significantly correlated with an increase in prostate weight at 3 and 5 months after initiation. Preliminary metabolomic analysis of the plasma revealed a distinct clustering of samples based on the consumed diet. Metagenomic analyses conducted at 1 and 3 months indicated a visible shift in the composition and diversity of gut microbiota in mice fed either a high- or low-fat diet. In conclusion, our study will shed light on the influence of dietary factors on prostate cancer development, providing valuable information for the development of targeted therapeutic strategies to combat this disease.

#4438 Time restricted eating improves antitumor immune responses via modulation of insulin-like growth factor 1 in patients with head and neck cancer.

M. Eysha[1], C. A. Galindo[1], J. Muzaffar[2], J. Mine[1], R. Chauriogonzalez[1], M. Baig[3], L. Lopez-bailon[1], M. Alhomsi[1], M. Hathout[3], J. Wang[1], W. Zhang[1], D. Rizvi[1], A. Huang[1], K. Lee[1], D. Kye[1], A. Sen[1], J. Conejo-Garcia[1], S. Bari[2];

[1]Duke University School of Medicine, Durham, NC, [2]Duke Cancer Institute, Durham, NC, [3]Duke University shcool of medicine, Durham, NC

Background- Treatment of metastatic head and neck cancer remains an area of unmet need with median survival less than a year. We tested the efficacy of a novel circadian aligned fasting intervention called “time restricted eating” (TRE), to improve ICB response in tumor bearing head and neck syngeneic mice models (MOC1), and showed significant reduction in tumor growth, which we then recapitulated in a pilot, open labeled, interventional clinical trial in 30 metastatic head and neck cancer patients. We noted significant improvement in median progression free survival (5 months vs not reached (NR), HR-0.2, p-0.0008) and overall survival (8 months vs NR, HR-0.00000045) in patients observing TRE vs those who did not. The favorable effect of TRE was mediated via modulation of gut microbiome, microbial tryptophan metabolome, and insulin signalling, specifically reduction in circulating insulin-like growth factor 1 (IGF1). We hypothesized that IGF1 mediates ICB resistance via protecting tumor cells from cytotoxic T cell activity.

Methods- We performed in vitro luciferase cytotoxicity assays using HLA-A2^{+}NY-ESO^{+} squamous cell cancer 4 (SCC-4) human cancer cells as targets, and HLA-A2-restricted NY-ESO-1-specific T cell receptor (TCR) -transduced T cells. We co-cultured the tumor cells and the T cells for 24 hours under different conditions of IGF-1 concentration (100 ng, 50 ng, and 10 ng) and T cell-to-tumor cell ratio (1:5, 1:10, and 1:20). We also treated the tumor cells with IGF-1 alone to assess its direct cytotoxic effect.

Results We observed that IGF-1 impaired the ability of the T cells to kill the tumor cells in a dose-dependent manner, while IGF-1 had no cytotoxic effect on the tumor cells in the absence of T cells.

Conclusion- While the role of IGF1 in treatment resistance has been described, its role and mechanism in antitumor immune response is largely unknown. We, for the first time demonstrate the role of IGF1 in impairing T cell mediated antitumor activity in a dose dependent fashion, thus contributing to ICB resistance. Further work will help us develop alternative strategies to modulate IGF1 and improve ICB resistance, in patients who are unable to tolerate TRE.

#4439 Decoding the metabolic symphony TP53 mutation-driven rewiring of cellular metabolism in non-small cell lung carcinoma.

J. Khan, Sr., A. Rehman, Sr., A. Mathur, Sr., Naveen Kumar Bhatrajuc, Anannya Tulid, Divya Rajput, Mohammad Askandar Iqbal, D. Saluja, Sr.;
University Of Delhi (North Campus), New Delhi, India

TP53 is a critical regulator of major metabolic pathways. Metabolic reprogramming is one of the "hallmarks of cancer" and drives tumorigenesis. Frequent p53mutations not only eradicate tumour suppressor capacities but also confer various activities that impact the alteration of metabolic pathways now regarded as central for tumour development and progression. We selected three hotspot mutants (R175H, R273H and R249S) and wtp53 to evaluate the effects in the human non-small cell lung carcinoma cell line (NCI-H1299). Differential expressions of p53 mutants were observed in normal and glucose/glutamine starvation. However, WTp53 expression was not found to be affected. Under both the glucose and glutamine starvation, inhibition of the cell growth and migratory potential of mutant cells was observed which was more prominent in glutamine starvation. Basal respiration and ATP production in $p53^{-/-}$ R273H and R249S significantly increased under glucose starvation. However, Non-mitochondrial oxygen consumption and maximal respiration were found to be decreased in all the cell lines. Importantly, the cells harbouring mutation R175H increase the glycolysis and TCA cycle. The metabolic intermediates of the urea cycle were found to be increased by nearly fourfold in R273H cells. Indicating increased utilization of the urea cycle instead of the TCA cycle, which has been known to be fueled by glutamine for anaplerosis. This study demonstrates that mutp53 influences several metabolic processes and has an influence on cancer cell aggression under starvation of main carbon sources (Glucose and Glutamine). In starved conditions, cells with p53 mutations enhance mitochondrial activity and use alternative pathways in non-small cell lung cancer cells. This might provide a foundation for the development of more effective targeted therapeutics/pharmacological approaches toward variants of mutant p53.

#4440 Topographical investigation of metabolites in excised squares (TIMES^2): Comprehensive cross-sectional metabolite quantification of pancreatic cancer *in vivo*.

P. Yu[1], R. Banh[1], A. Sohn[1], S. Martis[2], D. Biancur[1], K. Yamamoto[1], E. Lin[1], A. Kimmelman[1];

[1]NYU Grossman School of Medicine, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Pancreatic cancer is a lethal malignancy characterized by complex intratumoral metabolic reprogramming and intercellular nutrient sharing between cells in the tumor microenvironment (TME) that promote pancreatic cancer progression. However, this crosstalk, as well as regional variation in perfusion and oxygenation, can lead to metabolic heterogeneity that has not been appreciated by metabolomics of whole tumors. Here we quantify amino acids and tricarboxylic acid cycle (TCA) intermediates using a novel methodology that allows us to portray global tumor metabolite heterogeneity in a tumor.

Methods: Human PaTu-8902 or murine HY19636 (from female KPC mice LSL-KrasG12D; p53 L/+, Ptf1a-Cre+) pancreatic cancer cell lines were orthotopically injected into pancreata of NCr nude mice (n=3) or C57BL/6 mice (n=2). Mice were euthanized after 3-5 weeks and tumors were harvested. Tumor slices were further sectioned into 1mm x 1mm x 1mm cubes using a custom-made multisectional slicing device and each cube location was recorded. Each cube was extracted using methanol, water, and chloroform with labelled amino acid standards, derivitized, and resolved using gas chromatography-mass spectrometry (DB-35MS column with Agilent 7890B gas chromatograph coupled to a single quadrupole 5977B mass spectrometer). 22 metabolites (15 amino acids, 5 TCA intermediates, lactate, and pyruvate) were identified by unique fragments and retention time compared to known standards. Peaks were picked using OpenChrom and analyzed using MATLAB. Data was analyzed using Graphpad Prism. Principal Component Analysis (PCA) was visualized using Python on a Jupyter notebook.

Results: Both orthotopic human and murine pancreatic tumors demonstrated striking levels of intratumoral metabolite heterogeneity. Glycine, glutamine, and proline were the amino acids with the highest coefficient of variance, while leucine, isoleucine, and serine had the lowest coefficient of variance. α-ketoglutarate and succinate were the TCA intermediates with highest coefficient of variance. Lactate had the lowest coefficient of variance among all examined metabolites. Spatial mapping of each metabolite demonstrated distinct regions with varying abundance levels of metabolites. PCA demonstrated 75% of variance was carried by PC1 and 10% carried by PC2.

Conclusions: This study reveals insights into the degree of intratumoral heterogeneity present in pancreatic tumors that illustrate the difficulty of *in vivo* metabolomics analysis and suggest that high-resolution (single cell) metabolomics techniques will be critical to study metabolism in the complex TME.

#4441 The epigenetic factor BMI1 regulates metabolism and tumorigenesis in human pancreatic cancer cells.

J. N. Mills[1], D. Awad[1], H. K. Schofield[1], J. K. Thompson[1], H. Watkoske[1], D. Sutton[1], N. Nedzesky[1], D. Drouillard[2], Z. Nwosu[3], C. Espinoza[1], Y. Zhang[1], A. Del Vecchio[4], C. J. Halbrook[5], M. Pasca di Magliano[1], C. A. Lyssiotis[1], F. Bednar[1];

[1]University of Michigan, Ann Arbor, MI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Cornell University, Ithaca, NY, [4]Memorial Sloan Kettering, New York, NY, [5]University of California, Irvine, Irvine, CA

Dysregulation of epigenetic factors is a key component of tumorigenesis. BMI1, a member of the polycomb repressor complex 1 (PRC1), is an oncogenic factor studied in many types of cancer, including pancreatic ductal adenocarcinoma (PDAC). PDAC is the third most common cause of cancer-related death in the United States and investigation of the biology involved in transformation is critical for improving outcomes in this devastating disease. In PDAC, BMI1 is required for initiation of pancreatic cancer in mice and enhances *in vitro* growth of human and murine tumor cell lines. CRISPR-mediated knock out of BMI1 results in reduced subcutaneous and orthotopic tumor growth in mice and decreased expression of genes related to metabolism, specifically glycolysis, and cell proliferation. BMI1 has also been implicated in regulation of metabolism in other epithelial tumor types, including ovarian cancer. Given these preliminary findings, we hypothesized that loss of BMI1 in multiple human PDAC cell lines would result in altered metabolic activity, reducing the growth and tumorigenic properties of these cells. We demonstrated that BMI1 expression is higher in PDAC cell lines compared to normal pancreatic epithelial cells and normal human donor pancreatic tissue. Following CRISPR-mediated BMI1 knock out in human PDAC cell lines, we investigated the alterations to metabolism using metabolic flux analysis. Loss of BMI1 resulted in lower basal and compensatory rates of glycolysis and increased oxygen consumption rates compared to wild-type cells. Metabolomic analysis demonstrated reduction in all the enzymes involved in the glycolysis pathway with loss of BMI1. Cell growth was reduced by loss of BMI1 *in vitro*, and orthotopic injection into mice of human cells with BMI1 knock out resulted in decreased tumor size compared to wild-type, recapitulating these findings *in vivo*. Together, these data identify a role of BMI1 in promotion of tumor growth through regulation of metabolism in pancreatic cancer. Experiments are ongoing to determine the underlying mechanism of this regulation and implications on therapeutic targeting with BMI1/PRC1 complex inhibitors in conjunction with traditional chemotherapy.

#4442 Associations between pre-diagnostic plasma metabolites and biliary tract cancer risk in the prospective UK Biobank cohort.

V. Gunchick, G. Gia, W. Zheng;
Vanderbilt University Medical Center, Nashville, TN

Background Annually, approximately 200,000 people are diagnosed with biliary tract cancer (BTC). Most present with metastatic disease which encompasses a 5-year survival rate of <5%. Etiology is poorly understood though some studies suggest metabolic dysregulation may contribute to development. Previous evaluations of metabolites and BTC risk have primarily been limited to case-control studies, few metabolites, or post-diagnostic blood samples.
Methods We evaluated 248,285 adult participants with metabolite data in the UK Biobank, a prospective cohort study. Participants were excluded (6.2%) primarily due to a baseline history of cancer. To reduce potential influences of reverse causation, those who developed cancer or died within one year after baseline blood collection were also removed. Metabolites were trimmed to two standard deviations, log-transformed (ln[x+0.5]), z-scored, and evenly divided into tertiles. Cox proportional hazards regression was implemented to evaluate associations of BTC risk per 1-standard deviation (SD) and across tertiles with hazard ratios (HR) and 95% confidence intervals (95% CI). Models were adjusted for age, sex, education, income, fasting time, and statin use. A p-value of 0.001 was considered statistically significant after multiple comparison adjustment (0.05 divided by 50, the number of independent tests).
Results The analyzed cohort includes 232,781 UKB participants with a median age of 58, a median follow-up time of 11.8 years, and 268 first primary incident BTC cases. Multiple metabolites were significantly associated with BTC risk using continuous variables (per 1-SD increment). High triglyceride to total lipid ratios were associated with higher BTC risk, and the strongest association was for intermediate-density lipoproteins (the HR (95% CI) was 1.33 (1.15-1.54), p=0.0001). On the other hand, high cholesterol to total lipid ratios were associated with lower BTC risk, and the strongest association was for the free cholesterol to total lipids in small very-low-density lipoproteins (VLDL) (0.76 (0.66-0.88), p =0.0002). High glutamine was associated with lower BTC risk (0.68 (0.69-0.89), p =0.0003) as was the phospholipid to total lipid ratio in small VLDL (0.75 (0.65-0.87), p =0.0002). Analysis by tertile identified additional significant associations, including a higher polyunsaturated fatty acid to total fatty acid ratio being associated with lower BTC risk (the HR (95% CI) comparing the highest to lowest tertile, 0.50 (0.35-0.71), p-trend=0.0001). Notably, within polyunsaturated fatty acids, a higher omega-6 to omega-3 ratio trended toward higher risk (1.32 (0.94-1.85), p-trend=0.11).
Conclusion These findings indicate circulating metabolites may be biomarkers for BTC and suggest that triglycerides, cholesterols, fatty acids, phospholipids, and glutamine may be involved in BTC etiology.

#4443 Trans-population two-sample Mendelian randomization study of circulating metabolites and prostate cancer risk.

H. Fuller[1], R. Rohde[2], H. Highland[2], J. Shen[3], B. Yu[4], E. Boerwinkle[4], M. Grove[4], K. E. North[2], D. V. Conti[3], C. A. Haiman[3], K. Young[2], B. F. Darst[1]; [1]Fred Hutchinson Cancer Center, Seattle, WA, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of Southern California, Los Angeles, CA, [4]The University of Texas Health Science Center, Houston, TX

While prostate cancer (PCa) is highly heritable, mechanisms underlying disease risk and PCa disparities are not well understood. Here, we conducted a two-sample Mendelian randomization (MR) to assess whether serum metabolites are causally associated with PCa risk in European, African, and Hispanic populations.

MR analyses were performed on metabolite quantitative trait loci (mQTLs) for 250 metabolites quantified by untargeted mass spectroscopy via the Metabolon platform for 1,498 European and 1,740 African ancestry individuals from the Atherosclerosis Risk in Communities (ARIC) cohort and for 711 metabolites measured in 3,166 Hispanic individuals from the Hispanic Community Health Study/Study of Latinos (SOL). PCa GWAS summary statistics were obtained for men from European (122,188 cases, 604,640 controls), African (19,391 cases, 61,608 controls) and Hispanic (3,931 cases, 26,405 controls) populations from the PRACTICAL Consortium. Within each population, QTLs associated with metabolites at the genome-wide significance level ($P<5x10^{-8}$) were included in instruments upon removing rare (minor allele frequency≤0.01) or correlated (R^2≥0.2) SNPs calculated in ancestry-matched TOPMed populations. Inverse variance weighted (IVW) random effect models are presented as primary results. Sensitivity analyses were utilized to assess assumption violations (weighted mode, weighted median and MR egger). MR were conducted separately in each population, and fixed effect meta-analyses were conducted across population-specific MR results to identify trans-population associations. A false discovery rate was implemented to account for multiple testing.

In total, 22, 4 and 1 metabolites significantly associated with PCa risk in Hispanic, European and African populations, respectively. Of these, 13 metabolites had a MR instrument in ≥1 population, 12 of which were significant following a trans-population meta-analysis, including 5 fatty acids, 3 lysophospholipids, 1 amino acid, 1 carbohydrate, 1 nucleotide and 1 xenobiotic. All fatty acids were associated with decreased PCa odds (2%-10%), as were 4 other metabolites (amino acid 3-methyoxytyrosine, nucleotide 5-methyluridine and lysophospholipids 1-archidonoyl-GPC (20:4n6) and 1-archidonoyl-GPE (20:4n6), 4%-9%). The 3 remaining metabolites, erythritol, 1-linoleoyl-GPE (18:2) and mannose, were found to increase PCa odds by 10%, 6% and 4%, respectively. Additional metabolite harmonization efforts are underway to conduct trans-population analyses metabolome-wide.

This study provides evidence of associations between metabolites, such as fatty acids and lysophysopholipids, and PCa across diverse populations. These findings point to mechanisms that could inform preventive or therapeutic strategies pending functional investigations. Multivariable and bidirectional MR are ongoing to further assess findings.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Signaling Pathways That Regulate Metabolism 2
Poster Session

#4447 ZC3H18: A novel regulator of NAD^+ metabolism in high-grade serous ovarian cancer.
B. Wilson, N. Wilson, X. Chen, S. Zhang, C. Wang, L. M. Karnitz, S. H. Kaufmann, **A. Kanakkanthara**;
Mayo Clinic, Rochester, MN

ZC3H18 is a multifunctional regulator of gene expression that is lost in a subset of high-grade serous ovarian cancers (HGSOC). Our prior studies have established that the loss of ZC3H18 diminishes BRCA1 levels, leading to the disruption of homologous recombination DNA repair (HR) and heightened sensitivity of HGSOC cells to PARP inhibitors. Here we show an additional facet to ZC3H18's impact, showing that its loss also induces a reprogramming of energy metabolism in HGSOC. Our findings demonstrate that the depletion of ZC3H18 results in reduced mRNA and protein levels of the NAD^+-biosynthetic enzyme, NMNAT1, in HGSOC cells. Mechanistic studies uncovered that ZC3H18 occupies the *NMNAT1* promoter, facilitating *NMNAT1* transcription by recruiting CDK12 onto the promoter. Consistent with this mechanism, loss of ZC3H18 led to a reduction in CDK12 levels on the *NMNAT1* promoter, diminishing NMNAT1 abundance and subsequently causing a decline in cellular NAD levels. These observations unveil a previously unknown role for ZC3H18 in HGSOC, shedding light on its involvement in the regulation of energy metabolism. Importantly, our findings provide valuable insights into potential therapeutic pathways that leverage the metabolic changes linked to ZC3H18 deficiency.

#4448 Effects of adagrasib on cholesterol, lipid and glucose gene expression regulation in tumor xenograft models and patient samples.

F. Shelton[1], N. Hoffman[1], D. Trinh[1], X. M. Helu[1], A. Calinisan[1], A. Hebbert[1], L. Yan[1], D. M. Briere[1], L. Hover[2], J. Fernandez-Benet[2], K. Anderes[1], J. G. Christensen[1], **J. Hallin**[1], P. Olson[1];

[1]Mirati Therapeutics, San Diego, CA, [2]Monoceros Biosystems LLC, San Diego, CA

Introduction: Clinically active $KRAS^{G12C}$ inhibitors have represented a key research breakthrough and led to novel treatment options for lung, colorectal and other cancer patients harboring this mutation. While treatment with $KRAS^{G12C}$ inhibitors are clinically active in the majority of patients, the depth and duration of response is variable and most patients ultimately progress. This variation in therapeutic response highlights the need for a better understanding of drug mechanism of action and the identification of rational combination strategies. Oncogenic *KRAS* mutations hyperactivate the MAPK pathway, create an immunosuppressive tumor microenvironment, and promote glycolysis even in the presence of oxygen commonly known as the Warburg effect. This altered metabolic state is marked by increased glucose uptake and lactate production, providing necessary substrates for rapid tumor growth.

Results: Pharmacological inhibition of $KRAS^{G12C}$ with a potent and selective $KRAS^{G12C}$ inhibitor, adagrasib, revealed marked alterations of metabolic gene expression programs in tumor samples collected from mouse xenograft studies and repeat biopsies provided by patients enrolled on adagrasib clinical trials. Upregulation of genes involved in reverse cholesterol transport including ApoE, NR1H3 (LXRa) and ABCA1 was observed across both preclinical tumor xenografts and patient samples following adagrasib treatment. Additionally, decreased expression of Glut1 and low-density lipoprotein receptor (LDLR) genes were also observed in both tumor models and patients suggesting that adagrasib treatment results in an extensive shift in uptake and utilization of cholesterol, lipid, and glucose. The impact of adagrasib treatment on circulating metabolic parameters in tumor xenograft-bearing mice were investigated in follow up studies.

Conclusions: Taken together, these data suggest adagrasib modulates cholesterol efflux, glucose and lipid pathways and alters tumor and systemic metabolic regulation. Additional research may yield a targetable collateral vulnerability and rational combinatorial strategy.

#4449 Hepatic steatosis induced by bioactive lipids.

M. Alba[1], I. Slarve[1], B. Ebright[1], Y. Zhou[1], W. Cohn[2], Y. Jia[1], E. Elton[3], J. Khan[1], A. Datta[1], L. He[1], Q. Tang[1], P. Pammidimukkala[1], T. Tu[1], P. Nguyen[1], J. Katz[3], J. Whitelegge[2], S. Louie[1], B. Stiles[1];

[1]USC - University of Southern California, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]Ellison Institute of Technology, Los Angeles, CA

Introduction: HCC is the most common form of liver cancer and is the sixth most common cancer globally. Despite the clinical advancement of immune checkpoint inhibitors, median survival continues to be less than twenty months and most patients develop resistance making it one of the deadliest malignancies. The rate of liver cancer continues to rise, which is coupled to the high prevalence of steatosis and steatohepatitis that accounts for about 25% in the general population. Pathologically, 80% of liver cancer occurs in patients with an underlying liver disease that displays liver steatosis. Thus, it is paramount to better characterize the transition from steatosis to HCC.

Methods: Utilizing a *Pten* deleted mouse model (*Pten*$^{loxP/loxP;\ Alb\text{-}Cre^{\pm}}$) that recapitulates HCC progression, protein and lipid fractions were isolated to explore differentially expressed proteins and their correlations with bioactive lipid metabolism. Global untargeted differential proteomics was done with fractionation using a qExactive. Lipid fractions were analyzed using a Sciex 6500 for targeted lipidomic analysis. In addition, genetic knockout hepatocyte cell lines of each AKT isoform were used to explore the involvement of the PI3K/AKT signal. Further, a phosphoproteomic enrichment was performed to discover downstream signaling targets.

Results: The PTEN regulated PI3K/AKT signal is induced in 54% of all liver cancers and represents the dominant signaling pathway regulating liver cancer progression. Untargeted differential proteomic analysis of *Pten* deleted mice livers revealed significant dysregulation in oxidative stress and eicosanoid metabolism among the top enriched disease and biological functions when the phenotype progressed from steatosis to HCC. Analysis of publicly available liver cancer patient samples from the NCI Proteomic Data Commons further shows strong correlation between PTEN protein abundance and the expression of enzymes involved in eicosanoid metabolism. Our analysis using a bio-active lipid multi reaction monitoring panel of *Pten* deleted mouse livers further validates significant decreases in resolving eicosanoid levels along with increases in proinflammatory eicosanoid precursors as steatosis progress to HCC. These data suggest a potential hepatic AKT-dependency in regulating the shift towards proinflammatory eicosanoids. Primary isolated hepatocytes from mouse livers lacking either AKT1 or AKT2 were analyzed to elucidate AKT's regulatory role in hepatic eicosanoid metabolism. Proteomic and lipidomic analysis of these hepatocytes supported a unique AKT isoform specific role in the regulation of eicosanoids via potential isoform specific signaling interactions with MAPK.

Conclusion: Eicosanoid metabolism dysregulation plays a key role in the progression from steatosis to HCC and appears to be regulated in an AKT isoform specific manner via interactions with MAPK signaling.

#4450 MYC upregulates MCT4 expression and promotes metabolic reprogramming and enhanced lactate utilization in LKB1-deficient NSCLC.

Y. Qian[1], D. Molkentine[1], Y. Kong[1], Q. Huang[1], C. Yang[2], A. Poteete[1], A. P. Guimaraes[1], P. Jiang[1], F. Skoulidis[1], A. Reuben[1], J. D. Minna[2], R. J. DeBerardinis[2], J. V. Heymach[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]UT Southwestern Medical Center, Dallas, TX

STK11, which encodes the serine/threonine kinase LKB1, is the second most commonly altered tumor suppressor in non-small cell lung cancer (NSCLC). LKB1 loss is frequently co-mutated with *KRAS* and associated with primary resistance to immunotherapy, which is partially due to MCT4-dependent lactate secretion. However, the mechanisms driving MCT4 elevation and metabolic reprogramming remains unclear. We hypothesized that increased MYC expression, which is associated with LKB1 loss, plays a pivotal role in metabolic alterations, promoting lactate incorporation and maintaining redox homeostasis. To explore the impact of lactate on tumor cells with LKB1 loss, we performed metabolic profiling on KRAS mutant (K) murine lung cancer cells with or without LKB1 knockout (KL) treated with either glucose or lactate as the carbon source. PLS analysis indicated that there was no notable difference between K and KL cells after glucose treatment. However, we observed significant changes in metabolites between K and KL cells when treated with lactate. Differentially altered metabolites included TCA-related components such as acetyl-CoA and glutamate, indicating enhanced lactate utilization in KL tumor cells. We also noticed that KL cells showed increased oxidative phosphorylation (OXPHOS) with the addition of lactate, with increased GSH/GSSH and NADPH/NADP+ ratios, suggesting that, as compared to LKB1-intact cells, LKB1-deficient cells had an enhanced ability to utilize OXPHOS and maintain redox homeostasis with lower levels of ROS generation when utilizing lactate as an energy source. However, in KL cells, MYC knockout (KO) or MCT4 KO partially abolished the lactate-induced OXPHOS and increased ROS. Moreover, [U-13C]lactate tracing revealed that isotopologues were significantly enriched in TCA components in KL cells, and this was reversed by either MYC KO or MCT4 KO, suggesting that MYC and MCT4 were critical for lactate reutilization in KL tumor cells. We observed that MYC could directly bind to the promoter region and transcriptionally activate MCT4 expression, and restoring MCT4 in MYC KO cells enhanced lactate incorporation and decreased ROS levels. Finally, we injected KL murine tumor cells with or without MYC/MCT4 KO into mice and infused [U-13C]lactate to detect the isotopologues distribution in vivo. KL tumors showed significantly enhanced lactate incorporation as compared to K tumors, while MYC KO or MCT4 KO reversed these phenotypes. Collectively, our data indicates that in LKB1-deficient tumors, upregulation of MYC promotes MCT4 expression and increases lactate incorporation and utilization, and that can be inhibited by targeting MYC or MCT4. These findings provide insight into the mechanisms driving the metabolic reprogramming and aggressive phenotype of KRAS-mutant LKB1-deficient tumors and identify a novel therapeutic strategy for this recalcitrant subgroup.

#4451 Regulation of lipid metabolism and ferroptosis by DAXX.

W. Yang, N. Awasthee, Q. Chen, S. Hale, **D. Liao**;
University of Florida College of Medicine, Gainesville, FL

Intracellular lipid production in cancer cells supplies lipids to synthesize cell membranes and signaling molecules during rapid cell proliferation and tumor growth. Cancer cells also utilize fatty acid oxidation (FAO) to generate ATP to meet their energy demand. Notably, lipid metabolites can inhibit and trigger ferroptosis due to iron-dependent oxidation of polyunsaturated fatty acids (PUFAs). Therefore, identifying regulators that maintain the intricate balance of lipid biosynthesis required for cell proliferation and survival is critical in cancer biology and therapy. Lipid metabolism is regulated by two oncogenic signaling pathways: the RAS-RAF-MEK-MAPK and the mammalian target of rapamycin (mTOR) pathways. About 30% of all cancers harbor constitutively active mutations in KRAS, HRAS, or NRAS, resulting in hyperactive RAS-RAF-MEK-MAPK signaling to drive tumorigenesis, metastatic progression, immune evasion, and resistance to therapy. KRAS regulates lipid uptake, lipid synthesis, and FAO. mTOR is a serine/threonine kinase acting as a key intracellular signaling hub to regulate nutrient homeostasis, metabolism, protein synthesis, and autophagy. The mTORC1 complex promotes lipogenesis. The RAS and mTOR signaling pathways exhibit both positive and negative cross-regulation. The coordinated activity of both pathways is critical to sustained tumor growth. Notably, mTORC1 signaling inhibition enhances RAS-RAF-MEK-MAPK signaling to promote cancer cell survival and proliferation. Furthermore, constitutive mTORC1 signaling induces cell death when the supply of unsaturated FAs is limited. However, the molecular link for coordinating the activity of the RAS and mTOR signaling pathways remains poorly defined. Death domain-associated protein (DAXX) is essential for mouse embryonic development and has ill-defined pro-cell survival functions. Our lab has a long-standing interest in deciphering DAXX's complex biological functions. Our recent study shows that DAXX drives tumorigenesis by promoting lipogenic gene expression and lipid synthesis through interacting with sterol regulatory element-binding proteins SREBP1 and SREBP2 (SREBP1/2) (Mahmud et al., 2023, PMID 37045819). Unexpectedly, our new data reveal that DAXX inhibits ferroptosis. Significantly, phosphorylation via RAS signaling appears to regulate DAXX's activity in lipid synthesis and resistance to ferroptosis. Remarkably, disruption of DAXX-mediated lipid synthesis potentiates ferroptosis due to mTORC1 activity. Based on these observations, we propose that stimulated by the RAS-RAF-MEK-MAPK oncogenic signaling, DAXX promotes tumorigenesis through upregulating genes for lipid synthesis and resistance to ferroptosis, and that the lack of DAXX-mediated lipid synthesis leads to sensitization of cells to ferroptosis due to mTORC1's proliferative effects. (Supported by FDOH grant 23K03).

#4452 The macropinosome: Uncovering the molecular anatomy of an oncogene-driven organelle.

A. Manceau, K. M. O. Galenkamp, C. M. Galapate, C. Commisso;
Sanford Burnham Prebys Medical Discovery Institute, San Diego, CA

As an integral aspect of the metabolic reprogramming that occurs in cancer, oncogenic KRAS mutations drive the stimulation of macropinocytosis, a type of endocytosis that mediates nonselective fluid-phase uptake. Using KRAS-driven models of pancreatic ductal adenocarcinoma (PDAC), we were the first to demonstrate that macropinocytosis functions in tumor cells as a nutrient acquisition pathway. Macropinocytosis triggers the internalization of extracellular proteins via discrete endocytic vesicles called macropinosomes. The incoming protein cargo is targeted for lysosome-dependent degradation, causing the intracellular release of amino acids. These protein-derived amino acids support metabolic fitness by contributing to the intracellular amino acid pools, as well as to the biosynthesis of central carbon metabolites. In this way, macropinocytosis represents a novel amino acid supply route that tumor cells use to survive the nutrient-poor conditions of the tumor microenvironment. While the tenets of the signal transduction events that drive macropinocytosis in cancer have emerged, a detailed picture of the macropinosome itself is not yet available. With the aid of nanotechnology, we have developed a methodology to isolate a pure fraction of macropinosomes from PDAC cells. Using a large-scale proteomic approach, we have been able to generate a list of proteins that reside in macropinosomes. The specificity of this approach was confirmed through the identification and validation of proteins known to specifically localize to these organelles in different contexts, such as Rab5 or SDC1. Thanks to this innovative method, we have demonstrated the involvement of two calcium channels, ATP2B1 and ATP2B4, in the formation of macropinosomes. By elucidating the molecular anatomy of KRAS-driven macropinosomes, we will gain further insight into the regulation and function of macropinocytosis in cancer. Moreover, having a clearer picture of the macropinosome will make us better positioned to exploit this pathway therapeutically and deliver breakthroughs to patients.

#4454 Manipulation of the amino acid metabolism promotes therapeutic efficacy through targeting lysosome in glioblastoma.

Y. Jing, M. Kobayashi, A. Hirao;
Kanazawa University Cancer Research Institute, Kanazawa, Japan

Nutrients are converted by the body to smaller molecules, which are utilized for both anabolic and catabolic reactions. Cooperative regulation of these metabolic processes is critical for maintaining tissue homeostasis. Based on these findings, our group has been focusing on how the regulation of nutrient-driven metabolism controls the malignancy of cancer cells. Metabolic regulation has been considered crucial for cellular adaptation to environmental changes and promoting survival and proliferation. Recent studies showed the successful applications of targeting specific nutrients for cancer therapy. In this study, we developed a new lysosome-targeting therapeutic strategy, centered around the manipulation of the amino acid metabolism for GBM. Using patient-derived GBM cells, we found that lysosomal proteolytic activity is a unique metabolic biomarker representing malignant phenotypes of GBM and that it is closely correlated with the efficacy of current conventional therapy for GBM patients. Furthermore, the MiT/TFE family members, TFEB and TFE3, which are the master regulators of lysosomal biogenesis, controlled malignant progression and therapeutic efficacy in vitro and vivo. Combinatory analyses with clinical patient samples and xenograft models demonstrated that the MiT/TFE family plays a crucial role as a regulator of malignant properties in GBM. Analysis of The Cancer Genome Atlas (TCGA) glioma dataset, which includes data from patients with Grade 2, 3, and 4 (GBM) gliomas, showed that higher expression of the MiT/TFE family was significantly associated with shorter survival. Interestingly, we discovered that an essential amino acid controls lysosomal biogenesis and membrane integrity by regulation of nitric oxide signaling pathway. Finally, we screened the potential anti-cancer drugs, including temozolomide, exhibiting the synergy effect in amino acid-restriction conditions by conducting a drug screening using a clinically available anti-cancer drug library. Our study demonstrated that lysosomal function, supported by amino acid metabolism, plays a critical role in the regulation of GBM malignant status and proposed precision nutrition as a promising therapeutic approach.

#4455 Metabolic stress induces a double positive feedback loop between AMPK and p62 conferring dual activation of AMPK and NRF2 to synergize antioxidant defense.

Eun-Ji Choi[1], Hyun-Taek Oh[2], Seon-Hyeong Lee[3], Chen-Song Zhang[4], Mengqi Li[4], Soo-Youl Kim[3], Sunghyouk Park[2], Tong-Shin Chang[2], Byung-Hoon Lee[2], Sheng-Cai Lin[4], **Sang-Min Jeon**[2]

[1]Ajou University, Suwon, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of,[3]National Cancer Center, Goyang, Korea, Republic of,[4]Xiamen University, Fujian, China

Co-occurring mutations in KEAP1 in LKB1-mutant NSCLC activate NRF2 to compensate losing LKB1-AMPK activity during metabolic adaptation and survival. Here, we investigated the regulatory crosstalk between LKB1-AMPK and KEAP1-NRF2 pathways during metabolic stress. We found that metabolic stress activates NRF2 through the expression and phosphorylation of p62, causing the autophagic degradation of KEAP1. Intriguingly, the induction of p62 during metabolic stress is also required to activate AMPK by promoting AXIN-LKB1-AMPK complex formation and recruiting it to the lysosomal membrane. Importantly, the p62-driven dual-activation of AMPK and NRF2 was critical for tumour growth by synergizing antioxidant defences. In turn, the induction of p62 also required LKB1-AMPK activity, suggesting a double positive feedback loop between AMPK and p62. Mechanistically, the increase in lysosomal pH caused by low glucose metabolism and AMPK-dependent reduction of proton generation induced PP2A-dependent dephosphorylation of TFEB/TFE3 which increased the expression of p62. The increase of ROS caused by metabolic stress induced lysosomal MCOLN1-Ca^{2+} dependent activation of TAK1 which increased p62 phosphorylation. Protons provided by lactic acid abrogated all the effects caused by metabolic stress. This positive feedback loop between AMPK and p62 that activates AMPK and NRF2 can potentially explain why co-occurring mutations in LKB1 and KEAP1 occur and further provide promising therapeutic strategies for lung cancer.

#4457 Skeletal muscle-infiltrating CD8 T cells exacerbate muscle atrophy in a syngeneic lung cancer cachexia mouse model.

S.-Y. Park[1], B. Kim[1], M. Lee[2], H. Lee[2], N.-Y. Song[1];

[1]Yonsei University, Seoul, Korea, Republic of, [2]Pusan National University, Busan, Korea, Republic of

Cancer-associated cachexia (CAC) is a devastating syndrome of irreversible body weight loss and muscle wasting. CAC has been reported to often lead to poor outcomes of immune checkpoint inhibitors (ICIs), emerging as a standard treatment for various types of cancer. Previously, we have demonstrated that KRAS-mutant lung tumor tissues display an immunosuppressive microenvironment with decreased CD8 T cells and increased regulatory T cells (Tregs). In this orthotopic lung cancer mouse model, treatment with an anti-PD-L1 antibody, a representative ICI, reduced tumor burden, whereas accelerated loss of body weight and skeletal muscle mass. We thus assumed that CD8 T cells could facilitate skeletal muscle wasting in lung tumor-bearing mice, a key feature of CAC. First, we established a syngeneic CAC mouse model through orthotopic transplantation of murine lung cancer cells. At 7 weeks post-injection, these mice developed CAC, displaying over 20 % body weight loss, almost total loss of epididymal fats, and profound skeletal muscle wasting. In line with our assumption, CAC mice showed an increased number of CD8 T cells but a reduced number of Tregs in skeletal muscles, compared to tumor-free control mice. We then investigated whether skeletal muscle-infiltrating CD8 T cells directly induce muscle atrophy indeed. In CAC mice, CD8 neutralization led to restoration of muscle mass and downregulation of muscle atrophy markers, but was not able to significantly affect lung tumor burden. Moreover, direct co-culture with splenic CD8 T cells exacerbated C2C12 myotube atrophy in a conditioned medium from lung cancer cells, further supporting the involvement of CD8 T cells in CAC. To elucidate its underlying mechanism, RNA sequencing analysis was conducted in both skeletal muscles and lung tumors of CAC mice. Based on the differently expressed gene analysis, *Cxcl13* was upregulated in skeletal muscles of CAC mice, while downregulated in lung tumors. It is well documented that CXCL13 can mediate recruitment of CD8 T cells. In this regard, CXCL13 might be a plausible regulator in CD8 T cell-induced skeletal muscle atrophy, which requires further investigation to fully understand the molecular mechanism.

#4459 Metabolic liabilities of iron-dependent ferroptosis mediated through NRF2/GPX4 axis in osteosarcoma.

M. Abdullah, D. Lee, R. Li, J. Kim;
University of Florida, Gainesville, FL

Osteosarcoma is an aggressive bone malignancy that predominantly affects adolescents and young adults. Despite recent advancements in treatments, the challenges of recurrence and chemoresistance persist. Ferroptosis is a form of regulated cell death driven by iron-dependent lipid peroxidation, and emerging evidence suggests significant roles for NRF2 and GPX4 in iron metabolism, regulating tumor cell functions. In osteosarcoma, however, the molecular mechanisms of the NRF2/GPX4 axis and its therapeutic potential remain unknown. In this study, we first determined GPX4 and xCT expression levels and cellular responses to RSL3, a GPX4 inhibitor, and Erastin, an xCT inhibitor in osteosarcoma cells. A total of seven osteosarcoma cell lines, consisting of five human cell lines (HOS, 143B, Saos-2, MG-63, U2OS) and two canine cell lines (COS31 and DOUG), were used. Our results revealed that the IC50 values ranged from 0.02 uM to 1.01 uM in cells treated with RSL3 and from 0.35 uM to 1.41 uM in cells treated with Erastin, respectively. These values were proportional to GPX4 and xCT levels across the cell lines. Then, U2OS, as the most sensitive, and Saos-2, the least sensitive based on their IC50 values, were selected to examine the iron regulatory machinery. In U2OS cells, RSL3 treatment significantly decreased NRF2 and GPX4, while increasing ferroportin-1 and ferritin. GPX4 knockdown also led to comparable changes in NRF2, ferroportin-1, and ferritin expression. NRF2 appears to mediate iron metabolism, ferroportin-1 acts as an iron exporter, and ferritin stores intracellular iron. Therefore, our findings suggest that GPX4-mediated ferroptosis is regulated by iron metabolic pathways, potentially to prevent ferroptotic cell death. We also found that Ferrostatin-1, a lipid peroxidation inhibitor showed no changes in ferroportin-1, ferritin, and NRF2. In Saos-2, RSL3 induced a remarkable reduction in GPX4 expression, akin to U2OS. However, no significant change was found in NRF2, ferroportin-1, and ferritin. Instead, Ferrostatin-1 restored the decreased GPX4 and increased NRF2, ferroportin-1, and ferritin levels. In addition, Z-VAD (a pan-caspase inhibitor), Necrosatin-1s (a RIPK1 inhibitor), and Ferrostatin-1 were capable of preventing Saos-2, COS31, and DOUG cells from RSL3-induced cell death at lethal doses. Such protection was undetected in U2OS. These data suggest that metabolic pathways controlling intracellular iron are crucial for NRF2/GPX4-mediated ferroptosis in osteosarcoma cells. Furthermore, we generated RNA-seq and LC-MS/MS data to identify novel molecular targets governing the metabolic pathways of ferroptosis in osteosarcoma. Our ongoing work includes downstream molecular and functional assays following gene modifications in osteosarcoma cells (overexpression and knockout) and assessing metabolic vulnerabilities by targeting iron-mediated ferroptosis in xenografts.

#4460 Investigating a non-canonical role for SHP2 in pancreatic ductal adenocarcinoma metabolism and response to dietary modifications.

R. Walsh, J. L. Jack, A. E. Eades, B. A. Bye, M. T. Ruckert, J. Ambrose, M. N. VanSaun;
University of Kansas Medical Center, Kansas City, KS

Pancreatic ductal adenocarcinoma (PDAC) is predicted to be the second leading cause of cancer death in the US by 2025, with rising incidence. Mutant KRAS in >90% of PDAC cases promotes activation of the MAPK pathway, yet targeting the MAPK pathway clinically has failed to improve patient outcomes. SHP2 canonically promotes KRAS activation and is essential for PDAC development in mouse models. Because targeting MAPK is insufficient, yet SHP2 loss blocks PDAC development, we hypothesized SHP2 has both MAPK dependent and independent functions. Initial studies revealed that SHP2 inhibition with SHP099 in murine KPC [K8484: $KRAS^{G12D/+}$, $p53^{R172H/+}$, $Pdx1^{Cre/+}$] cells required concentrations exceeding 50 μM to elicit a minimal ERK inhibition. This led us to predict that there may be a tumor suppressive mechanism of SHP2 inhibition that is KRAS/MAPK independent. We utilized available RNAseq data (NCBI GEO: PRJNA558508) of PDAC MiaPaCa2 cells treated with the MEK inhibitor, Trametinib, or SHP099 to compare the direct effects of inhibition on transcriptional outcomes. We identified inositol phosphate signaling as a candidate target, whose downstream consequence is Ca^{2+} flux. We measured IL-1β induced Ca^{2+} flux in a panel of human PDAC cells exposed to MEK or SHP2 inhibition. Trametinib treated cells showed no effect on Ca^{2+} flux, however, SHP099 led to a drastic depletion of free Ca^{2+} and response to stimulus. We then validated the Ca^{2+} response to IL-1β stimulus in Crispr-Cas9 SHP2-knockout K8484 cells. While we did not observe a difference in basal free calcium, we still found a reduction in response to IL-1β stimulus. Because Ca^{2+} is an important co-factor for mitochondrial metabolism, we then interrogated metabolic effects. We tested mitochondrial function using a Seahorse Mito-Stress test and found that while MEK inhibition failed to affect mitochondrial metabolism, SHP2 inhibition ablated it. A Glycolysis-Stress Test revealed that SHP2 inhibition led to glucose consumption primarily through anaerobic respiration. TMT-labeled phospho-proteomic analysis comparing SHP2KO and MEK inhibited K8484s revealed SHP2 dependent deficiencies in mitochondrial proteins, among others, involved in mitochondrial fission and lipid metabolism. Western diets have been shown to promote tumor progression in GEM models of PDAC, so we used $KRAS^{G12D/+}$, $SHP2^{fl/fl\ or\ wt./wt}$, $Ptf1a^{Cre/+}$ (SKC and KC) mice to demonstrate that while diet-induced obesity affects KC tumor burden, the lack of SHP2 in SKCs prevents the diet associated discrepancy in tumor progression. Collectively, these data led us to conclude that while SHP2 has been studied as a contributor to KRAS signaling in PDAC, the outcomes of its role specifically on mitochondrial metabolism have yet to be appreciated or thoroughly investigated, opening the path for a new approach to its contribution to tumor progression.

#4461 Unveiling the links between methionine metabolism and epigenomic reprogramming in upper aerodigestive squamous cell carcinoma.

C. Nam;
Herman Ostrow School of Dentistry, University of Southern California, Los Angeles, CA

Upper aerodigestive squamous cell carcinoma (UASCC) presents as a prevalent and aggressive malignancy, posing challenges in terms of effective therapeutic interventions. In this study, we explored the intricacies of amino acid metabolism within UASCC, revealing an unexpected observation that distinguishes UASCC among all human cancers, having the highest methionine levels, driven by the overexpression of its transporter LAT1. Notably, LAT1 exhibits peak expression levels in UASCC, regulated at the transcriptional level by UASCC-specific promoters and enhancers, co-regulated by SCC master regulators TP63/KLF5/SREBF1.Surprisingly, our unbiased bioinformatic screen identifies EZH2 as a pivotal downstream target of the LAT1-methionine pathway, establishing a direct link between methionine metabolism and epigenomic reprogramming. This cascade emerges as crucial for the survival and proliferation of UASCC patient-derived tumor organoids. Furthermore, we find that LAT1 expression closely correlates with cellular sensitivity to inhibition of the LAT1-methionine-EZH2 axis.Significantly, the newly discovered LAT1-methionine-EZH2 cascade emerges as a promising target for intervention, with effective outcomes achievable through both pharmacological approaches and dietary interventions *in vivo*. In summary, this research unveils a novel mechanistic crosstalk connecting epigenomic reprogramming with methionine metabolism, revealing its biological significance in UASCC. Moreover, it identifies a unique tumor-specific vulnerability, providing avenues for exploitation through both pharmacological and dietary strategies

#4463 Metabolic reprogramming through Notch1 signaling promotes a survival advantage in pancreatic neuroendocrine tumor cells.

R. Guenter, W. Chen, B. Herring, Y. Golivi, M. Sammy, J. Whitt, R. Jaskula-Sztul, H. Chen, J. Rose;
University of Alabama at Birmingham, Birmingham, AL

Background: Cancer cells utilize both oxidative phosphorylation (OXPHOS) and glycolysis to generate energy. Switching between OXPHOS and glycolysis can promote tumor progression. The mechanisms governing oncogenic metabolic reprogramming are largely unknown, but recent data has suggested that Notch1 dysregulation in cancer cells can contribute to altered metabolic phenotypes. We hypothesized that Notch1 signaling supports metabolic reprogramming in pancreatic neuroendocrine tumor (pNET) cells.

Methods: We established a Notch1-knockout pNET cell line (BON-N1-KO) by deleting Notch1 at exon 3 in a pNET cell line (BON) using CRISPR/Cas9. Proliferation over time was measured using a trypan blue exclusion test. Seahorse Glycolytic Rate Assay and Mitochondria Stress Test were used to measure the glycolytic and mitochondrial activities of cells. A glycolysis deprivation assay was employed to determine cell viability at varying glucose concentrations. Single end RNAseq was performed using the Illumina NGS platform, to a read depth of 50M.

Results: Over time, pNET cells lacking Notch1 (BON-N1-KO) proliferated slower than wildtype (WT) cells (p=0.034). Compared to WT BON, the BON-N1-KO cells had reduced basal oxygen consumption rate (28.2 ± 1.3 vs. 40.7 ± 1.4; p=0.02, ATP production (21.9 ± 1.0 vs. 29.6 ± 0.98; p=0.04), and maximal respiration (39.4 ± 1.7 vs. 63.7 ± 2.1; p=0.004). BON-N1-KO cells also had a reduction in basal glycolysis, as measured by proton efflux rate, compared to WT (48.7 ± 2.6 vs. 57.7 ± 6.2; p=0.2). To further test metabolic reprogramming, WT and BON-N1-KO cells were starved of glucose (0mM), compared to normal glucose (17.5mM) and viability was measured over time. By day 5, the BON-N1-KO group had a viability of 0%, whereas 12.8% of WT cells were alive (p=0.038). To determine if Notch1 loss was associated with altered expression of established metabolic genes, we performed RNAseq. Differential gene expression analysis found that OXPHOS-related genes (*UQCC2, COX15, COX20*) and glycolysis-related genes (*Slc1a1, Slc2a4, Hk1, Hk2*) were significantly down-regulated in BON-N1-KO cells.

Conclusions: Our study shows that Notch1 signaling facilitates metabolic reprogramming as a survival advantage in pNET cells. Targeting Notch1 signaling to mediate cellular metabolism may be a novel therapeutic strategy in pNETs.

#4464 Ferredoxin 1 is essential for embryonic development and lipid homeostasis.

Jin Zhang, Sharkur Mohibi, Xinbin Chen, Vivian Perng, Yanhong Zhang

UC Davis, Davis, CA

Mammalian ferredoxin 1 and 2 (FDX1/2) belong to an evolutionary conserved family of iron-sulfur cluster containing proteins and act as electron shutters between ferredoxin reductase (FDXR) and numerous proteins involved in critical biological pathways. FDX1 is involved in biogenesis of steroids and bile acids, Vitamin A/D metabolism, and lipoylation of tricarboxylic acid (TCA) cycle enzymes. FDX1 has been extensively characterized biochemically but its role in physiology and lipid metabolism has not been explored. In this study, we generated Fdx1-deficient mice and showed that knockout of both alleles of the Fdx1 gene led to embryonic lethality. We also showed that like Fdxr+/− mice, Fdx1+/− mice had a shorter life span and were prone to steatohepatitis. However, unlike Fdxr+/− mice, Fdx1+/− mice were not prone to spontaneous tumors. Additionally, we showed that FDX1 deficiency led to lipid droplet accumulation possibly via the ABCA1-SREBP1/2 pathway. Specifically, untargeted lipidomic analysis showed that FDX1 deficiency led to alterations in several classes of lipids, including cholesterol, triacylglycerides, acylcarnitines, ceramides, phospholipids and lysophospholipids. Taken together, our data indicate that FDX1 is essential for mammalian embryonic development and lipid homeostasis at both cellular and organismal levels.

#4465 Galectin-1 regulates CD147 and downstream pathways critical for glioma progression.

M. R. Guda, A. J. Tsung, S. Asuthkar, K. Velpula;
University of Illinois College of Medicine, Peoria, IL

Galectin-1 (Gal-1) is an important protein for glioma progression and glioma stem cell maintenance. Gal-1 may act through CD147, a potential Gal-1 receptor. CD147, also known as Basigin or extracellular matrix metalloproteinase inducer (EMMPRIN), is a transmembrane glycoprotein highly expressed in various cancer cells. An analysis utilizing the Gliovis database and encompassing 667 Glioblastoma Multiforme (GBM) patients segregated based on median CD147 expression levels delineated cohorts with above-median (n=339) and below-median (n=328) CD147 expression. Kaplan-Meier survival curves unveiled a significant association between heightened CD147 expression and reduced overall survival (OS) in this patient population. Experimental approaches employing immunoblotting and immunohistochemistry techniques on shGal-1 treated cell lysates and mouse brain samples exhibited decreased CD147 expression compared to respective controls. Additionally, immunocytochemical studies corroborated an augmented colocalization of Gal-1 and CD147, with a subsequent reduction in this association following shGal-1 treatment. Next, we used AC-73, a selective CD147 inhibitor, to determine the levels of CD147 and Gal-1. Treatment with 20μM AC-73 and siRNA for CD147 showed reduced CD147 levels in GSC33 and GSC20 cells while maintaining unaltered Gal-1 expression. Inhibiting CD147 did not affect Gal-1 levels, further suggesting Gal-1 acts upstream. CD147 activates matrix metalloproteinase-9 (MMP9), and CD147 knockdown reduced MMP9 levels, elucidating a Gal-1-CD147-MMP9 pathway. Overall, Gal-1 appears to act upstream of CD147 to regulate MMP9, integrins, and other factors important for glioma progression. Further elucidation of these pathways will provide insights into glioma biology and potential therapeutic targets.

#4466 Omega-3 fatty acid-induced ferroptosis in 4T1 breast cancer through CD36/FABP5 axis.

A. Avellino, J. Hao, M. Yorek, J. Yu, B. Li;
University of Iowa, Iowa City, IA

Mammalian cells utilize energy from many different sources, and fatty acids are one of these sources. Dietary fats contain various structures of fatty acids, each impacting cell lipid metabolism in unique ways. Omega-3 fatty acids are known to induce breast cancer cell death through ferroptosis. However, the specific molecular mechanisms by which omega-3 fatty acids trigger ferroptosis have yet to be fully elucidated. Fatty acid binding proteins (FABPs) constitute a family of evolutionarily conserved lipid chaperones, facilitating the transport and utilization of fatty acids within cells. Notably, FABP5 is highly expressed in breast cancer, especially in the most aggressive form, triple-negative breast cancer. We hypothesized that FABP5 acts as a lipid sensor, mediating the ferroptosis induced by omega-3 fatty acids in triple-negative breast cancer cells. To test this, we created Fabp5 stable knockout cell lines in 4T1 and MDA-MB-231, two commonly used triple-negative breast cancer cell lines, using CRISPR/Cas9 technology. When treated with docosapentaenoic acid (DPA), these Fabp5-knockout cells exhibited reduced ferroptosis compared to their wild-type counterparts. Interestingly, blocking the surface protein CD36, either with inhibitors or antibodies, also reduced DPA-induced ferroptosis. Furthermore, mutations in Fabp5 decreased maximal mitochondrial respiration in both 4T1 and MDA-MB-231 cells, suggesting a crucial role for FABP5 in mediating oxygen consumption and reactive oxygen species (ROS) production during DPA-induced ferroptosis. Additionally, mice fed a high-fat diet rich in omega-3 fatty acids showed reduced tumor size and lung metastasis. Collectively, our data indicate that FABP5 is a key molecular sensor mediating oxygen consumption and ROS production, thus contributing to ferroptosis induced by omega-3 fatty acids in triple-negative breast cancer.

#4468 Elucidating the phosphoinositide-modulatory function of INPP5B in regulating cancer stemness and tumorigenesis in liver cancer.

L. Liu, Y. Wang, Y. Xie, M. Tong;
The Chinese University of Hong Kong, Shatin, NT, Hong Kong

Hepatocellular carcinoma (HCC) represents a major global health challenge, characterized by its heterogeneity and aggressive nature. Solid evidence has now suggested that tumor growth is driven by subpopulations of tumor cells with less differentiated cell states, called cancer stem cells (CSCs), which govern therapeutic resistance and tumor recurrence. Therefore, characterization of CSCs and their associated oncogenic signaling pathways is crucial to the development of more specific and sensitive HCC prognostic markers and to the design of novel targeted therapies against CSCs for HCC treatment. In search of the altered genes and pathways that are tightly associated with cancer stemness trait in HCC, we exploited the stemness and oncogenic dedifferentiation signature to mine the HCC dataset of the Cancer Genome Atlas. Phosphoinositide signaling was identified to be enriched and downregulated in the transcriptomes of HCC patients with strong stemness and dedifferentiated signature. Subsequent clinical correlation analysis found inositol polyphosphate-5-phosphatase B (INPP5B) to be the top downregulated gene in phosphoinositide signaling with its expression correlated with poor survival in HCC patients. Functional studies showed that INPP5B overexpression reversed the oncogenic and stemness properties while INPP5B knockout promoted tumor growth in immunocompetent mice. Subsequent RNA sequencing and molecular assays revealed INPP5B deregulation to be associated with lipid metabolism remodeling. Collectively, our results suggest an intricate relationship between phosphoinositide signaling and lipid metabolism through the regulation of INPP5B in HCC. The findings may open new avenue for future research aimed at devising targeted therapies to interfere with liver CSCs and enhance the prognosis of HCC patients.

CHEMISTRY: Drug Design and in Silico Screening
Poster Session

#4472 Discovery of potential RAF-selective back pocket as a promising biological target for BRAF inhibitors in the treatment of resistant melanoma: Design, synthesis, biological evaluation and *in silico* studies.

Usama Ammar[1], Mahmoud Gamal[2], Mohammed Abdel-Maksoud[2], Eslam Ali[3], Zeyad Mahmoud[4], Kim Deug[5], Park Jun[5], **Soo Lee**[6], Chang Oh[4]

[1]School of Applied Sciences, Edinburgh Napier University, Edinburgh, United Kingdom,[2]Medicinal & Pharmaceutical Chemistry Department, National Research Centre, Giza, Egypt,[3]School of Pharmacy and Pharmaceutical Sciences, UC Irvine, Irvine, CA,[4]Center for Biomaterials, Korea Institute of Science and Technology (KIST), Seoul, Korea, Republic of,[5]CTCBIO Inc., Gyeonggi-do, Korea, Republic of,[6]Department of Oncology/Hematology, Kyungpook National University, Daegu, Korea, Republic of

The mutated BRAF kinase (V600E) is considered the key component in the MAPK signaling pathway that was reported to be significantly contributed to melanoma disease. Vemurafenib and dabrafenib are examples of drugs that were approved by FDA to treat melanoma through inhibition of mutated BRAF kinase (V600E). However, drug resistance was reported after 6 - 7 months of treatment using these drugs due to activation of this signaling pathway through another RAF kinase (CRAF). As a Drug Discovery research group, we were interested to study and identify the possible biological target to inhibit this resistant form of cancer. We run molecular modelling simulation to study the key features of the active sites of RAF kinases and we taken vemurafenib as a starting point to design our compounds. We identified a selective back pocket in the active site of RAF kinases that can be targeted to enhance the inhibition of these kinases to overcome the drug resistance in the resistant melanoma. We designed a library of compounds based on imidazothiazole core scaffold decorated with different hydrophobic substituents to target the selectivity back pocket. Among the designed and synthesized series, KS16, that showed potent biological profile against RAF kinases compared to vemurafenib as a standard. In the cellular level, KS16 showed the same potencies against mutated BRAF-based melanoma cell line (A375) as that of vemurafenib. To evaluate the selectivity profile of KS16, kinase panel assay against 60 kinases has been investigated that showed high selectivity profile of KS16 (98 - 100% inhibition against ^{WT}BRAF, CRAF and ^{V600E}BRAF). In addition, KS16 was submitted to National Cancer Institute (NCI) to be tested against 60 human cancer cell lines in 5-point assay. It showed selective cytotoxic inhibition against melanoma cell lines compared to the other types of cancer cell lines. To evaluate the efficacy of KS16 against resistant melanoma, both KS16 and vemurafenib were tested against resistant melanoma cell line (A375R). The results revealed that KS16 showed the capability to inhibit the growth of resistant melanoma cell line in contrast to vemurafenib which failed to exhibit the same inhibition profile. The drug-candidate cardiac safety profile of KS16 was emphasized in this current project. KS16 was tested against hERG using E4031 (IC_{50} = 0.025 µM) as positive control to set up the hERG channel binding assay. The results revealed that KS16 showed relatively weak binding to hERG (% inh 64%) compared to that of the potent positive control (E4031, % inh 97%). The results revealed that KS16 is a potential drug candidate with minimal cardiotoxic effect. Further pharmacokinetic studies are being performed to KS16 to investigate and develop the ADME profile of KS16 to be a potential selected drug candidate against resistant melanoma disease.

#4473 Targeting matrix metalloproteinase-3 (MMP-3) in high-grade serous ovarian cancer.

V. G. Reyes-Burgos[1], E. Hernandez-O'Farrill[1], L. E. Vazquez Quinones[2], M. Flores-Colon[1], F. Valiyeva[3], P. E. Vivas-Mejia[1];
[1]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, [2]Interamerican University of Puerto Rico, Arecibo, Puerto Rico, [3]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

High-Grade Serous Ovarian Cancer (HGSOC) is the most aggressive and lethal gynecological malignancy. Surgery and chemotherapy (with platinum compounds) are the main treatments. Many patients relapse and develop chemotherapy resistance, limiting the therapeutic utility of these therapies. This persistent resistance makes HGSOC treatment difficult. Cisplatin-resistant ovarian cancer cells upregulate Matrix Metalloproteinase-3. MMP3 is an enzyme involved in active tissue remodeling and extracellular matrix protein breakdown during dynamic physiological processes. The structure of MMP3 includes the prodomain, the catalytic domain and the hemopexin domain. We showed that MMP3 protein levels are higher in cisplatin resistant as compared with cisplatin sensitive HGSOC cells. Our research team showed that small interference RNA (siRNA)-mediated MMP3 knockdown reduced cisplatin-resistant ovarian cancer cell growth and invasion. This data indicates that MMP3 may be a promising HGSOC treatment target. Targeting MMP3 with small chemical inhibitors (SCI) could represent a better option than siRNA because SCI are more stable and easier to deliver. The purpose of this project is to design SCI of MMP3 in the propeptide, catalytic, and hemopexin domains of MMP3. We used in silico methods to identify MMP3 inhibitors in these domains. The ZINC20 database of commercially compounds was used for virtual screening using Python Prescription (PyRx) software. We identified 25 ligands out of 370,000 with the greatest affinity for each MMP3 functional domains. SwissADME was then used to evaluate in silico absorption, distribution, metabolism, pharmacokinetics, drug-likeliness, and medicinal chemistry. This research lays the groundwork for HGSOC therapeutic strategies to improve treatment efficacy, especially for chemotherapy-resistant patients.

#4474 Novel analogs of 4-substituted pyrrolo[2,3-*d*]pyrimidines as dual-targeted mEGFR/AURKA inhibitors for lung cancer.

S. Kurup[1], G. Carpenter[1], S. Satawa[1], F. Amissah[1], E. Lisabeth[2], M. Giletto[2], E. Ellsworth[2];
[1]Ferris State University, Big Rapids, MI, [2]Michigan State University, East Lansing, MI

Small molecule, mutant epidermal growth factor receptor kinase (mEGFR) inhibitors such as osimertinib and erlotinib constitute the recommended therapy for mEGFR-positive non-small cell lung cancer (NSCLC). However, mEGFR inhibitors are ineffective in NSCLC over time due to mutations within mEGFR and redundant signaling pathways such as mutant KRAS (mKRAS) that bypass mEGFR inhibition. Simultaneous inhibition of multiple kinases has been suggested to provide synergistic effects on tumor growth inhibition and tumor resistance. Studies have shown that resistance to mEGFR inhibitors was overcome when mEGFR inhibitors were combined with aurora kinase (AURK) inhibitors. Additionally, mEGFR inhibitors were found to retain their anticancer effects in mKRAS-positive NSCLC cells if given concurrently with AURK inhibitors. Kurup *et al.* previously reported a series of 4-substituted pyrrolo[2,3-*d*]pyrimidines as dual mEGFR/AURKB inhibitors. Novel analogs of **1-5** have been designed to incorporate AURKA inhibition while maintaining mEGFR inhibition. Molecular modeling was utilized to guide selectivity for AURKA over AURKB. This study led to the identification of novel dual-targeted mEGFR/AURKA inhibitors with demonstrated inhibition of mKRAS+ NSCLC and mEGFR+ NSCLC. The design, synthesis, kinase inhibitory activities, and anticancer effects for these novel analogs will be presented. Structure-activity relationships for dual mEGFR/AURKA inhibition will be defined.

#4475 Discovery of an oral tricyclic STING agonist with superior pharmacokinetic properties and potent in vivo efficacy.

Hong-Yi Zhao, Zhongwei Liu, Shuai Mao, Miao He, Meilin Wang, Bo Wen, Wei Gao, Duxin Sun

University of Michigan, Ann Arbor, MI

Stimulator of interferon genes (STING) plays a pivotal role in regulating immune microenvironment for cancer immunotherapy. However, the use of most STING agonists has been hindered by the necessity for intra-tumoral or intravenous administration, underscoring the challenge in developing an orally bioavailable STING agonist with favorable pharmacokinetic (PK) properties. In this study, we discovered oral STING agonists featuring a novel tricyclic benzo[4,5]thieno[2,3-c]pyrrole-1,3-dione scaffold, thus achieving both superior PK properties and potent in vivo efficacy. Our lead compound, ZSA-51, exhibited nanomolar cellular STING activation activity (EC_{50} = 100 nM) in THP1 cells, surpassing the reported oral STING agonist MSA-2 by 32-fold (EC_{50} = 3200 nM). Furthermore, ZSA-51 demonstrated superior PK properties with an oral bioavailability of 49%, and robust in vivo antitumor activity both in colon and pancreatic cancers model upon oral administration. Notably, ZSA-51 displayed preferential distribution to the lymph nodes and spleen, enhancing its systemic immune-stimulating effects. The specificity of ZSA-51 was further confirmed by a comparison with a negative control compound (ZSA-52NC2) that was unable to stimulate in vitro and in vivo STING activity. Molecular docking and MD simulation confirmed that the active form of ZSA-51 stably bound to STING dimer with validated hydrogen bond network. Taken together, our findings suggest ZSA-51 as a promising oral STING agonist characterized by superior PK properties and potent in vivo efficacy, holding potential for future development for cancer immunotherapy.

#4476 Novel auristatins with improved tolerability and unique bystander activity profile.

P. N. Moquist, N. M. L. Eng-Duncan, T. Bovee, K. Snead, J. Wright, K. Smith, T. Blevins, B. Blackburn, M. Ulrich, F. Magunda, J. Simmons, P. D. Senter, S. O. Doronina;
Seagen, Bothell, WA

Auristatins are a class of clinically validated payloads used extensively in antibody-drug conjugate (ADC) technology. There are currently 4 FDA approved ADCs utilizing the vedotin drug linker to treat an array of solid tumors and lymphomas and several more in clinical trials. Auristatin payloads have several desirable properties, including strong anticancer cytotoxicity, bystander activity, and induction of immunologic cell death. While auristatin-based ADCs have been remarkably successful, there remain opportunities to further understand and improve payload properties. Bystander activity is one such property that can greatly impact the balance between efficacy and tolerability. Herein, we present a medicinal chemistry investigation into a series of auristatins with similar tubulin binding and biochemical potency that differ in lipophilicity and ability to cross the cell membrane. This design enabled us to focus on and characterize the impact of bystander activity while maintaining all other parameters. Ultimately, this effort resulted in ADCs with similar on-target in vitro cytotoxicity but differed in the extent of off-target bystander activity. Evaluation of in vivo efficacy, in vivo bystander activity, and rodent tolerability afforded a lead drug linker that was well-tolerated as an ADC and exhibited strong antitumor growth delay.

#4477 The development of a small molecule dual inhibitor of CXCR4 and Mcl-1 to target bortezomib resistant and stem-like cells in multiple myeloma.

W. O. Elbezanti[1], O. S. Al-Odat[2], S. C. Jonnalagadda[2], T. Budak-Alpdogan[1], M. K. Pandey[3];
[1]Cooper Univ. Hospital, Camden, NJ, [2]Rowan University, Camden, NJ, [3]Cooper Medical School of Rowan University, Camden, NJ

Multiple myeloma (MM) is a malignant plasma-cell illness defined by clonal growth of malignant plasma cells within the bone marrow (BM) microenvironment. Despite the availability of many therapeutic alternatives, MM remains consistently lethal, demanding the development of novel techniques. The intimate relationship between myeloma cells and the BM microenvironment is a distinguishing hallmark of MM. The chemokine stromal cell-derived factor-1 (SDF-1) and its receptor CXCR4 enhance the homing of MM cells to the BM, which has important functional implications. The BM microenvironment secretes a variety of hormones and cytokines that activate several signaling pathways, resulting in enhanced production of the anti-apoptotic Mcl-1 protein, boosting the proliferation, survival, and migration of MM cells and conferring resistance to standard chemotherapy. As a result, we created GA-A, a hybrid molecule in which we coupled an aralkyl carboxylic acid moiety, known to preferentially inhibit Mcl-1, to gambogic acid, which has previously been demonstrated to inhibit CXCR4 in MM. Our western blot has shown that this unique hybrid compound successfully suppressed CXCR4 and Mcl-1. Interestingly, using qPCR we found that CXCR4 was observed to be higher expressed in CD138- versus CD138+ cells, while GA-A inhibited CXCR4 in both subpopulations. In addition, using annexin-V flow cytometry staining we found that GA-A increased the apoptotic effect of bortezomib in MM stem-like cells while inhibiting the viability of bortezomib resistant cells. Using human cytokine array we found that GA-A activates some of proinflammatory cytokines that can activate the immune system such as GM-CSF, IFN gamma, IL-2 and IL-12. In summary, our findings indicate the successful creation of a novel dual CXCR4-Mcl1 inhibitor that demonstrates efficacy against the stem cell-like population and bortezomib resistant cells and enhances the effectiveness of bortezomib.

#4478 Development and characterization of kinase sparing TPX2-tethering Aurora kinase A ligands for cancer therapy.

A. Moschopoulou[1], M. Henning[1], B. Wagner[2], D. Flotgen[2], J. Reiner[2], Y. Skliarenko[1], S. Zwirner[1], C. Hinterleitner[1], M. Seehawer[1], L. dArtista[1], E. Rist[1], T. Pantsar[3], T. Kronenberger[2], D. Dauch[1], C. Gehring-Khav[1], A. Poso[3], L. Andreeva[1], M. Schwab[4], M. Forster[2], W. Albrecht[1], S. Laufer[2], **L. Zender**[1]; [1]University Hospital Tubingen, Tubingen, Germany, [2]University of Tubingen, Tubingen, Germany, [3]University of Eastern Finland, Kuopio, Finland, [4]Dr Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany

A major limitation in the treatment of cancer is the limited therapeutic index of currently available chemotherapies or molecularly targeted therapies. Drug related toxicities often necessitate restricted drug dosing regimens, resulting in subtotal tumor remissions, which represent an important cause for tumor recurrences and the development of therapy resistance. Following up on previous work suggesting Aurora kinase A (AURKA) as a promising therapeutic target for the treatment of *TP53* altered liver carcinomas (Dauch D. et al., *Nat. Med*., 2016) and *TP53*; *RB1* altered small cell lung carcinomas (Gong X. et al., *Cancer Discovery*, 2019), we here report on the development and characterization of first in class kinase sparing AURKA ligands, which selectively kill *TP53* deficient liver cancer cells and *TP53*; *RB1* deficient small cell lung cancer cells by tethering AURKA to its binding partner TPX2 in mitotic cells. Small molecule mediated stabilization of AURKA/TPX2 complexes resulted in formation of multipolar spindles and subsequent cell death through mitotic catastrophe. Mechanistically, we were able to show that the hypersensitivity of *TP53* deficient liver cancer cells and *TP53; Rb1* deficient small cell lung cancer cells towards AURKA ligands is due to low expression levels of the antiapoptotic protein MCL1, which is necessary for survival of cancer cells in prolonged mitosis. Our novel AURKA ligands do not affect the kinase function of AURKA and thus, in contrast to conventional AURKA kinase inhibitors, can be administered continuously to mice without inducing toxicity related to inhibition of kinase related non-canonical (non-mitotic) functions of AURKA in normal cells or *TP53* and *RB1* wildtype cancer cells. Preclinical therapy studies in cell-line derived xenograft (CDX) tumor models of small cell lung cancer (SCLC) and orthotopic models of *TP53* altered hepatocellular carcinoma and *TP53;Rb1* altered SCLC demonstrated marked monotherapeutic efficacy of AURKA ligands. Conceptually, our herein provided data suggest that small molecules designed to stabilize protein-protein interactions represent powerful anti-cancer drugs with exceptional therapeutic window and thus open a venue towards the development of novel cancer therapies.

#4479 Design, synthesis, and evaluation of amino acid conjugated niclosamide prodrugs as a PepT1 substrate.

Alaina C. McDonough[1], Jeffery Y. Cheng[1], Shabber Mohammed[1], Pui-Kai Li[1], Yangzom Bhutia[2]

[1]Ohio State Univ. College of Pharmacy, Columbus, OH,[2]Department of Cell Biology and Biochemistry, Texas Tech University, Lubbock, TX

The anthelmintic drug, Niclosamide, has a multitude of promising anticancer properties including inhibition of key signaling pathways involved in tumorigenesis, disruption of mitochondrial function, degradation of the overexpressed androgen receptor, and more. However, a key limitation of the clinical use of Niclosamide in cancer treatment is its low solubility and cellular uptake, which result in poor pharmacokinetic properties and dose-limiting GI toxicities at concentrations lower than the therapeutic threshold of the drug. To overcome this, we hypothesized that we could use amino acid conjugated niclosamide prodrugs to improve cellular uptake by creating a substrate of the PepT1 transport protein. The overexpression of the PepT1 transport protein that is involved in many hormonal cancers is being used to our advantage. Our study involved first synthesizing a group of niclosamide and niclosamide analogs conjugated with polar or nonpolar amino acids. Next, we conducted a Glycine-Sarcosine assay measuring changes in the uptake of the dipeptide glycyl-sarcosine (Gly-Sar). Our initial step was to examine if our conjugates could disrupt the absorption of Gly-Sar. The active conjugate will be tested whether they are substrates or inhibitors of the transporter. For the future, we have plans to determine the half-maximal inhibitory concentration (IC50) of niclosamide conjugates in various cancer cell lines and to quantify cleavage of the prodrugs intracellularly.

#4481 Enhancing AOH1996 through structure activity relationship exploration for caPCNA inhibition.

P. Haratipour, M. Zangi, M. Yaghoubi, L. Gu, J. Jossart, J. J. P. Perry, L. H. Malkas, R. J. Hickey;
Beckman Research Institute of City of Hope, Duarte, CA

Recently, we have developed AOH1996, a small molecule PCNA ligand currently in phase I clinical trial, designed to selectively inhibit the functions of cancer-associated PCNA (caPCNA). Seeking to enhance the potency and selectivity of AOH1996, we conducted an exhaustive Structure-Activity-Relationship (SAR) investigation. Over 100 analogues of AOH1996 were synthesized, systematically modifying its three main components: the naphthyl group, glycine linker, and diphenyl ether. The glycine linker underwent substitution with various natural and unnatural amino acids, while the 1-naphthyl group saw replacements with diverse monocyclic and bicyclic aromatic groups, including quinoline and isoquinoline derivatives. The diphenyl ether moiety was extensively explored by substituting the bridging oxygen with different functional groups (sulfonyl, imido, sulfur, amide), substituting both phenyl rings with various functional groups (fluorine, chlorine, hydroxy, methoxy, methyl, trifluoromethyl), and adopting a nitrogen-walk approach on the terminal phenyl ring to evaluate critical ligand/caPCNA-binding positions. This meticulous effort resulted in the identification of several analogues, such as AOH1160S (featuring a diphenyl thioether group), AOH1996S-4CH3 (with a methyl group at the para-position of the terminal thiophenyl ring), and AOH1996-3CH3 (incorporating an m-methoxy function in the terminal phenyl ring and bridging oxygen), exhibiting similar or superior potency compared to AOH1996. The target binding of these analogues was verified by capturing the binary complex of the more polar version of these analogues in the crystal structure. The synthesis, characterization, and detailed biological activities of these promising AOH analogues will be thoroughly described.

#4482 Development of small molecule inhibitors of lipocalin 2 for the treatment of aggressive cancers.

M. Flores-Colon[1], C. A. Pena-Vazquez[2], E. Hernandez-O'Farril[1], L. E. Vazquez-Quinones[3], P. E. Vivas-Mejia[1];
[1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Puerto Rico Rio Piedras Campus, San Juan, PR, [3]Interamerican University, Arecibo, PR

Lipocalin-2 (LCN2), a secreted protein pivotal in iron homeostasis, immune responses, siderophore transport, and epithelial cell differentiation. LCN2 is highly abundant in aggressive forms of many cancers including breast, pancreatic, ovarian, and esophageal cancer. Elevated LCN2 levels in aggressive tumors correlate with heightened cancer cell motility, proliferation, angiogenesis, invasion, and metastasis. After the protein folds it makes a barrel structure which encloses a three-calyx pocket that can bind and transport molecules. A first generation of small molecule inhibitors (SMIs) targeting LCN2 demonstrated efficacy in attenuating the proliferative capacity of Inflammatory breast cancer (IBC) cells. IBC stands as a rare and highly aggressive variant, accounting for 1 to 5% of all BC cases, with 20-30% presenting as de novo metastatic disease. In the previous studies the concentration of LCN2 inhibitors to reduce cell proliferation in 50% was around 10 µM. In pursuit of better LCN2 SMIs, we conducted in-silico analysis using a library of 369,000 ligands. Through the High-Performance Computer Facility at UPR Río Piedras, we employed AutoDock Vina for virtual screening, targeting the LCN2-calyx with Lys134 as the central coordinate. Docking protocols, predicting binding affinities, identified 8,162 out of 327,638 ligands that have been docked already with values below -9.6 kcal/mol for further consideration. The next phase involves subjecting these potential inhibitors to the SwissADME tool for a comprehensive evaluation of absorption, distribution, metabolism, and excretion parameters, as well as pharmacokinetics, drug-likeness, and medicinal chemistry considerations. The parameters to be evaluated are the Lipinski rules, which states that an orally active drug may have a maximum of one violation and the pann-assay interference compounds (PAINS) alerts tool, a source of false positives for biologically active compounds. The top candidates, exhibit binding affinities within the range of -11.5 to -12.2. After SwissADME filtering, we will re-rank the ligand list, identifying 30 commercially available candidates for subsequent cell viability assays in SUM149 (TNBC) and SUM190 (HER2+) cell lines. This multifaceted approach integrates computational methodologies with rigorous experimental validation, paving the way for potential therapeutic interventions in IBC treatment.

#4483 New drug development opportunities for PARP1.

P. Iglesias, D. Moreiras, L. Porres-Ventin, L. Gonzalez-Rendo, J. A. Zumalave, **V. M. Arce**, J. A. Costoya;
Universidad Santiago de Compostela, Santiago De Compostela, Spain

Personalized therapies allow, not only the increase of its therapeutic efficiency, but also the reduction of the secondary effects associated to the treatment of cancer. Data obtained in our group suggest that PARP1 could play a key role in the cell cycle regulation through its interaction with E2F1 transcription factor. Considering that most oncogenic processes is associated with cell cycle deregulation, the disruption of this interaction would provide a new therapeutic target of great interest and wide spectrum of indications. Therefore, our goal was to find molecules that interfere its role in cell-cycle regulation without affecting its function on DNA repair. The identification of novel compounds disrupting the PARP1/E2F1 interaction was carried out by combining *in silico* and *in vitro* screening, using a rational drug design. The virtual screen was performed using a molecular library of several million compounds at the selected target site, using AtomNet® (Atomwise), the first deep learning neural network for structure-based drug design and discovery. Since there is no complete structural information of the PARP-1/E2F1 protein-protein interaction, a homologous structure of BRCT domain of BRCA1 complex with the phospho-peptide (PDBID: 1T2V) was utilized to identify the potential binding interface of BRCT domain of PARP-1 (PDBID: 2COK) and the E2F1 protein. Top scoring compounds were clustered and filtered to arrive at a final subset of 83 compounds, library that were incorporated to our in vitro screening, which included both transcriptional (E2F1 activity) and survival studies. Twelve compounds were finally selected, based upon their higher capacity of inhibiting E2F1 activity.This work was supported by Agencia Estatal de Investigación (AEI/10.13039/501100011033), Xunta de Galicia (GPC GI-1862, ED431B 2020/26; ED431G 2019/02) and European Regional Development Fund-ERDF. AIMS Awards Program - Project A19-513, Atomwise Inc.

#4484 Discovery of a potential first-in-class Za targeted small molecule inhibitor of ADAR1 p150 which demonstrates strong anti-tumor efficacy.

A. Goswami[1], S. Goyal[1], K. Singh[1], P. Khurana[1], B. Deb[1], **A. Kulkarni**[2];
[1]Aten Porus Lifesciences, Bangalore, India, [2]Avammune Therapeutics, King of Prussia, PA

Background: Adenosine deaminase, RNA specific (ADAR1), catalyzes the hydrolytic deamination of adenosine (A) to inosine (I) in double-stranded (ds) RNAs. ADAR1 has two isoforms: p110 in the nucleus and p150 in the cytoplasm. Both isoforms alter the coding and non-coding sections of self-dsRNA. The ADAR1 p150 isoform is expressed from an interferon (IFN)-response promoter and has a Z-DNA/Z-RNA binding domain at the N-terminus. ADAR1 has been implicated in promoting cell survival and resistance to immune response in several cancer types like multiple myeloma, breast, lung, liver, and skin cancer. Inhibition of ADAR1 p150 has the potential to enhance anti-tumor efficacy as monotherapy and in combination with other therapeutic modalities. The Zα domain of ADAR1 p150 provides exclusivity to p150 compared to the other isoforms. Herein, we outline the discovery of a potential first-in-class Zα targeted ADAR1 p150 inhibitor and degrader for cancer immunotherapy.

Methods: AVA-ADR-001 was identified through a high throughput p110 knockout cell-based assay. The ability of AVA-ADR-001 to induce interferons was confirmed in various cell lines. The anti-tumor efficacy of AVA-ADR-001 was evaluated in B16F10 syngeneic melanoma mice model as monotherapy and in combination with anti-PD-1. PROTAC AVA-ADR-703 was used to demonstrate selective degradation of the ADAR1 p150 protein.

Results: We have discovered AVA-ADR-001, a novel small molecule inhibitor of ADAR1 which significantly increases the IFN response in vitro in an MDA5-dependent manner. In vitro binding studies confirm that AVA-ADR-001 binds to the Zα domain of ADAR1 with low nM potency. AVA-ADR-001 demonstrates anti-tumor efficacy 1.5X superior to anti-PD1 ICB non-responsive tumor models. In addition, the AVA-ADR-001 monotherapy and combination groups showed a significant upregulation of numerous interferon-stimulated genes, including IFIH1, IFN-β, and CXCL-10. Finally, targeted protein degradation of ADAR1 p150 while sparing ADAR1 p110 was confirmed when cells were treated with AVA-ADR-703 with nM DC_{50}, the PROTAC variant of AVA-ADR-001.

Conclusions: To our knowledge, AVA-ADR-001 and AVA-ADR-703 are the first selective Zα-targeted small molecule inhibitor and degrader of ADAR1 p150 respectively to be disclosed. As a powerful and targeted first-in-class ADAR1 inhibitor, AVA-ADR-001 has demonstrated a strong induction of interferon (IFN) in a number of cancer cell lines and *in vivo*. AVA-ADR-001 has also demonstrated strong *in vivo* anti-tumor efficacy as monotherapy and in combination with anti-PD1. Furthermore, AVA-ADR-703 demonstrates selective and highly efficient degradation of ADAR1 p150 while sparing ADAR1 p110. Given that ADAR1 has a pro-metastatic and immune-suppressive role, AVA-ADR-001 and AVA-ADR-703 have significant potential to emerge as strong cancer immunotherapy candidates.

#4485 Identification of novel lead compounds and repurposing FDA approved drugs as telomerase inhibitors using structure-based drug designing approach and their evaluation using in-vitro and ex-vivo assays.

D. Kaur, M. Chopra, D. Saluja;
Dr. B.R. Ambedkar Ctr. for Biomedical Res., Delhi, India

Introduction: Upregulated telomerase activity is an established hallmark in about 85-90% of cancer malignancies making it an attractive therapeutic target. However, the development of approved small-molecule telomerase inhibitors has been impeded by a lack of structural ambiguity for decades. In our study, we have employed a molecular dynamics approach to validate the binding site of BIBR1532, an approved telomerase inhibitor in the hTERT thumb domain followed by a structure-based drug designing approach to repurpose FDA-approved drugs and identify novel lead compounds targeting the enzyme.
Material and Methods: Due to the unavailability of a co-crystalized structure of BIBR1532 with the catalytic hTERT thumb domain, we employed a Molecular dynamics-based method to identify and validate the exact binding site of the inhibitor. Two pharmacophore models were generated for the putative and newly identified binding pockets which were screened virtually through an anti-cancer library and Drug Bank database. The models were validated on the basis of the fit value of the BIBR1532 and selectivity value indicating the favorable feature set required. The top hits obtained were filtered using drug-likeliness parameters like Lipinski, ADME, and TOPKAT followed by redocking into their binding site. Finally, lead molecules that were able to dock in the new pocket were validated using Molecular Dynamics (MD)simulation studies and their binding free energy was calculated using MM-PBSA calculations followed by their evaluation using in-vitro TRAP assay.
Results: Structural investigation, molecular docking studies, and confirmatory molecular dynamics revealed that the exact binding site of BIBR1532 is 8.4 Å away from the reported FVYL pocket strikingly with clinically relevant and characteristic interactions conserved. We have identified five lead compounds and four lead compounds from DrugBank and the anti-cancer library respectively, that were stable in the new binding pocket based on their MD trajectory analysis, and parameters like RMSD, RMSF, H-bonds and Radius of Gyration as well as their MM-PBSA scores. The lead compounds are being evaluated in vitro using TRAP assay and ex-vivo assays.
Conclusion: The study identified five existing FDA-approved drugs in the market for other diseases as potential telomerase inhibitors alongside four novel compounds that can be used for the treatment of cancer in the future after further validation studies.

#4486 Characterization of a novel mutant selective, EGFR sparing, ErbB2 inhibitor with activity across activating mutations in systemic and CNS tumors.

J. Fulton, T. Bettendorf, A. Blandon, K. Bouhana, R. K. Brizendine, L. Cable, M. J. Chicarelli, M. Crow, B. Fell, J. Fischer, A. Guarnieri, M. Hillman, R. Jalluri, V. Kumar, C. A. Malinky, R. Rieger, J. Robinson, L. Stunkard, F. Sullivan, J. I. Trujillo, S. Winski, Y. Zhou;
Cogent Biosciences, Inc., Boulder, CO

Alterations in ErbB2, including amplification, overexpression, insertions, and point mutations, are established oncogenic drivers in many solid tumors. These mutations are found in approximately 3-4% of breast cancers and 3% of advanced lung cancers and have emerged as mechanisms of acquired resistance to targeted therapies. ErbB2 alterations are also found in metastatic breast and lung cancers that have advanced to the brain and remain a major clinical challenge with limited therapeutic options. Currently approved ErbB2 tyrosine kinase inhibitors have inferior potency against these mutations and lack sufficient brain penetration to be an impactful treatment option for patients. Herein, we describe advanced preclinical profiling of our candidate series of brain-penetrant EGFR-sparing ErbB2 inhibitors with activity against prevalent point mutations and exon 20 YVMA insertions.

#4487 Simple modifications of 3-HPT for improved *in-vivo* activtiy.

R. E. B. Kern, S. Huang, U. Arunsi, A. Oyelere;
Georgia Institute of Technology, Atlanta, GA

One of the key targets in the treatment of castration resistant prostate cancer is HDAC6. HDAC6 removes acetyl groups from Heat shock protein 90 (HSP90), which is a protein chaperone that folds the androgen receptor. By inhibiting HDAC6 it is possible to prevent the expression of mutated androgen receptors, that are no longer responsive to androgen deprivation therapy, treating castration resistant prostate cancer. The Oyelere lab has previously demonstrated that 3-Hydroxypyridin-2-thione (3-HPT) can serve as a scaffold for HDAC6 inhibitors. While the unaltered 3-HPT has been shown on its own to inhibit HDAC6 in enzyme specific assays. The unaltered 3-HPT had no effect in whole cell assays. This work investigated simple modification of the 3-HPT scaffold to improve the in-vivo activity of 3-HPT. This work is an extension of work previously done in the Oyelere lab. The aim of this work is to apply simple modifications to the 3-HPT scaffold to improve the in-vitro activity. Previously 3-HPT was shown on its own to inhibit HDAC6 with an IC_{50} of 681nM but have no effect on cell assays. The hypothesis was that by converting the secondary amine into a tertiary amine the pharmacokinetic-properties of 3-HPT allowing can be improved focusing on cellular entry. The specific modification was the addition of alkanes and fluorinated alkanes at the secondary amine. This addition should improve the charge of the compounds improving the invitro activity. Based on molecular docking studies using Autodock vina, the introduction of fluorines improves the binding to HDAC6 by interacting with a hydrophilic pocket near the zinc ion. The preliminary in-vivo results in LnCAP and DU145 cells demonstrate that the addition of fluorinated alkanes has substantially improved the IC_{50} compared to the base 3-HPT compound. The base 3-HPT compound has an IC_{50} of greater than 100μM while the compounds with fluorinated alkanes have IC_{50} values in the range of 2-15μM. this data indicates improved drug likeness.

Preliminary IC50 values of compounds in prostate cancer cell lines

Compound Name	**LNCaP IC_{50}** (μM)	DU145 **IC_{50}** (μM)	Vero **IC_{50}** (μM)
SH-1-78	>100	>100	>100
SH-1-94	2.50	19.29	22.53
RK-1-187	96.95	95.45	88.57
SH-1-110	1.27	21.47	17.41
RK-2-16	2.09	62.86	18.76
RK-2-17	>100	>100	>100
RK-2-64	78.36	>100	76.45
RK-2-67	14.19	26.95	11.38

#4488 Newly developed organoiridium(III) complexes containing N,P-ligands possess antiproliferative activity in selected cancer cell lines.

R. Hezova[1], J. Hosek[1], N. Strakova[1], P. Simeckova[1], J. Masek[1], S. Kajabova[1], P. Starcha[2];
[1]Veterinary Research Institute, Brno, Czech Republic, [2]Palacky University Olomouc, Brno, Czech Republic

In conventional cancer treatment, platinum-based cytostatics are considered as standard therapy; however, they possess severe side effects. This fact leads to a constant effort to develop new non-platinum metallodrugs with different mechanism of action (MoA). In our study we developed new half-sandwich organoiridium(III) complexes, of general formulas $[Ir(\eta^5\text{-}Cp^*)Cl(L^{NP})]PF_6$ (1-3) and $[Ir(\eta^5\text{-}Cp^{ph})Cl(L^{NP})]PF_6$ (4-6) involving three different N,P-donor phosphinoalkylamines (L^{NP}), which we tested on 2D and 3D cancer models; HCp* = pentamethylcyclopentadiene, HCp^{ph}= (2,3,4,5-tetramethylcyclopenta-2,4-dien-1-yl)benzene. The most effective complexes 3 and 6 bearing 3-(diphenylphosphanyl)propan-1-amine had the highest cytotoxic effect against various cancer cell lines (THP-1, HeLa, SW982, A549, MOR) including a cisplatin-resistant lung carcinoma cell line (MOR/CPR) with IC_{50} values between 3.1 and 9.1 µM for specific cell lines. The cytotoxic effect was further demonstrated on 3D spheroids of lung cancer cells that revealed anti-cancer and anti-migration potential of complexes 3 and 6. Cell cycle and cell death analysis showed a different mechanism compared to the effect of cisplatin. Moreover, complex 3 did not decrease cell viability of non-cancerous cells (peripheral blood mononuclear cells and porcine chondrocytes) under 50% at a concentration of 20 µM. In addition, we report for the first time that organoiridium complexes showed high cytotoxic activity on cancer cell lines, including cisplatin-resistant cell line, with different MoA from cisplatin. They trigger expression of stress-related genes associated with oxidative stress, DNA damage, and endoplasmic reticulum stress and, moreover, complex 3 showed cytotoxic selectivity towards cancer cells. *This work was supported by the Czech health research council of the Ministry of Health of the Czech Republic (AZV Project NU22-08-00236).*

#4489 Developing dual FLT3/MNK inhibitors to overcome sorafenib resistance in FLT3-ITD AML cells.

L. Zhao[1], S. Zuo[1], K. Xing[1], X. Yue[1], H. Zhang[1], J. Zhang[1], S. Waxman[2], Y. Jing[1];

[1]Shenyang Pharmaceutical University, Shenyang, China, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Acute myeloid leukemia (AML) patients with FLT3-ITD mutations are associated with poor prognosis. FLT3-ITD inhibitors developed only result in transient disease remission with disease relapse and resistance. Agents overcoming FLT3-ITD inhibitor resistance need to be developed. Sorafenib is one of FLT3-ITD inhibitors used in clinic. Using FLT3-ITD AML MOLM-13 cell line, we established a sorafenib resistant subclone MOLM-13/Sor, explored the resistance mechanism and revealed the overactivated mTOR signaling. MNK as one of the alternative mTOR signaling pathways is activated. MNK inhibitor eFT508 could overcome sorafenib resistance. Previously we developed a dual pyrido[3,2-*d*]pyrimidine MNK/PIM inhibitor 21o. Through optimization of 21o we obtained two new compounds H104 (IC_{50} values: MNK1 19 nM; MNK2 8 nM; FLT3-ITD 46 nM; PIM1 1388 nM) and H118 (IC_{50} values: MNK1 35 nM; MNK2 21 nM; FLT3-ITD 25 nM; PIM1 518 nM) with selective inhibition of MNK and FLT3 and losing PIM inhibition ability. H104 and H118 show better antiproliferative efficacy in FLT3-ITD MOLM-13 cells (GI_{50}: 1.07±0.04 μM and 0.99±0.08 μM) than non-FLT3-ITD HL-60 cells (GI_{50}: 7.04±0.15 μM and 4.78±0.31 μM). More intriguingly H104 and H118 exhibit superior antiproliferative effects in sorafenib resistant MOLM-13/Sor cells (GI_{50}: 0.44±0.05 μM and 0.24±0.06 μM). H104 and H118 decreased the levels of p-eIF4E, c-myc and Mcl-1, the downstream substrates of FLT3-ITD and MNK. Our data indicate that the activated MNK is one mechanism of FLT3-ITD resistance and the dual MNK/FLT3 inhibitors have advantage for FLT3-ITD AML treatment.

#4490 Targeting NQO1 with Episesaminol: A new therapeutic option identified for colorectal cancer using integrated systems biology and structural biology-based approach.

Sohini Chakraborty[1], Gaurav Sharma[1], Sricheta Karmakar[1], Prarthana Chatterjee[1], Saptarshi Sinha[2], Pradipta Ghosh[2], Satarupa Banerjee[1]

[1]Department of Biotechnology, Vellore Institute of Technology, Vellore, India, [2]Department of Cellular and Molecular Medicine, University of California San Diego, San Diego, CA

Introduction: Colon and/or rectal cancer together constitute colorectal cancer (CRC), the 2nd most lethal and the 3rd common cancer worldwide. Drug resistance to modern chemotherapies results in decreased therapeutic efficacy and CRC treatment failure. Herein, multi-layered strategies are used for a better identification of the newer therapeutics.

Methodology: Different publicly available datasets were used for the identification of the differentially expressed genes (DEGs) between normal and CRC tissues. miRNAs, lncRNAs and small molecules interacting with those DEGs were mined from various databases. A complex network of interacting mRNA-miRNAs-lncRNAs-small molecules was created using the Cytoscape. Hub RNAs, significant modules and cliques were identified using Cytohubba and MClique plugins. The mRNAs from the top 30 cliques were analyzed by expression, oncoprint, survival and gene ontology. Polyphenols from the PhenolExplorer database were also assessed for their druggability and toxicity properties to finally obtain druggable polyphenols (DPs). A two-step molecular docking was done using PyRx for mRNAs from top 30 cliques and DPs and the top ten complexes were docked again using AutoDock. Molecular dynamics simulation (MDS) is performed for the best fit protein-proposed DP vs protein-known drug using GROMACS.

Results: 1915 DEGs, 2609 miRNAs, 1411 lncRNAs and 8790 small molecules (other than selected DPs) interactions were considered for generating a comprehensive interaction network. The 27 mRNAs from the top 30 cliques were subjected to an array of analyses. NCAPD2, CDK4 and FASN were found to be involved in different stages of CRC. IRF2BPL, CMPK1, CCNF and UST were found as survival biomarkers, whereas FAT4 was found to be the only genetically altered mRNA. Functional enrichment supported the analysis revealing significant CRC-associated gene ontology as well as pathways. 56 DPs when docked with the DEGs, the two-step docking revealed NQO1-Episesaminol to be the best target-drug complex. Results of docking were comparable when MDS was performed for NOQ1•Episesaminol Vs NQO1•Doxorubicin (approved drug).

Conclusion: In the current interaction network and MDS-based integrated analysis, significant druggable CRC biomarkers and their newer therapeutic solutions were identified. MDS reveals NQO1•Episesaminol as a potential target•drug combination for CRC.

#4491 Development of IRE-1 inhibitors for B cell cancer therapy.

A. Shao[1], C.-H. A. Tang[1], J. R. Del Valle[2], **C.-C. A. Hu[1]**;
[1]Houston Methodist Research Institute, Houston, TX, [2]University of Notre Dame, Notre Dame, IN

In response to the endoplasmic reticulum (ER) stress, the IRE-1 kinase/RNase splices the mRNA of the XBP-1 gene, resulting in the spliced XBP-1 (XBP-1s) mRNA that encodes the functional XBP-1s transcription factor. XBP-1s is critically important for the growth and survival of B cell leukemia, lymphoma, and multiple myeloma. When compared with other inhibitors targeting IRE-1, the tricyclic chromenone-based inhibitors B-I09 and D-F07, prodrugs harboring an aldehyde-masking group, emerged as the very reliable inhibitors for potent suppression of the XBP-1s protein. Protection of the aldehyde as a 1,3-dioxane acetal led to strong fluorescence emitted by the coumarin chromophore, enabling both B-I09 and D-F07 to be tracked inside the cell. We installed a photolabile structural cage on the hydroxy group of D-F07 to generate PC-D-F07. Such a modification significantly stabilized the 1,3-dioxane acetal protecting group, allowing for specific stimulus-mediated control of the inhibitory activity. Upon photoactivation, the re-exposed hydroxy group triggered the aldehyde-protecting 1,3-dioxane acetal to slowly decompose, leading to the inhibition of the RNase activity of IRE-1. Since chemical modifications of the hydroxy group could be used to tune 1,3-dioxane prodrug stability, we installed reactive oxygen species (ROS)-sensitive boronate cage groups onto B-I09 (BC-B-I09) and D-F07 (BC-D-F07) to achieve stimuli-responsive activities and improve tumor-targeting efficiency based on that cancerous B cells indeed produced higher levels of ROS than normal B cells. These boronate caged compounds could be further combined with the FDA-approved Auranofin, a thioredoxin reductase inhibitor, to achieve synergistic cancer-killing effects. These results led us to further develop a novel prodrug, TC-D-F07, in which a thiol-reactive dinitrobenzenesulfonyl (Dns) cage was installed onto the hydroxy group of D-F07. The electron-withdrawing Dns group in TC-D-F07 similarly stabilized the neighboring 1,3-dioxane acetal, allowing for stimulus-mediated control of its inhibitory activity. TC-D-F07 exhibited high sensitivity to intracellular thiols produced by cancerous B cells. In addition, when TC-D-F07 was decomposed into D-F07, we observed that a dinitrophenyl cysteine adduct resulting from cleavage of the Dns group could induce the ER stress, causing cancerous B cells to increase the expression of XBP-1s. However, the accumulated levels of D-F07 from TC-D-F07 and its gradual decomposition into the active IRE-1 inhibitor could eventually deprive cancer cells of all XBP-1s, leading to more severe apoptosis in TC-D-F07-treated than in D-F07-treated cells. Thus, TC-D-F07 with both ER stress-inducing and XBP-1s-inhibiting activities represents an IRE-1-targeting caged prodrug that can be used to treat B cell cancer effectively.

#4492 Deferiprone optimization for the treatment of triple-negative breast cancer.

A. Johnston, A. K. Oyelere;
Georgia Institute of Technology, Atlanta, GA

Triple-negative breast cancer (TNBC) is the leading cause of new cancer cases and the second leading cause of cancer deaths in American women disproportionately affecting Black and Hispanic women under 40. Currently, there is no targeted therapy for TNBC and treatment options to manage this lethal disease include surgery, adjuvant chemotherapy and radiotherapy. Among the chemotherapy agents, combination of the PARP inhibitors with DNA-damaging results in a more promising anti-tumor effect. A better understanding of TNBC etiology has aided in unraveling the roles of two additional cellular targets - androgen receptor (AR) and histone lysine demethylase (KDM) - in the viability and survival of TNBC. Interestingly, AR overexpression is the most important driver of prostate cancer (PCa). A class of current medications used to treat PCa act as androgen receptor (AR) antagonists (or antiandrogens). Antiandrogens are under investigation in the clinic as potential therapies for luminal AR (LAR) subtypes of TNBC, a particularly worrisome subtype that frequently metastasizes to regional lymph nodes and bones. Although LAR TNBC constitutes 15-20% of TNBCs, it is characterized by minimal response to chemotherapy and aggressiveness. It is therefore plausible to repurpose and optimize antiandrogens, in the context of designed multiple ligands; to obtain a TNBC-targeting therapy effective against several subtypes of this heterogenous disease, including the basal subtype that is responsible for ~80% of TNBC incidence. The proposed therapeutics are dual-acting antiandrogen-KDM inhibitors. The antiandrogen moiety of these agents will enable TNBC cell-targeting and translocation of the drug into the nucleus where inhibition of KDM will prevent transcription of KDMs that promote tumor growth. The three pharmacophores of these agents are (i) an AR binding group, (ii) a linker, and (iii) an iron-binding group. Two functional classes of these compounds, alkyl- and aryl-derivatives, vary in the design of the AR binding moiety. To optimize these agents, the methylene linker length is varied in each class for in vitro determination of the optimal length for increased drug efficacy. The compounds are tested on TNBC cell lines (MDA-MB-231, low AR+; and MDA-MB-453, high AR+), and ER+ BCa (MCF-7) while PCa cell lines (LNCaP PCa, AR+; and DU 145, PCa, AR-) serve as controls for AR dependency of the compounds. Longer linker length compounds exhibited low micromolar cytotoxicity and selectivity for AR+ TNBC and PCa cell lines. Further analysis of lead compounds in TNBC cells aided in understanding the effects on targets, transcriptomic effects via RNA sequencing analysis and the mechanism of action. Thus far, the designed dual-acting therapeutics have potential to revolutionize the design of anticancer drugs and improve treatment outcome for TNBC patients.

#4493 Protein structure inspired drug discovery.

F. Qiao[1], T. Binkowski[2], W. Anderson[3], W. Chen[1], G. Schiltz[4], K. Scheidt[4], A. Natarajan[1], R. Bergan[1];
[1]UNMC Eppley Institute, Fred & Pamela Buffett Cancer Center, Omaha, NE, [2]The University of Chicago, Chicago, IL, [3]Northwestern University, Chicago, IL, [4]Northwestern University, Evanston, IL

Introduction: Drug action is mediated by a small molecule therapeutic binding to a specific structural motif on a protein. As structure determines function, it follows that unique structural motifs are enriched for sites of unique function and high therapeutic target value. We hypothesized that protein structure constitutes high value *primary* information that can drive the discovery of novel therapeutic agents.
Method: We developed a unique physics-based protein structure analysis platform scaled to run on a supercomputer, allowing us to consider dynamic protein flexibility and the influence of solvent upon protein structure, and to probe large protein libraries as a primary source of structure information that can support up-front structure-based screens. We developed and then probed a high resolution protein x-ray crystallographic library, created and curated by us. From a 60 million compound library, we conducted virtual screens for docking to identified sites. 8-day colony formation assays were conducted on a panel of 8 human breast, prostate, lung and colon cancer cell lines, as well as 8- and 14-day trilineage hematopoietic colony formation assays on human cord blood stem cells.
Findings: From the first 180 deposited protein structures, we screened for unique protein surface structure. Structures were deemed unique if they were not otherwise known to be associated with any particular functional roles and were not the binding site of known therapeutics. Further selection included those that were clefts and possessed physical characteristics compatible with binding small chemicals whose properties have been linked to effective therapeutics. For each of 8 sites on 6 different proteins, a suite of analytics probed docking solutions from the compound library, generating a ranked list of 100 compounds for each site. Based on factors inclusive of availability and low potential for toxicity, compounds were acquired and used in in-parallel selection and de-selection functional assays. Cancer cell growth inhibition was a positive selection criterion, with additional ranking based on greater potency and broader efficacy. Bone marrow toxicity is limiting for most drugs, and inhibition of bone marrow stem cell growth was as a deselection criterion. Multiple compounds clustered around 2 sites on 2 different proteins. One compound, Dxr2-017, exhibited very high relative efficacy against colon and breast cancer cells. Evaluation of Dxr2-017 in the NCI-60 panel corroborated these findings, and showed even higher efficacy against melanoma. We demonstrated that Dxr2-017 inhibited melanoma growth with low nanomolar efficacy, while concentrations of over 2300-fold higher had only limited inhibitory effects on bone marrow stem cells.
Conclusions: This study provides proof-of-principle that protein structure constitutes high value primary information that can support identification of novel therapeutics. This approach is widely applicable and expandable.

#4494 Cryo-EM structure-based small molecule inhibitor drugs targeting CSPG4/NG2 in glioblastoma.

L. Neset, M. Nilsen, V. S. Arnesen, K. A. Alam, M. Chekenya, M. A. Rahman;
University of Bergen, Bergen, Norway

Background: Glioblastoma (GBM) is the most malignant primary brain tumor with a median survival of 15 months despite aggressive multimodal treatment. There is an urgent need for novel drug discovery for GBM. CSPG4/NG2 transmembrane proteoglycan is a validated target, upregulated in 50% of GBM patient tumours, drives malignant progression and is independently prognostic for poor survival. We have recently identified a cancer specific 13 bp frameshift deletion in the CSPG4/NG2 gene (CSPG4/NG2del13), which leads to reduced protein expression and slowed cell growth *in vitro* and tumor take *in vivo*. The 3D structure of CSPG4/NG2 has not yet been solved, and unsuited for structure prediction by AlphaFold2 due to its size and PTMs. The structure of CSPG4/NG2 domain 1 (residues 411-547), containing the site of the 13 bp deletion, has been solved using cryo-EM and can be useful for new drug design. We hypothesize that a small-molecule inhibitor that binds to this 13 bp region of the CSPG4/NG2 proteoglycan, might induce the same phenotype as the 13 bp deletion.
Methods: Using the published structure of domain 1, we performed *in silico* analysis to predict binding sites and docked 1280 compounds from the Prestwick Chemical library's database of FDA-approved drugs to these sites. The high ranked hits were further tested *in vitro* in GBM cells. Clonogenic survival, cell proliferation and scratch-wound assays were performed in patient derived P3, A172 and in CSPG4/NG2del13 heterozygous (HZ) GBM cells, that served as controls.
Results: Three binding sites were found in the close proximity to the 13 bp deletion region within the N-terminal domain 1 of CSPG4/NG2. Docking analysis revealed multiple drug candidates bound to the predicted binding site, three of which were further analyzed. Dopamine is found to closely interact with CSPG4/NG2 domain 1, near the 13 bp deletion site, forming hydrogen bonds with Glu413 and Glu521. Pyrazinamide forms two hydrogen bonds with Glu521. 5-Azacytidine fits well into active site 1, establishing hydrogen bonds with key residues Gly475, Glu482, Val472 and Thr473. The *in vitro* functional assays showed that the top hits have a dose dependent negative effect on colony formation and cell proliferation in P3 and A172 GBM cells ($P < 0.0001$). The treatment with the same drug IC_{50} doses led to a growth rescue in the CSPG4/NG2del13 HZ cells compared to the WT cells ($P < 0.001$). 5-Azacytidine showed a significant inhibitory effect ($P < 0.0001$) on cell migration in P3, A172 GBM cells and also in HZ cells, ($P < 0.001$).
Conclusion: The residues spanning the site of 13 bp deletion have chemical motifs that are salient for docking small molecule inhibitors that disrupt CSPG4/NG2 function. N-terminus domain 1 and full-length CSPG4/NG2 proteins for Cryo-EM 3D structure determination are being used to interrogate biochemical kinetics and identify new target regions.

#4495 Structure-based screening for potential ROR1 inhibitors and their potential as antitumor agents in pancreatic cancer cells.

I. K. Singh[1], S. R. Gupta[1], P. Mittal[2], S. Soni[2], J. H. Lo[2], F. Battaglin[2], Y. Yang[2], L. Torres-Gonzalez[2], S. Algaze[2], P. Jayachandran[2], K. Ashouri[2], A. Wong[2], W. Zhang[2], J. Millstein[2], H. J. Lenz[2];

[1]Deshbandhu College, University of Delhi, New Delhi, India, [2]USC - University of Southern California, Los Angeles, CA

Background: The identification of novel compounds that specifically target cancer cells while sparing normal tissues is crucial. The orphan tyrosine kinase-like receptor 1 (ROR1) is one such target expressed exclusively in various human malignancies, including pancreatic cancer, but not in normal adult tissues. Inhibiting ROR1 signaling shows promise in halting pancreatic cancer cell proliferation and invasion. In this study, lead compounds CSF1R-IN-1 and MCULE-8715589337 were found as potential inhibitors of the ROR1 and were further evaluated for its potential effect on pancreatic cancer cell viability.

Method: We curated a compound library of 6 million from PubChem, 2 million lead-like compounds from ZINC15, and 2 million compounds from diverse vendors. Employing Glide's HTVS followed by XP, we refined the selection based on docking scores lower than the reference molecule, Ponatinib. Compounds were shortlisted by pre-simulation MMGBSA calculations with Schrödinger Prime MM-GBSA module, focusing on compounds with energies below -100 kcal/mol. Then we performed MD simulation for 100ns. Post-simulation MMGBSA on the last 1 ns of simulation assessed change in ligands' binding energies. The selected leads underwent further validation utilizing two pancreatic cancer cell lines, MiaPaCa-2 and PANC-1. Half-maximal inhibitory concentration (IC50) was assessed using MTS cell viability assay.

Result: Comparing pre- and post-simulation MMGBSA energies, the reference compound showed increased, while CSF1R-IN-1 and MCULE-8715589337 exhibited decreased energies. The reference ligand's RMSD showed stability with fluctuations of 3 to 3.5 Å, whereas CSF1R-IN-1 and MCULE-8715589337 had stable and lower RMSD values (approximately 3 Å and 2.4 Å). Test compounds, CSF1R-IN-1 and MCULE-8715589337 showed better molecular interactions with ROR1 compared to reference. The reference compound formed hydrogen bonds with ILE555 and ASP633, along with pi-pi stacking with PHE552. CSF1R-IN-1 forms a hydrogen bond with ILE555 and ASP633, pi-pi stacking with PHE552, and interaction with SER632 through a water bridge. Additionally, compound MCULE-8715589337 forms hydrogen bonds with ASP633, SER632, LYS506, and GLU523. CSF1R-IN-1 notably inhibited proliferation in MiaPaCa-2 cells (IC50: 1.29 µM) while no efficacy in PANC-1 cells (IC50: 78.41 µM). MCULE-8715589337 showed relatively similar IC50 values of 39.06 µM and 37.73 µM in MiaPaCa-2 and PANC-1 cells, respectively.

Conclusion: The reduction in MMGBSA energies, low RMSD values, and a higher number of interactions highlight the better characteristics of both compounds compared to the reference. Our findings show CSF1R-IN-1 and MCULE-8715589337 have efficacy in pancreatic cancer cells, but further studies are required to validate and to understand the mechanism of action.

#4496 A computational initiative to determine the role of dietary polyphenols against oncogenic KRAS mutants.

P. Chatterjee[1], R. Karn[1], S. Chakraborty[1], S. Sinha[2], P. Ghosh[2], S. Banerjee[1];
[1]Vellore Institute of Technology, Vellore, India, [2]University of California San Diego, San Diego, CA

Introduction: Two oncogenic driver mutants (G12C and G14D) of KRAS have been reported to drive tumorigenesis in several cancers and targeting the switch I/II domain of mutant KRAS oncoprotein can be an efficient strategy for inhibiting the mutated KRAS-driven tumors. Modern clinical therapeutics are often associated with several adverse side effects and the eventual development of multi-drug resistance. Herein, exhaustive computational strategies are employed in designing dietary polyphenol-based small molecule inhibitors against such oncogenic KRAS tumors.
Methodology: Integrated bioinformatics strategies such as pharmacokinetic property prediction, analysis of medicinal chemistry profile, density functional theory (DFT) study, molecular docking, molecular dynamics simulation (MDS) and principal component analysis were performed to screen 930 dietary polyphenols to identify potent inhibitors against the G12C and G14D mutants. Sotorasib, an FDA-approved KRAS chemotherapeutic inhibitor was used as a reference drug in this study.
Results: Out of the 930 dietary polyphenols screened, based on the properties of pharmacokinetic descriptors and medicinal chemistry profile, 512 molecules were shortlisted for further studies. Five dietary polyphenols viz. Quercetin, Luteolin, Peonidin 3-O-glucoside, Myricetin, and Kaempferol identified via DFT and MDS exhibited the highest binding affinity and optimum energy profiles with our selected mutants G12C and G14D. An all-atom MDS study executed over 200 ns each revealed that Quercetin, Luteolin, and Peonidin 3-O-glucoside show favorable thermodynamic stability with significantly less conformational perturbations with G12C mutant. By contrast, mutant G12D complexed with Kaempferol and Myricetin exhibited the least thermodynamic flexibility and stable backbone trajectory, when compared to clinically standardized KRAS inhibitor Sotorasib. The efficient and higher binding stability of the polyphenols targeting the KRAS mutants, G12C and G14D switches I/II is mainly attributed to the formation of hydrogen bonds and other hydrophobic interactions at the molecular level. All five evaluated polyphenols qualified the parameters of cell-line cytotoxicity hinting at remarkable chemotherapeutic efficacy.
Conclusion: Computer-aided drug designing performed here aided the identification of natural dietary polyphenolic inhibitors as potential drug candidates exhibiting stable binding dynamics like Sotorasib, which thus awaits validation through further *in-vitro* analyses in inhibiting KRAS-driven tumorigenesis.

CHEMISTRY: Targeted Protein Degradation
Poster Session

#4500 A high-throughput approach to discover and characterize glueable ligase-target pairs.
A. Sen, P. Burke, R. Bansal, D. Krayushkina, D. Noble, K. McGowan, N. Seelam Murakowska, P. Reed, J. Barrett, **R. Lopez**;
A-Alpha Bio, Seattle, WA

Targeted protein degradation can be induced with monovalent small molecules, termed molecular glues, that modify the substrate-binding interface of E3 ligases and reroute them to novel targets. Despite there being over 600 E3 ligases encoded in the human genome, most glues have focused on only a few. Expanding to additional ligases and targets is challenging due to the low probability of successful 'glueing.' Many have suggested that a weak basal interaction between a ligase and neo-substrate is an important prerequisite for the function of a molecular glue, but such weak interactions are challenging to discover. To address this need, we have harnessed AlphaSeq, a synthetic biology platform that measures protein-protein interactions at scale and with high sensitivity, to identify and characterize novel E3-target pairs. Our approach is twofold. First, we test for novel weak interactions (~100nM to 10uM) between a panel of E3 ligases and a library of disease relevant target proteins. Second, starting from a weakly interacting protein pair, we build mutational libraries of both proteins and measure their binding strengths. Mutations that strengthen binding serve to validate the weak interaction, provide structural insights into the nature of binding, and help to inform subsequent small molecule discovery. Here, we present our approach to discover and evaluate glueable ligase-target pairs using AlphaSeq, validation through proof-of-concept experiments involving a known interaction agonized by small molecules, and examples of novel glueable ligase-target pairs that we have recently discovered.

#4501 First reported PIM kinase degraders: Design, profiling & optimization.

C. Legros[1], P. Ratcliffe[2], V. Porkolab[3], M. Modugno[4], O. Mirguet[1];

[1]Eurofins Discovery, Celle Levescault, France, [2]Eurofins Discovery, Ongar, United Kingdom, [3]Eurofins Cerep, Celle Levescault, France, [4]Eurofins DiscoveryOne, Ongar, United Kingdom

The PIM serine/threonine kinases (PIM1/PIM2/PIM3) are downstream effectors of ABL, JAK2 and Flt-3 oncogenes and are required for tumorigenesis. Overexpression has been reported in hematological and solid tumors, myeloma, lymphoma, leukemia and adenocarcinoma. The first generation of PIM inhibitors to make it to the clinic, including SGI-1776, AZD1208 and PIM447, are known to be pan-PIM inhibitors, while the aim of this project was to identify novel & selective PIM3 inhibitors. To this end, several Hit-finding approaches were employed to rapidly generate novel chemical matter, which were then assessed for their activity against PIM3 using a robust ADP-Glo™ assay. In parallel to this Hit-findings activity, we used AZD1208 scaffold as a starting point to generate PIM3 bifunctional protein degraders and designed a specific screening cascade in order to profile such modalities. The PIM degrader library, synthetized using Automated Robotics Lab, was characterized using ADP-Glo assays. It was then screened on our binding and activity kinase platforms, KINOME*scan*® and KinaseProfiler™, and then fully profiled including ternary complex formation with biophysics and *in vitro* Safety Pharmacology Profiling Panels. One example is the AZD1208 derivate degrader, i.e. EC108154-1, which showed nanomolar range affinity for PIM3 and the E3-ligase CRBN-DDB1, and its affinity range was also confirmed with the ternary complex in SPR and MST-TRIC. This comprehensive screening cascade ensures an in-depth characterization and optimization of protein degraders, with the possibility of monitoring the ternary complex formation with biophysics methods. It is a good illustration of how this combination of tests can be instrumental in selecting the best degraders to progress to the next step of drug discovery.

#4502 Design, synthesis, and evaluation of next-generation EGFR degraders to overcome osimertinib-resistance.

M. Baig[1], J. Bok[2], D. Kim[3], S. D. Nale[4], Y. Jo[1], C. Kim[5], T. Park[4], **J. Dong**[1], B. Moon[3];
[1]Yonsei University College of Medicine, Seoul, Korea, Republic of, [2]Handok. Inc., Seoul, Korea, Republic of, [3]Handok. Inc, Seoul, Korea, Republic of, [4]BNJbiopharma. Inc., Seoul, Korea, Republic of, [5]Catholic University, Seoul, Korea, Republic of

The occurrence of C797S mutation in epidermal growth factor receptor (EGFR) is a leading mechanism of clinically acquired resistance to third-generation EGFR inhibitors, including Osimertinib. L858R/T790M/C797S and del19/T790M/C797S are commonly observed tertiary EGFR mutants identified in Osimertinib-resistant tumors. As of now, no clinically approved treatment exists that specifically targets these mutants. Here, we report the design and synthesis of a series of highly effective next-generation EGFR degraders effectively degrading EGFR C797S-containing triple mutants. Most compounds demonstrated antiproliferation activity in the subnanomolar range when tested on Ba/F3$^{L858R/T790M/C797S \text{ and } del19/T790M/C797S}$ cells. Not only C797S but our designed degraders also degraded a wide range of EGFR mutants, including Exon19Del and L858R/T790M (DC50 <100nM). One representative Compound, HDBNJ2812, strongly degrades L858R/T790M/C797S and del19/T790M/C797S with DC50 of 34 nM (Dmax 88.5%) and 14 nM (Dmax 99.7%), respectively. This compound potently inhibits the proliferation of Ba/F3L858R/T790M/C797S (GI50 64 nM) and del19/T790M/C797S (GI50 40 nM). HDBNJ2812 demonstrated high inhibitory potential on HCC827 (del19) and H1975 (L858R/T790M) cell lines (GI50 18.9 and 85 nM, respectively). Furthermore, this degrader demonstrates weak cytotoxicity on non-mutant EGFR-expressing cells, such as A431, WI-26 (human lung fibroblast cells), and CHO-K1 (Chinese hamster ovary cells). Additionally, the *in vivo* PK/PD findings complement this compound's potential to be considered further. HDBNJ2812 may serve as a lead compound to render the greater therapeutic window for treating resistant non-small cell lung cancer patients with EGFR C797S mutants.

#4503 Preclinical characterization of PRT7732: A highly potent, selective, and orally bioavailable targeted protein degrader of SMARCA2.

A. Shvartsbart, K. Ito, J. Rager, M. Hulse, A. Agarwal, K. Vykuntam, J. Burtell, M. Wang, J. Kurian, M. Cowart, J. Cote, N. Stahl, M. Sivakumar, A. Reichelderfer, J. Carter, A. Grego, C. Bachner, A. Moore, N. Bhagwat, R. Kuskovsky, S. Ganesan, S. Ruepp, T. Emm, P. Pitis, C. Basch, K. Bersch, Y. Pan, S. Mei, R. Leal, J. Rose, D. Roth, C. Xu, G. Cao, K. Vaddi, S. Lee, S. Geeganage, A. Combs, P. Scherle;
Prelude Therapeutics, Wilmington, DE

SWI/SNF (BAF) complexes play an important role in controlling gene expression by remodeling chromatin. SMARCA2 (BRM) and SMARCA4 (BRG1) are the core catalytic subunits of the SWI/SNF complexes, containing an ATPase domain and a bromodomain. SMARCA4 protein expression is lost in some cancers due to loss-of-function (LOF) mutations and homozygous deletions, and SMARCA4-deleted cancer cells are highly dependent on its paralog gene SMARCA2 for their survival. Therefore, targeting SMARCA2 in SMARCA4-deficient cancers using selective SMARCA2 degraders induces synthetic lethality while sparing SMARCA4 wild type (WT) normal cells. We have recently identified a series of orally bioavailable SMARCA2 selective degraders that demonstrate robust efficacy in pre-clinical animal models with favorable pharmacokinetic properties and safety profiles. Our nomination candidate PRT7732 exhibits >1000x selectivity for SMARCA2 over SMARCA4 in cell-based assays, with DC_{50} values in cancer cell lines in the low nanomolar range. The PRT7732-induced SMARCA2 degradation was rescued by a proteasome inhibitor and neddylation inhibitor, indicating ubiquitin-proteasome dependent degradation. Furthermore, PRT7732 does not change levels of known CRBN ligand neo-substrates such as IKZF2/3, GSPT1 and SALL4. PRT7732 inhibits only SMARCA4-deficient cancer cell proliferation with IC_{50} values ranging from 5.0-50 nM, but not SMARCA4 WT cells in vitro. Oral administration of PRT7732 resulted in near-total degradation of SMARCA2 protein with complete selectivity over SMARCA4 protein in a SMARCA4 WT lung cancer model in mice, consistent with the SMARCA2 degradation kinetics-based pharmacodynamic prediction model. PRT7732 oral daily administration showed significant tumor growth inhibition of SMARCA4-deficient lung cancer xenograft models at well tolerated doses. The treated tumor tissues show robust SMARCA2 protein reduction for 24h post dosing. In summary, our orally bioavailable SMARCA2 degraders induce synthetic lethality in SMARCA4-deficient cancers in vitro and in vivo. Efforts to further evaluate these compounds in additional models and in combination with other agents are ongoing.

#4504 Discovery of CBPD-409 and CBPD-268 as highly potent and orally efficacious CBP/p300 PROTAC degraders for the treatment of castration-resistant prostate cancer.

Z. Chen[1], M. Wang[1], D. Wu[1], L. Zhao[1], T. Xu[1], H. Metwally[1], Y. Wang[1], D. McEachern[1], W. Jiang[1], L. Bai[1], J. Luo[2], M. Wang[1], R. Li[1], J. Takyi-Williams[1], L. Wang[1], Q. Li[1], B. Wen[1], D. Sun[1], A. M. Chinnaiyan[2], S. Wang[1];

[1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Medical School, Ann Arbor, MI

Prostate cancer remains the leading cause of cancer-related death globally in men. While current AR-targeted therapies are effective for the treatment of prostate cancer and improve patient survival, resistance in patients typically develops within 18 months. CBP/p300 are AR transcriptional co-activators and are promising therapeutic targets for the treatment of castration-resistant prostate cancer (CRPC). We developed a series of highly potent, selective, and orally efficacious CBP/p300 PROTAC degraders, with CBPD-409 being the best compound. CBPD-409 induces robust CBP/p300 degradation with DC_{50} 0.2-0.4 nM and displays strong anti-proliferative effects with IC_{50} 1.2-2.0 nM in VCaP, LNCaP and 22Rv1 AR+ cell lines. It has a favorable oral pharmacokinetic profile and achieves 50% of oral bioavailability in mice. A single oral administration of CBPD-409 at 1 mg/kg achieves >95% depletion of CBP/p300 proteins in the VCaP tumor tissue at 3 h and 24 h time points. CBPD-409 exhibits strong and dose/schedule-dependent tumor growth inhibition and is more potent and efficacious than two CBP/p300 inhibitors CCS1477 and GNE-049 and the AR antagonist Enzalutamide. To further improve the degradation potency and the oral bioavailability in rats, we developed a new class of CBP/p300 degraders based on our optimized CRBN ligand TX-16. Our efforts led to the discovery of CBPD-268 as an exceptionally potent, effective, and orally efficacious degrader of CBP/p300 proteins. In the VCaP, LNCaP and 22Rv1 cell lines, CBPD-268 induces consistent and robust CBP/p300 degradation with DC_{50} of ≤0.03 nM and D_{max} >95%, leading to potent cell growth inhibition. CBPD-268 has excellent oral bioavailability in both mice and rats and has a good ADME profile. Oral administration of CBPD-268 at 0.3-3 mg/kg resulted in profound and persistent depletion of CBP and p300 proteins in tumor tissues and achieved strong antitumor activity in the VCaP and 22Rv1 xenograft tumor models in mice, including tumor regression in the VCaP tumor model. CBPD-268 was well tolerated in mice and rats and displayed a therapeutic index of >10. Taken together, CBPD-409 and CBPD-268 are highly promising CBP/p300 degraders for further extensive evaluations for the treatment of CRPC and other types of human cancers.

#4505 Discovery of a cebrelon-based PTPN1/PTPN2 dual targeting degrader for cancer immunotherapy.

Z. Qu, Y. Bai, J. Dong, Z. Zhang, B. Huang, Y. Miao, A. W. Tao, P. S. Low, Z.-Y. Zhang;
Purdue University, West Lafayette, IN

Cancer immunotherapy has achieved notable clinical success, yet its broader application is impeded primarily by immune evasion mechanisms, predominantly stemming from factors such as tumor antigen loss, intrinsic low antigen presentation, and the inherent impermeability of current macromolecules, including cells, antibodies, and proteins. Consequently, there exists a pressing demand for more permeable agents that target intracellular components as viable alternatives. Among the various molecular players involved in immune evasion, PTPN1 and PTPN2, two protein tyrosine phosphatases (PTPs), play a non-redundant role in regulating tumor antigen presentation. They achieve this by modulating the JAK/STAT signaling pathway within tumor cells, with their deletion having been demonstrated to enhance MHC-I presentation across various cell types. Furthermore, PTPN1 and PTPN2 also negatively regulate T cell receptor (TCR) signaling in T cells, as supported by genetic studies. Consequently, these two proteins present as promising targets for the development of innovative cancer immunotherapies due to their dual impact on both tumor cells and T cells. Addressing the intrinsic impermeability challenges associated with macromolecules, we embarked on the development of small molecule agents that specifically target PTPN1 and PTPN2, culminating in the successful creation of a low-nanomolar proteolysis targeting chimera (PROTAC), designated as X1. PROTAC X1 exhibits sustained low-nanomolar binding affinity and exceptional selectivity toward PTPN1 and PTPN2 in in vitro settings. Furthermore, it has demonstrated a nano-molar half-maximal degradation concentration (DC50) in Jurkat T cells and numerous cancer cell lines, while concurrently exhibiting efficacy in eliciting TCR signaling and enhancing MHC-I presentation. Additionally, X1-treated CAR-T cells exhibited augmented cytotoxicity through increased IFN-γ secretion, thereby reinforcing its efficacy in T cell activation. To ascertain the anti-tumor efficacy of X1, we administered X1 to C57BL/6 mice bearing MC38 tumors, resulting in a significant retardation of tumor progression. Subsequent investigations revealed that X1 treatment induced an inflammatory response in the tumor microenvironment, characterized by enhanced T cell infiltration and the activation of CD8+ T cells. Notably, no discernible adverse effects, such as autoimmune symptoms, were observed during treatment. Collectively, these findings indicate that X1 represents a potent and safe agent for cancer immunotherapy. This study not only elucidates the mechanism of action of PTPN1B/TC-PTP pharmacological degradation as a viable approach for cancer treatment but also solidifies the potential of PTPN1B/TC-PTP degradation as a novel avenue for cancer immunotherapy.

#4506 Discovery of potent, highly selective and orally efficacious SMARCA2 degraders.

Lingying Leng, Lin Yang, Wenbin Tu, Rohan Rej, Srinivasa Rao Allu, Liyue Huang, Wei Jiang, Yu Wang, Jeanne Stuckey, Farzad R Sarkari, Meilin Wang, Lu Wang, Bo Wen, Duxin Sun, Shaomeng Wang

University of Michigan, Ann Arbor, MI

In human non-small cell lung cancer, melanoma and other types of human cancers, the mammalian SWItch/Sucrose Non-Fermentable (SWI/SNF) helicase SMARCA4 is frequently mutated, which leads to inactivation of its functions. SMARCA2, a close homologous protein of SMARCA4, is an attractive synthetic lethality target for human cancers with SMARCA4 deficiency. Herein, we report the discovery and biological evaluation of potent, highly selective, orally efficacious SMARCA2 PROTAC degraders exemplified by UM-SMD-8801. UM-SMD-8801 has DC_{50} <10 nM and Dmax >90% against SMARCA2 and >1,000-fold degradation selectivity over SMARCA4. Consistently, UM-SMD-8801 potently inhibits cell growth in SMARCA4 mutated cancer cell lines with low nanomolar IC_{50} values and shows >100-fold weaker activity in SMARCA4 wild-type cancer cell lines. UM-SMD-8801 has a good overall pharmacokinetic profile and an excellent oral bioavailability in mice. Oral administration of UM-SMD-8801 is highly effective in reducing SMARCA2 protein by >90% in tumor tissues in mice, while having minimal effect on SMARCA4 protein. UM-SMD-8801 represents a very promising SMARCA2 degrader for extensive evaluation as a potential new therapy for the treatment of SMARCA4-deficient human cancers.

#4507 Discovery of a smart molecular glue: A small-molecular compound selectively degrades Nrf2 in KEAP1-mutated tumor cells, by restoring the broken KEAP1 mutant/Nrf2 interaction.

X. Tian[1], T. Aboulkassim[1], Q. Liu[2], M. Hancock[3], J. Wu[1], G. Batist[1];

[1]Lady Davis Institute, Jewish General Hospital, McGill University, Montreal, QC, Canada, [2]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada, [3]McGill University, Montreal, QC, Canada

Overcoming therapeutic resistance without incurring prohibitive normal tissue toxicity is a great challenge in anticancer therapies. Transcription factor NRF2 is a master regulator of cellular protective response, which provides protective effects in normal tissues. KEAP1, the endogenous NRF2 inhibitor, binds NRF2 and redirect it towards proteasome-dependent degradation. KEAP1/NRF2 interaction is therefore critical for maintaining NRF2 at a basal level. Accumulated studies revealed cancer cells could hijack NRF2 pathway to confer drug resistance. A number of clinically-relevant KEAP1 mutations were shown to disrupt the KEAP1/NRF2 interaction, leading to elevated NRF2 level and confer drug resistance. Here, by structure-based drug design approach, we discovered a small-molecule NRF2 inhibitor, R16, which selectively binds KEAP1 mutants and restores their NRF2-inhibitory function in tumor cells. We performed in silico screening against the NCI-open database. Top-ranking candidates were initially evaluated by ARE-luc reporter assays, leading to discovery of R16. Effect of R16 in restoring interaction between KEAP1 mutants and NRF2 were evaluated by BRET2 assays. Among 14 KEAP1 mutations that result in disruption of KEAP1/NRF2 interaction, R16 is active against 11 of them. A variety of assays, including tryptophan quenching, cellular target engagement, BRET[2] and GST-pull down assays, indicated that R16 selectively engage KEAP1 mutants and restore their interaction with NRF2, leading to NRF2 degradation. R16 at 0.5 uM substantially sensitizes KEAP1-mutated tumor cells to cisplatin and gefitinib, with no obvious effect in wild-type KEAP1 cells. Importantly, R16 showed significant in-vivo efficacy in sensitizing A549 xenograft bearing KEAP1 G333C mutation to cisplatin, while it has no effect on xenograft with wild-type KEAP1. KEAP1-mutated tumors are emerging as a sub-group with severe resistance to currently available therapies. Here, we have identified a KEAP1 mutant-selective NRF2 inhibitor, which potently sensitizes KEAP1-mutated cells/tumors to anticancer agents, with little effects on the WT-KEAP1. Our work demonstrated it is feasible to restore the NRF2-inhibitory function of KEAP1 mutants, by targeting the mutants with compounds to repair the disrupted KEAP1 mutant/NRF2 interactions. The KEAP1 mutant-selectivity is critical, as NRF2 is a master regulator of cellular defense response in WT-KEAP1 normal tissues.

#4508 Defining PIM kinase protein regulation and PROTAC for pre-clinical testing.

H. Liou[1], J. Brognard[2], R. Swenson[3], P. Torres-Ayuso[4], N. Warfel[1];
[1]University of Arizona, Tucson, AZ, [2]NIH/CCR, Frederick, MD, [3]NHLBI, Rockville, MD, [4]Temple University, Philadelphia, PA

The PIM kinase family are serine/threonine kinases known to be overexpressed in castration-resistant prostate cancer (CRPC). PIM1, an isoform of PIM, is known to regulate cell survival, migration, and proliferation. Uniquely, PIM kinases are constitutively active due to the lack of a regulatory domain. Therefore, PIM protein levels are reflected in PIM activity and are regulated by protein degradation and synthesis. PIM inhibitors have been developed, targeting the PIM kinase activity and inhibiting phosphorylation of downstream targets, but have had limited efficacy. Our lab and others demonstrate that PIM inhibitor treatment increases total PIM protein levels, suggesting that PIM kinases control protein stability via autophosphorylation. To elucidate the mechanism of autophosphorylation dependent regulation of PIM1, we used phospho-proteomics to identify potential autophosphorylation sites on PIM1. We have identified overexpression of deubiquitinase USP28 inhibiting degradation of PIM1, leading to the investigation of the role of F-box protein Fbw7 in regulating PIM1. Dominant-negative expression of Fbw7 results in increased PIM1 total protein. Additionally, coimmunoprecipitation of Fbw7 knockdown cells resulted in decreased PM1 ubiquitination compared to control. Therefore, we have identified Fbw7 as a putative E3 ligase responsible for PIM1 degradation. To address the limited efficacy of PIM inhibitors, we have developed the first PIM-PROTAC (PIMTAC) with our collaborators. Proteolysis targeting chimera (PROTAC) is a promising approach to eliminating the pro-tumorigenic effects of PIM. The PIMTAC selectively targets PIM kinases for degradation and we have demonstrated *in vitro* efficacy. PIMTAC successfully maintains degradation of all isoforms of PIM for over 72 hours. In vitro assessment of anti-tumor efficacy demonstrated increased apoptotic death with PIMTAC alone compared to PIM inhibitor or docetaxel. Furthermore, dual treatment of PIMTAC and docetaxel had more apoptotic death compared to PIM inhibitor with docetaxel. We aim to develop the PIMTAC for pre-clinical testing.

#4509 Discovery of potent and highly efficacious STAT3 PROTAC degraders capable of achieving long-lasting tumor regression.

R. K. Acharyya, L. Bai, H. Zhao, D. Wu, M. Hoda, M. Donna, W. Bo, D. Sun, S. Wang;
University of Michigan, Ann Arbor, MI

STAT3 (signal transducer and activator of transcription 3) is a transcription factor and a promising therapeutic targets for cancer and other human diseases. We have previously reported the discovery of SD-36 and SD-91 as potent, selective and highly efficacious STAT3 degraders. In the present study, we report the discovery of highly potent, selective and efficacious new STAT3 degraders. These STAT3 degraders were designed using our high-affinity STAT3 ligands and high-affinity VHL-1 ligands, with UM-STAT3-3100 being the best. In direct comparison, UM-STAT3-3100 is >10-times more potent than SD-36 and SD-91 in inducing STAT3 degradation in cells and are highly selective over other STAT members *in vitro* and *in vivo*. A single intravenous administration of UM-STAT3-3100 resulted in complete and long-lasting depletion of STAT3 protein for >48 hrs in tumor and native tissues. Weekly administration of UM-STAT3-3100 at 10 mg/kg achieved complete and long-lasting tumor regression in animal models of human cancer without any signs of toxicity. UM-STAT3-3100 is a promising compound for extensive evaluation for the treatment of human cancers and other human diseases in which STAT3 plays a key role.

#4510 Potent and orally efficacious PROTAC degraders of estrogen receptor α (ERα).

R. K. Rej[1], Z. Chen[1], R. K. Acharyya[1], D. Wu[1], B. Hu[1], G. Xu[2], R. Nagilla[2], H. Metwally[1], Y. Wang[1], B. Wen[1], D. Sun[1], L. Bai[1], S. Wang[1];
[1]University of Michigan, Ann Arbor, MI, [2]Proteovant Therapeutics, Philadelphia, PA

The estrogen receptor α (ER*α*) plays a crucial role in hormonally driven breast cancer, making it a clinically validated oncology target. Over the past 30 years, SERMs, SERDs, and AIs have been the mainstay of endocrine therapy for ER+ breast cancer, but relapse and resistance remains a significant challenge for metastatic breast cancer, leading to cancer recurrences, metastasis, and mortality. We report the discovery and extensive evaluations of potent and orally efficacious ERα degraders using the PROTAC technology through extensive optimization of the cereblon ligands, the linker and ER ligands. Our lead compounds (UM-ERD-3111 and UM-ERD-4001) achieved sub-nanomlar DC_{50} values in ER degradation and demonstrate excellent oral bioavailability. Oral administration of these ER degraders effectively reduces the ER wild-type and ER mutated proteins in tumor tissues in mice. Both ERD-3111 and UM-ERD-4001 are capable of inducing tumor regression *in vivo* and are more efficacious than ARV-471, a PROTAC ER degrader currently in phase 3 clinical development. UM-ERD-3111 and UM-ERD-4001 are highly promising compounds for extensive evaluations as potential new therapies for the treatment of ER+ human breast cancer.

#4511 Discovery of the first-in-class G9a/GLP PROTAC degrader.

J. Velez, Y. Han, H. Yim, P. Yang, Z. Deng, K.-S. Park, M. Kabir, H. Kaniskan, Y. Xiong, J. Jin;
Icahn School of Medicine at Mount Sinai, New York, NY

G9a and GLP are lysine methyltransferases that catalyze dimethylation of histone H3 lysine 9 (H3K9me2), a transcriptionally repressive mark. Aberrantly expressed G9a/GLP has been implicated in numerous cancers, including prostate, lung, and leukemia. The oncogenic activity of G9a/GLP is attributed to both its catalytic and non-catalytic functions, such as forming co-activator complexes with p300, CARM1, GRIP1, and Mediator to positively regulate gene transcription. As such, current G9a/GLP enzymatic inhibitors display limited anti-cancer activity. As an alternative therapeutic strategy, PROTAC degraders harness the ubiquitin-proteasome system (UPS) to effectively eliminate oncoproteins and abrogate all catalytic and non-catalytic functions. Here, we present the first-in-class G9a/GLP PROTAC degrader, MS8709, which potently degrades G9a and GLP in a time-, concentration-, and UPS-dependent manner. Moreover, MS8709 induces superior cell growth inhibition compared to its parent inhibitor in prostate, lung, and leukemia cell lines. Overall, MS8709 is a useful chemical tool to investigate G9a/GLP biology and offers a novel approach for the treatment of G9a/GLP-dependent cancers.

#4512 Discovery of highly potent, selective, and orally bioavailable IKZF2 degrader and its anti-tumor activity in syngeneic mouse models.

S. Park[1], J. Moon[1], G. Lee[1], H. Kim[2], J.-H. Kim[1], **J. Hwang**[2];
[1]Korea Research Institute of Bioscience and Biotechnology (KRIBB), Daejeon, Korea, Republic of, [2]Korea Research Institute of Chemical Technology (KRICT), Daejeon, Korea, Republic of

Molecular glue degraders (MGDs) are emerging as innovative therapeutic modalities, owing to their efficacy in targeting previously undruggable targets. MGDs induce close proximity between the target protein and E3 ligase, resulting in the degradation of the target protein. In the wake of the remarkable success of PD-1/PD-L1 inhibitors, various approaches to modulate the activity of regulatory T cells (Tregs) activity have been explored. Tregs represent the primary immune suppressor and significantly impede antitumor immune responses. IKZF2, a marker of stable suppressive Treg, is essential for maintaining the stable Treg cell phenotype. Depletion of IKZF2 can induce a transition from Treg to effector T cell (Teff) phenotypes, thereby enhancing anti-tumor responses. Leveraging an Immunomodulatory drug (IMiD), Novartis has developed the IKZF2 degrader DKY709, which is currently undergoing Phase I clinical trials, both as a monotherapy and in combination with a PD-1 immune checkpoint inhibitor. In this presentation, we present the preclinical results of the best-in-class IKZF2 degrader, PRT-101. PRT-101 elicits rapid and robust degradation of IKZF2, demonstrating subnanomolar DC_{50} and achieving 100% D_{max} in a proteasome- and CRBN-dependent manner. However, PRT-101 does not induce the degradation of well-known neosubstrates, including IKZF1, IKZF3, SALL4, and CK1a. Global proteomic analysis reveals that PRT-101 exclusively facilitates IKZF2 degradation. The degradation of IKZF2 by PRT-101results in an increase in IL-2 secretion, a marker of T effector function. Furthermore, oral administration of PRT-101 exhibits excellent pharmacokinetics, concurrent with IKZF2 degradation, yielding superior anti-tumor effects compared to DKY709 in the MC38 mouse syngeneic model. In conclusion, our findings underscore the potential of the novel IKZF2 degrader as a promising immuno-oncology target for the treatment of solid tumors.

#4513 Exploration degradation of intrinsically disordered protein YAP induced by PROTACs.

C. Zhou[1], C. Sun[2], L. Pi[2], C. Li[1];
[1]University of Florida, Gainesville, FL, [2]Tulane University, New Orleans, LA

Yes-associated protein (YAP), a potent oncogene and a key player in the Hippo tumor suppression pathway, has long been considered challenging to target due to its partially intrinsically disordered nature. However, recent advancements in High-throughput Screening (HTS) have yielded a breakthrough, as several YAP binders have been identified, igniting new possibilities in the quest to combat YAP-driven malignancies. Building upon this progress, a novel approach utilizing Proteolysis-Targeting Chimera (PROTAC) technology was employed to design and synthesize a series of YAP degraders. Here, our degraders were created by linking NSC682769, a previously reported YAP binder, with either VHL ligand 2 or pomalidomide using various linkers of different lengths and types. Among these degraders, YZ-6 emerges as the most promising, inducing rapid and sustained YAP degradation via promoting its ubiquitination-proteasome-dependent proteolysis. This process effectively suppressed YAP/TEAD-led transcription in both YAP-dependent NCI-H226 and Huh7 cancer cell lines. In addition to its degradation capabilities, YZ-6 also exhibited antiproliferative activity in both cell lines. Importantly, YZ-6 efficiently suppressed tumor development in the Huh7 xenograft mouse model, accompanied by a remarkable decrease in YAP levels, without adverse effects on the mice. These findings highlight the potential of PROTAC-mediated degradation as a viable strategy for reducing oncogenic YAP levels and attenuating downstream signaling in cancer cells. Moreover, the development of PROTACs based on NSC672869 holds promise for treating YAP-driven malignancies, opening new avenues for cancer therapy.

#4514 Discovery of potent and orally bioavailable degraders of HPK1 based on a novel HPK1 binder.

Z. Zhang, M. Wu, L. Wang, X. Yang, Z. Zhang, L. Guo, H. Pan, M. Zhao, L. Wang, S. Liu, Z. Dong, C. Jiang, H. Zheng, **D. Liu**;
Huadong Medicine, Hangzhou, China

Background: Proteolysis targeting chimeras (PROTACs) are novel structures designed to target a protein of interest (POI) for ubiquitination and degradation, leading to the selective reduction in the expression levels of the POI. Hematopoietic progenitor kinase 1 (HPK1) is considered a promising target for tumor immunotherapy. PROTAC-involved disruption of HPK1 protein activity enhanced the treatment efficacy of CAR-T-cell-based immunotherapies in different solid tumors and mouse models. Thus, targeting HPK1 by PROTAC to restore T-cell activity is an attractive approach to induce a greater immune responses in cancer.

Results: We designed and synthesized a series of HPK1 degraders by tethering our previously discovered novel HPK1 inhibitor with CRBN binder through various linkage. The most potent PROTAC effectively degrades HPK1 proteins in the Ramous cell in a dose-dependent manner and achieves DC_{50} value <50 nM. The maximum degradation (D max) values achieved are >90%. Our PROTAC showed EC_{50} value <100 nM for IL-2 and IFNγ production. PK studies revealed a low clearance, high plasma exposure and oral bioavailability in mice and rats. Furthermore, our PROTAC is shown to induce robust and statistically significant tumor growth inhibition in the MC38 and CT26 syngeneic model with increased T cell signatures observed within the tumor. The PROTAC in combination with anti-PD1 also resulted in robust anti-tumor activity with TGI > 90%. The 14 days DRF experiment shows that the compound has a great safety window(>200 folds).

Conclusion: We show here that a potent oral HPK1 degrader demonstrates strong immune cell activation and robust anti-tumor activity in mouse syngeneic tumor models, as a single agent and in combination with anti-PD1. Further evaluation of these potent degraders in additional in vivo studies will continue to build upon our mechanistic understanding of HPK1 degradation as a novel immunomodulatory approach for anti-tumor immunity.

#4515 Orally bioavailable PROTAC based MDM2 degrader.

A. Aguilar, J. Yang, Y. Li, D. McEachern, S. Wang;
University of Michigan, Ann Arbor, MI

Activation of the tumor suppressor p53, through inhibition of the MDM2 protein, has been pursued as a cancer therapeutic strategy and has produced many distinct inhibitors that are in clinical trials. A limitation arising from inhibiting the MDM2-p53 interaction is the upregulation of MDM2, itself a target gene of p53, and this attenuates the activation of p53 and efficacy of the inhibitors. To circumvent this limitation, we previously reported the first PROTAC based MDM2 degraders. These induced and sustained robust degradation of MDM2, achieved stronger p53 activation, and more potent anticancer activity than MDM2 inhibitors thus representing a new therapeutic strategy for targeting MDM2. Currently, all the PROTAC based MDM2 degraders are all dosed intravenously. Here we describe our design, synthesis, and optimizations that led to the discovery of the first orally bioavailable PROTAC based MDM2 degrader and our investigation of its therapeutic potential and mechanism of action. Consistent with its design to effectively degrade MDM2, our PROTAC effectively induces rapid degradation of MDM2 resulting in accumulation of wild-type p53 protein and activates p53 transcriptional activity in leukemia cells without accumulation of MDM2 protein. Consequently, it potently inhibits cell growth and induces apoptosis at low nano-molar concentrations in ALL and AML cell lines >10-100 times more potent than MDM2 inhibitors; and, after 50 mg/kg oral dose, 5 days/week for 3 weeks, it increased the median survival by 26 days of mice with disseminated RS4;11 cancer.

#4516 Inhibiting YAP activity in cancers by targeted degradation of TEAD.

H. Chen[1], A. Gridnev[2], N. Schlamowitz[2], G. Zheng[1], J. Misra[2];
[1]University of Florida, Gainesville, FL, [2]University of Texas at Dallas, Richardson, TX

The oncogenic transcriptional coactivators YAP/TAZ function as the terminal effectors of the Hippo signaling pathway and are dysregulated in many human cancers, where they promote cancer cell proliferation, survival, stemness, and resistance to targeted therapies, and thus provide a critical point for therapeutic targeting. YAP/TAZ activity is regulated by phosphorylation mediated by the kinase cascade of the Hippo signaling pathway, where phosphorylation causes cytoplasmic retention. Aberrantly activated Hypo/unphosphorylated YAP/TAZ translocates into the nucleus, where it exerts its oncogenic activity by associating with the TEAD1-4 transcription factors and inducing expression of genes encoding pro-proliferative and antiapoptotic factors. Since YAP/TAZ cannot be directly therapeutically targeted, its oncogenic transcriptional activity can be controlled indirectly by targeted degradation of TEAD. Here we report on the development of Proteolysis Targeting Chimeras that potently induces degradation of TEAD and inhibits YAP transcriptional activity and cell proliferation in YAP-dependent cancers.

#4517 Novel chemical degraders targeting NSD2 in head and neck squamous cell carcinoma (HNSCC).

A. Ismail[1], E. Roshchina[2], I. Topchu[2], G. Schiltz[3], Y. Boumber[1];
[1]The University of Alabama At B, Birmingham, AL, [2]Northwestern University, Chicago, IL, [3]Northwestern University, Evanston, IL

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide. Despite advances in treatments and significant efficacy of immunotherapy drugs in HNSCC, no effective targeted therapies have been approved in this disease yet. NSD2 is a histone lysine methyltransferase, which is overexpressed in HNSCC and is implicated in tumor growth, cell cycle regulation, epithelial-mesenchymal transition (EMT) and metastasis not only in HNSCC, but also in many other solid tumors. Development of inhibitors to the catalytic activity of NSD2 has been rather limited to date, which necessitates an alternative approach. To target NSD2, we have recently developed a series of novel proteolysis targeting chimeras (PROTACs), which chemically degrade NSD2 utilizing native cellular machinery - ubiquitin-proteasome system - with VHL as an E3 ligase. A series of >40 compounds were tested in HNSCC cell lines (JHU-011 and FaDu) and NSD2-dependent multiple myeloma cell line (KMS11) for degradation activity against NSD2 protein, and H3K36me^2 chromatin mark reduction, using Western blot. We also tested their anti-proliferative activity in cell viability assay (CTB) and clonogenic assay. Compounds NUCC-0227381, NUCC-0227384, NUCC-0227414 and NUCC-0227383 show promising results by reducing NSD2 and H3K36me^2 levels. NUCC-0227383 compound was highly promising, as it was the most potent in reducing NSD2/K36me^2 levels without affecting NSD1/NSD3 levels and had profound effects on HNSCC cell growth. Lead compound NUCC-0227383 was chosen for further testing and in preliminary testing, showed a dose-dependent, VHL-mediated, and proteasome dependent function. Proteomics analysis, testing for specificity of NUCC-0227383 against a panel of histone methyltransferases, and in vivo testing of this promising compound against HNSCC is planned.

#4518 Proteolysis targeting chimera (PROTAC)-driven internalization of antibodies targeting oncogenic cell surface receptors.

E. J. Tolosa[1], L. Yang[1], J. Ayers-Ringler[1], J. Mallareddy[2], J. Schaefer-Klein[1], F. Kosari[1], A. Natarajan[2], A. S. Mansfield[1];
[1]Mayo Clinic College of Medicine and Science, Rochester, MN, [2]University of Nebraska Medical Center, Omaha, NE

Antibody-drug conjugates (ADCs) are increasingly being used in clinic, and many novel ADCs are being tested in clinical trials. Most ADCs act by delivering cytotoxic payloads into target cells. The activity of most ADCs is predicated upon internalization to release the cytotoxic payloads intracellularly to act on the malignant cells. The degree of ADC internalization is incomplete or absent for many cell surface targets, limiting the activity of ADCs. PROTACs are heterobifunctional molecules that result in the polyubiquitylation of their targets by inducing proximity with E3 ligases. The proteasome then recognizes the poly-ubiquitin chains and degrades these targets. We hypothesized that PROTACs that act on the same targets as ADCs could improve the internalization and efficacy of these ADCs.

Using multiple cell lines derived from breast, lung or pancreatic cancers that express the oncogenic cell surface proteins EGFR (ERBB1), HER2 (ERBB2) or MET (HGF), we measured antibody internalization with live cell imaging. Antibodies were labeled with a pH sensitive reagent that fluoresces red (640 nm) upon exposure to acidic environments. Fluorescence was measured over time to create an area under the curve which was compared between the cell lines that were treated with and without PROTACs. Antibody internalization was observed in all cell lines that expressed the targets recognized by the antibodies. The addition of PROTACs targeting the same oncogenic cell surface proteins as the antibodies significantly increased antibody internalization beyond that observed without PROTACs. Internalization of antibodies was confirmed by measuring intracellular immunoglobulins by Western blot. Antibody internalization with PROTACs was dose-dependent, increased over time and was blocked by either the clatharin inhibitor Dyngo4a or the proteasome inhibitor MG132. In the case of HER2 for which there are FDA-approved anti-HER2 ADCs, the cytotoxicity of trastuzumab emtansine (TDM1) significantly increased with the addition of a HER2-targeting PROTAC across a range of doses.

PROTACs that target the same oncogenic cell surface proteins as antibodies improve antibody internalization and ADC cytotoxicity, in a process dependent upon clatharin and the proteasome. This novel application of PROTACs may impact the use of ADCs, and provides a rationale to combine these agents in clinical trials.

#4519 Discovery of highly potent, selective and efficacious STAT3 PROTAC degraders capable of achieving complete tumor regression.

H. Zhou, **D. Wu**, L. Bai, R. K. Acharyya, H. Metwally, D. McEachern, B. Wen, D. Sun, S. Wang;
University of Michigan, Ann Arbor, MI

STAT3 (signal transducer and activator of transcription 3) is a transcription factor and a promising therapeutic targets for cancer and other human diseases. We have previously reported the discovery of SD-36 and SD-91 as potent, selective and highly efficacious STAT3 degraders. In the present study, we report the discovery and extensive evaluation of highly potent, selective and efficacious new STAT3 degraders designed using novel cereblon ligands and novel STAT3 ligands. Our most potent STAT3 degraders are >10-times more potent than SD-36 in inducing STAT3 degradation in cells and demonstrates >100-fold degradation selectivity over other STAT members. They achieve nanomolar IC_{50} values in leukemia and lymphoma cancer cell lines with activated STAT3. A single intravenous dose of these STAT3 degraders reduces the STAT3 protein for >48 hrs in xenograft tumor and native tissues, without reducing another other STAT members. Weekly administration of these STAT3 degraders is capable of achieving complete tumor regression in xenograft tumor models without any signs of toxicity. Taken together, these STAT3 degraders are promising lead compounds for extensive evaluation for the treatment of the treatment of human cancers and other human diseases in which STAT3 plays a key role.

#4521 Investigating bAP15, a new inhibitor of UCHL5/USP14 deubiquitinating enzymes, as a potential treatment for chondrosarcoma: A comprehensive *in vivo* and *in vitro* study.

K.-L. Kuo[1], F.-S. Hsu[2], S.-J. Chang[3], S.-M. Liao[1], W.-C. Lin[3], T.-Y. Ke[1], T.-T. Liu[3], K.-Y. Huang[4];
[1]National Taiwan University College of Medicine and Hospital, Taipei, Taiwan, [2]YangMing Branch of Taipei City Hospital, Taipei, Taiwan, [3]National Taiwan University Hospital, Taipei, Taiwan, [4]National Cheng Kung University Hospital, Tainan, Taiwan

Chondrosarcoma, a highly resilient cancer characterized by limited effective treatment options, represents a significant therapeutic challenge. bAP15, a novel inhibitor of deubiquitylating enzymes (DUBs), has emerged as a promising therapeutic agent, exhibiting anti-tumor activity in various cancer models. This study investigated the efficacy of bAP15 against chondrosarcoma in vitro and in vivo. To evaluate bAP15's effects on chondrosarcoma cells, the SW1353 and JJ012 cell lines were employed. Cell viability, apoptosis, and cell cycle progression were assessed using MTT assay and flow cytometry. Western blotting was utilized to analyze apoptosis, cell stress, and endoplasmic reticulum (ER) stress. Additionally, a xenograft mouse model was established to examine the in vivo anti-tumor potential of bAP15. Compared to normal cartilage tissue, chondrosarcoma cells exhibited significantly higher expression of the DUB UCHL5, suggesting its potential involvement in chondrosarcoma development. Treatment with bAP15 effectively induced apoptosis in chondrosarcoma cells by activating caspases and cleaving PARP. Furthermore, bAP15 enhanced ER stress by activating caspase-4 and CHOP. In the xenograft mouse model, bAP15 demonstrated remarkable anti-tumor efficacy with minimal toxicity. These findings highlight the potential of bAP15 as a therapeutic strategy for chondrosarcoma. Its ability to induce ER stress and cell cycle arrest, coupled with its in vivo anti-tumor activity, provides compelling evidence for its further development as a novel treatment option for this challenging cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Reactive Agents
Poster Session

#4525 Discovery of a highly potent and selective PARP1 inhibitor with superior PK and safety profiles.
y. wei, w. Li, z. li, m. li, k. kang, z. wen, t. yin, K.-L. Yu, G. Zhao, h. Yuan;
Acerand Therapeutics US, Carmel, IN

PARP inhibitors have been an effective treatment option for cancers deficient in homologous recombination repair, such as ovarian, breast, prostate, and pancreatic cancers, particularly those harboring BRCA mutations. However, their severe overlapping hematological and gastrointestinal toxicities have limited their clinical use, especially in the combination therapies with other anti-cancer agents. More recently, studies have shown that inhibiting PARP1 mainly drives anti-tumor activity while inhibiting PARP2 contributes to the hematological toxicity such as anemia due to its essential role in the survival of hematopoietic stem and progenitor cells. Thus, there is an urgent need for developing a selective PARP1 inhibitor. In this study, we report the discovery and characterization of a unique PARP1 inhibitor, ACE-86225106. This molecule is highly selective at inhibiting PARP1 over PARP2 as demonstrated in biochemical (72x) and DNA-trapping (131x) assays. It demonstrates potent anti-proliferative activities against BRCA mutant cancer cell lines (IC_{50} = 1-9 nM) but not against BRCA wild type cancer cells (IC_{50} >30,000 nM). As compared to the BRCA mutant cancer cells, this molecule is much less active at inhibiting the differentiation of $CD34^{+}$ hematopoietic stem cells (IC_{50} ≈ 450-1,400 nM), *i.e.*: erythroid, myeloid and megakaryocyte. The results of these studies show that ACE-86225106 is a highly potent and selective PARP1 inhibitor. This molecule has a unique PK profile characterized by its long half-life and low volume of distribution. As such, it demonstrates robust efficacy at low dose (1 mg/kg) with a less frequent dosing schedule (once a week). Importantly, there was no significant body weight loss observed in the treatment group even at much higher doses (10 mg/kg), but there was a significant body weight gain. The GLP toxicology studies have confirmed its superior safety profile as the maximum recommended safe starting first-in-human dose was >5-fold higher than the predicted human efficacious dose. Taken together, ACE-86225106 is a highly potent, selective PARP1 inhibitor with excellent PK and safety profile and expected to have a better safety profile, deeper and more durable clinical responses, and broader utility in the clinic as a preferred combination partner with other anti-cancer therapies. A phase 1 clinical trial to evaluate its safety, PK, and clinical utility is to begin in early 2024.

#4526 Inhibition of RNA Pol I transcription and induction of nucleolar stress in cancer cells treated with the experimental alpha-adrenergic receptor antagonist JP-1302.

S. Saproo, S. Papadaki, J. A. Espinoza, J. Bartek, **M. S. Lindstrom**;
Karolinska Institutet, Stockholm, Sweden

The inhibition of ribosome biogenesis through pharmacological means has drawn attention as a potential strategy in cancer therapy. In our previous study we highlighted a novel property of the FDA-approved antimalarial drug amodiaquine, demonstrating its ability to dose-dependently inhibit ribosomal RNA (rRNA) transcription, a critical step in ribosome biogenesis (Espinoza JA, et al Cell Death Diff, 2020). Amodiaquine was found to induce the degradation of the catalytic subunit of RNA polymerase I, known as POLR1A (RPA194), and resulting in nucleolar stress and the stabilization of p53. Notably, RNA Pol I shutdown occurred independently of DNA damage. Motivated by these findings, we sought to find additional inhibitors of ribosome biogenesis. Acridine derivatives display anti-cancer properties. The activity of acridines is mainly attributed to the planarity of these structures, which can intercalate within the DNA structure, and inhibition of chromatin associated protein targets including topoisomerases. JP-1302 is an experimental drug, on a 9-aminoacridine structural scaffold, acting as a selective alpha-2 adrenergic receptor antagonist. It was recently shown that JP-1302 inhibits transcription, blocking RNA Pol II phosphorylation and inhibiting p21 expression at a concentration of 10 µM (Mitchell DC, et al Nat Biotech, 2023). Given JP-1302's structural similarity to other acridine derivatives such as aminacrine, ethacridine, and the experimental compound BMH-21, all known to inhibit RNA Pol I transcription, we hypothesized that JP-1302 might share similar properties. The purpose of our new study was to evaluate JP-1302´s effect on ribosome biogenesis, p53, and cancer cell growth. We show here that JP-1302 acts as an inhibitor of RNA Pol I transcription. Treatment with JP-1302 induced a rapid decrease in the levels of POLR1A, cessation of rRNA synthesis and nucleolar stress already within six hours and at a concentration of 0.5 µM. JP-1302 treatment stabilized wild type p53 and enhanced p21 expression in the osteosarcoma line U2OS. RNA Pol I shutdown occurred in the absence of DNA damage response, as determined by gH2A.X staining. JP-1302 impaired the growth of both p53 wild type and p53 null HCT116 cells with GI50 values of around 0.6 µM, as well as in U2OS cells at 0.8 µM, as determined after 48 hours. Paradoxically, at very low concentrations JP-1302 appeared to transiently stimulate RNA synthesis, a phenomenon that will require further investigation. In conclusion, we identified JP-1302 as a novel inhibitor of ribosomal RNA synthesis, exerting this effect at concentrations that do not induce DNA damage, and independently of p53. Given that JP-1302 passes the blood-brain barrier in rodents, and accumulating in different brain regions, it is of future interest to evaluate this drug in brain tumor models.

#4527 TNG348 is synergistic with PARP inhibitors in tumor models with elevated replication stress.

A. Simoneau, H.-J. Wu, C. Pratt, G. Comer, S. Liu, S. Meier, T. Khendu, A. Choi, H. Zhang, B. Shen, D. Whittington, S. Sudsakorn, W. Zhang, Y. Yu, Y. Chen, B. Haines, A. Crystal, J. N. Andersen, J. Maxwell, S. Throner;
Tango Therapeutics, Boston, MA

Defective maintenance of genomic integrity is a hallmark of cancer cells that can result from oncogene-induced replication stress and by loss of DNA repair mechanisms. DNA repair deficiencies and elevated replication stress present targetable vulnerabilities for cancer treatment. Notably, BRCA1/2 mutant and homologous recombination deficient (HRD) tumors cannot repair double-strand breaks by homologous recombination and rely on alternative pathways of DNA repair. PARP inhibitors (PARPi), which are a standard of care in many BRCA1/2 mutant tumors, cause synthetic lethality with BRCA1/2 mutation by inhibiting the DNA base excision repair pathway. Despite the clinical benefit of PARPi, they are not effective in every HRD tumor and the acquisition of PARPi resistance limits long-term response. TNG348, a selective allosteric inhibitor of the deubiquitinating enzyme USP1, was specifically designed to target HRD vulnerabilities through an alternative mechanism. We previously showed that the anti-tumor activity of USP1 inhibition results from disruption of the translesion synthesis DNA damage tolerance pathway, a mechanism of action that is functionally distinct from base excision repair targeted by PARPi. Our preclinical studies show that TNG348 is active in HRD models and strongly synergizes with PARP inhibitors to drive strong anti-tumor responses. We have identified replication stress as a predictive biomarker of TNG348 response using cell line profiling and genome-wide CRISPR screens. For example, overexpression of oncogenes known to induce replication stress sensitized to the TNG348 and PARPi combination both in vitro and in vivo. These data indicate that cancer-specific elevated DNA replication stress could contribute to tumor sensitivity to TNG348 and provide additional patient stratification strategies and opportunities for indication expansion.

#4528 Improving carboplatin therapy: A novel albumin-targeted platinum(IV) prodrug with superior anticancer activity *in vivo*.

H. Schueffl[1], R. Weinmuellner[2], N. Sommerfeld[2], B. Keppler[3], W. Berger[1], C. Kowol[3], P. Heffeter[1];
[1]Medical University of Vienna, Vienna, Austria, [2]P4 Therpeutics GmbH, Vienna, Austria, [3]University of Vienna, Vienna, Austria

Platinum(II)-based chemotherapeutics are among the most commonly used anticancer drugs and are part of nearly every second treatment scheme. However, they lack in tumor specificity, causing severe sides effects, dose-dependent toxicity as well as drug resistance development. Due to their higher tolerability, platinum(IV) prodrugs are currently in the focus of interest. However, comparable to their platinum(II) counterparts, they show insufficient tumor accumulation and are frequently prematurely activated. A promising strategy to improve tumor targeting of anticancer drugs is to exploit the enhanced consumption and accumulation of albumin in the malignant tissue. Thus, we developed a new albumin-targeted maleimide-containing platinum(IV) prodrug, which releases carboplatin in a highly tumor-specific manner. The maleimide moieties enable the drug to selectively bind the endogenous albumin via its free thiol of cysteine 34. The aim of this study was to in-depth characterize the pharmacological behavior and anticancer activity *in vivo* of the new prodrug. To this end, several xenograft and allograft experiments were performed. To investigate tissue distribution and pharmacokinetics serum, urine, tumor and organ samples of mice were collected after drug treatment and were evaluated by (size-exclusion chromatography) inductively-coupled plasma mass spectrometry and immunohistochemistry (e.g cleaved caspase-3). These experiments revealed that the new prodrug fast and selectively binds to the serum albumin after intravenous injection, leading to an enhanced plasma half-life and an increased tumor accumulation in comparison to its corresponding platinum(II) drug carboplatin. Additionally, the new complex resulted in superior anticancer activity and prolonged overall survival based on the distinctly improved pharmacokinetic profile and enhanced apoptosis induction. In conclusion, these data support that albumin binding is a potent tool to increase the tumor specificity of platinum(IV) drugs and prevent their premature activation in other body compartments. Consequently, this very promising prodrug will be further developed towards clinical phase I testing.

#4529 Characterization of PARP inhibitor combination therapies in triple-negative breast cancer.

Elicia Fyle, Djihane Abdesselam, **Mallory Frederick**, Saima N. Hassan

University of Montreal, CRCHUM, Montreal, QC, Canada

Introduction: Triple-negative breast cancer (TNBC) is the most aggressive type of breast cancer, with limited targeted treatment options. TNBC patients can, however, benefit from targeted drugs known as Poly (ADP-Ribose) Polymerase inhibitors (PARPi). PARPi disrupt DNA repair pathways by targeting tumors with germline *BRCA1/2* mutations (*BRCA-MUT*) via synthetic lethality and PARP-DNA trapping mechanisms. Only 15-20% of the TNBC patient population are *BRCA-MUT* and can thus benefit from PARPi. However, preclinical studies and clinical trials have suggested that PARPi can also be effective in *BRCA1/2* wild-type (*BRCA-WT*) cancer cells that have genomic phenotypes similar to *BRCA-MUT* cells, a phenomenon known as BRCAness. Previously, we used whole transcriptome analysis in a panel of TNBC cell lines to identify a 63-gene signature for BRCAness. The 63-gene signature was shown to predict response to PARPi with an accuracy of 86% in patient-derived xenografts, and was present in 45% of TNBC patients. We hypothesize that targeting genes in this 63-gene signature can enhance the sensitivity of PARPi in *BRCA-WT* and *BRCA-MUT* TNBC cells. Our aim is to identify and target genes from this signature that are involved in DNA synthesis and repair pathways, to identify effective combination strategies with PARPi.

Methods: Using a PARPi-resistant TNBC cell line, MDAMB231, we carried out an siRNA screen of six genes from the 63-gene signature (*BARD1, BUB1, RRM2, FEN1, EXO1, and USP1*), chosen based on DNA repair functions and small-molecule inhibitor availability. The gene knockdowns were combined with the application of a potent PARPi, talazoparib, to determine the impact on DNA damage and cell death in TNBC cell lines. We then focused on targeting FEN1 function with the inhibitor LNT1. Using the Chou & Talalay combination index, we combined LNT1 with talazoparib to determine drug synergy in TNBC cell lines.

Results: The individual siRNA knockdowns of *BARD1*, *BUB1*, *FEN1*, *EXO1*, and *USP1*, in combination with talazoparib, led to increased γ-H2AX and cleaved-caspase 3 levels, indicating augmentation of DNA damage and apoptosis. In particular, the FEN1 inhibitor, LNT1 demonstrated efficacy as a single-agent and synergy in combination with talazoparib in both *BRCA-WT* and *BRCA-MUT* TNBC cell lines.

Conclusions: The siRNA screens, in combination with talazoparib, show that there are indeed targets within the 63-gene signature that can be used with PARPi that enhance DNA damage and cell death. The drug synergy shown between LNT1 and talazoparib in both *BRCA-WT and BRCA-MUT* TNBC cells suggests that LNT1 with PARPi could be an effective targeted combination approach, with great potential for TNBC patients.

#4530 Nuclear export inhibitor cooperates with PARP inhibitor to suppress the growth of metastatic castration resistant prostate cancer *in vivo*.

M. Uddin, A. Aboukameel, H. Y. Khan, S. F. Bannoura, F. Cackowski, R. Beydoun, G. Dyson, S. Kim, J. Boerner, V. Shidham, R. M. Mohammad, B. C. Pasche, A. S. Azmi, E. I. Heath;
Karmanos Cancer Institute, Wayne State University, Detroit, MI

Background: Aberrant nuclear protein transport, often observed in cancer, causes mislocalization-dependent inactivation of critical cellular proteins. Earlier we showed that overexpression of nuclear export protein exportin 1 (XPO1) is linked to higher grade and Gleason score in metastatic castration resistant prostate cancer (mCRPC). The network topology computational approach (NTCP) determined a higher synthetic lethal score between XPO1 and poly (ADP-ribose) polymerase (PARP1). We showed that selective inhibitor of nuclear export (SINE) could synergized with PARP inhibitors in mCRPC cell lines. Here we evaluated the efficacy of SINE and PARP inhibitor (PARPi) combination in cell line derived as well as patient derived xenograft (CDX and PDX) models and deciphered the mechanism of synergy.
Methods: For CDX model, the 22rv1 mCRPC cells were grown as subcutaneous xenografts in ICR-SCID male mice. For PDX model, tissue was collected from Champions Oncology (CTG-3581) and grown subcutaneously in CEIA/NOG male mice. SINE dosed orally at 10-15 mg/kg twice a week and PARPi dosed orally at 50 mg/kg daily. For *in vitro* mechanistic study, 22rv1 cells were subjected to RNAseq and proteomic analysis after treatment. Data analysis was performed using iPathwayGuide (advaitabio.com).
Results: The CDX and PDX showed pronounced anti-cancer efficacy by this combination compared to single agents without any significant weight loss. Survival analysis in CDX model demonstrated enhanced benefits to the mice of combination group. Immunohistochemistry (IHC) revealed apoptotic cell death in the combination group which is evident from cleaved caspase 3 staining and terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL). To decipher the mechanism of synergy we performed transcriptomic (RNAseq) and proteomic analysis *in vitro*. We observed downregulation of DNA replication related gene minichromosome maintenance complex component 6 (MCM6) and cell division cycle 6 (CDC6) in the combination treatment. Gene set enrichment analysis (GSEA) also showed low enrichment scores for DNA replication. Proteomic analysis revealed a down regulation of DNA replication modulators such as HMGB2 and DNAJC9 which work on DNA coiling and histone respectively.
Conclusions: Taken together, this study revealed the therapeutic potential of SINE-PARPi combination via targeting DNA damage response pathway in mCRPC. Further evaluation of molecular synergy in the xenograft models are underway through RNA interference (RNAi) technique and Digital Spatial Profiling (DSP).

#4531 The synergistic potential of PARP inhibitors and irinotecan in small cell lung cancer.

Songji Oh[1], Miso Kim[2], Soyeon Kim[1], Bhumsuk Keam[2], Jeonghwan Youk[2], Tae Min Kim[2], Dong-Wan Kim[3], Dae Seog Heo[4]

[1]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Cancer Research Institute, Integrated Major in Innovative Medical Science, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Cancer Research Institute, Seoul National University, Seoul, Korea, Republic of

Background: Small cell lung cancer (SCLC) is highly aggressive and associated with a poor prognosis. While effective treatment is limited after a relapse from platinum-based chemotherapy, recent research has identified novel pathway targets including DNA damage repair (DDR) pathway. Poly (ADP-ribose) polymerase inhibitors (PARPi) have been currently evaluated for their efficacy as a monotherapy and in combination with other agents, such as immunotherapy.
Methods: We evaluated the efficacy of combining PARPi and irinotecan in ten SCLC cell lines with diverse genetic backgrounds in the DDR genes. After treating the cells with three different PARPi in combination with irinotecan, we assessed cell viability and the combination effects. Furthermore, we confirmed protein changes in the DDR pathway through western blotting and measured the number of apoptotic cells using Annexin V staining.
Results: In our experiments, talazoparib had the most potent effect at low concentrations, while olaparib and venadaparib showed more pronounced synergistic effects (average fold change of IC_{50}: olaparib, 1649±4049; talazoparib, 25±34.21; venadaparib, 336±596.01; see Table). The combination of talazoparib or venadaparib with irinotecan led to a reduction of IC_{50} values to below 10 nM in 7 out of 10 tested cell lines. Three cell lines carrying *BRCA* mutations displayed a strong sensitivity to PARPi, whereas no significant correlation found with alterations in other DDR genes. The combined use of both drugs increased p-chk1 and p-p53 proteins, along with apoptosis signaling. Additionally, venadaparib alone did not induce cell toxicity but significantly increased apoptosis when combined with irinotecan, even at very low concentrations.

IC50 values of PARP inhibitors in SCLC cells w/ or w/o irinotecan 50 nM

	IC_{50} (nM)	Olaparib		Talazoparib		Venadaparib	
BRCA or *PTEN* status	Irinotecan 50 nM	-	+	-	+	-	+
BRCA1 deletion	NCI-H1694	5,933	148.9	52.38	2.19	>10,000	1.02
BRCA2 deletion	NCI-H211	392.8	37.20	2.28	0.99	3.82	0.94
BRCA2 deletion	NCI-H1048	1,704	282.7	9.74	2.36	62.01	3.02
PTEN deletion	NCI-H1341	>10,000	6,880	452.9	83.9	>10,000	>10,000
PTEN deletion	DMS 79	2,382	221.9	18.55	3.4	175.16	3.07
no mutation	NCI-H841	5,099	6,202	529.5	380.5	>10,000	>10,000
no mutation	NCI-H2029	>10,000	>10,000	478.2	56.16	>10,000	>10,000
no mutation	NCI-H2227	3,407	827.5	52.03	2.17	>10,000	0.69
no mutation	NCI-H146	5,094	3.31	56.11	0.86	1,295	0.93
no mutation	NCI-H209	579.2	0.05	5.24	0.05	8.18	0.04

Conclusions: The combination of a PARPi with irinotecan significantly inhibited cell growth more than the use of either agent alone. Our findings indicate that clinical trials are warranted to confirm the effectiveness of combining PARPi with irinotecan in patients with SCLC.

#4532 Discovery of DAT-1000A, a potent Polθ inhibitor that significantly enhances anti-tumor efficacy in combination with PARP inhibitor in homologous-recombination-deficient tumors.

D. Yan, Y. Zhang, Y. Zhang, J. Zhang, B. Wang, H. Chen, J. Shi, X. Lin, J. Zhuo, K. Zhou;
Danatlas Pharmaceuticals Co., Ltd., Beijing, China

Cancers exhibiting homologous recombination (HR) repair deficiencies due to mutations in genes like BRCA1 or BRCA2 rely on alternative DNA damage response (DDR) pathways to uphold genomic integrity. This vulnerability allows for the targeted disruption of these pathways through synthetic lethality approaches. DNA polymerase theta (Polθ, encoded by *POLQ*) assumes a crucial role in mending DNA double-strand breaks (DSB) via microhomology-mediated end-joining (MMEJ), one of the principal pathways for repairing DNA DSB. Notably, Polθ expression is minimal in normal tissues but becomes upregulated in HR-deficient cancer cells, positioning Polθ as a prime target for synthetic lethality in HRD cancers. Reversion mutations in HR-related genes frequently employ micro-homology deletion mechanisms. Consequently, the inhibition of Polθ holds the potential to thwart the emergence of PARPi resistance, primarily driven by BRCA reversion mutations. In this context, we introduce DAT-1000A, a novel small-molecule Polθ inhibitor exhibiting potent activity with a single-digital nanomolar IC_{50} value. Its efficacy in MMEJ functional assays validates its on-target cellular activity. Assessments of cell viability in HR-deficient BRCA2-KO DLD-1 cells, compared to their parental counterparts, reveal a striking synthetic lethality window exceeding 500-fold. Additionally, DAT-1000A displays synergistic anti-proliferative effects when combined with PARP inhibitors in BRCA1/2-mutated cells. In BRCA1/2-mutated xenograft models, DAT-1000A demonstrates robust and sustained tumor regression, as evidenced by the level of γH2AX, a common marker for double-strand breaks, which closely correlates with anti-tumor efficacy. Importantly, high-dose DAT-1000A treatment in mice elicits no significant abnormalities, underscoring its excellent tolerability. Collectively, DAT-1000A emerges as a novel Polθ inhibitor, offering both potent activity and a favorable safety profile, and holds promise for advancing therapeutic options in the realm of HRD cancer treatment.

#4533 Identification of DAT-2000A, a novel potent PARG inhibitor that selectively inhibits PARPi-resistant and homologous-recombination-deficient tumors.

D. Yan, Y. Zhang, Z. Yu, Y. Zhang, J. Zhang, B. Wang, H. Chen, J. Shi, Z. Bao, X. Lin, J. Zhuo, K. Zhou;
Danatlas Pharmaceuticals Co., Ltd., Beijing, China

A significant portion of patients with homologous recombination repair deficiencies(HRD) do not respond to PARP inhibitors, and even among those who initially respond, resistance often develops after PARP inhibitor treatment. This underscores the unmet clinical need to address the challenges in the treatment of HRD patients. Poly (ADP-ribose) glycohydrolase (PARG) plays a key role in hydrolyzing PAR chains from PARylated protein substrates, such as PARP1, serving as a critical checkpoint in DNA damage repair and the control of DNA replication stress. Therefore, PARG has emerged as a promising target for cancer therapy. Cancer cells experiencing replication stress, such as HRD breast cancer cells and those resistant to PARPi, exhibit sensitivity to PARG inhibition. DAT-2000A is a potent, selective, orally bioavailable small-molecule inhibitor of PARG, which directly binds to the catalytic domain of PARG, inducing the accumulation of poly-PAR chains at DNA lesions, and exhibits notable anti-proliferative activity across a wide range of HRD tumors both *in vitro* and *in vivo*. Biochemical assays confirm DAT-2000A's high potency and selectivity as an inhibitor of PAR-chain hydrolysis. In cellular assays, DAT-2000A demonstrates selective sensitivity in HRD cells, distinguishing itself from PARPi across various indications. Preclinical studies involving CDX and PDX xenograft models reveal that DAT-2000A exerts robust anti-tumor effects in both PARPi-sensitive and -resistant settings. Furthermore, it induces a dose and time-dependent accumulation of PAR chains, which may serve as a reliable pharmacodynamic biomarker indicative of PARG target engagement. In conclusion, DAT-2000A represents an innovative targeted therapy that warrants further investigation in clinical trials for the treatment of HRD cancers and beyond.

#4534 HSK40495, a highly selective PARP1 inhibitor with improved hematopoietic safety for the treatment of HRD cancers.

F. Li[1], X. Gou[2], L. Chen[2], Q. Meng[1], Y. Li[2], H. Dong[2], P. Tang[2], **J. Wang**[1], P. Yan[2];

[1]Haisco Pharmaceutical Group Co., Ltd., Shanghai, China, [2]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China

It is well known that several PARP inhibitors have been approved for tumors with homologous recombination repair deficiencies (HRD), such as BRCA mutations. However, the common side effect of these inhibitors is hematologic toxicity, which limits their therapeutic index and combination potential with first-line chemotherapies. One possible reason is that currently approved PARP inhibitors do not specifically target PARP1, and might also affect other PARP family members. Recent studies have shown that the synthetic lethality caused by PARP trapping with HRD is mainly dependent on PARP1 inhibition, but not other PARP family members. Accordingly, we developed a selective PARP1 inhibitor that effectively inhibits tumor growth with less hematologic toxicity. HSK40495 is a potent PARP1 inhibitor with highly selectivity of PARP2. HSK40495 inhibited PARP1 enzymatic activity with a single digit nanomolar potency and with greater than 5000-fold selectivity against PARP2 in the protein binding assay. In addition, HSK40495 exhibited potent anti-proliferation activity in both DLD1(BRCA KO) cell and MDA-MB-436 cell, while had minimal effects against BRCA-WT DLD1 cell up to 30 μM in an anti-proliferation assay. In a subcutaneous MDA-MB-436 xenograft tumor model, HSK40495 administered orally once daily achieved excellent tumor growth inhibition of 100% at 3mg/kg. HSK40495 demonstrated significant PARylation inhibition in tumor tissues. Importantly, in CD34+ human bone marrow progenitor cell, HSK40495 showed improved cytotoxicity when compare to first-generation PARP inhibitor, Talazoparib. Meanwhile, in a lineage-specific hematotoxicity assay, HSK40495 exhibited improved cytotoxic safety in the process of differentiation of myeloid, erythroid and megakaryocyte compared with Talazoparib treatment. In summary, HSK40495, a highly selective PARP1inhibitor over other PARP family members, exhibits excellent pharmacological and safety properties, and also has the favorable pharmacokinetics profile in preclinical studies. All these findings suggest that HSK40495 has the great potential to be a promising PARP1 inhibitor for further development in the patients with HRD tumors.

#4535 JAB-26766: A small-molecule, orally bioavailable PARP7 inhibitor with high potency and selectivity.

Di Kang, Yanping Wang, Xin Sun, Man Yan, Haijun Li, Mingming Chen, **Yiwei Lin**, Wei Long

Jacobio Pharmaceuticals Co., Ltd., Beijing, China

Background: PARP7 (also referred to as TIPARP or ARTD14) is a mono-ADP-ribosyl transferase that inhibits type I interferon (IFN) signaling. Targeting PARP7 to restore antitumor immunity represents a promising treatment strategy. We have developed JAB-26766, an orally bioavailable, highly potent, and selective PARP7 inhibitor.

Methods: A time-resolved fluorescence energy transfer (TR-FRET) assay was applied to determine the binding and inhibition of PARP7 by JAB-26766. IFN-β secretion assay, STAT1 phosphorylation assay, and ISG (interferon stimulated gene) mRNA assay were performed to evaluate the inhibitory activities of JAB-26766 on the downstream signaling of PARP7. CellTiter-Glo assay was performed to evaluate cell viability upon treatment of JAB-26766. *In vivo* PK-PD study was conducted to evaluate the relationship between JAB-26766 concentration and the level of tumor STAT1 phosphorylation. The antitumor activity of JAB-26766 either as a single agent or in different drug combinations was evaluated in multiple mouse models.

Results: High potency of JAB-26766 on PARP7 inhibition as well as >1800-fold selectivity over PARP2 was observed through biochemical assays. At the cellular level, JAB-26766 induced IFN-β secretion, up-regulated ISG mRNA levels, increased phosphorylation of STAT1, and inhibited cell viability of multiple tumor cell lines (with most IC_{50} values below 50 nM). JAB-26766 combined with a STING agonist resulted in synergistic activation of STING pathway, as evidenced by increased CXCL10 secretion, and inhibited tumor cell proliferation. *In vivo* PK-PD study showed that JAB-26766 exposure in plasma and tumor has good correlation with induction of tumor STAT1 phosphorylation. Furthermore, JAB-26766 showed potent antitumor activity and good tolerability either as monotherapy or combined with STING agonist or anti-PD-1 antibody in mouse models of non-small cell lung cancer, breast cancer and colorectal cancer.

Conclusions: JAB-26766 is an orally bioavailable, highly potent, and selective PARP7 inhibitor that shows early promising anti-tumor activities.

#4536 MTAP loss alters the epigenetic landscape and demonstrates superior therapeutic sensitivity to concomitant PRMT5 and PARP inhibition in cholangiocarcinoma.

Pooja A. Shah, Ajay Kumar Saw, William Padron, Ming Zhao, Argun Akcakanat, Kurt Evans, Funda Meric-Bernstam, Milind Javle, Jordi Rodon, Kunal Rai

UT MD Anderson Cancer Center, Houston, TX

5'-methylthioadenosine phosphorylase (*MTAP*), is deleted in 15% of all cancers (estimated 100,000 patients per year in the United States), including 12-15% of cholangiocarcinoma (CCA) cases. MTAP deficiency accumulates 5'-methylthioadenosine (MTA) that subsequently binds protein arginine methyl transferase 5 (PRMT5) and inhibits its activity. This renders selective targeting of MTAP null tumors with agents (MRTX1719, AMG193, TNG462, TNG908) targeting MTA bound PRMT5 (PRMT5:MTA), while sparing surrounding normal *MTAP* wild-type (WT) tissue. Early signs of clinical activity was seen with MRTX1719, including objective responses in patients with *MTAP* loss tumors, including biliary tract cancer from the phase I/II study (NCT05245500). Despite these advances, prolonged targeted therapy poses the risk of development of acquired resistance demanding the need for better therapeutic strategies. To address this pressing need, we co-treated CCA cell lines with MRTX1719 and PARP inhibitor olaparib. We hypothesize that since PRMT5 is a critical regulator of splicing and DNA damage pathways, inhibition of PRMT5 disrupts these downstream processes creating an additional vulnerability to DNA damage inducing agents such as PARP inhibitors. Our preliminary data combining MRTX1719 with olaparib in three *MTAP* loss CCA cell lines (RBE, YSCCC, TFK1) show synergy (combination index; CI<1), and significant reduction in cell viability as well as colony formation ability when compared to monotherapy *in vitro*. To further gain mechanistic insights into the biology of *MTAP* loss, we stably expressed MTAP in *MTAP* null CCA cell line, RBE and demonstrated that *MTAP* loss drives tumorigenesis *in vivo* highlighting its tumor suppressor function in CCA. Mass spectrometry-based profiling of histone modifications from the isogenic RBE cell lines showed heightened methylation and reduced acetylation marks in the absence of MTAP. We also noted substantial differences in the distribution of splicing events, with increased intron retention, 3' alternative splicing and decreased exon skipping as a result of *MTAP* loss. Similar differences in proportion of splicing events were also observed in *MTAP* loss CCA patient derived xenografts as compared to WT models. Collectively, these data implicate MTAP to be a crucial player in modulation of the chromatin and splicing events that may drive therapeutic response to PRMT5 inhibition.

#4537 VB15010 is a potent PARP1 selective inhibitor and durable trapper with improved pharmacological activities.

D. D. Fang, Y. Liu, Y. Liu, H. Zhang, J. Wu, J. Wei, W. Sha, C. Z. Ding;
Shenzhen Yangli Pharmaceutical Technology Co., Ltd., Shenzhen, China

PARP inhibitors have become the backbone of therapy for patients bearing cancers with homologous recombination deficiency (HRD). Currently approved PARP inhibitors, such as olaparib, are pan-PARP inhibitors targeting PARP1, PARP2, and other PARP family members. Emerging evidence suggests that targeting PARP1 is sufficient to exert antitumor effect, whereas targeting PARP2 causes hematological toxicity. Consequently, these pan-PARP inhibitors often lead to dose reduction and treatment discontinuation in clinics. Therefore, developing PARP1 selective inhibitors becomes advantageous to improving patient outcomes and broadening the applications of the targeted therapy. To this end, multiple PARP1 selective inhibitors are currently in preclinical or early clinical development worldwide. We report herein preclinical investigation of a novel, potent PARP1 selective inhibitor and durable DNA trapper, VB15010, which demonstrates improved pharmacokinetic (PK) and pharmacodynamics (PD) properties, and antitumor activity in comparison with an advanced agent in clinical development. Comparatively, VB15010 exhibited higher selectivity for PARP1 over other PARP family members (30 to 8,000-fold) in enzymatic assays, and superior selectivity for PARP1- over PARP2-DNA trapping (>1700-fold) in DNA trapping assays. Genetic knockout of *PARP1*, but not *PARP2*, abolished inhibition of PARylation by VB15010 in *PARP1/2* wild type cells, further validating its PARP1 selectivity. Besides, VB15010 induced substantially more durable PARP1-DNA trapping when compared to the reference agent. In addition, VB15010 demonstrated potent antiproliferative activity in *BRCA*m or HRD-positive cancer cell lines (IC_{50} < 100 nM), as well as induced an increase in DNA damage, cell cycle arrest in G2 phase, and apoptosis in *BRCA2*-deficient cells *in vitro*. *In vivo*, VB15010 showed excellent bioavailability in preclinical animal models. Moreover, VB15010 exerted substantial antitumor activity at a dose range from 0.1 to 30 mg/kg, leading to tumor regression at as low as 0.3 mg/kg in *BRCA*m human cancer cell line-derived and HRD-positive patient-derived mouse xenograft models with an excellent PK-PD correlation. Tumor-to-plasma ratios of drug exposures indicate that VB15010 displayed a preferable tumor tissue distribution compared with the reference agent. Collectively, with improved PK-PD properties, including durable DNA trapping capability, higher apoptosis-inducing potency, and favorable tumor-to-plasma distribution ratio, as well as potent antitumor activity, VB15010 may achieve enhanced clinical efficacy and reduced hematological toxicity with a higher therapeutic index in patients. Its IND filing is expected in the first quarter of 2024.

#4538 Brigatinib induces synergy with PARP inhibitors through dual inhibition of FAK and EphA2 in high-grade serous ovarian carcinoma.

J. R. Duffield, X. Hou, I. K. McKeon-Makki, A. M. Huehls, B. W. Wilson, A. Prasad, X. Wu, S. H. Kaufmann, L. M. Karnitz, J. J. Weroha, A. Kanakkanthara; Mayo Clinic, Rochester, MN

PARP inhibitors (PARPis) have now become a standard of care for high-grade serous ovarian cancer (HGSOC), especially for those with defects in homologous recombination (HR) DNA repair. However, the innate and acquired PARPi resistance in HGSOC poses a significant concern, necessitating the exploration of novel treatment options and strategies. Here we investigated the potential of combining brigatinib—a second-generation anaplastic lymphoma kinase (ALK) inhibitor approved for treating lung cancer—with PARPis as way to enhance PARPi activity in HGSOC. Clonogenic cell survival assays revealed that brigatinib synergizes with PARPis in HR-proficient and -deficient HGSOC cell lines. In subsequent proteomics approaches and cell-based confirmatory studies, we found that brigatnib suppressed tyrosine kinases FAK and EphA2 with reduction in downstream signaling. Follow-up pharmacologic and gene-silencing techniques demonstrated that dual FAK and EphA2 inhibition additively reduces PI3K/Akt and MAPK/ERK cell survival signaling to levels conferring PARPi sensitivity. Additionally, the efficacy of this therapeutic approach on tumor size reduction was assessed in HGSOC patient-derived xenograft (PDX) models, with combination treatment inducing tumor regression more effectively than either agent alone. Overall, our studies unveil a beneficial ALK-independent effect of brigatinib that may offer new avenues for considering its repurposing as a HGSOC therapy.

#4539 ZM-2311 a novel and highly potent Polθ inhibitor demonstrates synergistically anti-tumor activities in combination with different therapeutics.

F. Zhou[1], L. Liu[2], L. Jiang[2], S. Qian[2], L. Xue[1], M. Li[2], Z. Li[1], Z. Li[2], J. Li[2], R. Tang[1];
[1]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China, [2]Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Homologous recombination (HR) is a high-fidelity DNA double-strand break (DSB) repair pathway, and its dysfunction leads to cell genome instability and can result in tumorigenesis. In the situation of HR deficiency, DNA polymerase theta (Polθ) mediated microhomology-mediated end joining (MMEJ) is up-regulated to serve as a backup pathway for DSB repair. Several studies have proved that the inhibition of Polθ causes synthetic lethality with HR deficiency, and Polθ emerges as a potential DNA damage repair (DDR) target for the treatment of HR deficient tumors. In addition, there is evidence showing that the depletion of Polθ improves the sensitivity of some other DDR-related targeted therapies, chemotherapy, and radiotherapy. Here we identify a novel small molecular Polθ inhibitor, ZM-2311, which inhibits Polθ activity with an IC_{50} of 24 nM, and strongly inhibits cellular MMEJ pathway with a single nanomolar IC_{50}. ZM-2311 illustrates a robust potency against tumor growth in a MDA-MB-436 SHLD2-/- xenograft model, suggesting potential monotherapy application in BRCA1 mutation patients with TP53BP1/Shieldin complex deficiency. Besides monotherapy, ZM-2311 elicits strong synergetic anti-proliferation activities in combination with PARP inhibitors on $BRCA2^{-/-}$ DLD-1 and endogenous HR deficient tumor cells *in vitro* and *in vivo*. Tumor regression is observed even at a low dosage, indicating a high potency of ZM-2311. As reversion mutation of HR genes such as BRCA1/2 mediated by the MMEJ pathway is reported to be a mechanism of PARP inhibitor resistance, ZM-2311 is evaluated and demonstrates its potential to overcome the resistance to PARP inhibitors. Furthermore, the combination of ZM-2311 with other DDR agents, such as ATR inhibitors, induces fatal DNA damage to HR deficient cells. Considering a low risk of hematotoxicity of Polθ inhibition, ZM-2311 may provide a new combination option for DDR agents. Besides, ZM-2311 was assessed in combination with different therapies respectively which functionally induce DNA damage, such as radiotherapy and chemotherapy. ZM-2311 renders tumor cells more sensitive to radiotherapy in both HR deficient cells and proficient cells *in vitro*, accompanying with the upregulation of Polθ expression after radiotherapy and an enhanced phosphorylation level of H2AX in the combination treatment. Similarly, ZM-2311 also achieves a robust synergetic effect in combination with chemotherapy in cell lines with different HR statuses. These results indicate a potential application expansion of ZM-2311 to HR-proficient tumors, which is expected to bring better efficacy and reduced hematotoxicity. Taken together, ZM-2311 has proved to be a highly potent Polθ inhibitor and has promising combination potential with multiple therapy strategies.

#4540 SY-7021, a novel DNA-PK inhibitor, exhibits significant anti-tumor activity *in vitro* and *in vivo*.

K. Zhang, Z. Liu, Y. Gao, C. Lu, S. Cheng, X. Liu, **H. Luo**, Y. Sun;
Shouyao Holdings Co., Ltd, Beijing, China

Cancer therapies such as ionizing radiation or topoisomerase II inhibitors (for example, doxorubicin) induce DNA double-strand breaks (DSBs), which can subsequently be repaired by homologous recombination or non-homologous end joining (NHEJ). DNA-dependent protein kinase (DNA-PK), a nuclear serine/threonine protein kinase complex, is a pivotal component of the NHEJ process that maintain genome integrity. The critical role of DNA-PK in DNA damage response (DDR) and the dysregulated DNA-PK expression in cancer make it an intriguing therapeutic target for cancer, especially when combined with DSBs agents. Here, we identified a highly potent and selective DNA-PK inhibitor, SY-7021, with an IC_{50} value of 0.242 nM on DNA-PK kinase and high selectivity on ATM and ATR (greater than 400-fold) in biochemical assays. In a reporter assay for NHEJ repair, SY-7021 was able to dose-dependently reduce cellular NHEJ efficiency. Functionally, SY-7021 inhibited cell proliferation in multiple cancer cell lines alone or combined with doxorubicin. Basically, combination of SY-7021 and doxorubicin induced significant G2/M phase arrest and cell apoptosis, as well as enhanced the phosphorylation on Ser139 of γH2AX, Tyrosine 68 of CHK2 and Serine15 of p53 in MDA-MB-468 cells. In a subcutaneous NCI-H1703 xenograft tumor model, SY-7021 administered orally twice daily achieved dose-dependent tumor growth inhibition *in vivo*, with a tumor growth inhibition (TGI) of 105.6% at 60 mg/kg and no significant weight loss was observed. In addition, SY-7021 demonstrates good PK properties and acceptable safety profiles in *in vivo* studies. Collectively, SY-7021, a potent and selective DNA-PK inhibitor, shows significant inhibition on tumor growth in *in vitro* and *in vivo* studies, providing a rationale treatment for multiple tumors in monotherapy or in combination with other agents.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Combinations
Poster Session

#4546 Pegargiminase and melphalan as a novel drug combination strategy for uveal melanoma.

I. Pavlyk[1], J. Carpentier[1], E. A. Szlosarek[1], P. Y. Chan[2], J. S. Bomalaski[3], P. W. Szlosarek[1];

[1]Queen Mary University of London, London, United Kingdom, [2]The Wellcome Sanger Institute, London, United Kingdom, [3]Polaris Pharmaceuticals, Inc., San Diego, CA

Uveal melanoma (UM) is a hard-to-treat arginine auxotrophic cancer with approximately 50% of patients succumbing to metastases predominantly to the liver with a median overall survival of 19-22 months and a 5 year survival of around 10%. Novel drug strategies are urgently needed beyond the currently available immunotherapies that provide durable disease control in a small subset of patients. Arginine deprivation with pegylated arginine deiminase (ADI-PEG20; pegargiminase) is a novel anti-metabolite therapy which demonstrated activity in early phase trials in patients with UM, and more recently, increased survival in patients with the aggressive arginine-dependent cancer, non-epithelioid mesothelioma in the global phase 3 trial, ATOMIC-Meso. Here, we investigated the preclinical rationale for combining pegargiminase with melphalan, a drug which is delivered directly to the liver using an FDA-approved device from Delcath for patients with hepatic-centric UM disease. Two of four uveal melanoma cell lines were negative for expression of the rate-limiting enzyme for arginine production, argininosuccinate synthetase 1 (ASS1) and were submitted for drug evaluation accordingly. ADI-PEG20 treatment of ASS1-deficient cell lines 91.2 and MP41 demonstrated sensitivity to ADI-PEG20 (500ng/ml) compared to MP38 and MP46 ASS1-proficient cell lines. Moreover, the combination of ADI-PEG20 and melphalan (0.77µM) had at least an additive effect on ASS1 negative cell lines in 2D assay (92.1 p-value 0.0061; MP41 p-value is 0.0053). UM cell line proliferation was decreased by 50% in the combination group compared to ADI-PEG20 alone by 6 days of culture. Experiments to assess cytotoxicity and cell death analysis are ongoing. This drug combination therapy has the potential to improve outcomes in patients with uveal melanoma. Based on the good tolerability and safety of both drugs in patients, a clinical trial of pegargiminase with melphalan is planned for 2024 (ATOMIC-UM).

#4547 A novel drug combination with improved therapeutic efficacy over sorafenib in multiple preclinical models of hepatocellular carcinoma.

A. Chambers, S. Shrestha, A. Ladd, S. Duarte, A. Zarrinpar;
University of Florida Health Shands Cancer Hospital, Gainesville, FL

Introduction: Due to the heterogeneity of hepatocellular carcinoma (HCC), the incidence of resistance and toxicity to first-line therapy sorafenib is high. Combinations of drugs can be used to exploit synergistic effects to reduce adverse events, while improving efficacy and survival. *In-vitro* studies performed by our team identified irinotecan and sonidegib to have potential for synergistic therapeutic effects in combination with sorafenib. Follow up *in-vivo* dose optimization studies in a murine NASH induced HCC found this 3-drug combination to be more effective than sorafenib-alone at arresting tumor development and progression. In this study, we tested the *in-vivo* efficacy of the combination in two separate preclinical cell-line derived xenograft (CDX) models.

Experimental Procedure: HCC CDX models were generated by injecting two distinct HCC cell lines, Huh7 and HepG2, subcutaneously in the flank of male NOD.Cg-Prkdc^{scid}IL2rg^{tm1Wjl}/SzJ (NSG) mice. Mice were administered either vehicle, sorafenib, or a 3-drug combination, and mouse tumor volumes and weights were tracked for duration of study. Mice were all euthanized at study endpoint and tissues collected for analysis, including the assessment of tumor weights, differentiation, grade, necrosis, and proliferation status. Serum collected from endpoint blood was measured for human alpha fetoprotein (AFP) and alanine transaminase (ALT) levels. Changes in protein expression of tumors were assessed by western blot analysis.

Results: Huh7 and HepG2 tumors were both sensitive to sorafenib-alone treatment. However, Huh7 tumors treated with the 3-drug combination had a significant decrease in tumor volume and weight at endpoint compared to the vehicle and sorafenib-alone. HepG2 tumors treated with the combination also had a significant decrease in tumor volume and weight at endpoint compared to the vehicle. Though the difference in tumor volume and weight was not statistically significant for the combination compared to sorafenib, a trend towards decrease was observed. This was further confirmed by significantly reduced AFP levels in the combination compared to the vehicle and sorafenib in HepG2 and Huh7. Drug toxicities, measured by mouse weights and ALT levels, were not significantly different. Histological and immunohistochemical assessment of tumors showed necrosis and Ki67 staining to be significantly elevated in vehicle and sorafenib-alone compared to the 3-drug group. The targets for all three drugs present in the combination were downregulated in the combination compared to the vehicle and sorafenib-alone.

Conclusion: This study provides strong evidence that a novel 3-drug combination of irinotecan, sonidegib, and low dose sorafenib can significantly reduce tumor proliferation and burden in multiple independent pre-clinical *in-vivo* HCC models compared to high dose sorafenib monotherapy.

#4548 Discovering novel ALK-lung carcinoma therapeutic strategies by identifying combinations with Alectinib from ALK-positive lung carcinoma cell lines.

H. Madhi, H. Serhan, N. M. Vandecan, Z. Qin, A. Liu, A. Udager, S. D. Merajver, M. B. Soellner, N. Merrill;
University of Michigan, Ann Arbor, MI

Background: The therapeutic landscape for chromosomally rearranged anaplastic lymphoma kinase (ALK) has focused on the development of Tyrosine-kinase inhibitors (TKI) that specifically target ALK activity. However, as patients progress on first- and second line TKIs, over 50% of resistance is due to non-mutational resistance via compensatory pathways, also known as ALK-non dominant resistance. Alterations in other drivers such as EGFR, KRAS, MET account for some of the resistance mechanisms. Thus, here we explore the therapeutic activity of drug combinations that pair an ALK inhibitor with a drug that targets a "second driver". We describe our high-throughput drug screening platform that combines Alectinib, a selective blocker of ALK, with a panel of hundreds of chemical compounds curated to be active against a diverse array of pathways involved in cellular functions dysregulated in cancer. In this work, we identified several synergistic combinations that further increased the sensitivity of five ALK-positive lung cancer cell lines (DFCI 032, NCI-H3122, NCI-H2228, SNU2535, SNU324) to Alectinib in comparison to single treatment with the final goal of targeting resistance, before it emerges.
Methods: ALK-positive cancer cell sensitivity to different compounds was assessed by generating the IC50 curves in the presence and absence of Alectinib. Cells were characterized by bulk-RNAseq, bulk-DNA seq, Reverse-phase protein array, and Mass spectrometry to identify perturbed RNA pathways, DNA mutations, and proteome alterations.
Results: In this study, we present for the first time, a group of compounds, such as Gilteritinib, Trametinib, Dinaciclib, WYE-125132, Cenisertib, SN-38 which exhibit the capacity to induce cytotoxic effects in ALK-positive lung cancer cells, when combined with Alectinib. Our findings demonstrate a novel sensitivity of ALK driven by non-conventional parallel signaling, apart from conventional targets previously described, such as phosphoinositol-3kinase (PI3K)/Akt, signal transducer and activator of transcription 3 (STAT3), and extracellular signal-regulated kinases (ERK).
Conclusions: Through the integration of different multiomic approaches on five ALK-positive lung cancer cell lines, we have pinpointed a novel role of MAPK, CDK, and mTOR, pathways and their regulators, as a promising avenue for advancing treatment strategies for ALK-positive lung cancer. These findings, along with the identification of several other significant targetable elements illustrate a new approach towards the discovery of new drug combinations and targetable pathways to tackle ALK TKI resistance in ALK-positive patients before it emerges. We have previously generated Alectinib-resistant models and are in the process of screening to identify any resistant pathways that may align with those identified in the sensitive lines.

#4549 Combinations of ciclopirox olamine and metformin exert synergistic antitumor activity in triple-negative breast cancer.

Y. Wu[1], H. Lyu[1], C. Tan[1], M. Larsen[1], S. Huang[2], B. Liu[1];

[1]Departments of Interdisciplinary Oncology and Genetics, Stanley S. Scott Cancer Center, School of Medicine, Louisiana State University Health Sciences Center, New Orleans, LA, [2]Department of Biochemistry and Molecular Biology, Louisiana State University Health Sciences Center, Shreveport, LA

Introduction: Triple-negative breast cancer (TNBC) represents a challenging subtype of breast cancer because of its limited treatment options. Recent research has highlighted the potential benefits of combining pharmacological agents to enhance therapeutic outcomes. Studies show that Ciclopirox olamine (CPX), an off-patent anti-fungal drug, induces cell cycle G1-phase arrest and activates the intrinsic apoptosis pathway by downregulating the anti-apoptotic proteins. Meanwhile, metformin, a safe and first-line drug for the treatment of type II diabetes, has been shown to induce cell cycle S-phase arrest and activates the extrinsic apoptosis pathway via induction of endogenous TRAIL in TNBC cells. However, whether the combinations of CPX and metformin would exert potent antitumor activity against TNBC remains unclear.

Methods: Cell proliferation (MTS) assays and LIVE/DEAD cell imaging were used to determine the combined inhibitory effects on TNBC cells. IC50s and the combination index (CI) were calculated. Flow cytometry assays were carried out to analyze if the combinations are more potent to block cell cycle progression. Apoptotic-specific ELISA and flow cytometry analysis of Annexin V-PI staining were performed to assess if the combinations are significantly more effective to induce apoptosis. Western blot assays were used to examine if the combinations markedly induced the expression of TRAIL and cleavages of PARP and caspases. Tumor xenograft models will be established to test the in vivo antitumor activity of CPX and metformin either alone or in combinations.

Results: Data indicated that both CPX and metformin independently inhibited the proliferation of TNBC cells. A synergistic effect was observed when CPX and metformin were used in combination, resulting in a more potent inhibition of TNBC cell proliferation. The combinatorial treatment effectively suppressed colony formation of TNBC cells. Synergy between CPX and metformin was partially linked to the enhanced activation of the AMPK-mTOR pathway, as the combination significantly enhanced the phosphorylation of AMPKα. The combinations also induced enhanced apoptosis in TNBC cells through both the intrinsic and extrinsic pathways. The combinatorial effects of CPX and metformin on in vivo tumor growth are under investigation.

Conclusions: Combinations of CPX and metformin show synergistic effects on inhibiting TNBC cell proliferation. Our studies suggest a potential therapeutic strategy for TNBC, with the combinations of these agents exhibiting an enhanced antitumor activity. Further investigation is warranted to validate the results and explore their clinical applications.

Key words: Triple-negative breast cancer, Ciclopirox olamine, Metformin, Combination, Apoptosis

#4550 Synergistic combinations of lurbinectedin with ONC212 in pancreatic cancer.

T. Tummala, A. S. Sevilla Uruchurtu, N. R. Liguori, A. E. Abbas, C. G. Azzoli, W. S. El-Deiry;
Legorreta Cancer Center at Brown University, Providence, RI

Pancreatic cancer is a devastating disease with a poor five-year survival rate of approximately 12%. Given the poor prognosis of the disease, there is urgent need for novel therapeutic regimens. Lurbinectedin is chemotherapeutic compound that stalls and degrades RNA Polymerase II after binding to guanine-rich sequences in the minor groove of DNA. This stalls transcription machinery and leads to single- and double- stranded breaks in DNA and subsequent apoptosis. Our group recently described lurbinectedin's potency as both a single agent and combinatorial agent with irinotecan and 5-fluorouracil in pancreatic cancer cell lines. We also recently discovered a synergistic interaction between lurbinectedin and ONC201/TIC10, a novel compound that induces the TRAIL apoptotic pathway, in small cell lung cancer cell lines. Synergy was accompanied by an activation of p-Chk1 and the integrated stress response. We now demonstrate a synergistic combination of lurbinectedin and ONC212, an imipridone and chemical derivative of ONC201, results in highly efficient killing of pancreatic tumor cells at sub-nanomolar concentrations of lurbinectedin and sub-micromolar concentrations of ONC212. We hypothesize that the integrated stress response underlies lurbinectedin and ONC212 synergy. We further hypothesize a combination of lurbinectedin and ONC212 will sensitize the tumor cells to CD8+ T-cell killing, which will be examined via co-culture assays. Our results are developing insights into a novel combinatorial therapeutic regimen while investigating the molecular mechanisms underlying synergism.

#4551 A novel MET antibody-drug conjugate based combination therapy to overcome colorectal cancer plasticity and drug resistance.

S. Subramanian[1], T. A. Posey[2], J. Jacob[1], A. Aldana[3], K. S. Carmon[1];

[1]The University of Texas MD Anderson Cancer Center UTHealth Houston Graduate School of Biomedical Sciences, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]The University of Texas Health Science Center at Houston, Houston, TX

Despite therapeutic advancements, colorectal cancer (CRC) remains the second deadliest malignancy in the United States. Challenges encountered in CRC treatment may be attributed to cancer stem cells (CSC), an immortal tumor cell population. CSCs potentiate tumor relapse by exploiting its infinite replicative potential and inherent drug resistance. Moreover, CSCs exhibit plasticity, allowing them to transition between differentiated and undifferentiated states in response to environmental cues to evade therapy and drive metastatic progression. MET is a receptor tyrosine kinase frequently upregulated in CRCs. We previously demonstrated that treatment with chemotherapies or antibody-drug conjugates (ADCs) targeting the CSC marker LGR5 led to the loss of LGR5 expression with concomitant MET-STAT3 pathway activation in therapy-resistant CRC cells. Further, we showed that LGR5 couples to the scaffold protein IQGAP1, which correlates with poor prognosis in several cancer types. Interestingly, our new data revealed that LGR5 knockdown enhances IQGAP1 interaction with MET and STAT3 via co-immunoprecipitation assays, suggesting a role for IQGAP1 in mediating MET-STAT3 activation and plasticity of $LGR5^{+}$ CRC cells. To overcome therapy-induced plasticity, we generated MET-targeting ADCs conjugated to DNA-crosslinking payloads. First, we cloned and produced MET monoclonal antibodies (mAbs) and evaluated them for specificity and binding in a panel of CRC cell lines expressing different MET protein levels. MET mAbs demonstrated high selectivity for MET-expressing CRC cells and internalized to lysosomes, which is necessary for ADC payload release. To generate MET ADCs, we employed a site-specific conjugation methodology to attach cleavable peptide linker-drug moieties to the highest affinity MET mAb. MET ADCs were evaluated for cancer cell-killing efficacy *in vitro* in parallel with MET mAb, non-targeting control mAb (cmAb), and control ADC (cADC). Our MET ADC displayed high potency and efficacy in MET-expressing CRC cells, whereas MET mAb, cmAb, and cADC had minimal effects. MET ADCs were then tested in combination with chemotherapies or other targeted therapies. The combination of MET ADCs with 5-fluorouracil showed a synergistic effect *in vitro*. Future work involves investigating the safety and efficacy of MET ADCs alone and combined with chemotherapies in xenograft models of CRC. These findings present a mechanism underpinning CRC plasticity and the rationale for a novel treatment modality to potentially overcome CRC resistance and relapse.

#4552 EGFR inhibitors increase LGR5 expression and enhance potency of LGR5 antibody-drug conjugates targeting colorectal cancer stem cells.

Peyton C. High[1], Zhengdong Liang[2], Kendra S. Carmon[2]

[1]The University of Texas MD Anderson Cancer Center UT Health Houston Graduate School of Biomedical Sciences, Houston, TX, [2]The University of Texas Health Science Center at Houston, Houston, TX

Colorectal cancer (CRC) is the second leading cause of cancer-associated deaths in the United States. One of the primary challenges in treating CRC is therapy resistance thought to be mediated by cancer stem cells (CSCs), a subpopulation of cancer cells with infinite replicative potential that can differentiate to drive tumorigenesis and disease relapse. Antibody-drug conjugates (ADCs) are amongst the fastest growing classes of anticancer drugs and utilize the specificity of monoclonal antibodies (mAbs) to hone cytotoxic payloads to cancer cells. We generated ADCs directed against leucine-rich repeat-containing G protein-coupled receptor 5 (LGR5), a well-defined biomarker of CSCs that is highly overexpressed in CRCs. LGR5 ADCs demonstrated high specificity and efficacy in CRC cells and xenograft models, though tumor relapse after treatment withdrawal was a major obstacle. Interestingly, FDA-approved therapy targeting epidermal growth factor receptor (EGFR) has been shown to increase *LGR5* mRNA expression levels in patient-derived models of CRC. This study aims to determine the mechanism of EGFR-mediated regulation of LGR5 expression and evaluate the therapeutic efficacy of combination treatments targeting EGFR and LGR5 for the improved treatment of CRC. To first analyze the effect of EGFR inhibition on LGR5 expression, a panel of CRC cell lines of different KRAS and PI3CKA mutational statuses were treated with FDA-approved EGFR-targeted mAbs or small molecule inhibitors. LGR5 protein expression was shown to be upregulated by EGFR-targeted therapies in a dose- and time-dependent manner, independent of mutation status. Notably, treatment with EGF, MEK1/2 inhibitor trametinib, and EGFR-directed siRNA all resulted in concomitant reduction in EGFR and LGR5 protein levels, suggesting EGFR and LGR5 are co-degraded. Co-immunoprecipitation and immunocytochemistry experiments identified a novel EGFR-LGR5 interaction and co-internalization mechanism in CRC cells, respectively. Furthermore, we showed EGFR-LGR5 interaction is enhanced by treatment with the EGFR-targeting mAb, cetuximab (CTX). To evaluate efficacy of combination therapies targeting EGFR and LGR5, CRC cells were treated with LGR5 ADCs with or without CTX. Importantly, we showed CTX significantly enhanced the potency of LGR5 ADCs incorporating different classes of cytotoxic payloads. These results suggest combining LGR5 ADCs with EGFR inhibitors may be a more effective approach for the treatment of CRC and eliminating CSCs to overcome resistance and relapse.

#4553 DXC004A, a novel EGFR antibody-tubulysin analog conjugate demonstrated potential to broaden therapeutic opportunities for non-small cell lung cancer.

X. Cai, M. Cao, H. Guo, Q. Yang, Y. Chen, X. Kong, Y. Du, Z. Ye, Z. Guo, L. Zhang, L. Bai, J. Jia, Y. Zheng, W. Zheng, J. Zheng, W. Li, Y. Huang, Z. Fan, B. Chen, M. Dai, **R. Y. Zhao**;
Hangzhou DAC Biotechnology Co., Ltd., Hangzhou City, China

EGFR is a member of the epidermal growth factor receptor (HER) family, and the over-expression of EGFR plays an important role in the growth and progression of various tumors, including non-small cell lung cancer. Monoclonal EGFR antibodies, such as cetuximab and panitumumab, have proven efficacy in various types of cancer. However, treatment with the anti-EGFR agents can be associated with toxicities of the skin, nails, hair, and eyes. Nimotuzumab (Nimo) is the first humanized monoclonal antibody targeting EGFR and has been granted approval for use in squamous cell carcinoma of head and neck (SCCHN), glioma and nasopharyngeal cancer in different countries. In contrast to cetuximab, Nimotuzumab is distinguished by achieving higher or similar complete remission rate (CRR) or overall remission rate (ORR) of the primary tumor in clinical applications but much less toxicity, resulting in a better safety profile, which has been attributed to its about 10-fold lower affinity. Paclitaxel combined with cisplatin is the first-line chemotherapy regimen for non-small cell lung cancer. A phase 2 clinical trial has confirmed that Nimotuzumab combined with concurrent chemoradiation therapy (radiation concurrent with docetaxel and cisplatin, CCRT) was well tolerated for locally advanced squamous cell lung cancer. However, the combination strategy of Nimo-CCRT has only demonstrated similar OS and PFS to those in the CCRT group. DXC004A is an ADC drug targeting EGFR, in which a Nimotuzumab derivative and a Tubulysin B analog is conjugated by a functional linker. DXC004A is in phase I clinical trial and has demonstrated clinical activity in advanced non-small cell lung cancers and good tolerability. In vitro and in vivo results had confirmed that DXC004A monotherapy had better anti-tumor activity than the combination of Nimotuzumab and Tubulysin analog in HCC827 cell lines with high EGFR expression. Meanwhile, a single injection of low-dose DXC004 (2.5 mg/kg) in HCC827 xenograft model showed very good durable anti-tumor effect. Moreover, the combination of DXC004A with Cisplatin exhibited significantly better activities than that of Nimo-CCRT combination, DXC004A or cisplatin alone, in vitro and in vivo, which might solve the predicament of poor efficacy of Nimo-CCRT combination therapy. This synergy results suggested that DXC004A plus cisplatin would possibly be a new adjuvant therapy for non-small cell lung cancer in further clinical studies.

#4554 Novel combination therapy for treating proteasome inhibitor-resistant multiple myeloma.

B.-G. Kim[1], S. Choi[1], H. Nguyen[1], F.-S. Liang[1], S.-J. Kim[2], J. Letterio[1], A. Huang[1];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]MedPacto, Seoul, Korea, Republic of

Multiple myeloma (MM) is an incurable plasma cell malignancy characterized by osteolytic bone disease and immunosuppression. Proteasome inhibitors (PIs) have remarkably improved the survival of MM patients, but dose-limiting toxicities and the development of drug resistance limit their long-term utility. Elevated TGF-β levels in MM patient sera correlate with drug resistance, disease progression, metastasis and poor prognosis. Therefore, we evaluated the anti-MM therapeutic potential of a TGF-β type I receptor kinase inhibitor, Vactosertib. *In vitro* treatment of Vactosertib synergistically inhibited the growth of bortezomib (BTZ)-resistant MM cells in combination with either BTZ or ixazomib (IXZ) by suppressing TGF-β activation of Smad2/3 and expression of *PSMB5,* which encodes the proteasome 5 catalytic subunit targeted by PIs. Oral administration of Vactosertib as a single agent decreased MM progression and mortality of the mice bearing BTZ-resistant MM. Vactosertib alone also attenuated PSMB5 expression and proteasome activity, reduced the expansion of $CD11b^{+}Gr\text{-}1^{+}$ myeloid derived suppressor cells (MDSCs) in bone marrow (BM) tumor microenvironment (TME), and diminished the population of $Foxp3^{+}$ regulatory T cells (Treg) in the spleen. Combination therapy of Vactosertib plus PI (BTZ or IXZ) exhibited a synergistic anti-myeloma effect when compared to either Vactosertib or PI alone by greatly prolonged survival and significant a reduction in both MDSCs and Tregs. Furthermore, therapy of $BCMA^{+}$ CAR T cells in combination with Vactosertib exhibited a synergistic anti-tumor effect, compared to either CAR T cells or Vactosertib. Taken together, our data provide the rationale for clinical evaluation of Vactosertib in MM and demonstrate proof-of-concept that combination of Vactosertib and either PI or cell therapy may overcome drug resistance and enhance durable patient responses.

#4555 c-Met/AXL crosstalk in mediating therapeutic resistance in renal cell carcinoma.

A. Sabarwal[1], L. Rawat[1], J. Wedel[1], M. Balan[1], G.-S. M. Lee[2], T. K. Choueiri[2], S. Pal[1];
[1]Boston Children's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA

Receptor Tyrosine Kinase (RTK), c-Met, is overexpressed in renal cancer and correlates with a decreased survival rate. Upon binding with its specific ligand, Hepatocyte Growth Factor (HGF), c-Met activates pro-tumorigenic signaling. c-Met/RTK inhibitors are used for the treatment of advanced renal cell carcinoma (RCC). However, acquired therapeutic resistance is a major clinical problem and the underlying mechanisms are largely unknown. Hence, novel therapeutic targets are needed to overcome the clinical hurdles; and the RTK, AXL, can be a potential target. AXL is overexpressed and a poor prognostic marker in RCC. AXL overexpression drives wide-ranging processes, including epithelial-to-mesenchymal transition (EMT), tumor angiogenesis, and resistance to chemotherapeutics. Cabozantinib (XL184/Cabo), is approved for advanced-stage RCC and can inhibit c-Met and VEGFR2 activation (including AXL and a few other RTKs); however, it is not a specific/potent inhibitor of AXL. Hence, inhibiting c-Met alone may not be sufficient when AXL remains active. Therefore, the pro-tumorigenic role of AXL and its cross-talk with c-Met in renal cancer need to be thoroughly investigated. We compared the expression of c-Met and AXL in TCGA and found significantly high expression of both c-Met and AXL in primary renal tumor tissues compared to normal tissues. Our data showed that AXL forms a complex with c-Met and may have a significant cross-talk which can be involved in therapeutic resistance. We have also found that prolonged treatment of c-Met inhibitor Cabo, (including Crizotinib and PF-4217903) induced c-Met and AXL overexpression in RCC cells. Interestingly, c-Met inhibitor(s)-induced overexpressed c-Met can also be increasingly phosphorylated (at low concentrations) in the presence of HGF, which may cause enhanced downstream tumor-promoting signaling. To understand the role of AXL in tumor-promoting pathways and therapeutic resistance, we have generated CRISPR/Cas9-mediated AXL knock-out cells (AXL-KO) and found that silencing AXL can prevent c-Met-inhibitor(s)-mediated c-Met overexpression. Furthermore, to identify the effect of AXL-KO on pro-tumorigenic signaling, transcriptional profiles of control clones and AXL-KO cells were compared. The gene set enrichment analysis (GSEA) showed that genes involved in ‘EMT’, ‘Hypoxia’, and ‘K-Ras’ signaling pathways were significantly downregulated. We have also utilized an AXL-specific small molecule inhibitor, TP-0903, in combination with Cabo and validated our data. We have also generated a Cabo-resistant cell line (Caki-1) and found high expression of c-Met and AXL in these cells. Furthermore, either silencing of AXL (using siRNA) or inhibiting AXL (using TP0903) induced significant apoptosis in these Cabo-resistant cells. Together, our data suggest that inhibition of AXL along with c-Met can be beneficial in preventing acquired therapeutic resistance in RCC.

#4556 USP51-GRP78-ABCB1 axis promotes chemoresistance of triple negative breast cancer by decreasing the accumulation of doxorubicin in cells.

Y. Ou, K. Zhang, q. shuai, C. Wang, H. Hu, L. Cao, C. Qi, M. Guo, Z. Li, J. Shi, Y. Liu, S. Zuo, X. Chen, Y. Wang, M. Feng, H. Wang, Y. Shi, G. Yang, S. Yang; Nankai University, Tian Jin, China

Background: Resistance to chemotherapy remains an obstacle for triple-negative breast cancer (TNBC) patients. The core components of the ubiquitin-proteasome system have been demonstrated to regulate chemoresistance of TNBC. As a novel deubiquitinase (DUB), ubiquitin-specific peptidase 51 (USP51) plays a pivotal role in chemotherapeutic resistance in multiple malignancies. Herein, we sought to better understand how USP51 performs a cell-intrinsic role in mediating chemotherapeutic resistance in TNBC.

Methods: Western blotting, RNA-sequencing and CCK8 assays were used to identify the DUBs for chemoresistance of breast cancer. Coimmunoprecipitation, GST-pulldown, protein deubiquitination and immunohistochemistry assays were then used to determine the biological phenotypes of ectopic USP51 in TNBC chemoresistance and associated signaling pathways in several different cell lines, mouse models and patient tissue samples. Ubiquitin-7-amido-4-methylcoumarin (Ub-AMC)-based deubiquitinase activity, cellular thermal shift and surface plasmon resonance (SPR) analyses were performed to investigate the activity of USP51 inhibitors.

Results: To identify the critical DUBs involved in breast cancer chemoresistance, we established doxorubicin-resistant Cal51 and MDA-MB-231 TNBC cell lines by multiple dose exposure. We found ectopic USP51 in doxorubicin-resistant cells compared with their parental cells. Moreover, USP51-interfered chemoresistant tumor cells exhibited impaired cell viability as well as increased DNA damage and cell apoptosis upon treatment with doxorubicin. On the contrary, overexpression of USP51 performed the opposite effects to enhance cell viability but decrease DNA damage and apoptosis in response to doxorubicin; however, these outcomes were not shown for its catalytically inactive mutant $USP51^{C372S}$. At the molecular level, GRP78 was identified as a bona fide substrate of USP51. Importantly, knockdown USP51 increased doxorubicin-induced DNA damage and apoptosis, which was rescued by overexpression of GRP78 *in vitro* and *in vivo*. In addition, the activity of ABCB1, the main efflux pump of doxorubicin, was enhanced by GRP78. Consistently, the expression of USP51, GRP78 and ABCB1 were correlated with chemoresistant phenotypes in TNBC patients. Of note, we also explored a small molecular inhibitor of USP51, WCY-4-1, which conferred chemosensitization in TNBC.

Conclusion: These findings collectively indicated that ectopic USP51 enhances the activity of ABCB1 by deubiquitinating and stabilizing GRP78, which leads to decreased accumulation of doxorubicin as well as decreased DNA damage and cell apoptosis in TNBC. Our results also revealed that specific inhibition of USP51 significantly impairs doxorubicin-resistance in TNBC.

#4557 Overexpressed CPAP promotes cancer stemness and enhances chemo-resistance in HCC.

L.-Y. Hung;
National Cheng Kung University, Tainan, Taiwan

Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer and is highly resistant to chemotherapy and targeted therapy. It was reported that HCC cancer stem cells (CSCs) are involved in chemo-drug resistance by regulating multidrug resistance (MDR) gene expression, such as ABC transporters. Our previous reports indicated that CPAP, a centrosomal protein, can promote HCC progression by up-regulating NF-κB and STAT3 transcriptional activities. Here, we demonstrated that overexpressed CPAP can increase cancer stemness features and CSCs-derived sorafenib resistance in HCC by up-regulating the transcriptional activities of NF-κB and β-catenin. Importantly, CPAP stably expressed HCC spheroids are significantly resistance to sorafenib in vitro and in vivo. Our results suggested that CD24 and ABCG2 are two potential downstream effectors in CPAP overexpressed HCC. CPAP can transcriptionally up-regulate CD24 and ABCG2 expression via Wnt/β-catenin and NF-κB signaling pathways, respectively; high CPAP/ABCG2/CD24 expression levels are negatively correlated with disease-specific survival rates in HCC patients. Combined treatment with sorafenib and Wnt/β-catenin pathway inhibitor PRI-724 significantly inhibited CPAP-overexpressing Hep3B spheroids-derived tumor growth in a xenograft mouse model. Our study highlights the oncogenic role of CPAP in promoting CSCs-induced sorafenib resistance in HCC and provides insights into potential therapeutic strategies.

#4558 A triterpenoid derivative has strong antitumor activities in gemcitabine-resistant advanced bladder cancer models and promotes immune cell infiltration in a high grade murine syngeneic model.

J. R. Seremak, K. Gupta, S. S. Panda, B. L. Lokeshwar;
Augusta University, Augusta, GA

Bladder cancer (BC) presents a formidable challenge in treatment and patient survival, requiring particular attention to advanced stages, such as muscle-invasive stage (MIBC), due to its potential for rapid progression and substantial impact on patient morbidity and mortality. The five-year survival rate for MIBC is a meager 30%, which drops further down to 8% once tumors metastasize. Advanced bladder cancers (High grade T1) are treated with intravesical therapy with Gemcitabine and Cisplatin (G+C) combination and Stage T2 are treated neoadjuvant with G+C and cystectomy, thereby decreasing the quality of life for patients with BC. Furthermore, tumors progress beyond responding to other chemotherapy regimens such as dose-dense treatment with Methotrexate +Vinblastine + Adriamycin and Cis-platin (MVAC), all of which will further decrease the quality of life with persistent adverse toxicity. Our laboratory has developed a novel compound derived from the pentacyclic triterpenoid, Ursolic acid, termed N-methyl piperazine conjugated-Ursolic acid, or UA4, and have demonstrated its antitumor activities against both Gem-Sensitive (Gem-S) and Gem-Resistant (Gem-R) human advanced BC cell lines, T24 and 5637. We tested the combination of Gem, UA4 and Gem + UA4 in a murine non-MIBC model (MB49) to investigate the role of immune cell infiltration during tumor development and treatment response. UA4 treatment was equally effective in chemo-sensitive and chemo-resistant cell lines at dosages between 4-5µM. Previous *in vitro* mechanistic studies on UA4 and UA4+Gem combination treatments revealed cell death occurred through apoptosis and autophagy, along with a highly selective form of mitochondrial-mediated autophagy (mitophagy). These findings were confirmed with transmission electron microscopy ultrastructural analysis, cell cycle phase analyses, excess, changes in mitochondrial membrane potential and reactive oxygen species measurements. Gem-S and Gem-R xenografts in athymic mice further supported UA4's efficacy *in vivo*, demonstrating a significant reduction in both tumor weight and volume following oral gavage (100mg/kg), with mice exhibiting no signs of systemic toxicity. Combination treatment with UA4 and Gem synergistically increased antiproliferative activity. MB49 syngeneic mice model further supported UA4 as an effective therapy, and immunofluorescence assays with immune-related markers, suggested an anti-inflammatory effect *in vivo*. Overall, we demonstrate UA4 has a potential to be used as an efficacious, non-toxic compound for further adjuvant use in clinical settings.

#4559 SMAD3 mediates oxaliplatin resistance in esophageal adenocarcinoma.

F. Ballout, H. Lu, N. Bhat, L. Chen, D. Peng, Z. Chen, A. Zaika, O. McDonald, W. El-Rifai;
University of Miami Miller School of Medicine, Miami, FL

Background: Resistance to conventional treatments is a significant barrier to esophageal adenocarcinoma (EAC) therapy. TGF-β signaling appears to be important for EAC tumorigenesis; however, its role in EAC chemoresistance remains understudied. This study investigates the role of SMAD3 in EAC resistance to the frontline chemotherapeutic drug oxaliplatin.
Methods: Publicly available datasets were analyzed to determine SMAD3 expression in EAC versus normal samples. Western blot, quantitative real-time polymerase chain reaction, immunofluorescence staining, and flow cytometric analyses were utilized to validate bioinformatic results. Human EAC cell lines (OE33 and OE19) were treated with pharmacologic inhibitors or transfected with small interfering RNA and assessed for DNA damage and apoptotic cell death. Patient-derived organoids and patient-derived xenograft models of EAC were used to confirm our findings in vivo.
Results: SMAD3 was significantly upregulated in EAC versus normal tissue samples. Total and phosphorylated SMAD3 protein levels were upregulated in EAC tissues accompanied by increased expression of several genes regulated by SMAD3. Notably, oxaliplatin-resistant EAC cells exhibited overexpression of SMAD3. Chemotherapy non-responding patients showed enrichment of SMAD3 gene expression when compared to responders in the clinical dataset GSE165252. Knockdown or inhibition of SMAD3 hindered DNA repair and sensitized EAC cells to oxaliplatin treatment in vitro and in vivo. Mechanistically, SMAD3 promoted ATM phosphorylation by interacting with protein phosphatase 2A (PP2A) and sequentially inhibiting the binding of PP2A to ATM.
Conclusion: Our results reveal a pivotal role for SMAD3 in mediating oxaliplatin resistance in EAC and thus hold a significant potential in guiding future drug development and combination strategies.

#4560 Assessing cancer drug combination efficacy across 900+ PRISM cell lines in a multiplexed screening assay.

A. Bino George, S. Nair, M. Kocak, E. Nguyen, A. Kalathungal, A. Fazio, C. Ponsi, A. Golabi, M. A. Ronan, M. G. Rees, J. A. Roth;
Broad Institute of MIT and Harvard, Cambridge, MA

Combination therapies are crucial in cancer care, yet identifying which combination will benefit a specific patient is challenging. The vast array of clinical, investigational, and tool anticancer agents and diverse cancer contexts makes investigating many drug combinations over a large number of cell lines infeasible. Here, we describe a multiplexed screening approach using the PRISM assay, where drug combinations are screened on >900 DNA-barcoded cancer cell lines. We analyze cell viability data in drug combinations and single agents using established metrics to describe the combined effects such as additivity, synergy, and antagonism. Quantifying and classifying combined effects will help prioritize specific combinations for follow-up investigations and provide biological and mechanistic insights, thus enabling rationally designed combination therapies. We illustrate our methodology through data from three drug combinations that exemplify synergy and antagonism. In the first combination, temozolomide+O6-benzylguanine (alkylating agent + MGMT inhibitor), we found that cell lines expressing MGMT were sensitized to temozolomide in the presence of O6-benzylguanine, thus illustrating synergy. In the second combination, we screened two anti-apoptosis compounds A-1331852+AZD5991 (BCL-xL + MCL1 inhibitor) and found that BCL-xL and MCL1 inhibition were also synergistic. In the third combination, ML210+ferrostatin-1 (GPX4 inhibitor inducing ferroptosis + ferroptosis inhibitor), we found that ferrostatin-1 antagonized the effects of ML210. Our analysis also reveals the importance of appropriate dose selection and analytical metrics for reliably measuring combined effects. In conclusion, the PRISM platform's multiplexed cell line screening is a robust method for characterizing rationally designed drug combinations, offering a systematic approach to enhance the precision of combination therapy development in cancer care.

#4561 Mechanism of histone H3K27me3 demethylase therapy for restoring cisplatin sensitivity in refractory testicular cancer.

D. N. Shokry, R. Singh, M. Khan, Z. Fazal, R. Boyd, C. Powell, S. J. Freemantle, M. J. Spinella;
Department of Comparative Biosciences, College of Veterinary Medicine, Carle Illinois College of Medicine, Carl R. Woese Institute for Genomic Biology, and Cancer Center of Illinois, University of Illinois Urbana-Champaign, Urbana, IL

Testicular germ cell tumors (TGCTs) can be cured at a high rate with standard cisplatin-based chemotherapy, but 15% of metastatic patients are cisplatin resistant/refractory and die from progressive disease. In prior work, we used *de novo* pharmacogenetic approaches leveraging a series of unique cisplatin resistant cell models that uncovered an important role for polycomb and histone H3K27me3 methylation in mediating TGCT sensitivity and resistance to cisplatin. Importantly, we demonstrated that pharmacological inhibition of H3K27 methylation with the EZH2 inhibitor GSK-126 conferred cisplatin resistance to parental cells while induction of H3K27 methylation with the histone lysine demethylase inhibitor GSK-J4 resulted in a high degree of cisplatin sensitization of TGCT tumors including cisplatin resistant TGCT cells. In order to elucidate mechanisms that account for the remarkable cisplatin sensitization effects of GSKJ4 in TGCTs, we used two distinct cisplatin resistant TGCT cell lines 2102EP-C1 and NT2D1-A4. Cells were pretreated for three days with either vehicle control or 1μM GSK-J4 to modulate H3K27me3 followed by treatment with vehicle control or 0.5μM cisplatin for 6 hours. RNA was extracted from cells after 24 hours of cisplatin removal. This treatment protocol was designed to capture “early” transcriptional responses to GSKJ4 sensitization before the onset of cell death. RNA-seq transcriptomic profiling and differential gene expression analysis revealed as expected a severely attenuated transcriptional response to cisplatin in cisplatin refractory cells that was restored with GSKJ4 pretreatment. Interestingly GSKJ4 alone resulted in a robust transcriptional response with a large overlap with gene changed with cisplatin alone, despite the fact that GSKJ4 alone did not affect cell proliferation or survival. However, GSKJ4 uniquely regulated a subset of genes and uniquely restored cisplatin response to a subset of genes which are candidates for driving the remarkable cisplatin sensitizing effects of GSKJ4 in TGCTs. Further enrichment and biological classification analysis of these distinct gene subsets are ongoing and will be presented. In summary, our data suggests mechanisms to account for why directly targeting H3K27 methylation with GSKJ4 appear highly effective in treating cisplatin resistant/refractory TGCTs and may provide biomarkers for future clinical investigation of this strategy.

#4562 Activity of PARP1-selective inhibitor SNV-001 in models of HRD cancers as monotherapy and in combination.

Z. Li, Q. Fan, M. Gao, J. Pan, L. Wu, W. Yao, P. C. C. Liu;
Synnovation Therapeutics, Inc., Wilmington, DE

Current FDA approved poly (ADP-ribose) polymerase inhibitors (PARPi) inhibit both PARP1 and PARP2. Genetic studies indicate that loss of PARP1 is synthetic lethal with homologous recombination deficiency (HRD), including BRCA1/2 mutations, and PARP2 depletion may be linked to hematologic toxicity. To date, no first generation PARPi has been successfully combined with standard of care (SoC) agents in the clinic without significant reduction in dosing intensity because of overlapping toxicities. A selective inhibitor could potentially improve the therapeutic index and provide additional opportunities in combination strategies especially with drugs that are prone to myelosuppression. SNV-001 potently and selectively inhibits PARP1 in biochemical and cellular assays. SNV-001 inhibits PARylation in the low nanomolar range with over 500-fold selectivity against PARP2. SNV-001 did not inhibit any other PARP family member tested up to 10 uM in biochemical assays confirming its selectivity for PARP1. In human erythroid and myeloid colony formation assays, the IC50s of SNV-001 for both lineages were approximately 100-times higher than the target efficacious concentration based on the IC95 for inhibition of DLD1 (BRCA2 -/-) colony formation. In a subcutaneous MDA-MB-436 (BRCA1mut) xenograft model, oral administration of SNV-001 once daily resulted in a dose-dependent tumor regression. SNV-001 showed greater efficacy at lower doses compared to olaparib at 100 mg/kg or at equivalent doses of AZD9574. SNV-001 showed promising synergy with SoC chemotherapies or DDR inhibitors in cell proliferation assays. SNV-001 enhanced cytotoxicity of the DNA-damaging agent topotecan or carboplatin in Capan-1 (BRCA2mut) and HCC1395 (BRCA1mut) cells. Synergy was seen between SNV-001 and cell cycle check point inhibitors camonsertib (ATRi) or adavosertib (WEE1i) in DLD1 (BRCA2 -/-) and UWB1.289 (BRCA1mut) cells, as DNA damage induced by PARP1 trapping relies on cell cycle modulation for repair. Combination of SNV-001 with polymerase theta inhibitor ART558 or USP1 inhibitor KSQ4279 exhibited synergistic effects in DLD1 (BRCA2 -/-) or UWB1.289 (BRCA1mut) cells. These results suggest that inhibition of microhomology-mediated end-joining and translesion synthesis pathways may further exacerbate SNV-001-induced DDR in certain cellular contexts.In summary, the PARP1 selective inhibitor SNV-001 demonstrates potent antitumor activity and shows promising synergy between SoC chemotherapies or DDR inhibitors. Current data highlight a potential strategy for improving treatment efficacy and overcoming resistance. Further clinical investigations are warranted to validate this combination strategy.

#4563 Ferroptotic mechanism of drug induced toxicity of PARPi and AurKi in prostate cancer.

A. John, K. Luo, Z. Lou, L. Wang;
Mayo Clinic, Rochester, MN

BACKGROUND: Cancer is typically treated with a combination of drugs rather than monotherapy stratagems, but identification of synergistic drug combinations for the treatment of cancers is challenging. Here we present the combination of PARP and Aurora Kinase inhibitors synergize through induction of the ferroptosis pathway of cell death.
METHODS: We identified these drugs through an unbiased screen of enriched drug class response correlations. We then validated a synergistic cell killing effect of multiple drugs of each class by in vitro drug screening. Next, we performed reversal experiments using a ferroptosis inhibitor and lipid peroxide staining to confirm ferroptosis is a relevant cell death pathway. We performed Western immunoblot analysis in cells overexpressing putative Aurora Kinase phospho-substrates in the relevant pathway of interest, and performed site directed mutagenesis experiments to show the relevant amino acid altered by kinase activity. We also performed a series of qPCR and co-IP experiments to show PARPi effect on the antioxidant signaling pathway.
RESULTS: We validated and identified synergy in a prostate cancer specific context. Next, we found Talazoparib and Alisertib induced ferroptosis after synergy was reduced with a ferroptosis inhibitor and lipid peroxides increased accumulation. We found a novel mechanism action for Alisertib, wherein Aurora Kinase inhibitors can alter the phospho-status and activity of the iron reduction enzyme Steap3.We also found that PARP inhibitors can affect the Nrf2-driven antioxidant signaling pathway on a transcriptional level.
CONCLUSION: Aurora Kinase inhibitors and PARP inhibitors for the treatment of prostate cancer was identified and was validated as synergistic, which revealed new functional roles of both drugs in the context of cell killing. These findings represent a new clinical combination of drugs in prostate cancer and reveal a novel role for this drug class in ferroptosis.

#4564 Therapeutic potential of SOS1 and KRAS inhibitors in malignant peripheral nerve sheath tumors.

O. Yuce Petronczki, L. Pisarsky, P. L. Szabo, J. Brunmair, A. Geyer, N. Kraut, D. McConnell, I. Waizenegger;
Boehringer Ingelheim RCV GmbH & Co KG, Wien, Austria

Neurofibromatosis type 1 (NF1) is a genetic disorder that affects the nervous system. It is caused by mutations in the NF1 gene. NF1 loss of function leads to elevated RAS signaling, which plays a crucial role in cell growth and proliferation. Due to the dysregulated RAS signaling, individuals with NF1 are prone to the development of neurofibromas. These neurofibromas are typically benign and called Plexiform Neurofibromas (PNFs), in some cases, they can transform into malignant peripheral nerve sheath tumors (MPNSTs). MPNSTs are highly aggressive and invasive cancers that contribute to a significant proportion of soft tissue sarcomas. The exact mechanisms behind this transformation are not fully understood, however it involves additional genetic mutations and alterations in cellular signaling pathways. With limited effective targeted therapies available, surgical removal remains the primary treatment option. However, due to tumor size and location, surgery may not always be feasible. The MEK inihibitor, selumetinib, has received approval for the treatment of PNFs, however some patients who were treated with selumetinib continued to develop MPNSTs suggesting that MEK inhibitors may have limitations in addressing MPNSTs. To target the RAS pathway and mitigate the effects of NF1 gene alterations, we aim to explore the therapeutic potential of two novel, potent and orally bioavailable small molecule inhibitors targeting SOS1 (BI 1701963) or KRAS ($KRAS^{multi}$ inhibitor BI 3706674), as alternative treatment options for MPNSTs. The $KRAS^{multi}$ inhibitor BI 3706674 binds non-covalently to the KRAS wild type allele as well as multiple KRAS mutant alleles in the GDP-bound state and thereby disrupts KRAS signaling. Therefore, we hypothesize that both inhibitors will work in NF1 models by reducing activated KRAS levels. In this study, a series of *in vitro* and *in vivo* experiments were conducted to evaluate the efficacy of BI 1701963 and BI 3706674 inhibitors, both individually and in combination. The studies were done in comparison to the MEK inhibitor selumetinib. *In vitro* analysis revealed a synergistic anti-proliferative effect when combining BI 1701963 and BI 3706674 inhibitors both in 2D and 3D growth conditions, which led to the downregulation of the RAS pathway, specifically the MAPK and PI3K signaling cascade, and an increase in apoptosis. The *in vivo* efficacy of either BI 1701963 or BI 3706674 inhibitor alone or in combination was tested in four different *in vivo* MPNST models. We observed significant tumor growth stabilization as well as tumor regression in all tested models *in vivo*. In-depth pathway modulation and pharmaco-dynamic studies are ongoing. In conclusion, this study highlights the combined effects of SOS1 (BI 1701963) and KRAS (BI 3706674) inhibition in MPNSTs. The combination therapy of these novel therapeutics may hold promise as a potential treatment strategy for patients with MPNSTs.

#4565 Reckless mitotic entry as a chemosensitization approach for alkylating agents.

F. Lang, J. A. Cornwell, K. Kaur, M. I. Aladjem, M. Aregger, S. D. Cappell, C. Yang;
National Cancer Institute, Bethesda, MD

The cell cycle is tightly regulated by checkpoints, playing a vital role in controlling its progression and timing. Cancer cells exploit the G2/M checkpoint, which serves as a resistance mechanism against genotoxic anti-cancer treatments, allowing for DNA repair prior to cell division. Therefore, manipulating cell cycle timing has emerged as a potential strategy to augment the effectiveness of DNA damage-based therapies such as alkylating agents and radiation. In this study, we conducted a forward genome scale CRISPR/Cas9 chemogenomic screening with repeated exposure to the alkylating agent temozolomide (TMZ) to investigate the mechanisms underlying tumor cell survival under genotoxic stress. Our findings revealed that canonical DNA repair pathways, including ATM/Fanconi and mismatch repair, determine cell fate under genotoxic stress. Notably, we identified the critical role of the membrane-associated tyrosine- and threonine-specific cdc2-inhibitory kinase, known as Myt1 (encoded by PKMYT1), in ensuring cell survival. Analysis on patient cohort demonstrated that *PKMYT1* is not only highly presented in malignancy, but also predisposes an unfavorable disease outcome. Genetic depletion of PKMYT1 led to overwhelming TMZ-induced cytotoxicity in cancer cells. Isobologram analysis demonstrated potent drug synergy between TMZ and other clinically used alkylating agents, such as carmustine, busulfan, and dacarbazine, when combined with a novel Myt1 kinase inhibitor, RP-6306. Mechanistically, inhibiting Myt1 forced G2/M-arrested cells into an unscheduled transition to the mitotic phase without complete resolution of DNA damage, as indicated by a substantial increase in γH2AX-positive cells in mitosis. Moreover, RP-6306 dramatically altered cell cycle timing, reducing the threshold time for mitotic entry. This forced entry into mitosis, along with persistent DNA damage, resulted in severe mitotic abnormalities, including unaligned and partially condensed chromosomes, lagging chromosomes, chromosome bridges, and multipolar spindles. Ultimately, these aberrations led to mitotic exit with substantial apoptosis. Importantly, preclinical animal studies demonstrated that the combination regimen involving TMZ and RP-6306 prolonged the overall survival of glioma-bearing mice. Collectively, our findings highlight the potential of targeting cell cycle timing through Myt1 inhibition as an effective strategy to enhance the efficacy of current standard cancer therapies, potentially leading to improved disease outcomes.

#4566 Synergistic anticancer activity of cannabinoids and beta caryophyllene in xenograft mouse model of triple negative breast cancer.

M. Aare, I. Khan, A. Nathani, B. Boirie, A. Bagde, M. Singh;
Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL

Combination therapy, a treatment modality that studies the effect of two or more drugs is the most common strategy used to overcome drug resistance in cancer. Cannabinoids have been proven to be potential anticancer agents. Terpenes have also been demonstrated to exhibit anticancer activity. The purpose of this study was to evaluate the effect of combinations of various cannabinoids and terpenes against drug resistant lung and breast cancer. Several cannabinoids and terpenes such as cannabidiol (CBD), cannabichromene (CBC), cannabidiolic acid (CBDA), cannabidivarin (CBDV), cannabinol (CBN), cannabigerol (CBG) and β-caryophyllene (BC), bisabolol, myrcene, linalool, limonene, geraniol, neralidol, α-pinene, α-terpineol, γ-terpinene respectively were screened for their anticancer activity against MDA MB 231 DOX RT, H1975 OSM RT, PDX Lung cancer cell lines using 2D cytotoxicity and 3D spheroids assay. It was found that the cytotoxic potential of combinations of cannabinoids with BC increased by 10 folds in comparison to their individual anticancer activity. The combinations that exhibit synergistic action were determined from combination index (CI) values using compusyn software. Other assays such as colony formation, wound healing, apoptotic assay, cell cycle analysis by flow cytometry elucidated the possible mechanism underlying the synergism of the combinations investigated. CBC+BC was proven to be the most potent combination from all the *in-vitro* studies and hence was further evaluated in *in-vivo tumor* xenografts. Briefly, 5 million MDA MB 231 DOX RT cells were injected by S.C route in the right flank region of BALB/c nude mice. The animals were treated after the tumor volume reached 180-200mm^3. The animals were administered CBC (15mg/kg, i.p.), BC (100mg/kg, i.p.) and CBC+BC thrice a week for two weeks. The tumor volume in the combination group was reduced by 2 folds relative to individual treatments and 4 folds relative to control. Western blot analysis of tumor xenografts showed downregulation of apoptotic markers such as PARP, mTOR, pAMPK, Survivin, autophagy markers such as LC 3, Glypican 5 and migration markers such as vimentin and Integrin. Immune check point proteins such as PD-L1 and PD-1 were also downregulated by combination treatment. This was further validated by qPCR. In conclusion, CBC induces programmed cell death in tumors and induces autophagy whereas BC inhibits migration and thus this combination was able to overcome resistance than individual therapies in a synergistic fashion.

#4567 Dual targeting of HSP70 and AURKA improves treatment in neuroendocrine prostate cancer.

P. Xu[1], J. C. Yang[1], B. Chen[1], S. Ning[1], L. Wang[1], C. Nip[1], C. P. Evans[1], M. A. Dall'Era[1], A. C. Gao[1], J. Gestwicki[2], C. Liu[1];
[1]UC Davis, Sacramento, CA, [2]UCSF, San Francisco, CA

Background: Neuroendocrine prostate cancer (NEPC) is the most aggressive type of prostate cancer with no effective treatments. Therefore, there is an urgent need to develop new treatment strategies. N-Myc plays a key role in driving NEPC progression, and Aurora kinase A (AURKA) prevents N-Myc degradation by interact with N-Myc and disallowing the intervention of ubiquitin ligases. The AURKA inhibitor Alisertib inhibits NEPC tumor growth by disrupting N-Myc signaling, but it is failed in a phase II clinical trial. In this study, we tested the synergy of novel HSP70 allosteric inhibitor JG231 and Alisertib in NEPC cells, organoids, and patient derived xenograft (PDX) models, which will provide new therapeutic strategies for the NEPC treatment.
Methods: RT-PCR, western blotting, or immunohistochemistry (IHC) were used to determine the expression of N-Myc, neuroendocrine maker (NSE, SYP, CHGA, etc) in different prostate cancer cell lines and PDX tumors. After the knockdown of HSP70 and AURKA by siRNA transfection, cell proliferation and N-Myc expression were assessed by using cell viability assay, RT-PCR and Western blotting respectively. The co-immunoprecipitation assay was performed to detect the N-Myc ubiquitination. RNA-sequencing, gene set enrichment analysis was employed to determine the changes of JG231 on gene programs. The effects of JG231 and Alisertib on the proliferation were examined in NEPC cell lines and PDX organoids models.
Results: We determined that PC3, CWR22Rv1, H660 cell lines, LuCaP49, and LuCaP93 PDX tumors had significantly increased the expression of N-Myc and neuroendocrine makers. Knockdown of HSP70 or using the HSP70 inhibitor, JG231, significantly inhibit the growth of H660 and CWR22Rv1 cells and leads to a synergistic effect with Alisertib ($p<0.001$). JG231 combined with Alisertib also inhibits growth and induces the death of LuCaP93 and H660 tumor derived organoids in a dose-dependent manner ($p<0.001$). Mechanistically, JG231 inhibits the protein expression of N-Myc through the ubiquitin-proteasome system and promote STUB1 to enter the nucleus to bind to N-Myc.
Conclusions: JG231, a novel HSP70 inhibitor, can improves the treatment efficacy of AURKA inhibitor Alisertib against NEPC through the regulation of N-Myc protein homeostasis.

#4568 Rational targeting of BCL-xL and/or mTOR enhance the efficacy of KRAS^{G12D} inhibitor in pancreatic cancer.

S. Khan[1], L. Cao[1], V. Vudhata[2], Y. Yang[1], P. Zhang[3], G. Zheng[3], J. G. Trevino[2], D. Zhou[1];

[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Virginia Commonwealth University Massey Comprehensive Cancer Center, Richmond, VA, [3]University of Florida, Gainesville, FL

Background: Pancreatic cancer (PaCa) is a highly aggressive malignancy with a very low five-year survival rate secondary to late diagnosis, limited treatment options and resistance to existing therapies. While the emergence of mutant-selective KRAS^{G12D} (G12D) inhibitors brings promise for treating PaCa patients carrying these mutations, their effectiveness as single agents is expected to be limited as evident from the clinical efficacy of KRAS^{G12C} inhibitors.

Experimental Design: First, multiple G12D-mutated PaCa cell lines were treated with a G12D inhibitor (MRTX1133) and subjected to immunoblot analysis for the expression of KRAS effectors and BCL-2 family proteins. Next, a proteolysis-targeting chimera (PROTAC)-based platelet-sparing BCL-xL degrader (DT2216) and/or an mTOR inhibitor (everolimus) were evaluated in combination with MRTX1133 for viability, clonogenicity and apoptosis. Subsequently, mechanistic investigations were carried out using immunoblotting, senescence-associated β-galactosidase staining and qPCR. Finally, therapeutic efficacy and safety of the combinations were evaluated in cell-derived and patient-derived xenograft models.

Results: MRTX1133 treatment creates apoptotic vulnerabilities by inducing aberrations in BCL-2 family proteins, with elevated BIM levels and decreased NOXA levels, in G12D-mutated PaCa cells. Furthermore, DT2216 and everolimus were shown to release BIM and stabilize NOXA, respectively, and their combination with MRTX1133 synergistically killed G12D-mutated PaCa cells in vitro and caused significant tumor growth inhibition or regression compared to single agents in vivo. Additionally, MRTX1133 treatment led to induction of senescence in a fraction of PaCa cells. These senescent cells were found to be dependent on BCL-xL and MCL-1 for their survival and were effectively killed with a combination of DT2216 and everolimus through BCL-xL degradation and NOXA-mediated MCL-1 inhibition, respectively.

Conclusions: Our findings suggest that the single agent efficacy of MRTX1133 is limited due to apoptosis inhibition and complimentary senescence induction, and therefore its combination with DT2216 and/or everolimus is synergistic, which can potentially overcome resistance, by enhanced apoptosis and clearance of senescent cells.

#4569 APG-2449, a novel focal adhesion kinase (FAK) inhibitor, inhibits metastasis and enhances the antitumor efficacy of PEGylated liposome doxorubicin (PLD) in epithelial ovarian cancer (EOC).

Z. Yu[1], E. Liang[2], D. Liu[1], B. Wu[1], X. Yao[1], Y. Ji[1], D. Yang[1], Y. Zhai[1];
[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China, [2]Ascentage Pharma Group Inc., Rockville, MD

Ovarian cancer is the leading cause of cancer-related death in women and most cases are diagnosed at later stages, with distant metastasis. Standard-of-care therapy is surgery followed by platinum and paclitaxel; however, most patients who initially respond to therapy eventually relapse after developing metastatic disease and chemoresistance. FAK overexpression or activation occurs in a substantial proportion of EOCs and is predictive of poor clinical outcomes. Recent studies have reported that FAK plays an important role in cell migration and chemoresistance, rendering FAK inhibition a promising treatment approach to reduce metastasis of tumor cells and sensitize them to chemotherapy. The aim of this study was to evaluate the antitumor efficacy of investigational APG-2449, a novel FAK inhibitor, combined with PLD, a commonly used chemotherapy, in relapsed or refractory ovarian cancer. Four EOC cell lines (OVCAR-3, SK-OV-3, A2780, and Kuramochi) were used for *in vitro* experiments. Cell proliferation was measured by CellTiter-Glo assays. Cell migration ability was assessed by wound healing assays. OVCAR-3 xenograft and luciferase-tagged ID8 (ID8-Luc) peritoneal syngeneic models were established to evaluate the synergistic antitumor efficacy of combined APG-2449 and PLD *in vivo*. APG-2449 combined with doxorubicin showed synergistic antiproliferative effects in both platinum-resistant (OVCAR-3 and SK-OV-3) and platinum-sensitive (A2780 and Kuramochi) cell lines. In wound healing assays, FAK inhibition via APG-2449 alone attenuated migration of ovarian cancer cells (SK-OV-3, OVCAR-3, and ID8-Luc) in a dose-dependent manner. In the OVCAR-3 xenograft model, combined APG-2449 and PLD demonstrated enhanced antitumor effects compared with either APG-2449 or PLD monotherapy (synergistic index, 1.33). In the ID8-Luc peritoneal syngeneic model, the combination regimen outperformed PLD or APG-2449 monotherapy in tumor growth inhibition. This inhibitory effect persisted more than 1 month after stopping combination treatment, whereas the monotherapy groups experienced rapid disease relapse. The combination group also exhibited the longest ascites-free and survival times compared with PLD or APG-2449 monotherapy groups. Overall, our data suggest that inhibition of FAK by APG-2449 enhances the antitumor effect of PLD in EOC cell lines and the OVCAR-3 xenograft mouse model. The combination regimen can also prolong ascites-free and survival times, as shown in the ID8-Luc peritoneal syngeneic model. These promising results support future clinical development of this combination treatment for ovarian cancer.

#4570 Prostate-specific membrane antigen targeted chemo-photodynamic therapy for the treatment of prostate cancer.

X. Wang, A. Shirke, S. Chavali, L. Zhang, E. Walker, G. Ramamurthy, J. Basilion;
Case Western Reserve University, Cleveland, OH

Introduction: Prostate cancer is the most prevalent cancer among men in the United States and is their second leading cause of cancer death. During initial screen, about 17-31% of patients are diagnosed with non-metastatic high-risk localized prostate cancer. These patients have an increased risk of treatment failure and oncological progression. The contemporary treatment paradigm of high risk localized prostate cancer is moving toward a multidisciplinary integrated approach of systemic and local therapy. In addition, incorporation of molecular biomarkers can also improve the risk stratification and treatment of prostate cancer. Among the biomarkers for prostate cancer, prostate specific membrane antigen (PSMA) has been proven to be an excellent target for diagnosis and treatment of prostate cancer. We have generated a PSMA-targeted photodynamic therapy (PDT) agent, PSMA-1-Pc413, and a PSMA-targeted chemotherapeutic agent, PSMA-1-MMAE. The objective of this study is to generate a new molecule that combines PDT and chemotherapy to achieve improved antitumor activity.

Methods: Using a bifunctional PSMA ligand, a novel theranostic PSMA-targeting conjugate was synthesized, which integrated both the photosensitizer Pc413 and the microtubular inhibitor monomethyl auristatin E (MMAE) in one simple molecule, PSMA-1-MMAE-Pc413. This molecule was first tested for in vitro uptake and cytotoxicity studies using PSMA-positive PC3pip and PSMA-negative PC3flu cells. The conjugate was then tested for in vivo fluorescence imaging using mice bearing both PC3pip and PC3flu tumors. Finally, the antitumor activity of PSMA-1-MMAE-Pc413 was tested in mice with PC3pip tumors with and without light irradiation.

Results: In *in vitro* uptake studies, the uptake of PSMA-1-MMAE-Pc413 in PC3pip tumor was about 3-fold higher than that in PC3flu cells. In *in vitro* cytotoxicity studies, when exposed to 5 J/cm^2 of 672nm light, PSMA-1-MMAE-Pc413 demonstrated a synergistic effect leading to greater cytotoxicity for PC3pip cells (IC_{50}=2.77nM) when compared to PSMA-1-Pc413 with light irradiation (IC_{50}=372nM) or PSMA-1-MMAE-Pc413 without light irradiation (IC_{50}=12.6nM). In *in vivo* imaging studies, PSMA-1-MMAE-Pc413 demonstrated selective uptake in PC3pip tumors. Further, antitumor activity studies showed that PSMA-1-MMAE-Pc413 with light irradiation significantly inhibited PC3pip tumor growth and prolonged survival time as compared to mice receiving equimolar amounts of PSMA-1-Pc413 with light irradiation or PSMA-1-MMAE-Pc413 without light irradiation.

Conclusion: We have synthesized a new theranostic agent PSMA-1-MMAE-Pc413 that combines imaging, chemotherapy and PDT. The new molecule dramatically improves the treatment effect as compared to each single treatment alone. (The work is supported by NIH 1RO1CA255925-01A.)

#4571 Combination of FOLFIRI (5-FU, Leucovorin, and Irinotecan) and ProAgio on colon cancer growth and metastasis.

P. N. Ganji[1], J. B. Foote[1], M. S. Saddala[2], F. Mishra[3], S. Sarvesh[1], M. Malla[1], A. Masood[4], Z.-R. Liu[3], B. F. El-Rayes[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]University of California, Irvine, CA, [3]Georgia State University, Atlanta, GA, [4]Indiana University School of Medicine, Indianapolis, IN

Background/Objective: One of the common mechanisms of resistance of solid tumors, including colon cancers, is activation of integrins on endothelial cells (ECs) and cancer-associated fibroblasts (CAFs). ProAgio is a small molecule developed to target integrin alpha V beta 3 (αvβ3), located on surface of abnormal ECs and CAFs. ProAgio enhances apoptosis and inhibits angiogenesis via targeting αvβ3. The aim of the current study is to evaluate the ProAgio combination with FOLFIRI on the immune profile and tumor growth of colon cancer.
Material and Methods: Female BALB/CJ and male NSG (NOD.Cg-Prkdcscid Il2rgtm1Wjl/SzJ) mice were acquired from the Jackson Laboratory, and experiments were performed under the approval of The University of Alabama at Birmingham-Institutional Animal Care and Use Committee. For orthotropic tumor efficacy studies, BALB/CJ mice were injected with 2×10^5 CT-26 wild type and CT26.CL25 cells in 30ul 1:1 Matrigel Matrix and PBS into the Cecum. PDX (10mg) was orthotopically implanted into the NSG mice cecum. At Day five, mice were divided into four treatment groups: including 1) sterile water (vehicle), 2) ProAgio (15mg/kg; IP; once daily for nine days), 3) FOLFIRI (5-FU: 30mg/kg; Leucovorin 50mg/kg; Irinotecan; 20mg/kg - once every three days intraperitoneal) or 4) combination of ProAgio and FOLFIRI. The study completed on day 15, tumor weight was noted, and tumors were processed for histology and flow cytometry.
Results: ProAgio plus FOLFIRI significantly ($p<0.001$) reduced tumor weight in both models compared to individual treatments and vehicles. Combination-treated mice showed a significant ($p<0.001$) reduction in T-cell exhaustion ($CD8^{\pm}$ T cells that are positive for PD-1, TIM-3, and CTLA-4). Analysis of the myeloid compartment showed a significant ($p<0.001$) increase in the M1 macrophages that express F4/80 as well as CD86, MHC-II and a decrease in the M2 macrophage in the mice treated with ProAgio plus FOLFIRI. The combination therapy exhibited a significant ($p<0.001$) increase in the dendritic cell infiltration into the tumor microenvironment. Histology analysis showed that ProAgio treatment reduced the incidence of organ site metastasis (disseminated and locoregional spread) such as liver, pancreas, and diaphragm.
Conclusion: Our study offers encouraging observations that ProAgio plus FOLFIRI can suppress colon cancer growth and metastasis by inhibiting αvβ3 preclinically and may provide a novel therapeutic combination for the management of colon cancers.

#4572 Ginsenoside Rh3 increases the susceptibility of regorafenib-mediated cancer cell death by inhibiting the JAK/STAT3 signaling pathway in hepatocellular carcinoma.

Y. Jeon[1], H. Kwon[1], Y. Park[2], D.-Y. Woo[1], T. Kim[1], J. Ham[1], **Y.-J. Kim**[1];

[1]Korea Institute of Science and Technology (KIST), Gangneung, Korea, Republic of, [2]Yonsei University College of Medicine, Seoul, Korea, Republic of

Ginsenosides, bioactive compounds derived from Panax ginseng, exhibit diverse pharmacological effects, including anti-cancer properties. Regorafenib, a potent multi-kinase inhibitor, is employed as a second-line therapy for advanced hepatocellular carcinoma (HCC). However, the modest survival benefits observed in treated patients may be attributed to drug resistance. In this study, we screened a panel of 40 ginsenosides for their activity in combination with regorafenib in HCC cell lines and investigated their underlying cellular mechanisms. Synergistic effects were evaluated using the WST-8 assay, and optimal drug concentrations were determined through synergy scoring. A phospho-kinase assay was conducted to elucidate the mechanism of action, and in vivo experiments validated our findings. Ginsenoside Rh_3 emerged as a promising candidate, enhancing the sensitivity of HCC cells to regorafenib-induced anticancer effects by promoting apoptosis. The phospho-kinase array revealed that the combined treatment's apoptotic effect was associated with the inhibition of signal transducer and activator of transcription 3 (STAT3) activation through the Janus kinase pathway. *In vivo* results demonstrated the combination treatment's inhibitory effects on tumor growth. Our study proposes a novel treatment strategy, highlighting the potential efficacy of combining regorafenib and ginsenoside Rh_3 for HCC treatment.

#4573 Pre-clinical evaluation of small molecule CHK2 inhibitor, ART446, pre-IND candidate that enhances the olaparib and irinotecan.

T. Baik[1], Y. Kang[1], H. Lee[1], J. Kim[1], A. Jeong[1], J. Kim[2], W.-Y. Kim[3];

[1]Arum Therapeutics Inc., Seoul, Korea, Republic of, [2]Yeungnam University, Gyeongsan, Korea, Republic of, [3]Sookmyung Women's University, College of Pharmacy, Seoul, Korea, Republic of

Background: Poly (ADP-ribose) polymerase (PARP) plays a pivotal role in DNA damage repair. Tumors with DNA Damage Response (DDR) defects exhibit increased susceptibility to drugs targeting PARP. The drugs induce DNA damage like Irinotecan (a Topoisomerase I inhibitor) are widely used in clinic as well. However, intrinsic resistance remains a significant obstacle, leading to frequent treatment failures. Chk2 is activated in response to these DNA damage inducing agents and hold the cell cycle. We developed pre-IND candidate ART446, with the aim of exploring its therapeutic potential in sensitizing DNA damage-targeting reagents.

Results: In the radiometric HopSpot Kinase Assay, ART446 demonstrated significant inhibition of Chk2 (IC_{50}, 9 nM). In HT-29 colon adenocarcinomas, co-treatment with SN38 and ART446 exhibited a synergistic therapeutic effect in vitro, with a subsequent in vivo tumor growth assay demonstrating a remarkable combined effect (TGI: Irinotecan, 46%; ART446, 16%; combined, 83.4%). Further extending our investigation to triple-negative breast adenocarcinoma MDA-MB-436, characterized by a BRCA1 mutation, we explored the sensitization potential of ART446 to PARP inhibitors. Strikingly, the combination therapy with a PARP inhibitor, Olaparib surpassed monotherapy outcomes, resulting in complete tumor growth inhibition (TGI: Olaparib, 73%; ART446, 20%; combined, 102%). Mechanistic insights revealed an increase in gamma H2AX levels by ART446 and a decrease in active forms of Chk2 which were activated by Olaparib affirming that Olaparib-induced Chk2 inhibition contributed to the sensitization effect.

Conclusions: The pre-IND candidate ART446 exhibits promising potential in enhancing the therapeutic effects of Olaparib and Irinotecan. These findings provide a robust foundation for further clinical development, offering a strategic approach to overcome resistance in cancer treatment.

#4574 Next generation nuclear export blocker KPT8602 synergizes with KRAS^{G12D} inhibitor MRTX1133 resulting in improved antitumor effects against pancreatic ductal adenocarcinoma.

H. Y. Khan[1], A. Aboukameel[1], M. Uddin[1], S. F. Bannoura[1], K. Keffri[1], M. Jasti[1], R. Virga[1], S. Motorwala[1], K. Choucair[1], T. Hadid[1], M. Al-Hallak[1], E. Beal[1], M. Tobon[1], R. Beydoun[1], G. Dyson[1], S. Kim[1], M. Nagasaka[2], P. A. Philip[3], B. El-Rayes[4], H. Chen[4], A. Shields[1], R. Mohammad[1], B. Pasche[1], A. Azmi[1];
[1]Barbara Ann Karmanos Cancer Institute, Detroit, MI, [2]University of California Irvine School of Medicine, Orange, CA, [3]Henry Ford Health, Detroit, MI, [4]School of Medicine, University of Alabama, Birmingham, MI

Introduction: A novel KRAS inhibitor, MRTX1133, specifically targeting the G12D isoform, prevalent in pancreatic ductal adenocarcinoma (PDAC), holds promise for a substantial PDAC patient population. Nevertheless, given the clinical experience with sotorasib (a KRAS^{G12C} inhibitor) in lung cancer, it's anticipated that resistance to the KRAS^{G12D} inhibitor will eventually emerge in most PDAC patients. This underscores the need to identify strategies that can enhance the efficacy of KRAS inhibitors in PDAC. Emerging evidence suggests that the nuclear export protein exportin 1 (XPO1) is a druggable vulnerability in KRAS mutant cancers. XPO1 plays a pivotal role in shuttling various critical tumor suppressors, genome surveillance proteins, and transcription factors out of the nucleus and is frequently overexpressed in various cancers, including PDAC. In this study, we employed both *in vitro* and *in vivo* models to assess the potential of KPT8602, an investigational and next-generation selective XPO1 inhibitor, to synergize with the KRAS^{G12D} inhibitor MRTX1133 and sensitize MRTX1133-resistant PDAC cells.

Methods: We examined the cytotoxic and molecular effects of KRAS^{G12D} inhibitor MRTX1133 in combination with nuclear export blocker KPT8602 in KRAS^{G12D} mutant 2D and 3D cellular/spheroid models. The preclinical antitumor efficacy of the combination was evaluated in a KRAS^{G12D} mutant PDAC cell derived xenograft (CDX) model.

Results: KPT8602 synergized with MRTX1133 *in vitro* yielding suppressed proliferation of KRAS^{G12D} mutant PDAC cells. Similar synergistic effects were also seen in 3D cultures of KRAS^{G12D} mutant PDAC cancer cell lines and patient derived primary tumor cells where the combination suppressed spheroid formation and reduced spheroid viability. Also, the combination inhibited the clonogenic potential of KRAS^{G12D} mutant PDAC cells. In addition, we developed a PDAC cell line resistant to MRTX1133 and observed that such MRTX1133-resistant cell line was acutely sensitive to treatment with KPT8602. Mechanistically, KPT8602 and MRTX1133 combination led to reduction in protein expression of KRAS downstream effectors and cell cycle markers. Furthermore, a combined administration of KPT8602 and MRTX1133 at sub-optimal doses resulted in remarkable tumor growth inhibition in a KRAS^{G12D} mutant HPAC CDX mice model. Moreover, KPT8602 as a maintenance therapy also prevented tumor relapse.

Conclusion: This is the first study demonstrating that nuclear export blocker KPT8602 can synergize with KRAS^{G12D} inhibitor MRTX1133 and has the potential to target MRTX1133-resistant PDAC cells. This study provides a rationale for combining MRTX1133 with KPT8602 for the treatment of PDAC patients with KRAS^{G12D} mutant tumors.

#4575 FGFR3 altered bladder cancer exhibits a lineage-dependent vulnerability.

M. Koleilat, Y. Zhu, L. Kwong;
UT MD Anderson Cancer Center, Houston, TX

Fibroblast Growth Factor 3 (FGFR3) genomic alterations are oncogenic drivers in ~15% of bladder cancer patients. A novel FGFR inhibitor, Erdafitinib, was FDA approved in 2019 based off a Phase II trial with an overall response rate of 40%. However, the majority of patients rapidly relapse at a median of 6 months, requiring combination therapies to prevent drug resistance. We hypothesized that a genome-wide CRISPR screen would identify Erdafitinib-sensitizing co-targets. We screened UM-UC-14, an S249C FGFR3 mutated bladder cancer cell line, and identified Cyclin C as a top hit in addition to known MAPK effectors such as ERK2 and SHP2. Cyclin C is a non-cell cycle related cyclin and part of the CDK8/19 kinase module of Mediator. Pharmacological validation in 4 FGFR3 altered cell lines confirmed a high degree of synergy between Erdafitinib and the CDK8/19 inhibitor Sel120, while no effect was seen in 2 wildtype cell lines, suggesting strong specificity. Moreover, the synergy in FGFR3-mutant cells was superior to that of SHP2 inhibitor SHP099 or the ERK inhibitor BVD-523. Similarly, GATA3 and PPARG also scored highly in our CRISPR screen. These transcription factors have been shown to be sufficient to enforce a luminal identity but not necessarily to maintain it. We validated these 3 genes as sensitizers and show in luminal cells that loss of either GATA3 or PPARG leads to loss of luminal markers and gain of basal markers. In contrast, cells treated with Sel120 showed, on RNAseq, an increase in basal markers without loss of luminal markers. Interestingly, our data suggests that the gain of basal markers, commonly associated with a worse prognosis, is associated with a strong sensitization to FGFR inhibition in FGFR3 alteration driven bladder cancer. We conducted a xenograft experiment confirming that mice responded well to single agent Erdafitinib, but without frank tumor regression. By contrast, Sel120+Erdafitinib induced complete responses in 8/10 mice compared to 6/10 mice for SHP099+Erdafitinib. Remarkably, after 60 days of daily drugging and a 20-day washout, the tumors did not grow back in the complete responders. Importantly, no loss of body weight or other signs of morbidity were found. Our results suggest an immediate and promising benefit in combining either CDK8/19 or SHP2 inhibitors with Erdafitinib in treating patients with FGFR3 alteration driven bladder cancers. Furthermore, we identified a strategy in targeting lineage modulators as sensitizers to existing therapies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: HDAC and Methyltransferase Inhibitors
Poster Session

#4579 DNMT1 determines the sensitivity of Class I HDAC inhibitor Psammaplin A to induce apoptosis and DNA damage in hematological malignant cells.

Y. Bao[1], D. Liu[1], Z. Wu[1], Y. He[1], P. Gong[1], S. Waxman[2], Y. Jing[1];
[1]Shenyang Pharmaceutical University, Shenyang, China, [2]Icahn School of Medicine at Mount Sinai, New York, NY

Histone deacetylases (HDACs) and DNA methyltransferases (DNMTs) are overexpressed in cancer cells associated with dysregulated gene expression and tumor progression. DNMT1 partnered with Class I HDAC as complex to inhibit gene transcription. Several pan-HDAC inhibitors have been approved for T-cell lymphoma with evident side effects. More selective HDAC inhibitors need to be developed. Psammaplin A (PsA), a symmetrical bromotyrosine-derived disulfide dimer isolated from the *Psammaplysilla sponge*, is a selective Class I HDAC inhibitor. We tested its cell growth inhibition and apoptosis induction in 12 hematological malignant cell lines with 8 lines sensitive (more than 50% growth inhibition at 1 μM) and 4 lines insensitive (less than 20% growth inhibition at 1 μM). PsA induces acetylation of H3, but not α-tubulin, supporting the Class I HDAC inhibition selection. In the sensitive cell lines, PsA induces apoptosis with down-regulation of c-Flip and upregulation of NOXA as well as DNA damage detected by γ-H2A.X. RNA sequence analysis results confirm the regulation of PsA on *NOXA*, *c-Flip* and *p21* gene expression. The four insensitive cell lines express high levels of DNMT1 with resistance to apoptosis induction. Silencing DNMT1 with siRNA sensitizes PsA-induced apoptosis with induction of NOXA and γ-H2A.X. Azacytidine, the DNMT1 degrader, in combination with PsA induce synergistic cell growth inhibition and apoptosis in vitro. PsA (20 mg/kg) plus Azacytidine (2.5 mg/kg) synergistically inhibit tumor growth in insensitive mantle cell lymphoma Jeko-1 xenografts, without detected toxic signs in organ pathological analysis. We find a new mechanism of DNMT1 controlling the sensitivity of Class I HDAC inhibitor PsA and provide a rationale of PsA with azacytidine for combination therapy.

#4580 Selective HDAC3 inhibition e-sensitizes PARPi-resistant ovarian cancer cells to olaparib.

B. E. Fashemi[1], V. Gupta[1], M. Akande[1], Y. Ota[1], S. Mitra[1], B. Bitler[2], D. Khabele[1];

[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Colorado School of Medicine, Aurora, CO

High-grade serous ovarian cancer is a rare but deadly disease. Platinum-based therapy along with poly ADP ribose polymerase inhibitors (PARPi) maintenance therapy, is recommended to 80% of patients. However, acquired PARPi resistance is an ongoing clinical problem and there is a growing need for the development of more targeted therapies. We have previously shown that the class I histone deacetylase inhibitor (HDACi), entinostat, which is selective for HDAC1/2, resensitizes ovarian cancer cells to PARPi. Here, we propose to examine whether selective inhibition of HDAC3 will induce a synthetic lethality in PARPi-resistant ovarian cancer cells. BRD3308 is an HDACi that is a potent and highly selective inhibitor of HDAC3 and of HDAC1/2 to a lesser extent. To investigate these effects, we used two mouse ovarian cancer epithelial lines ID8 TP53-/-/BRCA2-/- (ID8) and an olaparib resistant line ID8 TP53-/-/BRCA2-/--OR (ID8_OR). We performed cell viability assays (MTS) by treating both cell lines with increasing concentrations of olaparib (0-40uM), BRD3308 (0-2uM), and in combination. When ID8_OR cells were treated with olaparib 5uM and 0.25uM of BRD3308 in combination, cell proliferation was significantly reduced when compared to olaparib treatment alone (p= 0.0077). We did not observe a significant differences in cell proliferation between olaparib alone and in combination with BRD3308 in the ID8 cells. Olaparib and BRD3308 treatment in the ID8_OR cells were found to be synergistic at four out of the five drug concentrations tested, with concentrations 2.5uM olaparib and 0.125 uM of BRD3008 scoring the highest (22, Loewe Synergy Score). In the presence of BRD3308, the olaparib EC50 reduced ~13-folds in the ID8_OR cells compared to only a 2-fold reduction in the ID8 cells. We hypothesizes that inhibition of HDAC3 induces apoptosis by downregulating homologous recombination repair in response to DNA damage. To examine these, we irradiated both ID8 cell lines and treated with olaparib (10 uM), BRD3308 (0.5uM) and in combination, for 24 hours, followed by western blot analysis. Rad51 expression was reduced following combination treatment when compared to control or olaparib alone. Lastly, our clonogenicity data revealed colony formation in both ID8 cell lines were reduced when treated with olaparib (5uM) and BRD3308 (0.25uM). Interestingly, BRD3308 alone reduced colony formation in the ID8_OR cells, but not in the ID8 cells. In conclusion, selective HDAC3 inhibition in combination with olaparib may be an effective therapy in the treatment of acquired PARPi resistant ovarian cancers.

#4581 Identifying class 1 HDACs as a vulnerability for aggressive uveal melanoma.

G. Yenisehirli[1], A. Zuniga[1], S. Rodriguez[1], E. V. Adis[1], G. Quintana[2], S. Borges[2], S. Lopez[2], K. Lopez[1], S. Braun[1], C. H. Volmar[1], J. W. Harbour[3], S. Kurtenbach[1];

[1]University of Miami Miller School of Medicine, Miami, FL, [2]University of Miami, Miami, FL, [3]University of Texas Southwestern Medical Center, Miami, FL

Uveal melanoma (UM) is the most common primary intraocular cancer in adults, with a strong propensity to metastasize, primarily to the liver. Metastatic UM is notoriously unresponsive to existing therapies, rendering it almost uniformly lethal. Virtually all UM tumors have activating mutations in the Gq signaling pathway, predominantly in GNAQ/11, and around half of tumors have additional loss-of-function mutations in the tumor suppressor BAP1. Mutations in the epigenetic modulator BAP1 are the most significant clinical marker of metastatic risk. The limited efficacy of current treatment options necessitates an urgent exploration of novel therapeutic approaches to improve patient prognosis. Thus, we conducted a large epigenetic compound library screen with the currently most well characterized, focused epigenetic library available, which consisted of 960 potent, cell permeable, medically active, epigenetic-directed small molecule modulators (TargetMol, L1200). We screened BAP1-mutant as well as BAP1-wildtype uveal melanoma cell lines and followed up with comprehensive dose-response and synergy tests. Our lead compounds were highly efficient in reducing viability of UM cells. We find that inhibitors with high specificity for class 1 HDAC inhibition are especially cytotoxic to UM cells. Together, our results reveal a possible mechanism of interfering with UM progression and identify lead compounds to be tested in clinical trials.

#4582 HDAC6 inhibition reshapes the epigenome of cancer *via* P300 stabilization.

M. Gottardi Zamperla[1], B. Illi[2], V. Barbi[1], C. Cencioni[3], S. Gagliardi[4], M. Garofalo[4], G. Zingale[5], I. Pandino[5], D. Sbardella[5], L. Cipolla[6], S. Sabbioneda[6], A. Farsetti[3], C. Ripamonti[7], G. Fossati[7], C. Steinkuhler[7], S. Atlante[3], C. Gaetano[1];

Bietti,, Roma, Italy, [6]Istituto di Genetica Molecolare "Luigi Luca Cavalli-Sforza", Pavia, Italy, [7]Italfarmaco Group, Cinisello Balsamo, Italy

Introduction: Histone deacetylases (HDACs)are crucial in regulating gene expression, DNA synthesis, and metabolic processes, including cancer, in various cellular environments. The unique structural and functional attributes of class IIb HDAC6 position it as a key player in influencing protein stability and chromatin dynamics. While its role in cancer progression and immunomodulation is well-recognized, the in-depth mechanisms following HDAC6 inactivation, particularly its influence on chromatin remodeling and gene regulation, are not thoroughly understood. This knowledge gap represents a critical area of investigation, given the potential of HDAC6 as a therapeutic target in oncology. This study aims to elucidate HDAC6 inactivation-dependent epigenetic effects of, exploring the possibility to exploit these latter for therapeutic purposes in cancer. This aim includes an examination of the stabilization of the lysine acetyltransferase P300 and its implications for chromatin structure and function.

Methods & Results: In this study, ITF3756 and CRISPR/Cas9 were employed to inactivate HDAC6 across a variety of cancer cell lines (Jurkat, MDA 231, HCC1806, 4T1, and B16F10 melanoma). ATAC-seq and H3K27Ac ChIP-seq were used to investigate changes in chromatin accessibility, revealing significant alterations, particularly in introns and distal intergenic regions. Gene Ontology (GO) analysis further supported this alteration in the chromatin landscape, which indicated a differential expression of genes involved in critical cellular processes like cell proliferation, adhesion, migration, and apoptosis. A notable outcome of this study was the stabilization of P300 following ITF3756 treatment, an effect that was paralleled by changes in the expression of critical genes, including AKT1, ITGB3, GAS6, SOX9, NF1, TGFB2, and CASP7. These genes are integral to cellular survival mechanisms, and their modulation emphasizes the role of HDAC6 in cancer cell physiology.

Conclusions: This research shows that the chemical or genetic inactivation of HDAC6 impacts cancer cell proliferation and chromatin architecture, underscoring the potential of HDAC6 as a target in cancer therapeutics.. A critical finding of this study is the stabilization of P300, which offers new perspectives on HDAC6's functionality and its role as an epigenetic modifier in cancer cells. This study contributes to the field by suggesting therapeutic strategies focusing on HDAC/HAT pharmacological targeting, thereby advancing our understanding of the role of HDAC6 in regulating cancer cell behavior and epigenetic landscape.

#4583 Development of selective HDAC6 inhibitors to improve cancer immunotherapy.

Nithya Gajendran[1], Manasa Suresh[1], David Quiceno[1], Xintang Li[1], Marie Durr[1], Sebastian J. Marquez Rodriguez[2], Mario A. Noboa[2], Sruthi Mohan[2], Barbora Havlinova[3], Julia Kudlacova[3], Satish Kumar Reddy Noonepalle[1], Cyril Barinka[3], Duncan J. Wardrop[2], Alejandro Villagra[1]

[1]Department of Oncology, Georgetown University Medical Center ,Lombardi Comprehensive Cancer Center, Washington, DC,[2]Department of Chemistry, University of Illinois at Chicago, Chicago, IL,[3]Institute of Biotechnology of the Czech Academy of Sciences, Prumyslova, Czech Republic

Histone Deacetylases (HDACs) are enzymes that modify histones and non-histone proteins. Our group has previously demonstrated that HDAC6 inhibitors (HDAC6is) modulate multiple immune pathways, including those that suppress the antitumoral M2 phenotype, leading to improved antitumor immunity. Despite the potential of HDAC6is, current inhibitors have poor selectivity and off-target effects and only work at micromolar concentrations. In this work, we designed a screening pipeline of HDAC6i, considering selectivity, potency, capacity to prevent the protumoral phenotype of macrophages, and low cytotoxicity on macrophages and other immune cells. This approach has not been tested before, as the standard screening method for antitumoral HDACis has focused on its cytotoxic effect on cancer cells. We initially designed in silico 980 compound derivatives from previously reported HDAC6i, such as SS208, Nexturastat A, and Suprastat. Twenty-four compounds with a high capacity to bind HDAC6 and chemical stability were screened by their ability to inhibit HDAC6 in cell-free conditions. Sixteen compounds demonstrated high potency and were further evaluated in murine macrophages by their cytotoxic effect using CellTox. The capacity to impede tubulin deacetylation was assessed by western blot and deacetylase activity by HDAC-Glo. The top six candidates were then evaluated by their selectivity compared to other HDAC members and by their effect on repressing the expression of protumoral M2 macrophages Arginase 1 and Fizz1, and activation of antitumoral markers TNFa and iNOS by western blot and qRT-PCR. The best three candidates were then evaluated at nanomolar concentrations to explore their immunomodulatory potential of M1 against M2 by performing antigen presentation (SIINFEKL presentation) and phagocytic capacity using microscopy. Two of these compounds, SM-06-09 and SM-05-947, will be further tested in syngeneic murine melanoma models for their ability in tumor regression and antitumor immunity. This study has yielded important insights into developing new and improved HDAC6is with minimal cytotoxicity, and we believe our work will help advance cancer research and ultimately lead to better patient outcomes.

#4584 Novel YAP1/TAZ pathway inhibitors identified through phenotypic screening with potent anti-tumor activity via blockade of GGTase-I and Rho-GTPase signaling.

Keith Graham[1], Philip Lienau[2], Benjamin Bader[1], Stefan Prechtl[1], Jan Naujoks[1], Ralf Lesche[1], Barbara Nicke[1], Wilhelm Bone[1], Sven Golfier[1], Krzysztof Brzezinka[1], Stefan Kaulfuss[1], Charlotte Kopitz[1], Holger Steuber[1], Nico Braeuer[1], Katrin Nowak-Reppel[1], Carlo Stresemann[1], Patrick Steigemann[1], Julia Kuehnlenz[2], Lisette Potze[1], Francesca Zanconato[3], Anna Montebaur[2], Sabine Pilari[2], Sikander Hayat[2], Atanas Kamburov[2], Andreas Steffen[2], Andreas Schlicker[2], Philipp Buchgraber[2], Nuria Aiguabella Font[2], Tobias Heinrich[2], Lara Kuhnke[2], Annette O. Walter[2], Simona Blotta[2], Matthias Ocker[2], Ashley Lakner[2], Dominik Mumberg[2], Knut Eis[2], Stefano Piccolo[3], **Martin Lange**[1]

YAP1/TAZ have been shown to be aberrantly activated oncogenes in several human solid tumors, resulting in enhanced cell proliferation, metastasis and provision of a pro-tumorigenic microenvironment, making YAP1/TAZ targets for novel cancer therapies. Yet, the development of effective inhibitors of these potent oncogenes has been challenging. In this work, we break new ground in this direction through the identification of novel inhibitors of YAP1/TAZ activity. This study describes the identification and target deconvolution of novel small molecule inhibitors of oncogenic YAP1/TAZ activity with potent anti-tumor activity in vivo. A high-throughput screen (HTS) of 3.8 million compounds was conducted using a cellular YAP1/TAZ reporter assay. HTS hits that selectively inhibited TEAD-luciferase, but not TK-Renilla-luciferase (n = 3.994) were subsequently assessed regarding their ability to induce translocation of YAP1 from the nucleus to the cytoplasm in MDA-MB-231 cells, which is the physiological mechanism of inactivation. Out of these, 392 hits showed activity to induce translocation of YAP1. Finally, selected hits active in both assays (n = 96) were assessed regarding their effect on endogenous YAP1/TAZ target genes. The small molecule BAY-856 demonstrated the most consistent YAP1/TAZ inhibitory activity of all selected hits, which warranted further exploration of the unknown direct drug target. Target deconvolution studies identified the geranylgeranyltransferase-I (GGTase-I) complex, as the direct target of YAP1/TAZ pathway inhibitor BAY-856. BAY-856 and close analogs with improved in vitro potency blocked the activation of Rho-GTPases, leading to subsequent inactivation of YAP1/TAZ and inhibition of cancer cell proliferation in several tumor types in vitro. Multi-parameter optimization resulted in BAY-593, an in vivo probe with favorable PK properties. BAY-593 demonstrated anti-tumor activity in solid tumor models and blockade of YAP1/TAZ signaling *in vivo*. BAY-593 is a novel tool compound to explore Rho-GTPase signaling and downstream YAP1/TAZ biology in vitro and in vivo.

#4585 Discovery of ETS-006, a highly potent YAP/TEADs PPI inhibitor with broad anti-tumor activity as a single agent.

J. Lu, M. Gao, W. Du, X. Fan, J. Li, M. Wang, L. Feng, Y. Li, J. Yao, J. Lu, W. Cui, Q. Zheng, **J. Zhu**;
ETERN Therapeutics Co., Ltd., Shanghai, China

The transcription co-activators YAP, pairing with the TEAD family of transcription factors, serve as essential effectors of the conserved Hippo signaling pathway. Hippo kinase cascade controls YAP nuclear entry and binding with TEADs by modulating its phosphorylation and stability. Overexpression and activation of YAP/TAZ are frequently observed in a variety of cancers. It has been well established that YAP aberration contributes to cancer development, metastasis, immunosurveillance escape and drug resistance. Disruption of YAP/TEADs PPI is an effective approach to inhibit YAP transcriptional activity. We previously have reported the identification of YAP/TEADs PPI hit compound through the fragment-based screen and advanced the hit to lead compound ETS-003. Here we reported the preclinical candidate of YAP/TEADs PPI inhibitor ETS-006 with much more potent anti-tumor activity and favorable safety profile. Compared to TEAD palmitoylation inhibitor, ETS-006 could completely disrupt the interaction of YAP/TEADs, resulting in a more profound downregulation of YAP target gene expression. ETS-006 demonstrated more robust anti-tumor activity than the competitor's YAP/TEADs PPI inhibitor in MPM CDX model with favorable ADME properties. Notably, ETS-006 showed promising efficacy across multiple solid tumor types, including head and neck squamous cell carcinoma, osteosarcoma, and triple-negative breast cancer with urgent unmet clinical needs. In conclusion, ETS-006 is a highly potent and orally available YAP/TEADs PPI inhibitor with broad anti-tumor activity as a single agent.

#4586 ITF3756 increases NKG2D expression and cytotoxic activity of activated human CD8 T cells.

C. Ripamonti, V. Spadotto, C. Steinkuhler, G. Fossati;
Italfarmaco S.p.A., Cinisello Balsamo, Italy

Effector cytolytic CD8 T cells play a major role in the recognition and killing of cancer cells. These cells are short living due to the loss of their self-renewal capacity and rapid exhaustion. Enduring antitumor immune response relies on the capacity of regenerating effector cells upon antigen re-encounter by memory cells. Focusing on molecules that could modulate the differentiation of T cells towards a memory subset with a prolonged anti-tumor activity is strategic for an efficient anti-tumor immunotherapy. Thus, we developed a selective HDAC6 inhibitor currently in Phase I clinical trial, ITF3756, which *in vitro* drives the differentiation of human CD8 T cells towards a central memory phenotype with reduced expression of exhaustion markers and higher expression of IFNγ and Granzyme b upon tumor cells coculture. This suggests that ITF3756-treated CD8 T cells could have a greater tumor killing activity. Moreover, if this augmented cytotoxic activity is directed not only towards tumor cells expressing MHC I but also towards MHC I negative cells, the anti-tumor efficacy could be improved. We thus selected the MHC I negative K562 leukemic cell line as target in an in vitro model of CD8 T cell killing assay. CD8 T cells were stimulated with anti CD3CD28 beads with or without ITF3756, and then co-cultivated with K562 cells for 4h. ITF3756 treatment improved significantly CD8 mediated K562 killing over this short period of time. However, since the effectiveness of memory cells is based on their capacity of maintaining a long-lasting immune response, we monitored the cytolytic activity over a period of 2 weeks. After 14 days of co-culture, ITF3756 treated CD8 T cells showed a higher cytotoxic capacity compared to control cells. These results indicate that ITF3756-treated CD8 T cells can kill a target tumor cell in a more efficient way independently of MHC I restricted tumor recognition, both after short and long term in vitro co-culture. Since it has been described that CD8 T cells can also kill MHC I-negative tumor cells through the NKG2D-NKG2DL axis, we assessed if ITF3756 could modulate the expression of NKG2D on CD8 T cells. Indeed, ITF3756-treated CD8 T cells had a significantly higher expression of NKG2D compared to untreated cells. In conclusion, we show that ITF3756 promotes the differentiation of cells that possess better effector activity when co-cultured with tumor cells for both short and long periods of time. ITF3756 increased the expression of NKG2D and this could be a driver of the increased cytolytic activity. One mechanism of tumor immune escape is the downregulation of MHC I. Our results suggest that ITF3756 could be used to improve the efficacy of T cell therapy by enhancing the cytolytic activity even in the absence of MHC I.

#4587 Development of highly selective, potent, orally available PIM1 inhibitor BLX0631 shows a therapeutics potential in multiple myeloma models.

Z. Li, C. Lin, D. J. Bearss, **H. Vankayalapati**;
Biolexis Therapeutics Inc., American Fork, UT

Background: The Proto-oncogenic PIMs family are nuclear and cytoplasmic Ser/Thr kinases (PIM1, PIM2, and PIM3) that are constitutively active and play a vital role in proliferation and survival in Multiple Myeloma (MM). Activated PIM1 kinase can induce progression of the cell cycle, inhibition of apoptosis, and modulation of other signal transduction pathways.

Methods: BLX-0631 and a few analogs evaluated against a panel of MM cell lines (EJM, IM-9, L-363, LP-1, MM-1R, MM.1S, MOLP-2, NCI-H929, OPM-2, RPMI8226 and U-266) and primary MM patient samples by CellTiter-Glo® (CTG) assays. Cellular apoptosis, Cell cycle analysis, Flow Cytometry, and bone marrow microenvironment experiments on the most sensitive cells were performed. PIM1 and downstream targets by western blot, cell migration, and invasion on our lead PIM1 inhibitor BLX-0631 along with, kinome selectivity, ADME-Tox, PK, and in vivo MM.1S efficacy experiments were conducted.

Results: The application of our empirical MolecuLern™ fragment library, PIM1 crystal structure, scaffold hopping, and the enumeration features of MolecuLern™ in combination with 3, 6, and 7-group analysis on pyridazine, lead to a synthesizable potential new lead series, representing Med Chem tractability and developable characteristics. Further, the consensus scoring, binding energies, and MolecuLern tractability filters were applied and led to the discovery of the BLX-0631 series that inhibits the PIM1 kinase. The active compounds, with their binding modes and lead optimization strategies, lead to the synthesis and testing of over 60 novel entities as PIM1 kinase inhibitors. Thus, based on our previous chemotype series and scaffold hopping method, the impact of changing the 3, 6, and 7 positions, while retaining the pyridazine core led to the discovery of BLX-0631 and its series of compounds exhibiting <5 nM potency. BLX-0631 in CTG assay demonstrated 100% cell growth inhibition across all MM cell lines tested. The lead compound BLX-0631 is a very potent inhibitor with an IC_{50} of 5.0/17/5.0 nM when tested against PIM1, PIM2, and PIM3 kinases respectively, and selective against a panel of 468 kinase panels. Dosing through IV and PO delivery routes, formulations, salt forms of BLX-0631 in mice, PK properties along with ADME-Tox, P450, and hERG results will be presented. *In vivo* MM.1S mouse xenograft models of BLX-0631 at 15, 30 and 45 mg/Kg, p.o, QD demonstrated TGI of 16.28%, 31.81% & 35.16% dose-dependently.

Conclusions: The present study demonstrates that PIM1 plays a vital role in the proliferation and survival of Multiple Myeloma. BLX-0631 induces full inhibition of all MM cell lines, suppresses cancer cell proliferation *in vitro,* and exhibits promising efficacy in MM tumor models. BLX-0631, a nominated IND candidate can serve as a novel targeted agent for treating Multiple Myeloma patients.

#4588 Combination of MTA-cooperative PRMT5 inhibitor and direct mutant-selective KRAS inhibitors as a novel therapeutic approach for MTAP-deficient pancreatic cancer.

K. Drizyte-Miller[1], W.-H. Chang[1], A. M. Waters[2], C. A. Stalnecker[3], J. Wang[4], A. J. Aguirre[4], A. D. Cox[3], C. J. Der[3],
[1]UNC Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Cincinnati, Cincinnati, OH, [3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC, [4]Broad Institute of MIT and Harvard, Boston, MA

KRAS is mutationally activated in 95% of pancreatic ductal adenocarcinoma (PDAC) patients. Direct KRAS inhibitors are under intense preclinical and clinical development, with two $KRAS^{G12C}$ mutant-selective inhibitors (G12Ci) now approved. However, treatment-associated resistance to KRAS inhibitors has been reported in the clinic highlighting an urgent need to identify both additional therapeutic targets and novel combination treatment strategies with KRAS inhibitors. To that end, we performed a CRISPR/Cas9 loss-of-function screen using a library targeting ~2,500 druggable genes in $KRAS^{G12C/D}$-mutant PDAC cell lines. We identified multiple genes that were essential for PDAC cell growth and selected PRMT5, a protein arginine methyltransferase, to assess as a novel therapeutic target for pancreatic cancer. We found that suppression of PRMT5 activity using two distinct first-generation clinical candidate small molecule inhibitors (JNJ-64619178 and GSK3326595) demonstrated single agent activity and reduced PDAC cell growth. We further assessed a mechanistically distinct MTA-cooperative clinical candidate PRMT5 inhibitor, MRTX1719, that is selective for *MTAP*-deleted tumors, which occur in ~25% of PDAC patients. We determined that MRTX1719 exhibited low nanomolar GI_{50} activities in *MTAP*-deficient but not *MTAP* wild-type KRAS-mutant cell lines. Unexpectedly, PDAC cells treated with MRTX1719 exhibited a paradoxical activation of ERK, suggesting that combined inhibition of PRMT5 and KRAS might be therapeutically advantageous. In support of our hypothesis, we demonstrated that combination treatment with MRTX1719 and mutant selective KRAS inhibitors (G12Ci/MRTX849 and G12Di/MRTX1133) further sensitized $KRAS^{G12C/D}$-mutant PDAC cells to KRAS inhibition in short- and long-term growth assays as well as *in vivo* xenograft studies. Our ongoing studies are evaluating the consequences of co-targeting PRMT5 and KRAS on gene expression changes using RNA-Seq and cancer cell signaling pathways using RPPA analyses. In summary, our data support concurrent inhibition of PRMT5 and KRAS as a promising therapeutic strategy for MTAP-deficient KRAS-mutant pancreatic cancer.

#4589 Synergistic effects of EZH1/2 dual inhibition and cisplatin on lung cancer cell lines with loss of *SMARCA4* and *SMARCA2*.

J. Lee[1], B. Keam[2], S. Kim[1], J. Youk[2], M. Kim[2], T. Kim[2], D.-W. Kim[2], H. Dae Seog[1];
[1]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

Purpose: *SMARCA4* mutations are observed in approximately 10% of non-small cell lung cancer (NSCLC) cases and are implicated in various biological functions. Lung cancers harboring these mutations are associated with poor prognosis and often exhibit resistance to conventional chemotherapies, highlighting the urgent need for innovative therapeutic strategies. We evaluated the efficacy of a novel EZH1/2 dual inhibitor, HM97662, and its synergistic potential with cisplatin in *SMARCA4*-deficient lung cancer cell lines.

Experimental Design: CCLE datasets were employed to identify cell lines harboring truncated mutations in the *SMARCA4* gene. Immunoblotting was conducted to verify the inactivation of *SMARCA4* and to check for the expression of SMARCA2. We assessed cellular viability and colony-forming capabilities of lung cancer cell lines
(NCI-H1975, PC9, A549, HCC15, NCI-H522, NCI-H1581, NCI-H1048, NCI-H841) to determine the cytotoxic effects of an EZH1/2 dual inhibitor as well as cisplatin, both as single agents and in combination.

Results: Immunoblotting showed distinct lung cancer cell lines characterized by three profiles: proficient SMARCA4 expression, absent SMARCA4 but present SMARCA2 expression, and concurrent loss of both SMARCA4 and SMARCA2. After 14 days of treatment with the EZH1/2 dual inhibitor HM97662, there was a significant reduction in cell proliferation, particularly in the both *SMARCA4*- and *SMARCA2*-loss cell lines. Furthermore, colony-forming assays demonstrated a significant decrease in colony-forming ability upon HM97662 treatment, an effect exclusive to the both SMARCA4 and SMARCA2 loss cell lines. Pre-treatment with 1 μM of HM97662 for 7 days potentiated the cytotoxicity of cisplatin compared to untreated controls in the SMARCA4/2 loss cell lines, as indicated by a lower IC50 value.

Conclusion: The novel EZH1/2 dual inhibitor, HM97662, exhibits antitumor activity and a synergistic effect with cisplatin in lung cancer cell lines with concomitant loss of *SMARCA4* and *SMARCA2*. These findings suggest the potential utility of EZH1/2 dual inhibition as a targeted therapeutic approach in lung cancers characterized by the dual loss of SMARCA4/2.

#4590 Antitumor effects of histone deacetylase inhibitors on breast cancer cell viability and mammosphere formation.

G. Asaadi Tehrani, B. Kubick, M. Datta;
University of Notre Dame, South Bend, IN

Histone deacetylases (HDACs) are overexpressed in various types of primary human cancer and have become attractive targets for cancer therapy. This study aimed to evaluate the cytotoxic properties of three HDAC inhibitors (suberoylanilide hydroxamic acid (SAHA, or Vorinostat), Valproic Acid (VPA) and CAY10603) and compare them to Paclitaxel (PTX), a chemotherapy agent used to treat Triple Negative Breast Cancers (TNBCs). In the present study, drug response in the MDA-MB-231, MDA-MB-468, and MCF-10A cell lines was evaluated by cell viability assays. Apoptosis and cell cycle distribution were analyzed by flow cytometry. Mammospheres generated from MDA-MB-231 and MDA-MB-468 breast cancer cells were also subjected to drug treatment; their response was assessed under both normoxic and hypoxic conditions.

We found that SAHA and CAY10603 inhibited breast cancer cell viability without significantly affecting MCF-10A cells. SAHA, CAY10603, and VPA all arrested a significant percentage of MDA-MB-231 cells at G2/M phase after 24h compared to controls. TNBC cells experienced an increase in both early and late apoptosis following treatment with the most effective concentrations of SAHA, CAY10603, and VPA (1.8μM, 2μM, and 0.4mM, respectively). SAHA proved to be the most effective drug for induction of apoptosis compared to the control, followed by CAY10603 (8.26% and 6%, 3.67%). In both TNBCs and mammospheres under hypoxic conditions, SAHA and CAY10603 down regulated *HIF-1α* expression significantly, but PTX did not. In contrast, VPA and PTX down regulated *CTNNB1* gene expression.

This study indicates that epi-drugs exert an anti-tumor effect on TNBCs, suggesting a potential role for HDAC inhibitors as novel therapeutics for breast cancer patients.

#4591 PH020-2: an MTA-cooperative PRMT5 inhibitor with excellent selectivity and brain-penetration capability that targets MTAP-deleted tumors.

F. Gao[1], B. Liu[1], J. Wang[1], L. Jing[2], Y. Wu[2], P. Zhang[1], Y. Gao[1], Z. Li[3], Y. Guo[1];
[1]Puhe Biopharma, Beijing, China, [2]Gongkang Bio, Suzhou, China, [3]Shiyu Children Foundation, Beijing, China

Background: Methylthioadenosine phosphorylase (MTAP) gene deletion is highly prevalent across many cancer types such as brain, pancreatic and lung cancer. Accumulated MTA in MTAP loss cells competes with S-adenosylmethionine (SAM, the methyl donor) and leads to partial inhibition on protein arginine methyltransferase 5 (PRMT5), resulting in the sensitivity of these cells to PRMT5 inhibition. On this basis, MTA cooperative PRMT5 inhibitors (such as MRTX1719 and TNG908) have been designed to stabilize the binding of PRMT5 to MTA, but not SAM, resulting in further improvement of selectivity window. The clinical data showed that MRTX1719 has the capability to inhibit MTAP-loss tumor growth while avoid hematology toxicity observed with first generation PRMT5 inhibitors.

Methods: A pair of HCT116 isogenic cell lines (MTAP-/- and MTAP+/+) were used to determine the effects of PH020-2 on cell proliferation and intracellular symmetric dimethylarginine (SDMA) content. Human CD34+ hematopoietic stem cells (HSCs) were collected to evaluate hematological toxicity. Intravenous injection of PH020-2 in rats were performed to assess the brain-penetration capability. The *in vivo* efficacy was tested in cell derived xenograft (CDX) mouse models with tumor harboring MTAP gene deletion. The *in vitro* and *in vivo* pharmacokinetic (PK) and safety properties were assessed with corresponding assay methods.

Results: PH020-2 dramatically decreased SDMA content and inhibited proliferation in HCT116 MTAP-/- cells (IC_{50}, SDMA, 0.31 nM; proliferation, 5.9 nM), but had very weak effect on HCT116 WT cells (IC_{50}, SDMA, 296.2 nM; proliferation, 1381 nM), suggesting an excellent selectivity (proliferation, 253×). In comparison, IC_{50} of MRTX1719 and TNG908 on MTAP-/- cell viability was 8.38 and 52.75 nM, respectively, generating a selectivity of 118× and 28×, respectively. PH020-2 mildly inhibited CD34+ HSC (IC_{50}=807.1 nM), compared to the test on MRTX1719 (IC_{50}=481.9 nM). The tests on a panel of cancer cells confirmed activity and selectivity of PH020-2. PH020-2 possessed excellent PK profiles in all species with absolute bioavailability of 98% in dogs. At the same time, PH020-2 showed outstanding brain penetration in rats (Kp, 0.67). In three CDX models (H838, H2170, Hup-T4), PH020-2 at a dose of 25 mg/kg BID potently inhibited tumor growth, and tumor regression was observed at higher doses in all tested models. Methyltransferase screening (44 targets) showed that PH020-2 potently inhibits PRMT5, but not others. Safety panel assays covering 47 targets demonstrated excellent safety profiles of PH020-2. All other *in vitro* and *in vivo* tests showed favorable results and supported for preclinical development.

Conclusion: The data suggest that PH020-2 is an MTA-cooperative PRMT5 inhibitor with excellent brain-penetration that selectively targets MTAP-deleted tumors.

#4592 Preclinical characterization of ATG-042-198, a novel MTAP ^{null}-selective PRMT5 inhibitor.

Y. Kong[1], M. Zhang[1], L. Jiang[1], R. Xu[2], B. Jiang[1], G. Dai[1], Y. He[1], H. Liu[2], J. Mei[3], B. Hou[3], **B. Shan**[3];
[1]Antengene Corporation Co., Ltd., Shanghai, China, [2]Antengene Biologics, Hangzhou, China, [3]Antengene Corporation Co., Ltd., Shaoxing, China

Background: PRMT5 inhibitors are considered as a promising approach for cancer therapy due to their crucial role in the initiation and progression of many types of malignancies. Nevertheless, the crucial involvement of PRMT5 in controlling hematopoiesis, even in normal cells, resulted in significant on-target-off-tumor hematological toxicity when using first-generation, non-selective PRMT5 inhibitors in clinical settings, which hampered the clinical development of these drugs. The MTAP gene is deleted in around 10-15% of all human malignancies. As a result, the loss of MTAP leads to the buildup of MTA, which can bind to PRMT5 and partially inhibit PRMT5 activity. Inhibitors targeting the PRMT5-MTA complex become a promising strategy for treating MTAP^{null} cancer in a synthetically lethal manner. Herein, we report the preclinical feature of ATG-042-198, a novel MTAP^{null}-selective PRMT5 inhibitor.

Methods: The in vitro activity and MTAP selectivity of ATG-042-198 on cell proliferation and cellular symmetric dimethylarginine (SDMA) expression were profiled using HCT116 MTAP wild type (wt) cells and HCT116 MTAP knock out (ko) cells, as well as in five MTAP^{null} cell lines. The in vivo efficacy was tested in cell derived xenograft (CDX) mouse models with HCT116 MTAP wt cells, HCT116 MTAP ko cells and LU99 cells (MTAP^{null}). The in vitro and in vivo pharmacokinetic properties were assessed with corresponding assay methods.

Results: ATG-042-198 demonstrated potent and selectively inhibitory effect on HCT116 MTAP ko cells' proliferation (IC_{50}=44nM) and SDMA expression (IC_{50}=0.146nM), but very weak effect on HCT116 MTAP wt cells' proliferation (IC_{50}=4550nM) and SDMA expression (IC_{50}>500nM). Consistently, ATG-042-198 showed excellent anti-proliferation activities on multiple endogenous MTAP^{null} cell lines (A549, IC_{50}=2nM; LU99, IC_{50}=6nM; U87MG, IC_{50}=11nM; NALM-6, IC_{50}=37nM; MIA PaCa-2, IC_{50}=43nM). ATG-042-198 demonstrated high permeability (Caco2 assay, ER=2), good metabolic stability (Human liver microsomes assay, T1/2>145min), and low risk of drug interaction (CYP inhibition assay, 3A4/2C19/2D6, all IC_{50}>10μM). In vivo PK study showed that ATG-042-198 was well absorbed, with a dose-dependent increase in plasma distribution and high oral bioavailability (F=108%). Plasma free drug concentrations were continuously higher than the IC_{50} of cell proliferation inhibition within 24 hours after 30mpk administration. In three CDX models (HCT116 MTAP wt, HCT116 MTAP ko and LU99), ATG-042-198 at a dose of 30 mg/kg QD potently and selectively inhibited tumor growth (TGI=-1%, 89% and 106%) without inducing body weight loss.

Conclusions: In summary, ATG-042-198 is an oral MTAP ^{null}-selective PRMT5 inhibitor with potent efficacy against MTAP^{null} tumor. It also demonstrated good tolerability and preclinical PK profiles.

#4593 A synergy between MDM2 and AURKB pathways in driving cell cycle and cell survival in lung cancer cells.

U. Natarajan, A. Rathinavelu;
Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Davie, FL

Lung cancer is the leading cause of cancer-related deaths worldwide and non-small cell lung cancer (NSCLC) is the most prevalent type among lung cancers, contributing to the high mortality seen with this deadly disease. Despite aggressive treatments, the 5-year survival rate for lung cancer is only 23.7% in the United States. MDM2 and AURKB are two cancer-driving genes that are highly expressed in a broad range of cancer types including lung cancers. Furthermore, MDM2 overexpression can positively impact AURKB expression and contribute to oncogenesis and cancer progression. Therefore, blocking MDM2 with specific inhibitors has become a promising strategy for the restoration of p53 function that could be used for the treatment of different types of cancers including lung cancers. In this regard, both MDM2 and AURKB inhibitors have shown promising antitumor activity against NSCLC. Therefore, the main objective of this study was to understand the molecular mechanisms linking MDM2 and ARKB using RG7388, CM272, BMS-582949 (p38 inhibitor), and Ralimetinib (p38 inhibitor) in A549 and H460 lung cancer cells. We analyzed the individual or combination treatment effects of these drugs on epigenetic modifications, cell cycle arrest, and cell death mechanisms, using the *in vitro* experimental model. When RG7388 was used individually, or in combination with BMS-582949 or Ralimetinib, a significant increase in the cytotoxic effect was observed in A549 and H460 cells. Induction of cell cycle arrest by RG7388 in cancer cells was evidenced by elevated p21 expression levels. In addition, RG7388 and combination treatments in NSCLC cells showed significant upregulation of p53, p27, Bax, cleaved PARP, phospho-FOXO3a and down-regulation in DNMT3a, DNMT1, FOXM1, AURKB, CDC25, and CDK4 levels. It appears that during treatments with a combination of MDM2 with DNMT or p38 inhibitor, two pathways might be blocked simultaneously, which could lead to increased cancer cell death. RG7388 appears to induce cell death in a p21-dependent manner and CM272, BMS-582949, and Ralimetinib seem to induce cell death *via* a p21-independent manner by inhibiting a downstream pathway. However, further studies are needed to fully understand the intracellular link between MDM2 and AURKB that is disrupted by the anti-cancer agents used in our study. (This project was supported by the PFRDG Grant of Nova Southeastern University and by the Generous support from the Royal Dames of Cancer Research Ft. Lauderdale, FL)

#4595 HSK41959-2: An oral MTA-cooperative PRMT5 inhibitor for MTAP deleted cancer.

P. Yan[1], **J. Wang**[2], M. Qian[1], X. Yu[1], Y. Li[1], H. Zhang[1], L. Tao[1], R. Kou[1], T. Hu[1], P. Tang[1], H. Dong[1], A. Wu[1], M. He[1];
[1]Haisco Pharmaceutical Group Co., Ltd., Chengdu, China, [2]Haisco Pharmaceutical Group Co., Ltd., Shanghai, China

Methylthioadenosine phosphorylase (MTAP) homozygous deletion occurs in 10-15% of all human cancers. Loss of MTAP result in methylthioadenosine (MTA) accumulation. PRMT5, which is a type II arginine methyltransferase that regulates multiple essential cellular functions via symmetric dimethylation of arginine (SDMA) in target proteins, was identified as a synthetic lethal target for MTAP del cancers. MTA-cooperative PRMT5 inhibitors may exhibit better safety profiling compared to first generation PRMT5i (which observe limiting heme-related toxicities in clinical), which preferentially inhibiting PRMT5 in MTAP del cancer cells to normal cells. HSK41959-2 is a MTA-cooperative PRMT5 inhibitor, which could selectively inhibits PRMT5 in the present of MTA with IC_{50} was 0.80 nM. In HCT116 MTAP Deleted cell line, HSK41959-2 significantly inhibits the cell proliferation with GI_{50} of 19.89 nM, which was around 45-fold selectivity in HCT116 cell line. In SDMA assay, HSK41959-2 also showed high potency in HCT116 MTAP-del cell line with IC_{50} was 3.39 nM, and much weaker in HCT116 MTAP-WT cell line with IC_{50} was 499 nM, around 147-fold selectivity. In vitro CD34+ Hematopoietic stem cell cell proliferation assay was used for evaluate the heme-related toxicities. HSK41959-2 weakly inhibited the cell proliferation with IC_{50} of 544 nM while the first generation PRMT5i with IC_{50} was 35.39 nM. This results indicated HSK41959-2 may has lower heme-related toxicities compared with the first generation PRMT5i. In the HCT116 MTAP-del xenograft model, daily orally administrated with 25 mpk and 100 mpk HSK41959-2 showed significant tumor growth inhibition, with TGI were 62% and 88%, and PRMT5-dependent SDMA protein inhibition were 89% and 95%, respectively. Meanwhile in the HCT116 MTAP-WT xenograft model, HSK41959-2 did not show tumor growth inhibition at 100 mpk. In conclusion, HSK41959-2 is a promising oral MTA-cooperative PRMT5 inhibitor, it was nominated as a development candidate.

#4596 Targeting arginine methylome in *9p21*/*MTAP*-deleted malignant cancers with a next generation PRMT5-specific inhibitor CTS3497.

Y. Liu[1], L. Wang[1], H. Shi[1], Y. Liu[1], Q. Ouyang[1], X. Fu[1], M. Wang[1], J. Guo[1], Y. Wang[2], Y. Wang[1], G. Xu[2], Y. Mi[1], H. Wu[1];
[1]CytosinLab Therapeutics Co., Ltd., Shanghai, China, [2]Center for Excellence in Molecular Cell Science, Chinese Academy of Science, Shanghai, China

It remains largely challenging to treat cancer patients with chromosome 9p21-deletion which occurs in approximately 15% of human cancers. Recently, specific targeting of protein arginine methyltransferase 5 (PRMT5), a key member of the type-II PRMT family and a master epigenetic modulator of arginine methylome essential for cancer progression, has emerged as a promising therapy in various hematological and solid tumors with *MTAP* deletion serving as a precision biomarker. To optimize the potential of targeting PRMT5, we developed CTS3497, a potent, brain-penetrable, orally bioavailable MTA-cooperative PRMT5 inhibitor, using our EpigenPLUS^{TM} platform. The overall excellent drug-like properties of CTS3497 support fast track IND application, and it is anticipated to enter Phase 1 trials in 2024. CTS3497 demonstrated potent PRMT5 inhibitory activity in cellular pharmacodynamics (PD) assays, evidenced by the suppression of symmetric dimethylarginine (SDMA). Additionally, it exhibited profound cell growth inhibition with a low single-digit nM IC50 and 171-fold high selectivity for *MTAP*^{null} over isogenic *MTAP*^{wt} cell lines. Moreover, CTS3497 displayed strong inhibitory effects on cell growth across diverse panels of *MTAP*^{null} cancer cell lines and patient-derived xenograft organoids (PDXOs) spanning various lineages. *In vivo*, oral administration of CTS3497 resulted in significant tumor regression in multiple *MTAP*-deleted xenograft models, notably *MTAP*^{null} brain tumors. The observed anti-tumor activity correlated with PRMT5 modulation, as indicated by reduced SDMA levels. Impressively, sustained tumor growth inhibition led to the complete tumor regression, with no regrowth even after discontinuation of CTS3497 treatment. The brain penetration property of CTS3497 underscores its therapeutic potential for both primary brain tumors, and brain metastases arising from specific cancers like lung cancer. At the molecular level, PRMT5 inhibition by CTS3497 induced substantial and distinctive RNA splicing defects and differentially expressed gene signatures, impacting key cellular activities downstream of arginine and epigenetic reprogramming in *MTAP*^{null} cancer cells. Furthermore, a synergistic anti-tumor effect was observed in multiple *MTAP*-deleted tumors when combining PRMT5 inhibition with CTS2190, an investigational type-I PRMT inhibitor currently in phase I/II clinical trials. In summary, CTS3497, a PRMT5 inhibitor selectively targeting *MTAP*^{null} tumor cells, demonstrated robust and durable anti-tumor responses both *in vitro* and *in vivo* across diverse lineages of *MTAP*-deleted tumors. Its superior ADME properties and favorable safety profiles observed in preclinical studies mark a breakthrough in the next generation epigenetic therapy. CTS3497 emerges as a promising therapeutic option for patients with *MTAP*-deleted malignancies.

#4597 RNA m^1A methyltransferase TRMT61A induces MAPK/ERK signaling and is a therapeutic target in colorectal cancer.

X. Zhang, N. Qin, F. Ji, H. Su, H. Chen, H. Shang, **H. Chen**;
Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

The widespread presence of N1-methyladenosine (m^1A) modifications controls RNA metabolism and is pivotal to fundamental biological processes. However, the understanding of RNA m^1A involved in cancer is still minimal. Here we reported the oncogenic role and the therapeutic targeting of RNA m^1A methyltransferase TRMT61A in colorectal cancer (CRC). We observed consistent elevation of TRMT61A expression and RNA m^1A levels in primary CRC tissues, which was significantly associated with poor patient survival in two independent cohorts (both $P<.001$). CRISPR/Cas9 screenings revealed that TRMT61A is the most essential gene among m^1A regulators. TRMT61A facilitates the growth and metastasis of CRC cells by increasing the stability of mRNA of crucial targets, such as ONECUT2, which leads to the activation of MAPK/ERK signaling in an m^1A-dependent manner. Notably, depletion of ONECUT2 or inhibition of MAPK/ERK could abrogate the tumor-promoting role of TRMT61A, implying that TRMT61A induces ONECUT2-MAPK/ERK axis to facilitate CRC. Inhibiting TRMT61A with nanoparticle-encapsulated siTRMT61A or our recently identified small molecule compound PGG shows promising anti-CRC effects in vitro and in vivo. Together, our study reveals the promoting role of TRMT61A-induced m^1A modification in MAPK/ERK signaling and highlights the potential of targeting TRMT61A as a promising therapeutic approach in CRC treatment.

#4598 Discovery of novel MTA-cooperative PRMT5 inhibitors as targeted therapeutics for MTAP-deleted cancers.

A. Radzimierski, A. Bobowska, A. Stachowicz, K. Kuś, K. Kozłowska-Tomczyk, A. Ludwig-Słomczyńska, P. Podkalicka-Gołda, A. Gołas, M. Żukowska, P. Lebed, P. Wyrębek, D. Szukiel, M. Stefaniak, O. Popika, J. Krzywik, S. Sasmal, P. Niedziejko-Ćwiertnia, K. Korta-Piątek, K. Fijołkowska, A. Więckowska, M. Olszak-Płachta, S. Nipunge, M. Świrski, M. Wronowski, H. Pawlik, Q. Vũ, K. Łagosz-Ćwik, M. Ryvu Therapeutics, Krakow, Poland

Homozygous deletions of the p16/CDKN2a (cyclin dependent kinase inhibitor 2A) locus, which is responsible for regulating the cell cycle, are commonly found in cancer and often involve the deletion of adjacent genes. One such adjacent gene is methylthioadenosine phosphorylase (MTAP), involved in metabolism, located on chromosome 9p21 in close proximity to the p16/CDKN2A tumor-suppressor locus. Co-deletion of MTAP is observed in approximately 80-90% of tumors with homozygous deletion of CDKN2A, representing 10-15% of all human tumors. These tumor types, including non-small cell lung cancer, pancreatic adenocarcinoma, glioblastoma, and mesothelioma, have a poor prognosis, highlighting the significant unmet medical need in this area.
Deletion of MTAP leads to a significant accumulation of methylthioadenosine (MTA) in cells. MTA, at high concentrations, selectively inhibits the PRMT5 methyltransferase enzyme, competing with the substrate S-adenosylmethionine (SAM) required for methylation reactions. As a result, the overall level of symmetric arginine dimethylation throughout the proteome is reduced. This heightened sensitivity to modulation of methylosome activity makes cells with MTAP deletion more susceptible to therapeutic targeting of PRMT5. Hence, selective targeting of PRMT5 in cancers with homozygous MTAP deletion represents a promising strategy for specifically eliminating cancer cells with this genetic alteration. Ryvu has developed MTA-cooperative PRMT5 inhibitors characterized by good drug-like physicochemical properties and inhibition of methyltransferase activity with IC50 values in the low nanomolar range. A structure-based lead optimization delivered compounds coming from two independent series with high selective potency in MTAP-deleted cell lines and DMPK profiles allowing an oral administration. The antitumor activities were compared in vitro and in vivo to MRTX1719 and AMG193 in MTAP null tumors such as HCT116 MTAP KO, DoHH-2 and Lu99. The correlation between compound exposure and on-target effect was confirmed in PK/PD and efficacy studies. Taken together, these studies confirm that MTA cooperative PRMT5 inhibitors exert strong synthetic lethal phenotype in MTAP deleted cancers and offer an exciting therapeutic opportunity for a large patient population.

#4599 A novel small molecule inhibitor targeting MYC oncogenic signaling as an enhancer of HDAC inhibitors for the treatment of high-risk medulloblastoma.

S. Ng, S. Gadde, Q. Wang, B. B. Cheung, G. M. Marshall;
Children's Cancer Institute Australia, Sydney, Australia

Background: Medulloblastoma (MB) is the most prevalent malignant childhood brain tumour. Although prognosis has improved over time, 95% of children with high-risk or relapsed MB eventually succumb to the disease. A key driver gene in high-risk MB is the c-*MYC* oncogene, for which there are currently no approved inhibitors. Histone deacetylases (HDACs) are transcriptional repressors that are dysregulated in many cancers, making them an attractive therapeutic target. Although several HDAC inhibitors have been FDA-approved for cancer treatment, they have been associated with high toxicity and limited efficacy as single agents. Therefore, simultaneously targeting c-*MYC* and HDACs may result in synergistic effects that could overcome drug resistance in high-risk MB.
Methods and Results: We previously reported a novel pyrido-benzimidazole analogue, SE486-11, which enhanced the therapeutic effect of HDAC inhibitors in MYCN-driven cancers. We recently developed analogues (UNSW-SC compounds) with more potent activity (IC_{50}: 0.017 to 3.70 μM). Here, we showed that these compounds significantly reduced cell viability and induced apoptosis in MB cells. MYC status was a key determinant of sensitivity of UNSW-SC compounds, with more than 3-fold higher cytotoxicity in high MYC compared to low MYC MB cells. The lead compound, UNSW-SC-22, was shown to reduce MYC protein expression and was found to be highly synergistic in enhancing the efficacy of HDAC inhibitors in MB cells. Most importantly, we demonstrated that UNSW-SC-22 was able to freely cross the blood brain barrier, reaching a concentration of 10.8 μM, with a half-life of 1.22 hours. UNSW-SC-22 directly bound to c-MYC and MYCN proteins at low micromolar equilibrium dissociation constant (KD) values which was demonstrated by surface plasmon resonance assay. In a MYCN-driven MB mouse model, we found that UNSW-SC-22 as a single agent at 90 mg/kg decreased tumor growth and prolonged survival. Through RNA-sequencing, we identified 512 differentially expressed genes after in vitro treatment with UNSW-SC-22. Importantly, GSEA analysis revealed MYC targets and cell cycle pathways as highly downregulated pathways, and upregulation in the p53 pathway. Several genes, such as MELK and USP1 were validated as down-stream targets of UNSW-SC-22. As UNSW-SC-22 is a first-in-class anticancer drug, which we are currently testing extensively in other MYC-driven MB mice models.
Conclusion: Collectively, our data strongly suggest that c-Myc and MYCN are the molecular targets of UNSW-SC compounds, and these compounds have strong potential to serve as specific targeted therapy to treat subgroup 3 and 4 of MB patients with c-Myc and MYCN overexpression and amplification.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanisms of Drug Resistance and Novel Combinations
Poster Session

#4603 Single-cell and spatial dissection of the effect of combined PD-L1 and TGFb blockade by bintrafusp alfa from the ICING window-of-opportunity trial in resectable locally advanced HNSCC patients.

C. Hoffmann[1], J.-T. Werle[2], J. Gal[3], P. Sirven[2], J. Klijanienko[2], J. Mesple[2], B. Demaille[2], W. Zeitouni[4], O. Choussy[2], G. Marret[2], N. Badois[2], A. Dubray-Vautrin[2], G. Dolivet[5], L. Geoffrois[5], M. Kamal[2], I. Bieche[2], L. Monard[6], C. Simon[6], C. Le Tourneau[2], H. Salmon[2];
[1]Owkin, Paris, France, [2]Institut Curie, Paris, France, [3]Centre Antoine Lacassagne, Nice, France, [4]Genosplice, Paris, France, [5]Institut de Cancerologie de Lorraine Alexis Vautrin, Vandouvre-les-Nancy, France, [6]Unicancer, Paris, France

Despite high tumor mutational burden, immune checkpoint blockade has shown limited efficacy in head and neck squamous cell carcinoma (HNSCC), highlighting the need for additional therapeutic targets. TGFb signaling has been associated with an immunosuppressive tumor microenvironment as well as a lack of response to anti-PD(L)1 therapy, which led to the development of combined therapeutic approaches. ICING is a prospective (NCT04428047) open label, multicenter, phase II, window-of-opportunity preoperative, single-agent trial. The primary objective was to evaluate the efficacy and biological activity of pre-operative combined PD-L1 and TGFb blockade by bintrafusp alfa in patients with untreated resectable stage III/IV locally advanced HNSCC and its effect on the tumor microenvironment (TME). Tumor samples were harvested at baseline prior to immunotherapy and at surgery after two doses (1200mg; D1 and D15) for pre- and post-treatment comparison. Treatment efficacy was assessed using the pathological response (PathR) with a 10% threshold for response as primary endpoint. Changes in the TME were determined by single-cell RNA sequencing (scRNAseq) and multiplexed imaging. Seven patients were included and six received the full treatment scheme (5 oral cavity and 2 oropharyngeal, all HPV-negative; median age = 61y, range 34y-74y). Four patients had a PathR exceeding 10%, including one with a major PathR above 50%. The TME pre-treatment of this major responder did not differ from the other samples, but this sample was set apart by the presence of proliferative, p16+, HPV-negative tumor cells with mildly higher genomic alterations whilst still classified as low tumor mutational burden. Regardless of treatment response, we report several changes in post-treatment samples: (i) the remodeling of the stromal architecture concomitant with a phenotypic shift in cancer-associated fibroblasts (CAF) with a reduction in activated LRRC15+ CAF and an increase in CD10+IL24+ CAF; (ii) a reduction of TGFb-induced genes in both stromal and cancer cells; (iii) a reduction in both conventional and regulatory CD4+ T cells; (iv) an increase in CD8+ T cell infiltration in previously excluded tumors; (v) an interferon gamma-mediated activation of monocytes, macrophages and dendritic cells expressing CXCL9 and CXCL10. Collectively, our study deciphers the effects of bintrafusp alfa both molecularly and spatially at unprecedented granularity, which is of major importance for the many combined PD(L)1 and TGFb blockade therapeutic approaches currently under clinical development.

#4604 Imipridones ONC201 and ONC212 exhibit anti-tumor activity in biliary tract cancers and synergy when combined with trametinib and olaparib *in vitro*.

G. Sun[1], A. J. Lannigan[1], J. Chan[1], M. Schwermann[1], V. V. Prabhu[2], L. Zhou[1], W. S. El-Deiry[1], A. G. Raufi[1];
[1]Brown University, Providence, RI, [2]Chimerix, Durham, NC

Background: Biliary tract cancers (BTCs) are an aggressive group of malignancies affecting 220,000 new individuals globally each year. Despite advances in immunotherapy and targeted therapies, 5-year survival remains at 2% for those with metastatic disease. Thus, new therapies are desperately needed. The novel imipridone class of antineoplastic agents show promising activity in preclinical pancreatic ductal adenocarcinoma models; however, have not been investigated in BTC. Dordaviprone (ONC201) is a dopamine receptor D2 and mitochondrial protease ClpP modulator that induces apoptosis in cancer cells through both upregulation of tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) and the integrated stress response. ONC212 is a second-generation imipridone that targets orphan GPCR 132 and ClpP, leading to reduced oxidative phosphorylation from ClpX suppression. We hypothesized that the ONC201 and ONC212 would demonstrate antitumor effects in BTCs, both alone, and in combination with MEK and PARP inhibition.
Methods: Two established BTC cell lines, RBE and HuCCT1, were used for these experiments. Sensitivity of RBE and HuCCT1 cells to ONC201, ONC212, MEK inhibition (trametinib), and PARP inhibition (olaparib) was assessed using CellTiter-Glo® luminescent cell viability assay. Each cell line was plated on 96-well plates and treated with ONC201 concentrations ranging from 0uM to 40uM for RBE and 0uM to 32uM for HuCCT1; ONC212 ranging from 0nM to 752nM for RBE and 0nM to 640nM for HuCCT1; trametinib ranging from 0nM to 24nM for RBE and 0nM to 16nM for HuCCT1; and olaparib ranging from 0uM to 256uM for RBE and 0uM to 124uM for HuCCT1. Results were analyzed after 72 hours of incubation. Synergy studies were conducted in both cell lines, combining each imipridone with either trametinib or olaparib, and SynergyFinder® was used to evaluate synergy. Western blotting was performed on lysates generated from treated cell lines.
Results: Both ONC201 and ONC212 demonstrated antineoplastic effects in two BTC cell lines. Half maximal inhibitory concentrations (IC50) of ONC201 in RBE and HuCCT1 cell lines were 2.5uM and 2.0uM, respectively. The IC50 of ONC212 in RBE and HuCCT1 was 47nM and 39nM, respectively, which was similar to IC50s demonstrated with cytotoxic chemotherapy (gemcitabine IC50 = 7.57nM (RBE) and 9.84nM (HuCCT1)). Both lines also demonstrated sensitivity to trametinib (IC50 = 5.9nM (RBE) and 3.7nM (HCCT1)), and to a lesser extent olaparib (IC50 = 64uM (RBE) and 31uM (HuCCT1)). Although synergy was noted with several combinations, this was most striking with the combination of ONC212 and either trametinib or olaparib. Further analysis of key signal transduction pathways, including MAPK and PI3K, as well as analysis of mechanisms of cell-death through apoptosis, autophagy, ferroptosis, and necroptosis is underway

#4605 AZD4573 in combination with CHOP increases combination benefit in preclinical peripheral T-cell lymphoma models.

D. S. Potter[1], I. Ott[1], J. Saeh[1], R. Olsson[2], S. Fawell[1], L. Drew[1], J. E. Roderick[1];

[1]AstraZeneca Oncology, Waltham, MA, [2]AstraZeneca Oncology, Gothenburg, Sweden

Peripheral T-cell Lymphoma (pTCL) makes up about 10% of non-Hodgkin's lymphoma in the United States. Patients with relapsed/refractory pTCL have limited treatment options and poor prognosis. Current standard of care for pTCL revolves around the chemotherapy regimens CHOP/E. Here we examine the efficacy of CDK9 inhibition for the treatment of pTCL. CDK9 regulates transcription through phosphorylation of RNA polymerase II. AZD4573 is a highly potent and selective CDK9 inhibitor; acute inhibition with AZD4573 downregulates short-lived proteins such as MCL-1, BFL-1, and c-MYC, which are often overexpressed in hematologic tumors. It has been shown that the expression pattern of the anti-apoptotic BCL-2 family members in pTCL cell line models closely resembled the expression patterns in pTCL patient samples (Koch *et al.* 2019). Expression of BCL-2 family members is highly heterogeneous in pTCL, with MCL-1 being the most universally expressed. Using MCL-1 inhibitor AZD5991, we showed statistically significant benefit in survival when combined with CHOP in MCL-1 dependent preclinical pTCL PDX models (Koch *et al.* 2019). In addition, we have previously reported the importance of the anti-apoptotic protein BFL-1 in cell survival in NHL, including a subset of pTCL (Boiko *et al* 2021). AZD4573 treatment showed a range of activity across the panel of 18 human pTCL cell lines, in a 6-hour caspase-3/7 activation assay. 14 of the cell lines were sensitive, with EC_{50} values less than 100 nM, and 13 reached a max caspase activation of over 40%. pTCL subtypes that responded to AZD4573 treatment included ALCL, NK-TCL, and PTCL-NOS and CTCL. Acute AZD4573 treatment resulted in decreased pSer2-RNAP2 and reduced protein levels of c-MYC and MCL-1. To determine what was driving the apoptotic phenotype, we used ribonucleoprotein (RNP) mediated CRISPR knock out (KO) of *MYC* and *MCL1* genes. While pTCL cell lines were dependent on c-MYC and MCL-1 for viability after KO, only MCL-1 KO impaired AZD4573 treatment, suggesting that efficacy is mediated through MCL-1 in ALCL pTCL cell lines assessed. To determine if combining AZD4573 with CHOP improved efficacy, we tested 5 pTCL cell lines in a 6x6 combination dosing matrix and measured viability after 24-72 hours using RealTime-Glo after 24hr exposure to CHOP with AZD4573 added for the last 6hrs. Adding AZD4573 to CHOP *in vitro* increased the efficacy in pTCL ALCL cell lines with MCL-1 dependency, but not in CTCL cell line with BCL-xL dependency and resistance to AZD4573. CHOP treatment *in vitro* resulted in a decrease in c-MYC levels but not MCL-1, suggesting that combination benefit may be driven through c-MYC. This data suggests that treatment with AZD4573 as a monotherapy or in combination with CHOP regimen would be an effective therapeutic strategy in pTCL.

#4606 Combinatorial effects of a sequence of trabectedin (T) and CD13-targeted tissue factor tTF-NGR on human vascular endothelial cells (HUVEC) and in soft tissue sarcoma (STS) models.

C. Brand, S. Pavelka, K. Hessling, H. Hintelmann, A. F. Berdel, S. Baumer, N. Baumer, G. Lenz, C. Schliemann, **W. E. Berdel**, C. Schwoppe;
University of Munster, Muenster, Germany

Trabectedin represents a standard treatment option for relapsed or refractory soft tissue sarcomas. CD13 is a neutral aminopeptidase expressed on remodeling and invasive endothelial cells such as in the tumor vasculature. CD13-targeted tissue factor (tTF-NGR) is a recombinant pro-coagulatory fusion protein which accumulates in the tumor vasculature leading to tumor vascular occlusion and ultimately to tumor infarction. Giving both compounds in sequence could trap trabectedin inside tumors and thus increase its efficacy. This *vice versa* can optimize the activity of tTF-NGR. To prepare a multicenter clinical trial of a combination of trabectedin and tTF-NGR in patients with advanced soft tissue sarcomas refractory to 1st line systemic therapy (TRABTRAP), preclinical experiments on the mechanism of action of this combination, its efficacy and pharmacokinetics (PK) were performed. We first tested the pro-apoptotic function of trabectedin on human vascular endothelial cells (HUVEC) and human HT1080 sarcoma cells *in vitro*. Trabectedin significantly ($p<.0001$) increased the presence of phosphatidylserine (PS) on the outer leaflet of the phospholipid bilayer of the cell membrane in a dose- and time-dependent manner. The resulting optimized phospholipid milieu significantly potentiated the pro-coagulatory efficacy of tTF-NGR within the factor X:factor VIIa:tTF-NGR:CD13 complex on the outer cell membrane when compared to cultures without trabectedin ($p<.05$). This effect was specifically dependent on the presence of PS as it could be abolished by masking PS via preincubation with annexin V, whereas corticosteroids had no effect on the pro-coagulatory response of HUVEC in the presence of tTF-NGR. In an *in vivo* HT1080 human sarcoma xenograft model in athymic mice, systemic combination treatment of trabectedin followed by tTF-NGR (n=11) inhibited tumor growth to a greater extent than either compound alone (trabectedin n=9, tTF-NGR n=9) and compared to a saline control (n=8). The terminal half-life of tTF-NGR infused intravenously over 1 hour, was 9 hours (phase I trial). To further characterize the duration of tTF-NGR presence upon binding to the endothelial cell surface molecule CD13, we performed flow cytometry and fluorescence labeling experiments with tTF-NGR and HUVEC *in vitro*. After coincubation with HUVEC, the cells rapidly internalized the tTF-NGR:CD13 complex into the cytoplasm of the cells (approx. 50% of the labeled tTF-NGR after 3 h at 37^{o}C), a process which exposed the protein to intracellular degradation. The multicenter TRABTRAP trial is actively recruiting patients (EudraCT 2020-005858-21).

#4607 Targeted nanoparticle delivery of irinotecan and Ewing sarcoma-specific siRNA is an effective combination therapy for Ewing sarcoma.

S. A. Mitra[1], J.-H. Parmentier[1], H.-G. Kang[1], T. J. Triche[2];
[1]Children's Hospital Los Angeles, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA

Background: Ewing sarcoma (ES) is an aggressive bone and soft tissue tumor affecting children and adolescents with an overall survival rate of 50%. Irinotecan (IR) is an effective chemotherapeutic agent but is associated with significant toxicity. Using an anti-CD99 targeted hybrid polymerized lipid nanoparticle containing IR, NV103, in pre-clinical mouse xenograft model of the disease, tumor ablation was achieved at 2mg/kg of IR versus 50mg/kg for free IR. All ES harbor a chromosomal translocation resulting in expression of a fusion EWS-FLI1 protein or equivalent. This chimeric gene is a transcriptional regulator that upregulates the FEZF1 and FEZF1-AS1 genes. Both EWS-FLI1 and FEZF1-AS1 genes are unique to ES and are not expressed in normal adult tissues. EWS-FLI1 promotes cell growth while the FEZF1-AS1 complex promotes tumor metastasis, a hallmark of ES. *In vitro* RNAi targeting of EF and FEZF1-AS1 results in tumor cell death. We hypothesized that combining EWS-FLI1 and/or FEZF1-AS1 targeted RNAi therapy with NV103 cytotoxic therapy would be more effective than any single modality therapy.
Methods: NV103 was provided by NanoValent Pharmaceuticals. siRNA containing lipid nanoparticles (LNP-siRNA) were generated using PreciGenome NanoGenerator. siRNA was quantified using the ribogreen assay. Nanoparticles were analyzed for size and particle numbers by NanoSight. siRNA was used to target the following genes- EWS-FLI1, FEZF1, FEZF1-AS1, or GFP. A673 cells expressing GFP were used for this *in vitro* study. Various doses of IR and siRNA were used in combination and cell growth/death was imaged live using Incucyte. ATP assay was used to confirm live cells and to determine minimum effective dose (MED) over 72 hours of treatment.
Results: LNP-siRNA, mean diameter 70nm and PDI<0.2, encapsulated 90% of the siRNA in solution. LNP are stable at 4°C for at least 4 weeks with minimal-to-no loss of activity. NV103 had a MED of 1μM. MED of various siRNA was 30 to 50nM. Combination of NV103 and LNP-siRNA reduced MED of IR to 250nM. One treatment dose of LNP-siRNA followed by NV103 treatment three days later maintained significant cell death over 10 days post treatment initiation. Control cells were 97% more confluent than NV103/ EWS-FLI1 siRNA treated ones, 85% more than NV103/ FEZF1 siRNA cells and 92% more than NV103/ FEZF1-AS1 treated cells. siRNA combinations of EWS-FLI1 and FEZF1 or FEZF1-AS1 along with NV103 added no further benefit.
Conclusion: Combination nanoparticle therapy of IR and ES-specific siRNA reduces IR MED by four-fold. LNP delivery of siRNA enables tumor-specific gene targeting. Most have no available small molecule therapy. Targeting ES cells with both a low dose (250nM) of IR and 30-50nM of siRNA against unique tumor biomarkers results in increased cell death with no IR toxicity. Further animal studies are required to determine the effectiveness of such therapy *in vivo*.

#4608 Combinations of Cdc-like kinase (CLK) inhibitors with targeted oncology agents or standard chemotherapy in patient-derived multi-cell type tumor spheroids.

T. S. Dexheimer[1], T. Silvers[1], **N. P. Coussens**[1], S. D. Gore[2], J. H. Doroshow[2], B. A. Teicher[2];
[1]Frederick National Laboratory for Cancer Research, Frederick, MD, [2]National Cancer Institute, Bethesda, MD

The alternative splicing of mRNA precursors allows one gene the capacity to yield multiple protein isoforms, each with distinct functions. Although this intricate process is subject to stringent regulation under normal physiological conditions, aberrant alternative splicing can generate atypical proteins and contribute to various diseases, including cancer. By activating splicing factors, Cdc-like kinases (CLKs) serve as pivotal regulators of alternative splicing and are considered promising therapeutic targets for various tumors. In this study, we investigated the activity of two CLK inhibitors, cirtuvivint (SM08502) and CC-671, in combination with precision oncology agents or conventional chemotherapeutics. Thirty highly characterized patient-derived cancer cell lines were selected from the National Cancer Institute's Patient-Derived Models Repository (https://pdmr.cancer.gov/models/database.htm). The cell lines were derived from a range of cancer types including head and neck, bladder, pancreas, endometrial, colon, and melanoma, and contained clinically relevant variants of KRAS (G12C, G12D). Multi-cell type tumor spheroids were grown from a ratio of 6:2.5:1.5 malignant cells, endothelial cells, and mesenchymal stem cells, respectively. Following three days of growth, the spheroids were treated with single agents or combinations at concentrations up to their clinical C_{max} value, if reported. After seven days of continuous drug exposure, cell viability was assessed using the CellTiter-Glo 3D assay. As a single agent, cirtuvivint showed concentration-dependent activity in all spheroid types with 1 – 3 logs of cytotoxicity, whereas CC-671 did not show activity in all spheroid types and achieved no more than 1 log of cytotoxicity. Among the standard chemotherapeutic drugs, doxorubicin and SN-38 demonstrated additive and greater-than-additive cytotoxicity in various spheroid types when combined with either CLK inhibitor. Several of the targeted oncology drugs exhibited noteworthy additive and greater-than-additive cytotoxicity when combined with a CLK inhibitor. These agents included the XPO1 inhibitor, eltanexor, the MCL-1 inhibitor, tapotoclax, the α-isoform-specific PI3K inhibitor, inavolisib, and the pan-PI3K inhibitor, copanlisib. Notably, combinations of the CLK inhibitors with the KRAS G12D variant-specific inhibitor, MRTX-1133, showed selective activity against all tumor cell lines harboring this genetic variant. Interestingly, a strong antagonistic interaction between paclitaxel and CC-671 was observed in all thirty spheroid types, while no such interaction was observed with cirtuvivint. This project was funded in part with federal funds from the NCI, NIH, under contract no. HHSN261201500003I.

#4609 Plixorafenib (plixo) synergizes with MEK inhibitors (MEKi) in MAPK pathway inhibition in BRAF V600 and non V600 alterations, with higher potency compared to early generation BRAFi and pan-RAFi.

G. Tarcic[1], L. Cohen[1], **S. P. Shepherd**[2], N. Filippov Levy[1], H. Billauer[1], L. Birnbaum[1], S. Gasasa[1], R. Maor[1], R. Abu-Liel[1], E. Goldfarb[1]; [1]Fore Biotherapeutics Inc., Ness Ziona, Israel, [2]Fore Biotherapeutics Inc., Philadelphia, PA

The efficacy of BRAFi in V600 mutated tumors is established and requires effective inhibition of the MAPK pathway. However, the use approved BRAFi leads to paradoxical MAPK pathway activation associated with toxicities and to acquired resistance. Therefore, these inhibitors were combined with MEKi to mitigate toxicities, which has been shown to be more effective than monotherapy in some settings. Although effective, these combinations result in bothersome side effects, a high discontinuation rate, and risk of secondary malignancies, indicating a continued unmet need. Also, ~35% of all BRAF mutations occur outside the V600 codon, composed of a wide array of missense mutations, fusions, and in-frame deletions, which are not targeted by the earlier generation BRAFi. By design, plixo (FORE8394; PLX8394), a clinical stage BRAFi, binds the monomeric form of BRAF and inhibits its dimerization, while sparing the WT form, avoiding paradoxical MAPK pathway activation. We hypothesized that the combination of plixo with a MEKi will improve its efficacy and potency through maximal suppression of the MAPK pathway. Using ForeSight assay, a unique platform for testing MAPK signaling, we tested the efficacy of plixo and 4 MEKi (trametinib, cobimetinib, binimetinib and mirdametinib) across a cohort 18 BRAF alterations (V600E, 2 class II and 15 fusions) as single agents and in combinations. The combinations of plixo with the different MEKi were synergistic across all BRAF alterations tested. Furthermore, we compared the potency of a combination of plixo with binimetinib (bini) to that of another BRAFi (vemurafenib) or pan-RAFi's (tovorafenib and lifirafenib) with bini in 2 class I, 3 class II and 7 BRAF fusions using the foresight assay. The IC:50 of BRAF V600E expressing cells treated with plixo + bini was 6nM compared with 57nM, 103nM and 190nM for the tovorafenib, vemurafenib, and lifirafenib combinations with bini respectively. A similar trend was shown in 9 of 11 additional alterations tested, indicating the potency of the combination of plixo + bini. Results were validated using western blot analysis and cell viability assays of both melanoma and CRC V600E mutated cell lines. Western blot correlated with ForeSight results both in single agents and combination treatment. Cells treated with plixo + bini showed complete growth inhibition while the same drug concentrations of vemurafenib + bini and tovorafenib + binimetinib showed no growth inhibition beyond the effect of bini single agent. These results indicate the improved efficacy of plixo + bini combination in inhibiting MAPK signaling and cancer cell proliferation. Overall results support that maximal suppression of the MAPK pathway with plixo is more potent in combination with a MEK inhibitor in BRAF V600 and non-V600 nonclinical models compared to BRAF or pan-RAF combinations.

#4610 Dual inhibition of CDK4/6 and IL-6 pathways as a novel therapeutic approach for triple-negative breast cancer cells.

K. Caroland[1], C. Shi[1], H.-W. Lo[2], J. Lin[1];

[1]University of Maryland, Baltimore, Baltimore, MD, [2]Department of Neurosurgery and the University of Texas McGovern Medical School at Houston, Houston, TX

Triplenegative breast cancer (TNBC) is highly aggressive and associated with poor clinical outcomes. TNBC stands as a major cause of death among breast cancer patients and offers only a few therapeutic options. Abemaciclib, a cyclin dependent kinase 4/6 (CDK4/6) inhibitor, has received FDA approval for use in hormone receptor-positive, HER2-negative, and metastatic breast cancers. However, acquired resistance to CDK4/6 inhibitors in treating TNBC is becoming an increasing concern. Our recent results indicated that CDK4/6 inhibitors can induce IL-6 levels in TNBC cells as a potential resistance mechanism by augment IL-6 signaling axis, and that targeting IL-6 signaling can sensitize TNBC cells to CDK4/6 inhibitor therapy. In this study, combination of Abemaciclib with an IL-6/GP130 inhibitor (bazedoxifene) was tested in TNBC cells. We examined the effect of the combination on cell viability, cell migration, and invasion of human and mouse TNBC cell lines. Our data demonstrated that the bazedoxifene and abemaciclib combination treatment synergistically inhibited TNBC cell viability, cell migration, and invasion *in vitro*. These results support dual inhibition of CDK4/6 and IL-6 as a novel therapeutic approach for TNBC.

#4611 The co-targeting of PLK1 and FoxM1 contributes to synergistic antitumor effects in PTC.

P. Poyil, A. K. Siraj, D. Padmaja, S. K. Parvathareddy, S. Thangavel, S. Al-Sobhi, F. Al-Dayel, K. S. Al-Kuraya;
King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia

Polo-like Kinase 1 (PLK1) plays a key role in cell proliferation with vital regulatory functions in mitosis and cell survival. We investigated the expression of PLK1 protein in a large cohort of PTC patient's samples and explored its functional role in PTC cell lines *in vitro* and *in vivo*. PLK1 overexpression was observed in 54% of all PTC and was significantly associated with aggressive clinico-pathological parameter and it was found to be independent prognostic marker for recurrence-free survival. PLK1 inhibition indeed inhibited cell proliferation and induced cell cycle arrest and apoptosis in PTC cell lines. Importantly, silencing of PLK1 decreases the self-renewal ability of spheroids generated from PTC cells. Immunoprecipitation analysis shows that PLK1 binds to FoxM1 and vice versa *in vitro*. Mechanistically, PLK1 knockdown suppresses FoxM1 expression, whereas inhibition of FoxM1 does not affect PLK1 expression, which suggests that PLK1 acts through the FoxM1 pathway. The combined inhibition of PLK1 with volasertib and FoxM1 with thiostrepton synergistically attenuated PTC cell growth *in vitro* and *in vivo*. Our findings suggest that co-targeting of PLK1 and FoxM1 could be a viable therapeutic strategy for treating patients with an aggressive subtype of PTC.

#4612 Inhibition of BCL2 and XPO1 demonstrates synergistic effects in triple-negative breast cancer cell lines.

M. M. Jackson, S. G. Smoots, A. T. A. Dominguez, E. Dus, S. Bagby, C. Binns, T. M. Pitts, J. R. Diamond;
University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer, accounting for about 15-20% of all breast cancers. Characterized by a lack of estrogen and progesterone receptors and non-amplified HER2, treatment options are limited compared to other breast cancer subtypes. The aim of this study was to evaluate eltanexor (Elta), an XPO1 inhibitor, in combination with venetoclax (Ven), a Bcl-2 inhibitor to promote apoptosis in TNBC models.

Methods: CellTiter-Glo Cell Viability Assay was utilized to determine cell viability in 6 TNBC cell lines after 72-hour exposure to no drug, Elta, Ven or the combination. Synergy scores were determined using the Bliss model in SynergyFinder+, scores 10 or above indicating synergy. Apoptosis (by Annexin V) was assessed after 24- and 48-hour exposure to drug via flow cytometry. Immunoblots were used to assess the mechanism of action in cell lines treated for 24 hours.

Results: CellTiter Glo displayed greater anti-proliferative activity in combination versus single agent exposure. Synergy was observed in CAL-120, BT-20, and MDA-MB-468 cell lines, with synergy score values ranging from -13.22 - 25.07. Additive effects were observed in other cell lines. An increase in apoptosis was observed in CAL-51 and MDA-MB-231 cells after 24- and 48-hour treatment that was greater with the combination. CAL-51 cells exposed to single agent Ven or Elta [0.5 µM] for 24 hours had significantly less apoptosis than those exposed to the combo ($p = <0.0001$). After a 48-hour exposure, CAL-51 cells exposed to single agent Ven had less apoptosis than in combination with Elta [0.1 µM] ($p = 0.0431$) or Elta [0.5 µM] ($p = 0.0036$ µM]. Additionally, single agent Elta [0.5 µM] resulted in less apoptosis than the combination ($p = 0.0067$). Similar results were observed in MDA-MB-231 cells. We observed an increase in apoptotic markers with the combination in all cell lines treated. In all cell lines, DNA-damage marker pH2Ax increased with Ven and the combination. In the CAL-51 cells, p53 increased following Elta or combination exposure. In the MDA-MB-231 cells, a decrease in the anti-apoptotic protein MCL1 was observed with Elta or combination.

Conclusion: The combination of Elta and Ven resulted in increased apoptosis and antiproliferative activity in TNBC cell lines. Combined, the two drugs synergistically functioned to increase DNA damage and promote apoptotic cell death. This work supports the continued evaluation of Elta and Ven in TNBC.

#4613 Tumor-derived interleukin 35 facilitates the gemcitabine resistance in pancreatic adenocarcinoma by mediating the dissemination of chemoresistance among PDAC cells.

C. Huang, H. Sun, A. Chang, J. Hao;
Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Rapid drug resistance after chemotherapy is a key cause of treatment failure in human pancreatic ductal adenocarcinoma (PDAC). Here, we found that tumor-derived interleukin 35 (IL-35) mediated the rapid resistance of PDAC to gemcitabine (GEM). The role of IL-35 in GEM resistance was determined by molecular and cell biology approaches in PDAC cells and in patient-derived tumor xenograft (PDX) models. We used whole genome RNA sequencing, molecular cloning and other molecular biological methods to study the molecular mechanism of IL-35 mediated GEM resistance. An anti-IL-35 neutralizing antibody was used in mouse models to investigate the feasibility of targeting IL-35 to overcome drug resistance in pancreatic cancer. We observed the phenomenon that GEM resistance could spread from GEM resistant PDAC cells to GEM sensitive ones. The results of sequencing and experiments confirmed that the IL-35 secretion is responsible for the dissemination of chemoresistance. IL-35 secreted from GEM resistant cells activated the IL35 expression in GEM sensitive cells and upregulated SOD2 expression via GP130-STAT1 signaling, which scavenges reactive oxygen species (ROS) and then leads to GEM resistance.Furthermore, we found that a neutralizing antibody against IL-35 significantly enhanced the tumor suppressive effect of GEM. These findings collectively reveal that IL-35 plays crucial roles in mediating GEM resistance in pancreatic cancer. Moreover, IL-35 might serve as a promising therapeutic target for combating PDAC chemoresistance.

#4614 Inhibition of NEK2 promotes chemosensitivity and reduces primary effusion lymphoma burden.

M. C. White, J. P. Wong, B. Damania;
UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC

Non-Hodgkin lymphoma (NHL) is a common cancer in both men and women, and represents a significant cancer burden worldwide. Primary effusion lymphoma (PEL) is a subtype of NHL infected with Kaposi sarcoma-associated herpesvirus (KSHV). PEL is an aggressive and lethal cancer with no current standard of care, owing largely to its propensity to develop resistance to current chemotherapeutic regimens. Here, we report a reliance of PEL on the mitotic kinase, NEK2, for survival. Genetic and pharmacologic targeting of NEK2 resulted in caspase 3-mediated apoptotic cell death of PEL. Furthermore, inhibition of NEK2 significantly prolonged survival and reduced tumor burden in a PEL mouse model. We also report that the ABC transporter proteins, MDR1 and MRP, are most active in PEL and that NEK2 inhibition of PEL reduced the expression and activity of these ABC transporter proteins, which are known to mediate drug resistance in cancer. Additionally, NEK2 inhibition sensitized both viral and non-viral NHL to other chemotherapeutic agents such as rapamycin, resulting in enhanced cancer cell death. Overall, these data offer insight into the mechanisms underlying PEL survival and drug resistance, and suggest that NEK2 is a viable therapeutic target for PEL.

#4615 HC-7366, a potent GCN2 activator, complements belzutifan, a HIF-2α antagonist, by providing combination benefit in belzutifan-sensitive models and monotherapy activity in belzutifan-resistant models.

M. E. Stokes, F. Tameire, P. Wojnarowicz, S. Fujisawa, **C. Dudgeon**, S. Huang, N. Collette, B. Harrison, A. LaCayo, X. Qiu, T. Kangas, W. Zhang, J. Drees, D. Surguladze, E. S. Lightcap, N. Bose;
HiberCell, Roseville, MN

Recent approval of the HIF-2α antagonist belzutifan (Welireg) for patients with *VHL* disease has enabled the clinical opportunity to target the HIF-2 axis in cancer. This is particularly important for patients with clear cell renal cell carcinoma (ccRCC), in which 90% of tumors are *VHL* deficient, and approximately one in four primary tumors express HIF-2α exclusively. Clinical studies to date suggest an overall response rate (ORR) of 20-25% for belzutifan monotherapy, highlighting the need for a rational combination strategy to improve patient outcomes. This has led to multiple clinical trials testing belzutifan in combination with diverse therapeutic agents, including immune-checkpoint inhibitors, VEGFR-TKIs, and CDK4/6 inhibitors.

HiberCell is developing a first-in-class GCN2 activator currently undergoing Ph1 clinical evaluation in patients with solid tumors (NCT05121948). GCN2 activation by HC-7366 drives the Integrated Stress Response (ISR), resulting in translation inhibition and delayed cell cycle progression in cancer cells. In preclinical studies, HC-7366 demonstrated significant antitumor activity associated with HIF suppression across diverse tumor models, including ccRCC (70% TGI), head and neck (33% regression), sarcoma (84% TGI) and prostate (100% TGI). Analysis of tumor samples revealed that HC-7366 inhibited both HIF-1α and HIF-2α, as well as multiple cell cycle regulators. Given the mechanistic link between HIF-2 and cell cycle regulation, and the noted combination benefit reported when CDK inhibitors are combined with belzutifan, we hypothesized that HC-7366 would enhance the antitumor effects of belzutifan in RCC.

Combination studies in HIF-2 dependent 786-O and A-498 RCC xenografts demonstrated that HC-7366 improved the antitumor effects of belzutifan at clinically relevant doses. The combination of HC-7366 and belzutifan in A-498 drove robust tumor inhibition (~90% TGI). In 786-O, HC-7366 increased the number of complete responses from 2 of 8 tumors in the belzutifan-treated animals to 6 of 8 in the combination group. When tested in two belzutifan-resistant PDX models, HC-7366 resulted in significant monotherapy activity, achieving 17% regression as a maximal response, and inhibiting both HIF and cell cycle markers.

Belzutifan is currently being tested in indications beyond RCC, so we evaluated the combination in *VHL*wt endometrial cancer model, MFE-280. Consistent with RCC models, the combination of HC-7366 and belzutifan resulted in tumor stasis with activation of ISR, enhanced inhibition of HIF and cell cycle markers in the combination vs belzutifan monotherapy.

Together, these findings suggest that HC-7366 enhances belzutifan activity and serves as a rationale supporting clinical evaluation of this therapeutic combination.

#4616 TBK1 and GSK3 mediated TRAF2 phosphorylation confers resistance to PI3K-AKT inhibition in breast cancer cells.

H. Habelhah, L. Zhang;
University of Iowa, Iowa City, IA

Breast cancer (BC) is the most frequently diagnosed malignancy and the second leading cause of cancer mortality in Western women. As is the case for most other solid tumors, metastasis and drug resistance are the main causes of death. In ~80% of BC cases, the PI3K-AKT pathway is aberrantly activated, due to the alterations in genes encoding the pathway components, such as Ras, Her2, PTEN, PIK3C and AKT. Consequently, over 100 clinical trials are currently underway worldwide to evaluate the therapeutic efficacy of PI3K and AKT inhibitors in BC; however, initial data revealed that inhibition of this pathway is either not effective or often results in development of resistance and relapse of the disease. Thus, identification of additional targets and therapeutic combinations are urgently needed. We previously reported that TBK1-mediated TRAF2 Ser-11 phosphorylation enhances NF-κB activation to promote cancer cell survival under conditions of cellular stresses. Recently, we discovered that GSK3β directly phosphorylates TRAF2 at Thr-7 upon Ser-11 phosphorylation by TBK1, and that phosphorylation of both Thr-7 and Ser-11 is essential for sustained NF-κB activation and BC cell resistance to PI3K-AKT inhibition. TBK1 and its close homologue IKKε are overexpressed in ~70% of BC and play critical roles in BC cell survival. GSK3β is a constitutively active kinase activity in unstimulated normal cells, but its activity is suppressed in most cancer cell types by AKT-mediated phosphorylation. These published reports and our new findings suggest that inhibition of AKT in BC cells leads to increased phosphorylation of TRAF2 by TBK1 and GSK3β, which confers resistance to PI3K-ATK inhibition. Bioinformatic analyses revealed that TRAF2 and GSK3β are also overexpressed in invasive BC, and significantly correlate with poor prognosis. As expected, inhibition of both AKT and TBK1 or GSK3b synergistically induced apoptosis in BC cell lines *in vitro* and significantly suppressed xenograft BC tumor growth *in vivo*. Thus, our data suggest that further investigation of the efficacies of combined PI3K/AKT and TBK1/GSK3β inhibition in PDX models of BC has the potential to develop new strategies for BC treatment.

#4617 Fisetin, a multi-kinase inhibitor enhances chemotherapeutic sensitivity in head and neck cancer.

D. Tailor[1], D. Mishra[2], S. V. Malhotra[1], **R. P. Singh**[2];

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Jawaharlal Nehru University, New Delhi, India

Background: The limitations of chemotherapeutic applications are often imposed by dose-related toxicity and the emergence of therapeutic resistance. Fisetin, a naturally occurring flavonoid, has demonstrated anticancer properties in various cancer types. Despite its proven effectiveness against cancer, the molecular target of fisetin remains unknown.

Methods: Our study focused on understanding how fisetin and chemotherapy work together to inhibit the growth and survival of human HNC. We conducted *in silico, in vitro* and *in vivo* investigations. We employed target prediction, kinase profiling, transcriptome analysis and tumor xenograft to identify the chemosensitivity efficacy and mechanism of fisetin.

Results: *In-silico* target prediction suggested that fisetin might target multiple kinases. Based on this lead, we have screened fisetin for different kinase inhibition activities and found that it inhibits multiple CDKs including CDK1, 2, 4, 5 and 6 at nanomolar concentration. To test its cellular activity, we have selected the head and neck cancer (HNC) model and found that fisetin treatment strongly inhibited cell proliferation and arrested the HNC cells in G1 phase followed by apoptotic cell death. In tumor xenograft experiment, we found that oral fisetin treatment inhibited the FaDu and SAS tumor growth in the athymic mouse model. Transcriptome analysis on FaDu and SAS cell lines indicated that fisetin treatment significantly modulates pathways associated with cell cycle progression and regulation. These pathways include cellular assembly, DNA replication, cell death, and cell morphology. Pretreatment of HNC cells with fisetin improved the effectiveness of chemotherapy drugs including cisplatin, 5-fluorouracil, and docetaxel. Consistent with this, fisetin pre-treated cells showed elevated levels of cellular and mitochondrial ROS followed by the activation of caspases and apoptosis induction when compared with that in control cells after cisplatin, 5-FU, or docetaxel treatment.

Conclusion: These results imply that fisetin has the potential to be utilized as a multi-kinase inhibitor in cancer cells. The study revealed that fisetin has a strong potential for increasing the sensitivity of cancer cells to chemotherapy.

#4618 PIM kinases drive cell adhesion mediated drug resistance in prostate cancer.

C. Flores, S. Chauhan, C. Miranti, A. Cress, G. Rogers, N. Warfel;
University of Arizona, Tucson, AZ

Introduction: Castration-resistant prostate cancer (CRPC) is an incurable and lethal progression of the disease that does not respond to any treatment options. Cell adhesion to the extracellular matrix (ECM) activates survival pathways, allowing cancer cells to evade anti-cancer therapy, a phenomenon known as cell adhesion-mediated drug resistance. Bone, which is the primary site of prostate cancer metastasis, is known to be enriched in laminin, a ubiquitous ECM protein. In addition, laminin binding integrins, α6β1 and α3β1, are the major integrins expressed in CRPC, suggesting that laminin-dependent adhesion provides a survival advantage. Based on these findings, activation of the laminin-binding integrin, α6β1, is an intriguing factor mediating resistance to therapy in CRPC. PIM1 is an oncogenic Ser/Thr kinase that is elevated in CRPC and is known to promote resistance to therapy. In contrast, to many pro-survival kinases, PIM kinases do not possess any obvious regulatory domains. Current evidence suggests that PIM1 is constitutively active when it is expressed, so PIM1 expression level directly correlates with its catalytic activity. Despite this fact, little is known about the internal and external mechanisms that dictate PIM1 protein levels and spatial activation in cancer cells. Here, we identify PIM1 as a key survival signal that contributes to cell adhesion-mediated drug resistance.
Experimental procedures: Supporting the importance of this signaling axis in human tumors, multiplex IHC of a TMA containing prostate adenocarcinoma and CRPC bone metastases to show that integrin α6 and PIM1 are coexpressed and spatially correlated in primary and metastatic prostate cancer. To examine the spatiotemporal dynamics of PIM1 during cell adhesion, We developed a kinase activity reporter (PIMKAR) to monitor PIM catalytic activity in live cells. Because we observed PIM was highly localized to the membrane in patient tumors, we tagged PIMKAR with a myristylation sequence to specifically measure PIM activity at the membrane vs cytosol. Immunofluorescence and biochemical techniques were used to demonstrate the effect of PIM1 on mitophagy and oxidative stress.
Conclusions: We demonstrate that activation of integrin α6β1 downstream of cell adhesion stabilizes PIM1 by blocking its proteasomal degradation. The resulting upregulation of PIM1 serves to reduce oxidative stress through complementary mechanisms reducing mitochondrial fragmentation and increasing the removal of damaged mitochondria by increasing mitophagy. Mechanistically, PIM1 upregulates BNIP3 to enhance mitophagy and thereby reduce oxidative stress in the cell. Together, these results expand our understanding of the mechanisms regulating PIM1 activation and provide evidence for the use of PIM inhibitors in bone mCRPC and other cancers where laminin is a major component of the ECM

#4619 Prolonged inhibition of androgen receptor signaling induces expression of Nuclear ErbB3 which renders prostate cancer cells susceptible to targeted inhibitors.

M. K. Jathal, M. M. Mudryj, P. M. Ghosh;
UC Davis, Sacramento, CA

Objective: Nuclear expression of the receptor tyrosine kinase (RTK) ErbB3/HER3 increases in highly aggressive prostate cancer cells, but its nuclear transport mechanism is currently unknown. Prostate tumors rely on the androgen receptor (AR), whose activation transcriptionally controls ErbB3 expression, but its role in ErbB3 nuclear localization had not previously been reported. Here, we investigated the mechanism by which subcellular localization of ErbB3 was altered in prostate cancer.

Methods: ErbB3 localization was investigated in the human prostate cancer tumor progression model LNCaP, C4, C4-2 and C4-2B. ErbB3 was stimulated with heregulin-1β (HRG). Nuclear translocation was tested with a nucleocytoplasmic transport inhibitor panel (chlorpromazine, filipin III, amiloride and Leptomycin B) LNCaP and C4 cells were continuously cultured with the AR activation inhibitor abiraterone acetate (AbiAc) or ethanol (VEH) or treated with the AR inhibitors enzalutamide, darolutamide and apalutamide. ErbB3 activity and subcellular localization were analyzed using confocal microscopy/subcellular fractionation/immunoblot. Cell viability was determined by MTT assay. Proliferation and apoptosis were determined by flow cytometry. Invasive potential was investigated by crystal violet staining of cell colonies. ErbB3 expression was reduced by siRNA technology.

Results: The ratio of nuclear to cytoplasmic ErbB3 increased in untreated cells from LNCaP<C4-2<C4<C4-2B. In all four lines, nuclear localization of ErbB3 peaked at 30 minutes after HRG treatment, with a rapid return to the cytoplasm in LNCaP cells (at 1 hour), slower in C4 cells (at 4 hours), and continued accumulation in the nucleus in C4-2 and C4-2B 8 hours following HRG treatment. Treatment with the transport inhibitor panel showed that nuclear accumulation of ErbB3 was prevented by the clathrin-dependent endocytosis inhibitor Chlorpromazine (CPZ) but not by the others. In LN-VEH and C4-VEH cells, HRG induced nuclear translocation of ErbB3 but not in LN-AbiAc or C4-AbiAc cells. Accordingly, HRG increased ErbB3 phosphorylation at Y1328 and nuclear Akt phosphorylation at S473 in VEH but not AbiAc cells. C4 cells, which had high baseline nuclear ErbB3, were more sensitive to the AR inhibitors and showed decreased viability and invasive potential compared to LNCaP cells.

Conclusions: These results indicate that (1) ErbB3 nuclear localization required clathrin-dependent endocytosis (2) ligand binding of ErbB3 as well as the presence of an active AR is necessary for ErbB3 nuclear localization and (3) the presence of nuclear ErbB3 increases sensitivity to AR inhibitors.

#4620 Exploring the role of GHRH antagonist MIA-602 in overcoming doxorubicin resistance in acute myeloid leukemia.

S. I. Gaumond[1], J. Costoya, Jr.[1], A. V. Schally[2], J. J. Jimenez[1];

[1]University of Miami Miller School of Medicine, Miami, FL, [2]Veterans Affairs Medical Center, Miami, FL

Acute Myeloid Leukemia (AML) is characterized by the uncontrolled proliferation of immature hematopoietic progenitors, often associated with a poor prognosis. Conventional therapies involve chemotherapy and bone marrow stem cell transplantation. The growth hormone releasing hormone receptor (GHRH-R) antagonist MIA-602 has exhibited inhibitory effects on the growth of various human cancer cell lines, including AML cells. This study aimed to investigate the impact of MIA-602 alone and in combination with doxorubicin on three doxorubicin-resistant AML cell lines, K-562, U-937, and KG-1A. Initial examinations confirmed the presence of GHRH receptors in both wild-type and doxorubicin-resistant cell lines through western blot analysis. Doxorubicin was administered at concentrations of 0.005, 0.01, and 0.05 µg/ml, while MIA-602 was used at 5 µmol/L. Subsequent experiments involved culturing both wild-type and doxorubicin-resistant clones with MIA-602 at concentrations ranging from 0.05 µmol/L to 5 µmol/L for 24 and 48 hours. The results revealed a significant, dose- and time-dependent reduction in cell proliferation across all six cell lines. Both wild-type and doxorubicin-resistant clones exhibited a comparable decrease in cell proliferation when exposed to MIA-602 at concentrations greater than 0.05 µmol/L ($p < 0.05$) after 24 and 48 hours. In conclusion, our study demonstrates that these three AML cell lines and their doxorubicin-resistant clones remain susceptible to GHRH antagonist MIA-602. These findings may pave the way for the development of novel therapies or drug combinations using GHRH antagonists such as MIA-602 for treating AML. This is of particular interest for those who are resistant to conventional chemotherapy, further broadening the spectrum of treatment options available. Additional investigations are warranted to progress these findings to *in vivo* xenograft models.

#4621 Dual targeting as an effective therapeutic strategy for malignant brain tumors.

E. Y. Magnan, K. Gourishetti, S. Thomas, D. Bhere;
University of South Carolina, School of Medicine - Columbia, Columbia, SC

Glioblastoma, a type of brain cancer known for its aggressive nature and resistance to traditional treatments, remains a significant challenge for the medical community. Despite advances in surgical, radiation, and chemotherapy strategies, patients with glioblastoma typically have a poor prognosis, with a median survival time of only 15 months. While temporary symptom relief may be possible for some patients, complete tumor remission is often not achieved. Given the complexity of this disease, effective treatment options for glioblastoma are highly sought after. In this study, we have evaluated the effectiveness of a combinatorial approach using stem cell-derived exosomes enriched with miR-124 cargo paired with viral oncolysis for treating glioblastoma.

Human Umbilical Cord Stem cells (hUCs) are genetically modified with specific miR plasmids, and then cultivated in a specialized medium that has been depleted of exosomes. The exosomes (exo) that contain the target miR are subsequently extracted, purified, quantified, and characterized. These exosomes are then utilized for all subsequent investigations. Using a combination of cell viability assays and microscopy, the overall effect of the exo-miR-124 and oncolytic virus on both established and patient-derived primary GBM cells is analyzed. Additionally, a time course western blot analysis is conducted to comprehend the molecular mechanisms underlying the effects of the miR modification and viral oncolysis on cell proliferation and death pathways. Orthotopic animal models of GBM will be utilized to assess the effects of miR modulation and viral oncolysis *in vivo.*

Our research has shown that stem cell-derived exosomes are an effective way to deliver microRNA to specific cells, including tumor cells. This is because they can evade the immune system and target cells directly. Our experiments have shown that combining miR modulation paired with viral oncolysis as a promising approach for treating glioblastoma. Specifically, we have found that miR modulation and viral oncolysis can halt tumor cell proliferation in vitro by targeting multiple pathways involved in GBM growth and progression.

#4622 Anti-tumor activity of CDK2 inhibitor BLU-222 in combination with CDK4/6 inhibitors for overcoming resistance in HR positive and triple negative metastatic breast cancers models.

L. Luo[1], Y. Wang[1], T. Bui[1], M. Li[1], S. Kim[1], J. Navarro-Yepes[1], N. M. Kettner[1], D. Tripathy[1], K. K. Hunt[1], K. Faia[2], K. Keyomarsi[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Blueprint Medicines Corporation, Cambridge, MA

Background: Cyclin-dependent-kinase-4/6 inhibitors (CDK4/6is) plus endocrine therapy (ET) are standard of care first-line treatment for patients with hormone receptor (HR)-positive, HER2-negative metastatic breast cancer (mBC). However, the emergence of resistance to CDK4/6is plus ET presents a clinical challenge with few treatment alternatives. The effectiveness of CDK4/6is in patients with triple-negative (TN) breast cancer remains uncertain, although the potential synergy with other targeted therapies is currently under investigation. Our study demonstrates the enhanced and synergistic activity of BLU-222, a selective CDK2 inhibitor, when combined with CDK4/6is in preclinical models of both HR+/HER2- and TN breast cancer resistant to CDK4/6is. Methods: Palbociclib resistant (PR) HR+/HER2- (MCF7 and T47D) and TN (MDA-MB-231 and BT-20) breast cancer cell lines were generated by escalating palbociclib concentrations in culture. Using SynergyFinder, we assessed the effect of BLU-222 alone and in combination with palbociclib in the highest single-agent model in vitro. The effectiveness of BLU-222, alone or in combination with palbociclib, was further evaluated in four patient-derived xenograft (PDX) models from HR+/HER2- patients whose tumors progressed after palbociclib plus ET, two TN PDX models, and a TN breast cancer transgenic model driven by tumor-specific forms of cyclin E. Results: The PR HR+/HER2- and TN breast cancer cell lines, unresponsive to palbociclib, exhibited significantly increased sensitivity to BLU-222. The combination of BLU-222 and palbociclib in all four cell lines revealed a robust synergistic effect in PR cells, inducing enhanced apoptosis and cell cycle alterations in G1 or G2/M phases. Treatment with BLU-222 and palbociclib demonstrated substantial antitumor activity in all six PDX models and the cyclin E high TN transgenic models, surpassing the effects of individual treatments in each model. This combination led to lasting tumor regression and extended survival, even after treatment discontinuation. Mechanistically, treatment with BLU-222, alone or combined with palbociclib, induced the expression of p21 and/or p27 in all in vivo models, which we hypothesize sensitizes tumors to palbociclib. In vitro, the CRISPR knockout of p21 or p27 in MCF-7 PR cells abolished the synergistic activity of BLU-222 and palbociclib, confirming the crucial involvement of p21 and p27 in influencing the treatment's effectiveness. Conclusions: We found robust activity of the CDK2 inhibitor, BLU-222 when combined with CDK4/6is in resistant HR+/HER2- and TN breast cancer cell lines and in vivo models. These results support the potential clinical utility of BLU-222 in combination with CDK4/6is for the treatment of both subtypes of breast cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Molecular Classification of Tumors for Diagnostics, Prognostics, and Therapeutic Outcomes Poster Session

#4626 A kit targeting detection of *ESR1* mutations from circulating exosomal RNA and cell-free DNA supports longitudinal studies into endocrine therapy resistance in a broadly accessible RT-qPCR format.

J. T. Brown[1], J. R. Thibert[1], L. Chen[1], M. Church[1], H. Dale[1], J. Myers[1], E. Hallmark[1], M. Yociss[1], J. Sanchez[2], K. Franzen[2], J. Skog[2], G. Latham[1], B. Haynes[1], **S. Statt**[1];

[1]Asuragen, a Bio-Techne Brand, Austin, TX, [2]Exosome Diagnostics, a Bio-Techne Brand, Austin, TX

Introduction: The most prevalent subtype of breast cancer is HR+/HER2- (positive for hormone receptor, negative for human epidermal growth factor receptor 2). For metastatic breast cancer (mBC), a frequent occurrence is resistance to the aromatase inhibitors used in endocrine therapy (ET). Resistance is mediated through mutations in the ligand binding domain of estrogen receptor 1 (*ESR1*). Approval of elacestrant, a second-line agent for HR+/HER2-/*ESR1* mutated mBC , underscores the need for early detection of ESR1 resistance mutations. We have developed sensitive RT-qPCR reagents for targeted longitudinal studies into the emergence of *ESR1* resistance mutations in plasma. This all-inclusive kit analyzes circulating exosomal RNA (exoRNA) and cell-free DNA (cfDNA) to accurately identify low copy number mutations with a rapid turnaround time.

Methods: Challenge panels were constructed using blends of synthetic nucleic acids of known mutational status in a background of partially fragmented wild-type DNA from cell lines. Additionally, plasma samples collected from subjects with stage IV mBC (HR+/HER2-) on active aromatase inhibitor therapy, +/- CDK 4/6 inhibitor for a minimum of one year, were subjected to an in-house method optimized to co-enrich exoRNA and cfDNA. Multiplex RT-qPCR-based target enrichment performed on 11 *ESR1* mutations and an internal control were evaluated on widely used thermal cycler and qPCR instruments.

Results: We developed technology that interrogates 11 key *ESR1* mutations associated with ET resistance in HR+/HER2- mBC cases. Earlier studies performed in simplex analyzed plasmid-based *ESR1* mutations with detection of 10 or fewer mutant copies, estimating analytical sensitivity of at least 0.1% (5 mutant copies in a background of 5,000 WT copies). Herein, we describe the subsequent work to complete the methodology employed in the kit, including the incorporation of an endogenous control, external batch run control materials (positive, negative), deeply optimized reagents (RT, pre-amplification, qPCR), and automated analysis. We report on the results of studies into the kit's performance characteristics against their targets: analytical sensitivity of the equivalent of 5 copies of mutation per mL plasma, high precision across replicates at 0.1% allele fraction, analytical specificity of ≥90% negative results in mutation-negative replicates, as well as workflow attributes (reduced pipetting steps and turnaround time).

Conclusion: Our solution to detect *ESR1* resistance mutations facilitates the generation of nucleic acid sample to results within one day using liquid biopsy samples and a multiplexed RT-qPCR. Enhancing mutation detection sensitivity by complementing cfDNA with exoRNA will facilitate future research into breast cancer treatment options.

#4627 Metastatic renal cell carcinoma with occult primary: Clinical and biological evidence for a new entity of cancers of unknown primary that beneficiates from tissue-tailored treatment.

Nicolas Jacquin[1], Julien Masliah-Planchon[2], Guillaume Grisay[3], Ronan Flippot[3], Riwan Brillet[4], Celia Dupain[5], Maud Kamal[5], Isabelle Guillou[5], Nadege Gruel[1], Nicolas Servant[6], Pierre Gestraud[6], Jennifer Wong[7], Vincent Cockenpot[8], Andreia Goncalves[8], Janick Selves[9], Helene Blons[10], Etienne Rouleau[11], Oliver Delattre[1], Christophe Le Tourneau[5], Ivan Bieche[2], Yves Allory[8], Laurence Albiges[3], Sarah Watson[1]

[1]INSERM U830, Diversity and Plasticity of Childhood Tumors Lab, Institut Curie Hospital, Paris, France,[2]Department of Genetics, Institut Curie Hospital, Paris, France,[3]Department of Cancer Medicine, Institut Gustave Roussy, Villejuif, France,[4]Clinical Bioinformatic Unit, Department of Diagnostic and Theranostic Medecine, Institut Curie Hospital, Paris, France,[5]Department of Drug Development and Innovation, Institut Curie Hospital, Paris, France,[6]INSERM U900, CBIO-Centre for Computational Biology, Institut Curie Hospital, Paris, France,[7]Somatic Genetic Unit, Department of Genetics, Institut Curie Hospital, Paris, France,[8]Department of Pathology, Institut Curie Hospital, Paris, France,[9]Department of Pathology, University Hospital of Toulouse (IUCT), Toulouse, France,[10]Department of Biochemistry, Georges Pompidou European Hospital, Paris, France,[11]PRISM Center for Personalized medicine, Institut Gustave Roussy, Villejuif, France

Background: Cancers of unknown primary (CUP) is a heterogenous group of malignancies characterized by distant metastases in the absence of detectable primary. Specifics subgroups of CUP that share similarities with cancers of known primary beneficiate from tissue-tailored therapeutic strategies. The objective of this study was to characterize the clinical and biological presentation of a cohort of patients with suspected CUP of renal origin (rCUP) and to evaluate their optimal therapeutic management.

Methods: All Patients with rCUP identified prospectively between 2020 and 2023 within the French National Multidisciplinary Tumor Board for CUP were included. Centralized pathological review and immunohistochemical stainings were performed. Whole Exome Sequencing (WES), whole transcriptomic sequencing (RNAseq) and application of the deep-learning based algorithm TransCUPtomics for prediction of tissue of origin, and DNA methylation analysis were performed and compared to public renal cell carcinomas (RCC). Progression Free Survival (PFS) and Overall Survival (OS) were calculated using Kaplan-Meier estimates.

Results: 23 patients were included. The median age at diagnosis was 57 yo and 17/23 were male. The most common metastatic sites were the bones (N=17) and the lymph nodes (N=14). 19/23 patients presented with at least two distinct distant metastatic sites. Genomic analyses performed in 10 patients led to the identification of recurrent inactivating mutations in genes commonly altered in RCC, including NF2 (N=7), SETD2 (N=3), or VHL (N=1). 10/11 samples analyzed by RNAseq were predicted as RCC by the TransCUPtomics classifier based on their gene expression profiles. DNA methylation profiling performed in 7 samples showed major similarity with known RCC subtypes.Centralized pathological review and integration of molecular characteristics led to the final diagnoses of papillary RCC (N=2), clear cell RCC (N=7), renal medullary carcinoma (N=1), TFEB-amplified RCC (N=1) and unclassified RCC (N=12). 20/23 patients received at least one line of systemic treatment based on the renal origin, including anti-angiogenic TKI, anti-PD1/PDL1 antibody, anti-CTLA4 antibody or mTOR inhibitor. The median PFS under the first renal-oriented systemic treatment was 5 months and 10 patients remained progression-free for more than 6 months under tailored-treatment. The median OS was 31 months, and 11 patients are still alive in October 2023.

Conclusions: This study shows that rCUP represent a new entity within CUPs that shares major similarities with classical RCC despite the more frequent presentation of unfavorable prognostic factors. Prolonged survival can be observed with renal-tailored systemic treatment, supporting the individualization of these patients within CUP.

#4628 Validation of an automated, scalable comprehensive genomic profiling assay for hematologic malignancies.

Grant Hogg[1], Tong Liu[1], Helen Cao[1], Adib Shafi[1], Ashraf Shabaneh[1], Jon Williams[1], John Howitt[2], Amanda Williamson[2], Rachel Dango[2], Xiaojun Guan[1], Heidi Hoffmann[3], Michael Mooney[2], John Pruitt[2], Scott Parker[2], Henry Dong[4], Stan Letovsky[3], Li Cai[2], Eric A. Severson[2], Shakti H. Ramkissoon[2], Anjen Chenn[2], Marcia Eisenberg[5], Brian Caveney[5], Eyad Almasri[1], Taylor J. Jensen[1]

[1]Labcorp, San Diego, CA,[2]Labcorp, Durham, NC,[3]Labcorp, Westborough, MA,[4]Labcorp, New York, NY,[5]Labcorp, Burlington, NC

Optimal diagnosis, prognosis, and treatment selection for hematologic malignancies requires assessment of somatic mutations across a subset of clinically relevant genes. Here we present the analytical validation results of an expanded targeted next generation sequencing (NGS) panel of 141 clinically relevant genes for myeloid and lymphoid malignancies. Based on review of clinical guidelines, 141 genes including 79 myeloid and 84 lymphoid associated genes were selected. The expanded hematological panel interrogates all coding exons of the 141 genes to detect single nucleotide variants (SNVs) and insertions/deletions (indels). The panel also identifies copy number aberrations (CNAs) in 16 genes, *FLT3* internal tandem duplicates (ITDs), select non-coding pathogenic variants, and patient sex. The custom hybrid capture-based assay utilizes genomic libraries created from 250 ng gDNA extracted from peripheral blood, bone marrow, or cell suspensions, followed by sequencing on Illumina® instruments. Concordance studies were performed on clinical samples previously assessed using an orthogonal NGS-based laboratory developed test for SNVs/indels/*FLT3*-ITDs or digital multiplexed ligation-dependent probe amplification for CNAs. In total, 308 patient samples were evaluated and included 72 (23.4%) acute myeloid leukemia and 58 (18.8%) myelodysplastic syndromes samples among other indications, of which 240 (77.9%) were bone marrow specimens. Analysis of concordance demonstrated a positive percent agreement (PPA) of 99.7% for SNVs (750/752), 99.5% for indels <25bp (206/207), and 95.7% for indels ≥ 25bp (22/23). Variants were from 45 genes including *TP53*, *NPM1*, and *IDH1/2*. PPA was 100% for *FLT3*-ITDs (38/38; size range 18-300 bp) and sex (294/294). For CNAs, PPA was 96.4% (132/137) and negative percent agreement (NPA) was 98.3% (931/947). Assay precision was determined using three replicates of 15 clinical samples for both intra and inter-assay precision using multiple operators, instruments, and reagent lots. 100% concordance was observed for SNVs (36/36), indels (11/11), a 24 bp *FLT3*-ITD (1/1), CNAs (24/24), and sex (15/15). Analytical specificity was assessed using 5 replicates of NA12878 showing specificity >99.99% for SNVs/indels with variant allele frequency ≥ 3%, and >99.99% for CNAs with copy number ≤0.85 or ≥1.15. Dilution series to determine analytical sensitivity are in progress. This study highlights the analytical validation of the expanded NGS panel for the detection of clinically informative genomic alterations in hematologic malignancies. Results from this validation study, when complete, will include at least 576 samples plus orthogonal testing. These data describe the performance of the assay to enable a comprehensive evaluation of genomic alterations using a single sample, further facilitating the use of broad NGS assays in patients with hematologic malignancies.

#4629 QClamp™ Plex VEXAS syndrome UBA1 mutation detection assay: A noval XNA based assay to simultaneously detect eight UBA1 somatic mutations associated with VEXAS syndrome.

Y. Ma;
DiaCarta, Inc., Pleasanton, CA

VEXAS syndrome (acronym for Vacuoles, E1 enzyme, X-linked, Autoinflammatory, Somatic) is a monogenic disease discovered in December 2020. It is an adult-onset systemic inflammatory disorder genetically characterized by somatic mutation of the UBA1 gene which encodes the ubiquitin like modifier activating enzyme 1. VEXAS patients have overlapping rheumatologic and hematologic manifestations, including increased risk for myelodysplastic syndrome (MDS). It is critically important to diagnose VEXAS syndrome, but UBA1 mutation test is still not commercially available. The three most frequent mutations of UBA1 gene are p.M41T(122T>C), p.M41V (c.121A>G), and p.M41L (c.121A>C) in codon 41 of exon 3. Other mutations including splice site mutations at exon 3 (c.118-2A>C, c.118-1G>C and c.118- 9_118-2del), p.S56F (c.167C>T) in codon 56 of exon 3, and p.S621C (c.1861A>T) in codon 621 of exon 16 have been reported. Based on XNA technology, we developed a QClampTM Plex platform to detect all the eight mutations in a single reaction with Luminex system. XNA technology enriches mutant target sequence in a PCR reaction by using synthetic DNA analog XNA (xenonucleic acid) to block wild type DNA. With spiking synthetic mutant DNA in GM24385 cell line DNA, we determined that this assay can detect mutations with a detection limit of variant allele frequency (VAF) for M41T at 0.1%, M41V at 0.1%, M41L at 0.25%, c.118-2A>C at 1%, c.118-1G>C at 1%, c.118- 9_118-2del at 1%, S56F at 0.25% and S621C at 1%, respectively, and specificity of 100% for all mutations. We tested saved DNA samples extracted from whole blood previously collected from suspected VEXAS patients and tested at the National Cancer Institute by Sanger sequencing, including 13 positive and 20 negative samples. Our assay detected all corresponding UBA1 mutations in the 13 positive patient samples, and did not detect UBA1 mutation in 18 of the 20 negative patient samples. Two of the 20 negative samples were also tested positive for UBA1 M41T and M41L on our assay, respectively, due to its significantly higher sensitivity than the Sanger sequencing platform, which has a detection limit of 15-20% VAF.

#4630 Clinical and epidemiological profile of neuroendocrine differentiation- A hospital-based retrospective study.

Y. Wen, S. Shi;
Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Neuroendocrine differentiation (NED) in carcinomas is poorly studied globally, despite its distinct clinical features, disease progression, pathology, treatment outcomes, and poor prognosis. Therefore, it is imperative to conduct further analysis utilizing extensive clinical samples to unveil the clinical and epidemiological profile of NED.
Methods: A retrospective study was conducted to analyze the histopathological samples of patients diagnosed with malignant tumor using immunohistochemical techniques for NED markers, such as ChrA, Syno and CD56. The morbidity and prognosis of NED patient would be analyzed subsequently. Eligible patients must have pathologically confirmed gastric cancer, colorectal cancer, lung cancer, esophageal cancer and prostate cancer with no prior neoadjuvant chemotherapy or radiotherapy received before surgery. Patients aged 18-75 years with normal organ functions were enrolled.
Results: Between January 2017 and June 2018, over 450 cases were enrolled. Preliminary analysis focused on 36 esophageal cancer (EC) and 44 prostatic cancer (PC) samples. NED markers were expressed in 4 (11.1%) of 36 EC patients, including 4 cases positive for Syno, 1 case positive for ChrA, and 2 cases positive for CD56. Meanwhile, NED markers were expressed in 15 (34.1%) of 44 PC patients, including 10 cases positive for Syno, 15 cases positive for ChrA, and 2 cases positive for CD56.
Conclusion: Neuroendocrine differentiation is obviously observed in EC and PC. The encouraging prevalence rate of NED may have clinical implications for individualized treatment. Further research is needed to explore this area in more detail.

#4631 Evaluation of the impact of homozygous MTAP truncations on the activity and selectivity of MTA-cooperative PRMT5 inhibitors.

M. R. Tonini, A. A. Mignault, D. A. Whittington, S. A. Lombardo, B. Shen, H. Stowe, S. Yoda, S. Liu, M. Zhang, K. M. Cottrell, S. R. Meier, H. Rego, J. Morawiak, E. Hooper, Y. Yu, H. DiBenedetto, A. S. Crystal, T. Teng, **K. Briggs**;
Tango Therapeutics, Boston, MA

Homozygous deletion of the MTAP gene occurs in 10-15% of all human cancers. To benefit this large and diverse patient population, MTA-cooperative PRMT5 inhibitors, including TNG908 and TNG462, have been developed to leverage the synthetic lethal relationship between MTAP deletion and PRMT5 inhibition. MTA-cooperative PRMT5 inhibitors selectively bind the PRMT5-MTA complex driving selective inhibition of PRMT5 in MTAP-deleted cancers while sparing normal, MTAP-proficient cells. Our PRMT5 inhibitors are currently in Phase I/II clinical trials (NCT05275478 and NCT05732831), and eligibility is restricted to patients with tumors with confirmed MTAP loss either detected by next-generation sequencing (NGS) or immunohistochemistry.
MTAP gene loss occurs in cancers because of its chromosomal proximity to one of the most common genetically altered tumor suppressor genes, CDKN2A, but the chromosomal 9p breakpoints for the co-deletion are not uniform. Indeed, while clinical NGS testing and preclinical data confirm that homozygous intragenic MTAP breakpoints occur, the functional consequence of any given breakpoint on MTAP enzymatic activity and protein function remains unknown. Given the potential implications for homozygous intragenic MTAP deletions to impact the clinical response to MTA-cooperative PRMT5 inhibitors, we have started to evaluate the loss-of-function phenotype of various MTAP truncations to determine whether they retain MTAP activity. Here, we present our initial functional genomics analysis of this important diagnostic biomarker using in vitro cDNA reconstitution approaches for MTAP activity combined with analysis of PRMT5 inhibitor sensitivity. Ultimately, these data may help refine patient enrollment on clinical trials to drive the maximum benefit for patients with MTAP-deleted cancers.

#4632 Lineage plasticity as a determinant of antibody-drug conjugate target expression in urothelial bladder cancer.

J. Luo[1], S. P. Gao[1], F. Kuo[1], G. Gokturk Ozcan[1], M. Basar[1], F. Koll[1], J. E. Tallman[1], S. M. Alam[1], C. E. Chu[2], Z. Chen[1], E. J. Pietzak[1], G. Iyer[1], J. E. Rosenberg[1], D. B. Solit[1], H. Al-Ahmadie[1];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]University of California, San Francisco, San Francisco, CA

Bladder cancers display a wide spectrum of morphologies that frequently co-exist within individual tumors. Several histologic variants, including plasmacytoid, neuroendocrine, and micropapillary subtypes, are associated with an increased bladder cancer recurrence risk and cancer-specific mortality. The molecular basis and therapeutic implications of this phenotypical plasticity remain poorly understood. Enfortumab vedotin (EV), an antibody-drug conjugate targeting Nectin-4, has also emerged as a new standard-of-care for metastatic bladder cancer patients, but the association between lineage plasticity as manifested by morphologic heterogeneity in bladder cancer, Nectin-4 expression and ADC response remains poorly defined. Previous DNA-based molecular profiling studies of histologic variants revealed that *CDH1* mutations were the pathognomonic molecular alteration in plasmacytoid urothelial carcinoma, but no recurrent driver mutations have been found to be unique to the aberrant histology regions of other mixed histology subtypes. Thus, to explore the molecular basis for the lineage plasticity of bladder cancers with aberrant histology and to define the association between lineage plasticity manifested as morphologic heterogeneity and the expression of Nectin-4, HER2 and other potential ADC targets, we performed RNA-seq of pure urothelial carcinomas (n=118, not otherwise specified, UC-NOS) and bladder tumors with divergent differentiation or histologic subtypes (n=199). Our cohort included a subset of tumors in which RNA-seq was performed on microdissected UC-NOS and variant histology regions of the same tumor. Tumors with neuroendocrine, sarcomatoid and squamous histology had the lowest Nectin-4 expression, whereas histologic subtypes that retained a luminal transcriptional profile such as micropapillary, plasmacytoid and nested histology had higher levels of Nectin-4 expression. In mixed histology tumors, Nectin-4 and/or HER2 expression was often restricted to only one of the two histologic components. Gene Set Enrichment Analysis noted enrichment of distinct oncogenic pathway gene sets in different histologic variants. Preliminary investigation into the mechanism(s) of Nectin-4 regulation using bladder cancer cell lines and patient-derived organoids (PDOs) has identified targetable pathways which when inhibited revert lineage plasticity and induce Nectin-4 expression. In sum, lineage plasticity manifested as heterogenous histomorphologies was associated with heterogeneous Nectin-4 expression in some but not all histologic variants of bladder cancer. Ongoing studies using PDOs from bladder cancer patients with mixed histology will seek to identify molecular pathways whose inhibition leads to increased expression of Nectin-4 or other ADC targets such as HER2 and thus increased sensitivity of ADCs targeting these cell surface proteins.

#4633 Differentiation driver gene HOXD4 as a potential prognostic indicator and therapeutic target in anaplastic thyroid cancer.

K. Kopec, T. Jarboe, N. R. DeSouza, H. K. Islam, J. Geliebter, R. K. Tiwari;
New York Medical College, Valhalla, NY

Anaplastic thyroid cancer (ATC) is always diagnosed as stage IV with a 5 year survival rate of less than 3% due to its aggressive metastatic phenotype. ATC lacks differentiation and loses its thyroid-like functions making it a difficult cancer to treat due to its lack of targetable genetic lesions and unresponsiveness to conventional treatments. Therefore, we investigated genes that had aberrant expression in ATC in relation to differentiation. Using NCBI Gene expression omnibus (GSE33630, GSE85457), which provides publicly available transcriptomic datasets, and bioinformatics software, GEO2R, we found that Homeobox D4 (HOXD4) has 12.5FC higher expression in ATC vs. normal tissue (p=0.000552) and 4.36FC higher in ATC vs. papillary thyroid cancer (PTC) in human patients (p=6.69e-08). HOXD4 is a transcription factor that plays a crucial role in cell differentiation and has been associated with a worse prognosis in cancers such as ovarian serous carcinoma. As loss of differentiation is essential to ATC's refractory nature and therapeutic resistance, we are exploring modulation of differentiation by all-trans retinoic acid (ATRA). ATRA was used to induce differentiation in ATC cell line T238 therefore abrogating the aggressive phenotype of this cancer. T238 treated with ATRA had a 26% decrease in proliferation at 24 hours, 46% at 48 hours, and 87% at 72 hours measured using a trypan blue exclusion assay. T238 treated with ATRA also had a 44% decrease in migratory capacity at 24 hours and 24% at 48 hours measured by a cell scratch wound assay. Immortalized normal thyroid cell line NTHY-ori-3-1 did not have a significant decrease in either proliferation or migratory capacity when treated with ATRA. T238 cells treated with ATRA for 24 hours had a 30% decrease in HOXD4 protein levels. Lastly, immunohistochemistry staining of HOXD4 in human patient tissue samples confirmed the over-expression of HOXD4 in ATC (19.5% staining) vs. normal tissue (2.5%) and PTC (7.5%). Overall, we hypothesize that the aberrant expression of HOXD4 in ATC plays a crucial role in the aggressive metastatic phenotype and therefore differentiation agents such as ATRA can target this biomarker to modulate the ATC phenotype. Therefore, HOXD4 can be used as a potential prognostic indicator for early detection of ATC. Future studies will involve CRISPRi based knockdown of HOXD4 in vitro and validation of these results in animal in vivo models.

#4634 Inhibitory-κB kinase alpha as a biomarker and therapeutic target in colorectal cancer.

K. A. F. Pennel[1], M. McKenzie[1], G.-Y. Lian[1], J. A. Quinn[1], S. Samir Foad Al-Badran[1], C. S. D. Roxburgh[1], S. P. Mackay[2], J. Birch[1], J. Edwards[1];
[1]University of Glasgow, Glasgow, United Kingdom, [2]University of Strathclyde, Glasgow, United Kingdom

Introduction/Aims: Colorectal cancer (CRC) remains a leading cause of cancer-related mortality. The canonical NF-κB pathway driven by IKKβ has been implicated in CRC development and progression, however less research has focused on non-canonical NF-κB signaling, regulated by inhibitory-κB kinase alpha (IKKα). This project aimed to assess IKKα, phospho-IKKα (pIKKα^{s176}) and IKKβ expression in a retrospective CRC cohort to establish association with survival outcomes. Subsequently, this project aimed to determine the effect of abrogating IKKα activity without perturbing the canonical NF-κB pathway controlled by IKKβ using a first-in-class selective IKKα inhibitor in vitro/ex vivo.

Methods: Immunohistochemical staining for IKKα/pIKKα ^{s176}/IKKβ was performed using tissue microarrays from a CRC patient cohort (n=787). QuPath® software was used to semi-quantitively assess expression levels and scores were analyzed for association with cancer-specific survival (CSS). CRC cell lines (n=3), patient-derived organoids (PDOs; n=5) and patient-derived explants (n=5) were treated with novel IKKα inhibitor SU1644 and assessed for cell viability and proliferation.

Results: Positive staining for IKKα, pIKKα^{s176} and IKKβ was detected in tumor specimens. High cytoplasmic expression of IKKα within tumor cells was associated with reduced CSS in patients with right-sided colon cancer (HR=3.091, 95%CI; 1.128-9.467, log rank p=0.021). Conversely, high IKKβ expression was a marker of good prognosis (HR=0.627, 95%CI; 0.457-0.861, log rank p=0.004). A high ratio of IKKα to IKKβ was associated with reduced CSS in the full cohort (HR=1.404, 95%CI; 1.050-1.879, log rank p=0.021) and this was potentiated in right-sided colon cases (HR=1.772, 95%CI; 1.107-2.837, log rank p=0.016). Selective inhibition of IKKα using 1μM SU1644 in vitro caused a significant reduction in HT29 colony formation (p=0.012) and cell viability (p=0.039). PDOs showed altered cell morphology, reduced cell viability and proliferation when treated with SU1644. In the patient-derived explant model, Ki67 expression was reduced in tumor explants treated with SU1644.

Conclusions: These data establish high cytoplasmic IKKα expression within tumor cells as a marker of poor prognosis in CRC and conversely high IKKβ expression as a marker of good prognosis. This highlights the importance of development of selective IKKα inhibitor SU1644. IKKα inhibition using SU1644 demonstrated anti-cancer activity in recapitulative CRC disease models.

#4635 RNF208: A novel diagnostic and prognostic biomarker for colorectal cancer and key regulator of malignant behavior.

Fangyue Guo, Shanfeng Zhang, **Pei Li**

Basic Medical Experimental Center, School of Basic Medical Sciences, Zhengzhou University, Zhengzhou, Henan, China

Background: RNF208, a member of the RING finger protein family, has been implicated in ubiquitin-mediated degradation of Vimentin, regulating invasion in breast cancer, and serves as a prognostic factor in uveal melanoma. However, its diagnostic and prognostic value in colorectal cancer (CRC), as well as its role in regulating malignant behavior in CRC, remains unclear. This study aims to reveal the potential of RNF208 as a diagnostic and prognostic marker for CRC and its function in regulating malignant behavior in CRC through bioinformatics analysis and experimental validation.

Methods: In this study, based on the ExoRbase2.0 human plasma exosome database (CRC=35; Healthy=118) and TCGA-COAD dataset (CRC=478; Healthy=41), we conducted bioinformatics analysis of the transcriptomic differences in plasma exosomes between CRC patients and normal individuals using ExoRbase2.0. Survival data from the TCGA-COAD dataset were integrated to select key molecules for CRC diagnosis and prognosis. Plasma samples from 39 CRC patients and 16 normal individuals were collected from hospital, and exosomes were isolated and purified using a reagent kit. qPCR was employed to validate the levels of RNF208 in plasma exosomes, confirming the results of bioinformatics analysis. Biological behavior was assessed through CCK-8 proliferation assays, flow cytometry experiments, and Transwell migration assays to investigate the relationship between RNF208 and malignant behavior in the HCT116 colorectal cancer cell line.

Results: Bioinformatics analysis revealed a significant correlation between elevated RNF208 expression in plasma exosomes and the incidence of CRC, as well as poor prognosis. The qPCR results from clinical samples further confirmed this correlation, and ROC curves demonstrated high sensitivity and accuracy, suggesting RNF208's potential as a diagnostic and independent prognostic factor for CRC. CCK-8 experiments showed that RNF208 knockdown suppressed proliferation activity in HCT116 cells, flow cytometry indicated that RNF208 knockdown promoted apoptosis in HCT116 cells, and Transwell migration assays demonstrated that RNF208 knockdown inhibited the migration of HCT116 cells.

Conclusion: RNF208 serves as a novel diagnostic and prognostic biomarker for colorectal cancer, promoting the proliferation and migration of colorectal cancer cells and contributing to the further deterioration of the disease.

#4636 Genome-wide drug anchor screens identify CAAP1 and AKAP17A as regulators of PRMT5 inhibitor sensitivity.

S. Yoda, M. R. Tonini, H. E. Nicolson, S. Poleretzky, S. Fenoglio, S. Lombardo, L. Grove, S. R. Meier, A. Choi, Y. Yu, K. M. Cottrell, J. P. Maxwell, T. Teng, J. N. Andersen, K. J. Briggs;
Tango Therapeutics, Boston, MA

MTA-cooperative PRMT5 inhibitors are an emerging treatment option for patients with one of the 10-15% of all human cancers harboring MTAP homozygous deletion. To identify potential regulators of sensitivity to PRMT5 inhibitors, we performed genome-wide CRISPR knockout screens in the presence and absence of an MTA-cooperative PRMT5 inhibitor. Knockout of CAAP1 and AKAP17A were among the strongest sensitizing hits across multiple MTAP-deleted cancer cell lines representing different histologies. Strikingly, the CAAP1 gene co-localizes with MTAP and CDKN2A on chromosome 9p21. Co-deletion of CAAP1 is reported in 20 percent of MTAP-deleted cancers in the TCGA PanCancer Atlas. CAAP1 or AKAP17A knockout in MTAP-deleted cancer cell lines sensitized the cells to PRMT5 inhibitors including the clinical stage MTA-cooperative inhibitors, TNG908 and TNG462, and the non-MTA-cooperative inhibitor, GSK3326595. Moreover, we discovered that CAAP1 and AKAP17A protein levels are interdependent, as knockout of either gene caused decreased protein levels for the other. Consistent with this finding, CAAP1 reconstitution in CAAP1-deleted cell lines led to increased AKAP17A levels. Endogenous CAAP1 and AKAP17A protein levels are positively correlated across a panel of cancer cell lines and MTAP-deleted patient-derived xenograft models. Consistent with a previous report (Ni et al., 2023), exogenous CAAP1 and AKAP17A co-immunoprecipitation studies suggest that the proteins form a protein complex. AKAP17A and CAAP1 are not well-characterized proteins, but PRMT5 inhibitors induce global alternative splicing events (ASEs) in cancer cells, and based on preliminary studies a possible function for the CAAP1/AKAP17A complex could be to mitigate ASEs induced by PRMT5 inhibition. Collectively, these data indicate that CAAP1 and AKAP17A exist interdependently and mediate sensitivity to PRMT5 inhibitors. The colocalization and 20 percent incidence of CAAP1 deletion in the setting of MTAP deletion may suggest that such patients will have improved responses to PRMT5-targeted therapy. S. Yoda and M. R. Tonini contributed equally.

#4637 National multidisciplinary tumor board improves diagnostic stratification and therapeutic management in cancers of unknown primary.

C. Dupain[1], N. Jacquin[1], I. Guillou[1], E. Rouleau[2], J. Masliah Planchon[1], I. Soubeyran[3], C. De La Fouchardiere[4], C. Tlemsani[5], H. Blons[6], L. Marisa[6], A. Patrikidou[2], F. Escande[7], P. Blanc[8], J. Wong[1], P. Saintigny[9], S. Boyault[9], A. Buisson[9], Y. Allory[10], A. Vincent-Salomon[1], V. Cockenpot[1], J. Selves[11], I. Bieche[1], M. Kamal[1], C. Le Tourneau[1], S. Watson[1];

[1]Institut Curie, Paris, France, [2]Gustave Roussy, Villejuif, France, [3]Institut Bergonie, Bordeaux, France, [4]Institut Paoli Calmettes, Marseille, France, [5]APHP Institut Cochin, Paris, France, [6]APHP Hopital Europeen Georges Pompidou, Paris, France, [7]CHRU Lille, Lille, France, [8]Laboratoire SeqOIA, Paris, France, [9]Centre Leon Berard, Lyon, France, [10]Institut Curie, Saint-Cloud, France, [11]IUCT Oncopole, Toulouse, France

Introduction: With the increasing complexity of current diagnostic investigations, the integration of clinical, pathological and genomic characteristics is crucial for the management of patients (pts) with cancers of unknown primary (CUP). A national multidisciplinary tumor board (NatCUPMTB) was created in July 2020 in France to discuss the diagnostic and therapeutic management of CUP pts. The objective of this study was to evaluate the diagnostic, prognostic and therapeutic impact of this NatCUPMTB after 39 months of activity.

Methods: This was a multicenter retrospective study with prospective follow-up. All pts discussed at least once in the NatCUPMTB between July 2020 and October 2023 were included. Pts and tumors characteristics, pathological and genomic analyses including WGS, WES and transcriptome analysis performed on the two PFMG2025 (French Genomic Medecine Plan 2025) national sequencing laboratories, multidisciplinary tumor board (MTB) conclusions, and follow-up after MTB were collected.

Results: 244 pts were included. The median age at diagnosis was 60 yo, 53% were female, and the majority of patients had an OMS status <2. The median number of metastatic sites at diagnosis was 2, with a majority located in the lymph nodes (62%). The median time between diagnosis and first MTB presentation was 3 months (1-20). At the time of analysis, NatCUPMTB conclusions were available for 129 pts with a second MTB presentation. MTB investigations enabled to identify a likely primary origin in 89/129 (69%) pts, the most frequent being breast carcinoma (N=15), renal carcinoma (N=13) and lung carcinoma (N=13). The most frequently molecular alterations found were in *TP53 (37%), KRAS (19%), CDKN2A (18%), NF2 (12%), KMT2C (10%), CDKN2B (9%), PBRM1 (9%)* genes. MTB diagnoses were based on the combination of clinical, pathological and genomic investigations in 51/89 (59%) of pts. Importantly, a personalized therapeutic strategy was recommended by NatCUPMTB in 91/129 (71%) of pts. Among these recommendations, 72/91 (79%) were based on the diagnosis of tissue of origin (TOO), 9/91 (10%) on an actionable molecular alteration validated in the TOO indication, 8/91 (9%) on an actionable molecular alteration not validated in the TOO indication and 2/91 (2%) based on a druggable alteration only independently from the TOO. After a median follow-up of 1.5 months, the median overall survival (OS) was 17.7 months from the 2nd MTB presentation.

Conclusion: NatCUPMTB provides significant diagnostic in 69% of pts with CUP and a therapeutic strategy recommendation for 71% of pts.

#4638 Integrated proteogenomic characterization of longitudinal glioblastoma.

[1]Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL, [2]National Cancer Center, Goyang, Korea, Republic of, [3]Ospedali Riuniti di Livorno, Livorno, Italy, [4]Pitie Salpetriere Hospital, Paris, France, [5]Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [6]Korea University College of Medicine, Seoul, Korea, Republic of

Glioblastoma multiforme (GBM) is the most aggressive form of primary brain tumor, with no curative treatment options and median patient survival time of almost one year. Despite multi-modal therapy including surgery, irradiation and chemotherapy, all patients experience tumor progression and recurrence. Our group proposed and validated the first single cell guided functional classification of primary GBM in four tumor-intrinsic cell states which informed clinical outcome and delivered therapeutic options. However, recurrent GBM remains therapeutically unresolved due in part to the diffusely invasive nature and in part to marked cellular heterogeneity of the tumor.The evolutionary trajectory of glioblastoma after therapy is a multifaceted biological process that extends beyond discrete genetic alterations alone. Here, we profiled by multi-omics platforms the largest dataset of matched primary and recurrent GBM including 123 longitudinal glioblastoma pairs, temporally separated by standard-of-care treatment. Genomics, proteomics, and phosphoproteomics all independently captured the loss of proliferative-progenitor characteristics and a significant upregulation of specialized neuronal and synaptic signaling programs in recurrent GBM. Proteomic and phosphoproteomic analyses revealed that the molecular transition from proliferative to neuronal state at recurrence is marked by coherent post-translational activation of the WNT/PCP signaling pathway and the BRAF protein kinase. Multi-omic analysis of Patient-Derived Xenograft (PDX) models mimicked the patterns of evolutionary trajectory, consisting of marked activation of neuronal signaling programs in recurrent patients. Inhibition of the BRAF kinase with small molecule inhibitors impaired both neuronal transition and migration capability of recurrent glioblastoma cells, which are the phenotypic hallmarks of glioblastoma progression after therapy. Accordingly, combinatorial treatment of temozolomide with BRAF inhibitor, vemurafenib, significantly prolonged the survival of mouse PDX models. This work provides comprehensive insights into the biological mechanisms of glioblastoma evolution and treatment resistance and highlights new therapeutic opportunities to effectively counter them in the clinic.

#4639 Unraveling the oncogenic network of USP37 and USP14 in gynecological cancers: Decrypting the molecular landscape of chemoresistance.

R. Chauhan[1], A. Gupta[1], G. Dagar[1], L. Malhotra[2], E. Rai[3], M. A Macha[4], A. A Bhat[5], E. A Samath[1], M. Singh[1];
[1]All India Institute of Medical Sciences (AIIMS), New Delhi, India, [2]Sri Venkateswara College, University of Delhi, New Delhi, India, [3]Jawaharlal Nehru University, New Delhi, India, [4]Islamic University of Science and Technology, Pulwama, India, [5]Sidra Medicine, Doha, Qatar

Background: Gynecological cancers (GC) involve female reproductive system malignancies, and acquired chemoresistance is a challenge in the treatment of GC. Protein deubiquitination, mediated by deubiquitinating enzymes (DUBs) like ubiquitin-specific proteases (USPs), holds therapeutic promise in cancer treatment. This study delves into the mechanistic understanding of DUBs, particularly in acquired chemoresistance in GC.
Methodology: We initially examined TCGA database to assess the impact of Ubiquitin Specific Proteases (USPs), specifically USP37 and USP14, on prognosis in Gynaecological Cancers (GCs). Subsequently, we evaluated their expression in various GC cell lines at both protein and RNA levels. Cell proliferation and metastasis assays were performed to analyze the effect of depleting these USPs on survival and metastasis in GC cells under replication stress. Proteomics analysis was conducted on cells with altered expression of USP37 and USP14 to identify interacting proteins regulating proliferation and metastasis. To investigate DUBs role in chemoresistance, we generated chemoresistant (CR) cell lines with cisplatin exposure, characterized their viability and proliferation, conducted cell cycle and apoptosis analyses, and performed proteomic profiling to explore the USP37 and USP14 specific interactome in chemoresistant cell lines.
Results: Examination of TCGA database revealed an association between elevated USP37 and USP14 expression and poor Overall Survival (OS) and Disease-free Survival (DFS) in Gynaecological Cancers (GC) cohort. Increased expression of USP37 and USP14 at RNA and protein levels was observed in GC cell lines. Inhibiting USP37 and USP14 reduced GC cell proliferation under replication stress and hindered metastasis. Proteomics analysis identified proteins linked to replication (PCNA), DNA damage (Chk-1), cell cycle, and metastasis. Cisplatin-resistant GC cell lines were successfully established, demonstrating prolonged survival and increased proliferative capacity after cisplatin treatment compared to chemosensitive (CS) cell lines. FACS analysis indicated altered cell cycle distribution and increased proliferation in CR cells. Comparative interactome analysis revealed altered protein sets associated with USP37 and USP14 in CR and CS GC cells.
Conclusion: This study provides evidence that supports the participation of USP37 and USP14 in the onset of gynecological cancers (GC). We present evidence of alterations in the oncogenic network linked to USP37 and USP14 in GC. Additionally, we elucidate the roles of these deubiquitinating enzymes (DUBs) in chemoresistant cell lines.

#4640 Pan-cancer analysis of the influence of ERBB2 alteration on HER2 expression.

T. Lee, S. Shin, H. Song, S. Park, S. Pereira, D. Yoo, J. Ro, J. Moon, S. Cho, C. Ahn, C.-Y. Ock, S. M. Ali;
Lunit, Seoul, Korea, Republic of

Introduction: HER2 (ERBB2) is a target for various anti-cancer therapies, including large (Trastuzumab deruxtecan) or small molecules (Neratinib). Quantitative assessment of HER2 expression at the cellular level may improve therapeutic efficacy prediction. While ERBB2 mutations are known oncogenic drivers, their impact on tumor cell HER2 expression is unclear. In this study, we focused on common ERBB2 mutations, and analyzed HER2 expression via AI-powered image analysis in pan-cancer tumor specimens to identify possible mutation-expression correlations.

Methods: We analyzed 183,292 pan-cancer samples from AACR GENIE, and 10,967 from TCGA. A set of 156 cases with both ERBB2 mutation status and HER2 4B5 IHC WSIs was obtained (Neogenomics). An AI-powered HER2 analyzer (Lunit SCOPE HER2) was previously developed using 1,133 HER2 IHC-stained WSIs of breast cancer stained with 4B5. Single-cell HER2 intensity was analyzed and aggregated, reported based on breast ASCO/CAP criteria. ERBB2 RNA levels were analyzed for mutations and amplification.

Results: We identified 2,735 cases with ERBB2 mutations (2,603/183,292 [1.4%] in GENIE and 132/10,967 [1.2%] in TCGA). These mutations were categorized for analysis based on their highest frequency and previous characterization: exon 20 insertions (ex20ins, including Y772dup (YVMA) and G776InsVC), S310x, and other pathogenic mutations. In the dataset, ex20ins cases were predominantly non-small cell lung cancer (NSCLC, 381/482 [79.0%]) and S310x cases were enriched in urothelial, NSCLC, and breast cancers (269/683 [39.4%], 64/683 [9.4%], and 47/683 [6.9%], respectively). Of the 156 ERBB2-mutated cases with HER2 IHC images, 59 had ex20ins, 24 had S310x, and 73 had other mutations. AI analysis in each case type indicates a significantly higher proportion of HER2 3+ tumor cells in S310x and ex20ins cases than other mutations (median, 7.5% vs. 6.1% vs. 2.8%, p = 0.003). As such, high HER2 expression was observed in S310x and ex20ins cases compared to other mutation cases (HER2 3+ 10/24 [41.7%], 22/59 [37.3%], and 14/73 [19.2%]). Additionally, in NSCLC, ex20ins and S310x cases exhibited a modest enrichment for high HER2 expression relative to other mutation cases (21/56 [37.5%], 3/9 [33.3%], and 5/20 [27.6%]). RNA analyses from TCGA showed higher levels for ex20ins (median 13.6; interquartile range 13.1-13.7 in log2 scale), compared to S310x (12.4; 11.9-13.6) and other mutations (12.6; 12.1-13.3), but lower than that of amplified ERBB2 (15.5; 13.8-17.0).

Conclusion: An AI-powered pan-cancer image analysis of HER2 IHC of tumor cells in conjunction with genomic data reveals a positive correlation between ex20ins and S310x ERBB2 mutation and protein expression. This correlation is also seen at the RNA level, but the lesser levels relative to ERBB2 amplified cases suggests the effect may be mediated at the protein level.

#4641 Preclinical evaluation of the novel curcumin Analogue AKT-100 demonstrates therapeutic effectiveness in p53-mutated cancer cells.

K. K. Leslie, J. L. Padilla, G. L. Williams, H.-Y. Fan, C. G. Bologa, E. R. Prossnitz, J.-Y. Choe, L. E. Smith, A. Goss, R. J. Lake, A. D. Sahu;
University of New Mexico Health Sciences Ctr., Albuquerque, NM

Among the myriad of molecular alterations associated with cancer, loss of the normal tumor suppressive functions of p53, the “guardian of the genome,” is the most consistent. Thus, the possibility of targeting oncogenic, mutant p53 proteins has long been a therapeutic goal. However, that aspiration has not been fully realized, leaving patients vulnerable to aggressive disease that is resistant to chemotherapy and to targeted agents such as PARP inhibitors and immunotherapy owing to the loss of wild type p53 functionality and the gain of new oncogenic functions when mutant p53 is expressed. An effective therapeutic strategy is urgently needed for p53 mutant cancers, and our team is developing novel analogues of curcumin with the potential to convert mutant p53 to a wild type conformation and restore its tumor suppressive functions. In this study, we investigated the effects of AKT-100, which was developed from the parent molecule and curcumin analogue HO-3867. Effects were compared to another drug believed to reactivate p53 functionality, APR-246, using CyQUANT IC50 cell proliferation assays and bulk and single cell RNA sequencing. Structural analyses are underway investigating the specific sites of interaction of AKT-100 with various mutant forms of p53. Our findings indicate that, *first*, AKT-100 exhibits impressive cell killing in multiple ovarian and serous endometrial cancer cells at concentrations ranging from 100-300 nM and is synergistic with the PARP inhibitor olaparib. *Second*, RNA sequencing demonstrates the reactivation of wild type p53 genes associated with normal cell cycle regulation (induction of *CDKN1A* encoding p21 and *GADD45A*), apoptosis (induction of *PMAIP1* encoding Noxa and *DR5* encoding Death Receptor 5), and the inhibition of DNA replication and multiple alternative mechanisms of DNA repair employed by malignant cells. *Third*, RNA sequencing indicates that AKT-100 acts through both p53-dependent and independent pathways to inhibit cancer cell proliferation. Gene expression is impacted in ways that portend a therapeutic effect as well as highlight potential resistance pathways (e.g. significant induction of *PLK5* encoding polo like kinase 5) that can be further targeted to create synthetic lethal drug combinations with AKT-100 chosen specifically to target the various mutant forms of p53. Taken together, these results identify novel curcumin analogues in early development with the potential to improve therapy for p53 mutant cancers. Through this strategy it is also possible to identify and block resistance pathways that are activated by different forms of mutant p53 in response to AKT-100 and to create synthetic lethal precision drug combinations.

#4642 Fatty acid synthase as a novel prognostic biomarker and a potential therapeutic target in diffuse malignant peritoneal mesothelioma.

V. Doldi[1], S. Martini[1], C. Ciniselli[1], A. Beretta[1], M. Deraco[1], S. Kusamura[1], D. Baratti[1], P. Gandellini[2], P. Verderio[1], N. Zaffaroni[1];
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]University of Milan, Milan, Italy

Diffuse malignant peritoneal mesothelioma (DMPM) is a rare and locally aggressive tumor with a dismal prognosis. The availability of new therapies and biomarkers for patients' selection is still an urgent need. Altered lipid metabolism, which has been reported in several tumors, has not yet been studied in DMPM. By comparatively analyzing gene expression profiles of tumors form relapsed (n=18) and non-relapsed (n=18) DMPM patients, we initially found that fatty acid synthase (FASN) was up-modulated in relapsed tumors, with a significant linear correlation between FASN expression and shorter patient relapse-free survival (RFS), suggesting a potential role of FASN in DMPM progression. The prognostic significance of FASN was further assessed in a cohort of 80 DMPM patients who underwent cytoreductive surgery combined with hyperthermic intraperitoneal chemotherapy. Our results indicated that high FASN staining was significantly associated with reduced RFS (hazard ration (HR): 1.930; p=0.014) and Overall Survival (OS) (HR: 1.854; p=0.032) as assessed by immunohistochemistry in tissues microarray samples. The prognostic value of FASN, along with Ki67 staining and patient age, was also maintained in multivariate analysis in terms of both RFS (HR: 2.240; p=0.007) and OS (HR: 2.246; p=0.014). To validate FASN as a therapeutic target, we investigated the cytotoxic effects of non-selective (orlistat) and selective (cerulenin and C75) FASN inhibitors on patient-derived DMPM cell lines, both as single agents and in combination with selinexor -a selective inhibitor of the exportin chromosome maintenance protein. FASN pharmacological inhibition in DMPM cells resulted in a significant reduction of cell proliferation, especially upon C75 exposure. In combination experiments, we observed a synergistic activity of FASN inhibitors and selinexor, as determined by Chou and Talalay method. Through western blotting and flow cytometry analysis, we gained further insight into the mechanisms by which FASN inhibitors and selinexor synergize to reduce DMPM cell proliferation. Compared to single agents, the combined treatments resulted in increased apoptosis response and cell cycle impairment, as indicated by caspase-dependent apoptosis activation and cell accumulation in the G2-phase. Overall, our results support the relevance of FASN as a prognostic biomarker for DMPM patients and underscore its potential as a novel therapeutic target.

#4643 A novel epigenomic profiling assay reveals disease biology and therapeutic targets in gastro-esophageal cancer from 1 ml of plasma.

J. Beagan[1], **A. Gorthi**[1], A. D'Ippolito[1], T. Clark[1], M. Coyne[1], T. Tamakloe[1], A. Donahue[1], B. Tran[1], H.-H. Jeong[1], K. Cibulskis[1], H. Sawaengsri[1], C. A. Painter[1], J. Chmielecki[1], J. Barrett[1], M. F. Afreen[2], A. Pandey[2], I. Schechter[3], M. S. Taylor[2], M. R. Strickland[2], M. Eaton[1], S. J. Klempner[2];

[1]Precede Biosciences, Inc., Boston, MA, [2]Massachusetts General Cancer Center, Boston, MA, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA

INTRODUCTION: Gastro-esophageal adenocarcinoma (GEA) is an aggressive and heterogeneous disease with a poor prognosis. Targeted therapies have failed largely due to challenges associated with biopsy collection, tumor antigen heterogeneity, and accurately distinguishing transcriptionally distinct esophageal, GE junction or gastric tumor types. We developed a novel, multimodal liquid biopsy assay that profiles genome-wide transcriptional activation. Here, we deploy this assay to define clinically relevant insights in a cohort of GEA patients.

METHODS: 1 ml of plasma from whole blood samples was used to assess genome-wide enhancer, promoter and DNA methylation loci in 11 GEA patients (Stage III: 1, Stage IV: 10) and 7 healthy volunteers. 6 patients were confirmed as HER2+ based on standard tissue IHC/ISH methods. ctDNA estimation was performed using the ichorCNA algorithm on low pass whole genome sequencing data. A multimodal HER2 classifier developed previously using genome-wide features including HER2 was used to predict HER2 status of the GEA samples.

RESULTS: Epigenomic profiling and comparison of GEA and healthy volunteer plasma samples revealed distinct genome-wide transcriptional activation patterns associated with gastroesophageal adenocarcinoma, including (i) the characteristic upregulation of HER2, FGFR2 and VEGF (ii) SOX2, KLF4, GATA6 transcription factor circuitry, and (iii) DNA methylation at the CHFR and MGMT promoters. We then explored if epigenomic profiling of liquid biopsies could infer the activation status of antibody-drug conjugate (ADC) targets currently under investigation in GEA cancers. Simultaneous examination of multiple target genes including HER2, HER3, TROP2, CLDN18, CEACAM5 and MET demonstrated patient-specific differences and dynamic range in transcriptional activation of a subset of these target genes. Finally, we investigated if HER2 status could be assigned accurately and quantitatively from a liquid biopsy using the multimodal HER2 classifier. HER2 positivity by IHC was predicted accurately in 8/11 samples corresponding to an area under the ROC curve (AUC) greater than 0.85. Discordance between plasma and tissue HER2 calls could be partially attributed to variability associated with tumor site/section used for tissue collection, IHC staining, and time between biopsy collection and blood draw.

CONCLUSIONS: We demonstrate the feasibility of comprehensive epigenomic profiling from low input volume of 1ml of plasma to provide a snapshot of the tumor's transcriptional state to derive clinically actionable insights. The HER2 classifier overcomes several of the challenges with IHC profiling by providing a uniform and quantitative measurement of HER2 activation. This non-invasive assay provides an accurate reflection of tumor transcriptional biology that can inform optimal patient selection strategies.

#4644 Single strand DNA GAP accumulation as a functional biomarker for USP1 inhibitor sensitivity in ovarian cancer patient-derived organoid models.

A. B. Da Costa, O. Somuncu, R. Ravindranathan, S. Mukkavalli, D. Martigneti, H. Nguyen, Y. Jiao, B. Lamarre, G. Sadatrezai, L. Moreau, J. Liu, D. Iyer, J.-B. Lazaro, G. Shapiro, K. Parmar, A. D. D'Andrea;
DFCI/Harvard Medical School, Boston, MA

Recent studies suggest that PARP inhibitors and POLQ inhibitors confer synthetic lethality in BRCA1-deficient tumors by accumulation of single-stranded DNA gaps (ssDNA gaps) at replication forks. Loss of USP1, a deubiquitinating enzyme, is also synthetic lethal with BRCA1 deficiency, and USP1 inhibitors are now undergoing clinical development for these cancers. Here, we show that USP1 inhibitors also promote the accumulation of ssDNA gaps during replication in BRCA1-deficient cells. USP1 inhibition increased monoubiquitinated PCNA at replication forks and resulted in accumulation of ssDNA gaps in BRCA1-deficient cancer cells. Knockdown of RAD18, the E3 ubiquitin ligase known to ubiquitinate PCNA, caused USP1 inhibitor resistance and suppression of ssDNA gaps. ssDNA gap accumulation induced by USP1 inhibition correlates with drug sensitivity of *BRCA1*-mutated cancer cells and overcomes PARP inhibitor resistance in cell line and xenograft models. Furthermore, USP1 inhibition was synergistic with PARP and POLQ inhibition in *BRCA1*-mutant cells, with enhanced ssDNA gap accumulation. A set of patient-derived ovarian cancer organoids (PDOs) were used to confirm the sensitivity of *BRCA1*-deficient cells to USP1 inhibition. Five PDOs were derived from patients with high grade-serous ovarian cancer (HGSOC). Among the five PDOs, two of them were from tumors harboring germline *BRCA1* pathogenic mutations. *BRCA1*-mutant PDOs, but not *BRCA1*-WT PDOs, were sensitive to a USP1 inhibitor and to PARP inhibitor monotherapies. The accumulation of ssDNA gaps after treatment with a USP1 inhibitor or a PARP inhibitor correlated with the sensitivity to these drugs in all the models tested. Moreover, the combination of a PARP inhibitor and a USP1 inhibitor showed synergy in a *BRCA1*-WT model, which was resistant to both monotherapies. Interestingly, ssDNA gaps accumulated with the combination treatment and not with monotherapy in this model. Ovarian cancer PDOs therefore provide a powerful tool for rapid *in vitro* sensitivity testing. The detection of ssDNA gap accumulation may be a useful predictive biomarker for response to USP1 inhibition as monotherapy or in combination in ongoing clinical trials.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Compounds and Drug Targets
Poster Session

#4648 Metabolic vulnerabilities of drug-resistant melanoma with therapeutic potential.

Y. Yu[1], L. Huang[1], W. Chen[2], G. Merlino[1];
[1]National Cancer Institute, Bethesda, MD, [2]National Institutes of Health, Bethesda, MD

Melanoma has been at the center of revolutions in both targeted BRAF therapy and immune therapy. However, the resistance to current therapeutic drugs has been a formidable obstacle to continuing benefit to patients. Overcoming resistance and new therapeutic agents and strategies are the primary goals of current cancer research. We currently found that metabolic pathways altered significantly in BRAFi-resistant melanoma. We hypothesized that BRAFi-resistant melanoma rewires its metabolic routes to reach its needs in energy and biosynthetic precursors, both essential for escaping the BRAFi attack. We found that five amino acids transporters and metabolic enzymes (ASNS, slc7a11, slc7a5, slc3a2, slc4a7) were the significant increase in resistant melanoma. Knockdown by shRNA or knockout by crispr/cas9 of these amino acids transporters or/and metabolic enzymes enhanced the sensitivity of BRAFi resistant melanoma to BRAFi. In contrast, overexpression of these amino acid transporters or/and metabolic enzymes promoted the ability of resistance of BRAFi in parent melanoma cells. Moreover, the inhibition of these amino acid transporters and metabolic enzymes by small molecular inhibitors significantly attenuated the resistance of the BRAFi-resistant melanoma whereas less affected the parent melanoma. Notably, we confirmed that blocking these amino acid transporters and metabolic enzymes by shRNA and/or small molecular inhibitors could rescue the sensitivity of resistant melanoma cells and inhibit resistant-melanoma cell growth in the preclinical mouse model in vivo. Importantly, we found that overexpression of slc7a11, slc7a5 and slc3a2 correlated with worse survival in melanoma in SK-TCGA data. Our findings uncovered the mechanism of how metabolic reprogramming fueled melanoma cell growth and proliferation for escaping drug attacks and offered a rational strategy to guide clinical treatment. The identified novel molecular proteins represented a promising therapeutic target for BRAF mutant melanoma patients with resistance to current therapy.

#4649 BLX-3030, a potent, selective, orally available small molecule CDK9 inhibitor for aggressive variant prostate cancers.

Z. Li, C. Lin, K. Medley, H. Vankayalapati, D. J. Bearss;
Biolexis Therapeutics Inc., American Fork, UT

Background: The use of novel, potent targeted therapies in prostate cancers has led to the development of highly aggressive variant cancers, including neuroendocrine prostate cancer (NEPC). Gene amplification of N-MYC and C-MYC oncogenes leads to its overexpression in NEPC and mCRPC patients, highly prevalent in these lethal subtypes of cancers detected in 2% of all Prostate Cancers (PCa) and over 10-17% of mCRPC patients. N-MYC is a transcriptional target of CDK9, which acts as an oncogenic driver sufficient to transform human-derived prostate cancer to take on NEPC phenotypic changes resulting in a more aggressive disease identified in late-stage human PCa patients. Additionally, N-MYC and C-MYC are required for tumor drug resistance, and their downregulation through CDK9 inhibition lowers tumor growth. Our efforts have demonstrated that targeting both N-MYC and C-MYC as a driver of NEPC and mCRPC with highly selective CDK9 inhibitor BLX-3030 is a viable approach for therapeutic intervention of mCRPC and NEPC.

Materials and Methods: Our empirical data-driven AI/ML MolecuLern™ fragment library, workflows, LigEdit design strategies, and hit2-lead optimization methods are employed. I*n vitro* experiments include kinase glo, cell titer glo, selectivity profiler, ADME-Tox, FACS/apoptosis, cell migration, live cell imaging, immunofluorescent, western blot, combination studies and *in vivo* experiments including PK, prostate tumor models, 7-day tox, BLX-3030 non (GMP) scaleup and safety pharmacology experiments conducted.

Results: We synthesized a series of novel small molecule CDK9 inhibitors that reversibly bind to CDK9, competitively block the ATP site with an IC_{50} of 1.06 nM, and elicit pharmacological responses in N-MYC, C-MYC, and other prostate cancer cells *in vitro* and *in vivo*. We studied the CDK9 N-MYC expression detected in PC-3, DU-145, LNCaP, and in LASCPC-01, NCI-H660, and 22RV1 cell lines. BLX-3030 exhibited potent cellular efficacy with an IC_{50} of 22 to 590 nM in PC cell lines and in N-MYC expressed cells had an activity of 76, 470, and 132 nM respectively, and reduced *p*CDK9, C-MYC, Mcl-1, N-MYC and its downstream RNA Pol II (Ser-2) and *p*AR (Ser-81) dose-dependently. BLX-3030 exhibits in vivo antitumor activity in LASCPC-01, 22RV1, and C4-2 prostate cancer mouse models. Several ADME-Tox, MTD, dose range finding, hERG and other in vivo safety pharmacology experiments have advanced BLX-3030 to the IND enabling studies.

Conclusions: BLX-3030 is currently being investigated in non-clinical toxicology, toxicokinetic, and core battery of safety pharmacology studies including the assessment of effects on cardiovascular, central nervous, and respiratory systems.

#4650 RalBP1, a novel approach for ovarian cancer therapy.

S. S. Singhal[1], S. Ramisetty[1], A. Mohanty[1], P. Kulkarni[1], D. Horne[1], S. Awasthi[2], R. Salgia[1];
[1]City of Hope National Medical Center, Monrovia, CA, [2]CTMH Doctors Hospital in Cayman Islands, George Town, Cayman Islands

Ovarian cancer (OC) is the most devastating gynecologic cancer. The ever-climbing incidence rate of OC makes it the most lethal female reproductive disorder. Triggering apoptosis is one of the potential strategies to overcome chemoresistance. Recent evidence suggests that the failure of drug-induced apoptosis may be an underlying cause of drug-resistance. Molecular mechanisms of failed apoptosis in chemoresistant OC cells include p53 mutations, abnormal expression of the Bcl2 family proteins, and upregulation of other inhibitors of apoptosis that block caspases and stabilize the mitochondrial permeability pore. RalBP1 (Ral-binding protein) is a required stress-defense protein for OC, and its specific depletion or inhibition will cause apoptosis in cancer cells expressing RalBP1. RalBP1 is a multifunctional 76 kDa protein encoded as a splice variant in the human *RALBP1* gene (18p11.22). RalBP1 is an ATP dependent efflux transporter for glutathione (GSH) conjugates (GS-E) of products of oxidative stress, like 4HNE and GSH-conjugates of chemotherapy drugs. Our recent studies indicate that upon depletion/inhibition of RalBP1, malignant cells are significantly more sensitive to apoptosis than non-malignant cells, suggesting that the stress-protective, anti-apoptotic activity of RalBP1 is necessary for malignant cells. This differential sensitivity to RalBP1 translates into tumor regression, a lack of toxicity, and the prolonged survival of mice bearing subcutaneous OC cells in which RalBP1 is inhibited by anti-RalBP1 IgG or depleted using RalBP1 antisense oligonucleotides. These studies demonstrate that inhibition or depletion of RalBP1 exerts anti-neoplastic effects in OC and indicate that this GS-E and xenobiotic transporter occupies an important position in the hierarchy of stress defense mechanisms necessary for cancer cell survival. Overall, the present research focuses on hypothesis-driven studies to define novel relationships between RalBP1 and signaling pathways, and to determine the suitability of RalBP1 as an anticancer target for OC.

#4651 A macrocyclic kinase inhibitor overcomes the compound mutations that cause the resistance to all approved EGFR inhibitors in EGFR-positive lung cancer.

R. Katayama, K. Uchibori, M. Nishio, N. Fujita;
Japanese Foundation for Cancer Research, Tokyo, Japan

EGFR mutant cancers account for 20-30 % of non-small cell lung cancers and show marked sensitivity to EGFR tyrosine kinase inhibitors (TKIs). However, the tumor almost inevitably relapses due to acquired resistance. To date, several EGFR-TKIs have been approved, and the third-generation EGFR-TKI, osimertinib, has been widely used both as first-line therapy and for patients with the EGFR-T790M mutation after 1st or 2nd generation EGFR-TKI therapy. However, the EGFR-T790M+C797S compound mutation confers resistance to all approved EGFR-TKIs. In our previous study, we experimentally demonstrated that brigatinib with anti-EGFR antibody was effective against osimertinib-resistant EGFR-C797S and EGFR-T790M+C797S mutants, and is currently undergoing clinical studies. However, the tumor would relapse because of the acquisition of additional resistance mutations. Here, we first demonstrated the binding mode of brigatinib to the EGFR-T790M/C797S mutant by crystal structure analysis and predicted brigatinib-resistant mutations through a cell-based assay, including N-ethyl-N-nitrosourea (ENU) mutagenesis. We found that clinically reported L718 and G796 compound mutations appeared, consistent with their proximity to the binding site of brigatinib, and brigatinib-resistant quadruple mutants, such as EGFR-activating mutation/T790M/C797S/L718M, were resistant to all clinically available EGFR-TKIs. BI-4020, a fourth-generation macrocyclic EGFR inhibitor plus anti-EGFR antibody, overcomes the quadruple and major EGFR-activating mutants in vitro and in vivo, but not the minor mutants such as L747P. Microsecond molecular dynamics simulations revealed the binding mode and affinity between BI-4020 and the EGFR mutants. This study identified potential therapeutic strategies using new-generation macrocyclic EGFR inhibitor to overcome the emerging resistance mutants.

#4652 Combined inhibition of MCL-1 and MEK reduces tumor growth in a triple-negative/inflammatory breast cancer, MEK-resistant xenograft mouse model.

M. Mughees[1], A. Tan[1], L. Iles[1], M. White[2], D. Tripathy[1], S. Krishnamurthy[1], J. Wang[1], W. A. Woodward[1], G. Bartholomeusz[1], C. Bartholomeusz[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]AstraZeneca, Waltham, MA

Background: Triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC) are highly aggressive subtypes of invasive breast cancer. Our previous work showed that the MEK inhibitor (MEKi) selumetinib (AZD6244) prevents lung metastasis in a xenograft model. However, clinical studies have shown that MEKi's as single agents have only modest activity against solid tumors. Using a genome-wide synthetic lethal siRNA screening, we identified myeloid cell leukemia-1 (*MCL1*) as a potential contributor to selumetinib resistance. MCL-1 is an anti-apoptotic protein associated with cell immortalization, transformation, and chemoresistance in numerous cancers. We hypothesized that MCL-1 promotes MEKi resistance in TNBC/IBC and inhibition of MCL-1 in the presence of AZD6244 overcomes this MEKi resistance.

Methods & Results: To understand MCL1's role in MEKi resistance, we established two AZD6244 -resistant TNBC/IBC cell lines: MDA-MB-231-R and SUM149-R. These cells showed increased cell viability, colony formation, migration, cells in G1 phase, $CD44^{+}CD24^{low}$, mammosphere count, anchorage-independent growth and high MCL-1 expression. MCL-1's biological role was evaluated by transient and stably knock down (KD) of MCL-1 in the resistant cells which showed decreased cell viability, colony formation, and increased apoptosis. To understand the mechanism mediating apoptosis, we examined the expression of MCL-1's binding partners in the MCL-1-KD-R cells in the presence of AZD6244. These cells showed a high expression of the PUMA, NOXA, BAK, and BAX in the presence of AZD6244. Further, we treated resistant cells with MEKi AZD6244 and an MCL-1i (AZD5991) that confirmed restoration of MEK sensitivity in both resistant cell lines, resulting in decreased cell viability, colony formation and increased apoptosis. We compared tumor formation capability between SUM149 parental and SUM149 resistant cells by injecting them in *nu/nu* mice and observed a time-dependent increase (avg. 4-fold) in tumor growth with SUM149-R cells compared to parental cells ($P \leq 0.0001$). Moreover, IHC analysis showed high expression of MCL-1 ($P \leq 0.01$), Ki67 (ns), CD44 ($P \leq 0.0001$), and ALDHA1 ($P \leq 0.0001$) in the mammary gland tumor tissues of SUM149-R-injected mice compared to SUM149-P-injected mice. Next, we evaluated the therapeutic effect of AZD6244 in mice harboring SUM149-R - MCL-1-deficient tumors. AZD6244 treatment significantly reduced tumor development in mice harboring SUM149-R - MCL-1-KD tumors compared to control mice ($P<0.0001$), suggesting that MCL-1 mediates MEK resistance in triple-negative/inflammatory breast cancer.

Conclusion: Our results suggest that MCL-1 is important for inducing acquired MEK resistance and combining an MCL-1i with a MEKi could improve treatment outcomes of patients with TNBC or IBC who have developed resistance to single-agent MEKi.

#4653 Unraveling the vulnerabilities of targeted therapy-tolerant persister cells in NSCLC.

D. Kim[1], D. Kuchenov[1], A. Zaman[1], N. Bennett[2], E. Ramos[1], K. Nakamura[2], A. P. Wiita[1], S. Bandyopadhyay[1], T. Bivona[1];
[1]UCSF - University of California San Francisco, San Francisco, CA, [2]Gladstone Institutes, San Francisco, CA

Genetic profiling and the development of targeted therapy has improved survival of many cancer patients, but resistance to targeted therapy remains a major barrier to long-term patient survival. To develop more pro-active strategies to improve clinical outcomes, our research focuses on drug-tolerant persister cells that constitute a reservoir of cancer cells that survive and adapt during the initial stage of therapy. These cells typically display therapy resistance in a reversible manner and set the stage for the subsequent emergence of cells with full acquired resistance. We utilized quantitative proteomics to characterize persister cells generated from EGFRmut, KRASmut, and ALKmut non-small cell lung cancer (NSCLC) cell lines after treatment with osimertinib, sotorasib, and lorlatinib, respectively. Integrating proteomics data with network analysis revealed a decrease in the signaling network associated with cell cycle regulation and DNA replication. Meanwhile, persister cells exhibited an enrichment in proteins linked to lysosomes, amino acids, and fatty acid metabolism. The data revealed a consistent metabolic shift in persister cells, with an increased dependence on oxidative phosphorylation (OXPHOS) for ATP generation. Small-scale drug screening was performed based on findings from proteomics and confirmed that persister cells are vulnerable to inhibitors of OXPHOS mitochondrial complexes. Combination treatment of OXPHOS inhibitors and each targeted therapy delayed the emergence of resistance. One complex V inhibitor, Gboxin, selectively inhibited the growth of persister cells. The therapeutic potential of complex V was further validated by CRISPR-based genetic knockdown studies. The metabolic transition in drug tolerant persister cells may serve as a critical adaptive resistance mechanism to provide a survival advantage under targeted therapy-induced stress. Understanding this metabolic shift may lead to new treatments that aim to prevent or delay the onset of acquired resistance in NSCLC.

#4654 Targeting poly-resistant stem cells in high-grade serous ovarian cancer via synthetic lethal drugs.

Wa Xian[1], Frank McKeon[1], Christopher Crum[1], Jaffer Ajani[2], Peter Davies[3], Matthew Vincent[4], William Bachovchin[5], Hung-Sen Lai[5], Shuang Pan[5], Melina Khorrami[1], Melika khorrami[1], Raul caballero Montes[1], Paria Mosaffa[1], Ashley Hoffman[1], Amber Su[1]

[1]University of Houston, Houston, TX,[2]MD Anderson Cancer Center, Houston, TX,[3]Texas A&M, Houston, TX,[4]Tract Bio, Houston, TX,[5]Tufts University, Boston, MA

High-grade serous ovarian cancer (HGSOC) is remarkably responsive to chemotherapy and yet recurs at high rates as resistant disease. Using novel technology that selects for rare clonogenic cells which recapitulate HGSOC in immunodeficient mice, we have identified, in therapy-naive HGSOC, a minor population of clones that are intrinsically resistant to paclitaxel/carboplatin as well as to a broad spectrum of oncology drugs. These intrinsic "polyresistant" cells are a common, albeit minor, component of clonogenic cells in all therapy-naive tumors analyzed. Importantly, the polyresistant clonogenic cells share a gene expression signature distinct from the majority of clonogenic cells that are exquisitely sensitive to paclitaxel/carboplatin, and this gene signature of polyresistant cells extends to all polyresistant clones within a patient and across HGSOC cases. We have exploited these polyresistant clones to perform high-throughput screening of small molecule "bioactive" libraries to identify compounds that circumvent this resistance. While single agent "hits" were obtained, these showed minimal therapeutic windows relative to normal stem cells of the liver and gastrointestinal tract. Adaptations of synthetic lethal strategies have yielded lead drug combinations that eliminate polyresistant clones from all four cases tested at low nanomolar concentrations *in vitro*. We have improved these combinations via the synthesis of new chemical entities that show potent effects against both subcutaneous and peritoneal tumor models in immunodeficient mice derived from polyresistant HGSOC clones. Clonogenic analyses of these treated and untreated xenografts support the notion that these drug combinations are targeting the stem cell populations within these tumors. We anticipate that these drug combinations will assist in preventing or treating recurrent HGSOC.

#4655 Targeting FAK improves the tumor penetration of antibody-drug conjugates to strengthen the anti-cancer responses.

B. Zhang[1], Z. Zhang[2], J. Gao[1], S. Lu[1], R. Pang[1], D. Li[2], X. Huang[2], N. Qin[1], L. Liu[1], Z. Wang[1];
[1]InxMed (Shanghai) Co., Ltd., Shanghai, China, [2]WuXi AppTec, Shanghai, China

Antibody-drug conjugates (ADCs) such as HER2 ADC Enhertu and TROP2 ADC Trodelvy have been proved to be the promising therapeutic agents in portion of cancer diseases. However, there are still numerous patients refractory to the therapy, indicating that the efficacy of ADCs may need to be further optimized. Here, we report that the excessive cancer-associated fibroblasts (CAFs) can serve as a fibrotic barrier, to the detriment of anti-tumor effects from ADCs by alleviating their tissue penetration. Mechanistically, the cancer cells can transform the normal fibrotic cells into CAFs which are featured by the hyperactivated focal adhesion kinase (FAK) signaling. The fast-growing CAFs would decrease the tumor uptake of the big molecules, conferring drug resistance of ADCs to the cancer cells. Targeting FAK with a small molecule inhibitor IN10018 is capable to reduce CAFs associated tumor barrier, elevating the tissue penetration of different types of ADCs regardless their respective targets. The combination regimen comprising IN10018 and the ADCs targeting either HER2 or TROP2 outperformed each monotherapy with respect to antitumor outcomes in different animal experiments. The preclinical evidence for the dual regimen of IN10018 and ADCs warrants a further validation in clinical settings.

#4656 Novel mitochondria-based targeting overcomes resistance in prostate cancer.

Yan Ou[1], Adrian Lim[1], Ning Zhai[1], Mouad Edderkaoui[1], Stephen Pandol[1], Ruoxiang Wang[1], Yi Zhang[2]

[1]Department of Medicine, Cedars Sinai Medical Center, Los Angeles, CA,[2]Department of Biomedical Sciences, Cedars Sinai Medical Center, Los Angeles, CA

Background: Prostate cancer (PC) is a major contributor to cancer-related mortality in men, with metastatic castration-resistant PC (mCRPC) presenting a significant obstacle due to its resistance to standard treatments. Current therapies, including nonsteroidal antiandrogens and chemotherapy drugs, provide limited effectiveness and are often accompanied by severe side effects. Recently, statins have gained attention as antitumor agents, demonstrating chemopreventive effects on a range of human cancers while maintaining a well-established safety profile. However, the use of statins as standalone treatment is limited by insufficient cancer cell targeting.

Methods: We synthesized a DZ-simvastatin (DZ-SIM) conjugate that combines a near-infrared heptamethine carbocyanine dye (DZ) with simvastatin for selective tumor cell targeting. Cancer cell survival was measured by crystal violet and MTT assay. Co-localization of DZ-SIM with mitochondria and lysosome in cells was detected under confocal microscope using Mitotracker and Lysotracker. Cellular and mitochondrial cholesterol levels were detected by LC-MS. Male nude mice were inoculated subcutaneously with 22Rv1-Luc cells as a prostate cancer xenograft mouse model. We used Swiss-PDB and Rosetta algorithms to model the structure of the OATP1B3 channel. Oxygen consumption rate and extracellular acidification rate were measured by Seahorse assay. After treatment with DZ-SIM, differentially expressed genes profiling of prostate cancer cells was performed using RNAseq.

Results: Our research demonstrates the conjugate's ability to effectively kill androgen-independent and metastatic PC cells without harming normal cells. Furthermore, DZ-SIM has been shown to kill multiple human PC cell lines, regardless of androgen receptor status or therapeutic resistance. DZ-SIM has been shown to inhibit growth in human prostate cancer cell line xenograft models. NIR fluorescence imaging showed specific localization of DZ-SIM to cancer, but not to normal cells and tissues. It could localize into cancer cells by binding the transmembrane transporter OATP to primarily target subcellular organelle mitochondria, decreasing the OCR and ECAR of cancer cells. DZ-SIM can bind to multiple cytosolic and mitochondrial proteins as detected by NIRF imaging. Cholesterol levels also decrease in whole cells and mitochondria. Ingenuity Pathway Analysis (IPA) of RNAseq showed that the four signaling pathways in the DZ-SIM treatment group are significantly enriched in genes related to cholesterol synthesis.

Conclusion: DZ-SIM specifically targets PC cells and their mitochondria, resulting in loss of mitochondrial function and consequent cell death. With a unique subcellular targeting strategy, the conjugate holds the potential to outperform existing chemotherapeutic drugs.

#4657 PHI-501 is a novel potent next-generation pan-RAF/DDRs inhibitor, and overcomes resistance to RAF or MEK inhibitor in melanoma via dual inhibition of RAF and DDR1/2 signaling.

Sue Min Kim[1], Sungmin Cho[1], Gi-Jun Sung[2], Ky-Youb Nam[2], June Han[2], Sang Joon Shin[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Pharos iBio CO., Ltd., Anyang, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, Korea, Republic of

Background: The prevalent mutation of BRAF (~50%) and NRAS (~30%) in malignant melanomas has led to the aggressive development of RAF and MEK inhibitors as anticancer drugs. However, the major hurdle of targeted therapies for melanoma is resistance to RAF or MEK inhibitors, either intrinsic- or acquired-resistance. PHI-501 is an orally bioavailable and highly effective pan-RAF inhibitor. PHI-501 has dual inhibition activity against pan-RAF and discoidin domain receptor (DDR), a collagen-activated receptor tyrosine kinase. In this study, we evaluated the ability of PHI-501 to overcome drug-resistance to RAF or MEK inhibitors in melanoma harboring NRAS or BRAF mutations.

Methods: Three drug-resistant cell lines were established by long-term treatment of belvarafenib in SK-MEL-2 (SK-MEL2BR) and each of dabrafenib and trametinib in SK-MEL-3 (SK-MEL3DR and SK-MEL3TR, respectively). RNA-seq of each resistant cell line and in-depth analysis of sequencing data was conducted, including GSEA. The anti-proliferative activity and signaling inhibition of PHI-501 were evaluated by CCK-8 assay and western blots. A long-term clonogenic assay was performed to confirm cell survival upon PHI-501 treatment. In vivo efficacy was evaluated in SK-MEL-3DR cell line xenograft models.

Results: PHI-501 demonstrated significant anti-proliferative effects (GI50 < 1 μM, Mean GI50: 0.3 μM) in all 12 melanoma cell lines tested in this study. PHI-501 exerted cell growth inhibitory activities at least 3 to 50 times stronger than other RAF or MEK inhibitors in each of the resistance cell lines. Moreover, PHI-501 doses of less than 100 nM, significantly inhibited the colony formation of drug-resistant cells. Western blot revealed that PHI-501 retained strong inhibition of both ERK and AKT phosphorylation through downregulating pDDRs. In the SK-MER3DR xenograft mouse model, treatment of PHI-501 alone induced a rapid tumor reduction (TGI 72.1%), whereas the vehicle or dabrafenib did not display an anti-melanoma effect (TGI -7.4%). A comprehensive pathway analysis showed the TNFA-NFKB, IL6-JAK-STAT3, and KRAS signaling enriched in drug-resistant cells compared to the parental cells. PHI-501 treatment effectively downregulated those pathways in all three drug-resistant cells. In particular, PHI-501 downregulates the geneset in epithelial-mesenchymal transition (EMT) signaling more effectively in SK-MEL2BR, SK-MEL3DR, and SK-MEL3TR (Adjusted P=<.0001, and NES: -2.01, -1.72, -2.30, respectively).

Conclusion: Novel pan-RAF/DDR dual inhibitor PHI-501 has greater anti-tumor activity in RAF or MEK inhibitor-resistant melanoma, which is through downregulation of MAPK signaling and EMT-related genesets and promoting apoptosis. These data support that the clinical development of PHI-501 for melanoma refractory to MAPK inhibitors.

#4658 Genome wide CRISPR/Cas9 library screening identifies aurora kinase A as a regulator of elraglusib sensitivity in pancreatic cancer.

L. Ding[1], E. Maeder[1], C. Zhang[1], T. Weiskittel[1], D. Schmitt[2], A. Mazar[2], H. Li[1], D. Billadeau[1];

[1]Mayo Clinic, Rochester, MN, [2]Actuate Therapeutics, Inc, Fort Worth, TX

Pancreatic ductal adenocarcinoma (PDAC) is a deadly malignancy with a dismal 5-year survival rate, highlighting the urgent need to improve drug response and overcome primary or acquired (secondary) resistance to conventional chemotherapy. Glycogen synthase kinase 3β (GSK-3β) is a target in PDAC and the GSK-3 inhibitor, elraglusib, has been shown to improve chemosensitivity of PDAC and survival in preclinical cancer models. In addition, data from phase II clinical trials in patients with previously untreated metastatic pancreatic cancer is demonstrating preliminary evidence of clinical benefit in patients receiving a combination of gemcitabine/nab-paclitaxel. While this early evidence is highly encouraging, the biological determinants of elraglusib response are unknown. Using genome wide CRISPR/Cas9 library screening, we identify aurora kinase A (AURKA), an oncogenic kinase with major roles in mitosis, as a critical regulator for elraglusib sensitivity. Elraglusib treatment activates AURKA by inducing a G2/M cell cycle arrest. We show that knocking out AURKA reduces the phosphorylation of polo like kinase 1 (PLK1), arresting cells in mitosis, and leading to mitotic catastrophe and significant apoptosis after elraglusib treatment. Strikingly, the AURKA inhibitor, alisertib, works synergistically with elraglusib to inhibit PDAC cell line growth and induce apoptosis. In summary, our results demonstrate that targeting AURKA is an effective approach to sensitize PDAC tumors to elraglusib.

#4659 A genome-wide CRISPR screen identifies *ARID1A* as a potential resistance marker of IDH1 inhibitor in *IDH1*-mutant cholangiocarcinoma cell.

T. Kondo[1], O. Kikuchi[2], Y. Wang[1], Y. Nakai[1], T. Ida[1], Y. Cao[1], T. H. N. Vu[2], Y. Kondo[1], T. Sunami[1], Y. Yamamoto[1], T. Saito[1], S. Kataoka[1], A. Yamada[1], M. Kanai[1], S. Ohashi[1], M. Muto[1];

[1]Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Kyoto University Center for Immunotherapy and Immunobiology, Kyoto, Japan

Background: Isocitrate dehydrogenase 1 (*IDH1*) mutations have been identified in approximately 20% of intrahepatic cholangiocarcinoma cases. These predominant gain-of-function mutations at codon 132 lead to abnormal production of the oncometabolite D-2-hydroxyglutarate. Targeted pharmacological disruption of the *IDH1* mutation demonstrates tumor growth inhibition in *IDH1*-mutated cholangiocarcinoma. However, the efficacy of an IDH1 inhibitor (AG-120) as monotherapy for *IDH1*-mutated cholangiocarcinoma has been proven clinically insufficient, suggesting a need for investigating predictive biomarkers. In this study, we employed a genome-wide CRISPR screen to pursue resistance mechanisms to pharmacological IDH1 inhibition.

Methods: The screening utilized SNU1079 cells harboring the *IDH1* R132C mutation and the Brunello genome-wide CRISPR knockout (KO) pooled library (Addgene #73178, Broad Institute GPP, 4 guides/gene). The read couns of sgRNAs were normalized to reads per million, and then log2 was transformed. The log fold change (LFC) of each sgRNA of the AG-120-treated group was determined relative to that of the DMSO-treated group. Hypergeometric distribution was used to determine statistical significance. P values per gene were calculated as the average -log10(P value) of individual sgRNAs. We validated the CRISPR screening outcomes *in vitro* using both *IDH1*^{R132C} mutant (SNU1079) and *IDH1*^{R132S} mutant (RBE) cells by WST-1 assays, clonogenic assay and competition assay. (Tsujino T et al. *Nat Commun*. 2023) In competition assay, GFP was constitutively expressed in *ARID1A*-knockout cells and cultured together with *ARID1A* intact cells, under treatment with 1 μM AG120 or DMSO for 21 days. Relative cell numbers of GFP-positive (*ARID1A*-KO) cells in comparison with GFP-negative (*ARID1A* intact) cells were quantified using a BD LSRFortessa Analyzer (BD Biosciences).

Results: Based on a volcano plot analysis, we identified three genes (*SMCHD1*, *ARID1A*, and *PGP*) with LFC > 1.5. Following a recent report of frequent *ARID1A* alteration (20%; 84/412) in a clinical study (Boerner, et al. *Hepatology*. 2021), we focused our research on *ARID1A* (LFC = 1.531; $-\log_{10} P = 3.75$). WST-1 assays and clonogenic assays as short-term (3-7 days) assays failed to validate the results of CRISPR screening; however, in competition assays under treatment with AG120, cells with *ARID1A*-KO exhibited significantly greater proliferation in comparison with *ARID1A* intact cells in two different cell lines (SNU1079, RBE).

Conclusions: The results demonstrated that ARID1A disruption reduced the efficacy of the IDH1 inhibitor against *IDH1*-mutatedcholangiocarcinoma cells. Based on these findings, we are planning comprehensive analyses employing *in vivo* models and clinical data to substantiate these observations.

#4660 Characterization of a nicotinamide-based kinase inhibitor HSN748 for inhibition of RET-driven tumors.

U. Khatri[1], N. Dayal[2], T. Shen[1], X. Hu[1], H. Sintim[2], J. Wu[1];
[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Purdue University, West Lafayette, IN

Rearranged during transfection (RET) is a protein tyrosine kinase that is aberrantly activated by gene fusions or mutations in many types of human cancer including thyroid cancer and non-small cell lung cancer (NSCLC). Selpercatinib (LOXO-292) and pralsetinib (BLU-667) are FDA approved RET-selective tyrosine kinase inhibitors (TKIs) being used to treat RET-altered cancer. However, these tumors develop selpercatinib/pralsetinib-resistance via acquisition of RET(G810C/R/S) mutations located at the solvent front of the ATP binding pocket. The overall goal of our research is to discover next-generation of RET kinase inhibitors to inhibit selpercatinib/pralsetinib-resistant RET solvent-front mutants. In this study, we characterized one of the nicotinamide-based RET kinase inhibitor, HSN748, *in vitro* and *in vivo*. HSN748 was able to inhibit selpercatinib/pralsetinib-resistant RET(G810C/R) solvent-front mutations. In BaF3/KIF5B-RET(G810C) tumor xenograft experiment, HSN748 treatment resulted in tumor regression. In immune competent transgenic mice, KIF5B-RET-induced lung tumors regressed after HSN748 treatment by oral gavage for one month (10-15 mg/kg, QD) without affecting body weight. These results identify HSN748 as an orally available RET inhibitor capable of inhibiting KIF5B-RET and its solvent-front mutant-driven tumors.

#4661 A dual degrader of HER2 and EGFR obliterates oncogenic signaling, overcomes therapy resistance, and inhibits metastatic lesions in HER2-positive breast cancer models.

L. Yang[1], A. Bhattacharya[1], D. Peterson[1], Y. Li[1], X. Liu[2], E. Marangoni[3], V. Robila[1], Y. Zhang[4];
[1]Virginia Commonwealth University, Richmond, VA, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]Institute of Curie, Paris, France, [4]Massey Comprehensive Cancer Center, Virginia Commonwealth University, Richmond, VA

Background: HER2 is an oncogenic receptor tyrosine kinase (RTK) implicated in several types of human cancer. It is strongly expressed in about 20% of breast cancer (BC), known as HER2-positive BC (HER2+ BC), due to gene amplification. HER2 amplification or overexpression is a strong predictor of poor disease prognosis. HER2-targeted therapies are the linchpin of treating HER2+ BC. However, drug resistance is common. The main resistance mechanism is unknown. We exploited cell lines and mouse models (orthotopic patient-derived xenografts, and metastatic lesions in the brain and lung of therapy-resistant HER2+ BC) for experiments of genetic and pharmacologic depletion of HER2 and its family member EGFR, analysis of RTKs and no-RTKs, and evaluation of cell and tumor growth, to delineate the mechanism of HER2+ BC resistance to HER2 inhibitors and assess the therapeutic activity of $PEPD^{G278D}$. $PEPD^{G278D}$, a recombinant human protein, is the first-in-class dual degrader of HER2 and EGFR.
Results: Trastuzumab-resistant HER2+ BC cells and tumors are highly vulnerable to targeted degradation of HER2 and EGFR. Trastuzumab is the most commonly used HER2 inhibitor in the clinic. Targeted degradation of HER2 and EGFR by $PEPD^{G278D}$, which binds to their extracellular domains, causes extensive inhibition of oncogenic signaling proteins in HER2+ BC cells resistant to trastuzumab. This is accompanied by strong growth inhibition of cultured cells, orthotopic patient-derived xenografts, and metastatic lesions in the brain and lung of trastuzumab-resistant HER2+ BC. siRNA knockdown shows that eliminating both HER2 and EGFR is important to maximize therapeutic outcome. Collectively, our results reveal the key vulnerability of trastuzumab-resistant HER2+ BC and shows a promising strategy that overcomes trastuzumab resistance by targeting this vulnerability.
Conclusions & Therapeutic Relevance: This study identifies a key therapeutic vulnerability of drug-resistant HER2+ BC and shows that an agent that targets this vulnerability is highly effective in overcoming drug resistance in this disease. The findings provide new insights and innovations to advance treatment of drug-resistant HER2+ BC that remains an unmet problem.

#4662 High-throughput screening identifies potential combinatorial therapies to overcome lenvatinib resistance in liver cancer.

K. Chau, M. S. J. McDermott, K. Gong, D. J. Slamon;
UCLA - University of California Los Angeles, Los Angeles, CA

Liver cancer has seen an increase in mortality rate over recent decades due to limited targeted therapies and growth in specific etiologies. Lenvatinib, a multi-TKI inhibitor, is used as a first-line therapy for liver cancer patients who cannot receive immunotherapy, which is a component of the current standard of care. Unfortunately, lenvatinib efficacy is short. Understanding why liver cancers become resistant and identifying interventions to restore sensitivity can help prolong the clinical efficacy of lenvatinib. A panel of 20 liver cancer lines was screened to identify four lenvatinib-sensitive lines. These lines were subsequently conditioned to grow under increasing lenvatinib concentrations to generate lenvatinib-resistant (LR) models. One such model, Hep3B LR, exhibited a stable resistance to lenvatinib for up to 12 weeks in culture. Hep3B LR showed cross-resistance to selective inhibitors of FGFR4 and FGFR1 but not of MAPK14 and PDGFR, suggesting that the resistance phenotype may result from FGFR dysfunction. Unlike parental Hep3B, Hep3B LR exhibited a 3.4X increase in migration. Western blot detected an increase in pAKT, a survival marker. Additionally, proteins associated with cancer drug resistance were higher in Hep3B LR cells: Notch receptors and ligands, pStat3, and Axl. To identify means of overcoming lenvatinib resistance in Hep3B LR, a Cell-Titer Glo high-throughput assay was developed to measure the growth inhibition of candidate drugs in the presence and absence of lenvatinib. Preliminary results from the first 24 drugs screened reproduced known drug sensitivities associated with lenvatinib resistance (i.e., MEK/ERK, EGFR, GPX4 inhibition) but also identified novel sensitivities to inhibition of PKMYT1 or γ-secretase, the latter a cleavage enzyme involved in Notch signaling activation. Validation of these candidate hits using a grid-based titration of both drugs showed additive growth inhibition of lenvatinib in combination with ERK, EGFR, or GPX4 inhibitors but not with PKMYT1 or γ-secretase inhibitors in resistant cells. Interestingly, EGFRi and lenvatinib were substantially synergistic in parental cells, suggesting that an upfront combination of these inhibitors could potentially be used before the emergence of lenvatinib resistance in liver cancer. We have established a lenvatinib-resistant liver cancer cell model and validated a drug screening assay to identify potential combinatorial therapies to overcome lenvatinib resistance in liver cancer.

#4663 Establishing the role of PRMT5 in lung cancer tumorigenicity and modulation of expression in smokers.

Syed N. Ali, Meet Patel, Bamby Dieng, Cody Lund, Neelu Puri

University of Illinois College of Medicine Rockford, Rockford, IL

Studies show that PRMT5 (protein arginine methyl transferase 5) is responsible for increased tumorigenicity by activation of the PI3K/Akt signaling pathway promoting increased cancer cell proliferation. However, the role of PRMT5 in modulating EGFR TKI resistance is minimally studied. We hypothesize that over-expression of PRMT5 could promote tumorigenesis and TKI resistance by activating PI3K-Akt-mTOR signaling pathways. Hence, modulating this key biomarker may help reduce tumorigenicity and overcome TKI resistance. We performed qPCR to study the expression of PRMT5 in normal lung cells and NSCLC cell lines. We also compared the expression of these biomarkers in erlotinib resistant (ER) and Osimertinib resistant (OR) cells using Western blotting. PRMT5 was inhibited using GSK591 (PRMT5i) to evaluate its sensitivity to EGFR TKIs (ER and OR). PRMT5 expression in normal lung cells and NSCLC cells treated with Cigarette smoke extract (CSE) were also studied and correlated with immunostaining results from smoker and non-smoker lung tumor tissue samples. Changes in PRMT5 expression were analyzed in WT-EGFR lung cancer cell lines (H358, H2170), mutant EGFR lung cancer cell lines (H3255, H1975, PC9) and normal lung fibroblast cells (HLF). PRMT5 expression was upregulated by 1.6-2.1 fold in HLF, H2170 and H358 cells after 1 week of treatment with CSE. CSE treatment also upregulated expression of inflammatory cytokines (IL-1β, IL-8 and TNF-α) in H358 cells by 1.6-7 fold as analyzed by qPCR. PRMT5 expression was upregulated in EGFR-TKI resistant cell lines, by 1.5-1.9 fold in PC9ER, PC9OR and H2170ER cells, compared to parental cells. Similar results were found using qPCR, with 1.6-2.3 fold increase in PRMT5 mRNA expression in H2170OR, PC9ER/OR and H3255OR cells compared to parental cells. An MTT assay was done to assess percentage viability of cells after treatment of PRMT5i. While 2μM PRMT5i treatment of PC9OR cells decreased cell viability by 42%, an inhibitory effect that was more than additive was seen with a combination of 2μM of PRMT5i and 21nM of OR. Similar results were also observed in H2170ER cells. Migratory properties of OR resistant cells, were studied by wound healing assays. Percentage wound area in PRMT5i treated PC9OR cells was 29.3% as compared to 6.1% and 10.5% in diluent and OR treated cells respectively after 48 hrs. Combination treatment of PRMT5i and OR further inhibited cell migration with higher wound area of 41.7%. Immunostaining of lung tumor sections from smokers and non-smokers showed high expression of PRMT5 localized in the cytoplasm and nucleus. Microscopic analysis of 20 tumor sections from smokers showed higher expression of PRMT5 ($p<0.05$) compared to non-smokers. We can conclude that PRMT5 is upregulated in TKI resistant cells causing tumorigenesis. Modulation of PRMT5 can prove to be groundbreaking and revolutionary, as it may increase the efficacy of EGFR TKIs.
[S.N.A. and M.P. contributed equally to this work.]

#4664 Therapeutic targeting of *TP53*-mutated acute myeloid leukemia by inhibiting cell cycle checkpoint.

D. Gwak, D. Kim, H. Jang, J. Liu, S. Min, J. Byun, Y. Koh, J. Hong, S.-s. Yoon, D.-Y. Shin, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of;
Seoul National University, Seoul, Korea, Republic of

Acute myeloid leukemia (AML) is a hematological malignancy characterized by various somatic mutations leading to abnormal proliferation and differentiation of hematopoietic cells. Mutations on the *TP53* gene occur in 5% to 10% of patients with *de novo* AML, with higher frequency in patients with relapsed and refractory (R/R) AML. Patients with *TP53*-mutated AML typically exhibit a poor response to conventional induction therapy and have a short overall survival (OS) rate, with a median duration of 5-9 months. Although various target agents have been developed for the treatment of AML, treatment options for *TP53*-mutated AML remain limited. Here, we have discovered a novel drug combination that can enhance the efficacy of the conventional therapeutic regimen for *TP53*-mutated AML patients. For *in vitro* analysis, we used the human AML cell line Kasumi-1(AML-M2), which harbors a homozygous *TP53* R248Q mutation. We treated kasumi-1 cells with a combination of cytarabine and Idarubicin to produce drug tolerant persisters (DTPs) which is a minor population that survived the drug treatment. The Kasumi-1 DTPs displayed temporal G2/M phase cell cycle arrest and significant resistance to further repeated drug treatment. To discover drug candidates targeting *TP53*-mutated DTPs, we first examined the differentially expressed genes (DEGs) of *TP53*-mutated AML patients using patients' RNA expression data deposited in the cancer genome atlas (TCGA) database. Using selected DEGs, drug candidates potentially affecting *TP53*-mutated AML cells were extracted from the connectivity map (CMap build 02) database. In addition, through a literature search, drugs with the ability to reactivate mutant p53, drugs that directly target mutant p53, synthetic lethal partners with mutant p53, and drugs that target leukemia stem cells were selected as candidate groups. As a result, we selected 46 drug candidates that would be effective for *TP53*-mutated AML through *in silico* analysis and therapy strategies targeting p53. Using *in vitro* cytotoxicity assay, we screened 46 candidate compounds at multiple doses and confirmed several drugs that effectively eliminate DTPs. The drug screening showed that cell cycle checkpoint inhibitors not only resulted in a significant reduction of G2/M phase arrested cells but also induction of apoptotic cells at the subG1 phase. Furthermore, the zero interaction potency (ZIP) model of SynergyFinder (https://synergyfinder.fimm.fi) analysis showed that cell cycle checkpoint inhibitors synergistically enhanced the cytotoxic effect of cytarabine on Kasumi-1 DTPs. Collectively, this study suggests that novel combination treatment of cell cycle checkpoint inhibitors with conventional drugs selectively inhibits *TP53*-mutated AML DTPs.

#4665 USP18 promotes anlotinib resistance in medullary thyroid carcinoma by stabilizing aurora B kinase.

X. Qin[1], X. Wan[1], D. Li[1], Y. Liu[1], X. Ruan[1], F. Luan[2], K. Xu[2], J. Li[2], R. Xiang[2], Y. Piao[2], Y. Shi[2], X. Zheng[1];
[1]Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China, [2]Nankai University, Tianjin, China

Targeted therapy resistance is the main cause of disease progression in advanced medullary thyroid carcinoma (MTC). However, the key molecules and mechanisms remain unclear. We previously performed a genome-wide in vitro screen of Anlotinib resistance-related genes in human MTC cell line TT using CRISPR-dCas9-SAM system and identified ubiquitin-specific protease 18 (USP18) as a key molecule mediating Anlotinib resistance in MTC. However, its downstream mechanism needs further clarification. Based on the high-throughput DNA sequencing results of the control group and the Anlotinib screening group, a group of key genes related to Anlotinib resistance in MTC was screened through the MAGeCK algorithm and the enrichment ratio of sgRNA in the Anlotinib screening group. Among them, USP18 ranked first in the enrichment results. Analysis of the correlation between the expression level of USP18 in MTC patient specimens and survival revealed that patients with high USP18 expression in tumor cells had poorer prognosis. Overexpression of USP18 in MTC tumor cells significantly promoted the growth of subcutaneous xenograft tumors in NOD/SCID mice treated with Anlotinib. In vitro cell experiments also showed that overexpression of USP18 promoted the proliferation of MTC tumor cells and significantly inhibited the proportion of cell apoptosis after Anlotinib treatment. Further research found that USP18, as a deubiquitinating enzyme that can specifically remove ISG15-like ubiquitin-like proteins from substrate proteins, can improve the kinase stability of Aurora B by removing ISG15-like ubiquitin modification and promote MTC tumor cell proliferation through the activation of PI3K-Akt signaling regulated by Aurora B kinase. Application of Aurora B kinase inhibitor in Anlotinib-resistant MTC cell lines significantly inhibited tumor cell proliferation, and Aurora B kinase inhibitor significantly increased the proportion of cell apoptosis in MTC tumor cells overexpressing USP18. In the subcutaneous xenograft tumor model of MTC in NOD/SCID mice, the growth of xenograft tumors in the Anlotinib combined with Aurora B kinase inhibitor treatment group was also significantly inhibited. In summary, overexpressed USP18 can activate PI3K-Akt signaling and promote tumor cell proliferation by increasing the stability of Aurora B kinase, ultimately leading to the formation of Anlotinib resistance in MTC patients. Combined use of Aurora B kinase inhibitor is a potentially effective combined treatment strategy for Anlotinib-resistant MTC patients.

#4666 HC-7366, a potent GCN2 kinase activator, augments osimertinib therapy to delay resistance in EGFR mutant NSCLC models.

C. Dudgeon, S. Fujisawa, O. Funk, F. Tameire, T. O. Kangas, W. Zhang, E. S. Lightcap, D. Surguladze, N. Bose;
HiberCell, Roseville, MN

Despite the efficacy seen with EGFR tyrosine kinase inhibitors (TKIs) in the treatment of EGFR mutant NSCLC, the long-term prognosis remains unfavorable due to resistance. Osimertinib is used as the first- and second-line treatment for EGFR exon 19 deletion, L858R mutation, and acquired T790M mutation. Resistance is driven by both EGFR-dependent and independent events, such as gene amplification and upregulation of HIF1α. Metabolic events also drive resistance by increasing oxidative phosphorylation (OXPHOS) caused by osimertinib-induced glycolysis inhibition. HiberCell has developed HC-7366, a GCN2 activator currently being investigated in a Ph1 clinical trial in patients with solid tumors (NCT05121948). GCN2 activation by HC-7366 drives the integrated stress response (ISR) by inducing the expression of ATF4. This results in translation inhibition, cell cycle arrest, HIF1α suppression, and apoptosis in cancer cells. Our preclinical data suggest HC-7366 can reduce glycolysis, TCA cycle metabolites, and OXPHOS, thereby causing mitochondrial dysregulation. We hypothesized that combination of HC-7366 with osimertinib could reduce resistance by evading the adaptive resistance mechanisms. We treated the NCI-H1975 xenograft model with HC-7366, a clinically relevant dose of osimertinib, and the combination for 21 days and then followed for tumor regrowth. At day 21, the HC-7366 group showed efficacy with tumor growth inhibition (TGI) of 55%, while osimertinib resulted in tumor regression of 97% with 8/10 CRs and 2/10 PRs. The combination had tumor regression of 99% with 10/10 CRs. After treatment cessation for 74 days, tumors in the osimertinib group quickly regrew with 6/10 tumors progressing and 4/10 mice tumor-free. In contrast, the combination group had only 2/10 tumors regrow with 8/10 mice tumor-free. In an EGFR-dependent resistance model NCI-H1975 (EGFR C797S), combination achieved 63% TGI versus 31% with osimertinib. In an EGFR-independent resistant PDX with EGFR exon 19 deletion, combination benefit was seen at 70% TGI compared to 40% for osimertinib, while a PDX with EGFR L858R showed a trend for combination benefit. To understand the mechanism of action, we examined osimertinib-resistance pathways to determine how GCN2 activation could affect them. Combination with HC-7366 reduced the expression of short-lived proteins involved in osimertinib resistance, including HIF1α, MET, cyclin D1, and CDK4. Combination decreased TIM17A and TIM23, proteins essential for mitochondrial protein translocation, potentially causing mitochondrial dysfunction. We found a proliferation reduction by Ki67 and an increase in apoptotic proteins CHOP, PUMA, and cleaved caspase 3. Taken together, these data reveal that combination of HC-7366 and osimertinib, and potentially other EGFR TKIs, may be an effective treatment strategy at targeting adaptive resistance mechanisms.

#4667 HDAC9 as a potential regulator of lenvatinib resistance in hepatocellular carcinoma.

Y. Xie[1], M. Zhang[1], Y. Liu[1], L. Liu[1], A.-L. Cheng[1], S. Ma[2], M. Tong[1];

[1]The Chinese University of Hong Kong, Shatin, NT, Hong Kong, [2]The University of Hong Kong, Pok Fu Lam, Hong Kong Island, Hong Kong

Lenvatinib is used as the first-line therapy for advanced hepatocellular carcinoma (HCC) patients. However, poor response and compromised therapeutic effect with prolonged treatment are frequently observed in HCC patients. To elucidate the underlying mechanisms, lenvatinib responsive and non-responsive stages were modeled in liver tumor-bearing immunocompetent mice which were divided into lenvatinib and vehicle control treatment groups. Tumor tissues after short and prolonged lenvatinib treatment were harvested for single-cell RNA sequencing. Results from single-cell RNA sequencing revealed heterogenous tumor cell sub-populations associated with tumor differentiation and identified an upregulated expression of class IIa histone acetylase HDAC9 in lenvatinib-treated tumor at the non-responsive stage. Upregulation of HDAC9 was similarly observed in lenvatinib-resistant human patient-derived xenograft (PDX). Functional studies suggested that suppressing HDAC9 could re-sensitize lenvatinib response in both in vitro and in vivo models. In sum, we identified a potential regulator of lenvatinib treatment response in HCC.

#4668 Characterization of fourth-generation EGFR inhibitors in binding experiments with C797S mutant EGFR and cell-based assays with osimertinib-resistant non-small cell lung cancer cell lines.

J. J. T. Melis[1], K. Kevenaar[1], J. J. Kooijman[1], Y. Grobben[1], J. Ytsma[1], J. Bertran-Alamillo[2], M.-A. Molina-Vila[2], N. Willemsen-Seegers[1], G. J. R. Zaman[1]; [1]Oncolines B.V., Oss, Netherlands, [2]Pangaea Oncology, Barcelona, Spain

Osimertinib is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor that inhibits the EGFR kinase domain by irreversible binding of the cysteine-797 residue (C797). Osimertinib was originally designed to target the T790M mutation, which is clinically the most frequently observed resistance mechanism to treatment with first- or second-generation EGFR inhibitors. Osimertinib has a high selectivity for the classical EGFR driver mutations (exon 19 deletion and L858R) compared to wild-type EGFR. Due to this favorable selectivity profile, osimertinib has become the standard first-line therapy for non-small cell lung cancer (NSCLC).

Common resistance mechanisms following osimertinib treatment are *MET* oncogene amplification, and cysteine-to-serine substitution at position 797 (C797S) of EGFR, which precludes binding of osimertinib. Fourth-generation EGFR inhibitors and combinations with other targeted agents are potential strategies to overcome osimertinib resistance or to increase its efficacy.

Three fourth-generation EGFR inhibitors were profiled in biochemical and cell-based assays: BDTX-1535, BLU-945, and JBJ-09-063. The binding kinetics for wild-type and C797S mutant EGFR were determined in surface plasmon resonance binding experiments on a Biacore 1S+ (Cytiva). The effect on osimertinib-resistant cells, generated using two different approaches, was studied in cell viability assays. In the first model, subclones of the NSCLC cell line PC-9, harboring an exon 19 deletion activating EGFR mutation, were selected for osimertinib resistance by *in vitro* drug selection [1]. In the second model, the EGFR C797S mutation was introduced into the NSCLC cell line NCI-H1975, which expresses both the L858R activating mutation and the T790M resistance mutation, by gene-editing with CRISPR-Cas9. Synergies with fourth-generation EGFR inhibitors were determined by profiling combinations in a 6-by-6 matrix, and quantifying synergistic effects using the Excess over Bliss score.

We will present a detailed comparison of the binding kinetics of the three fourth-generation EGFR inhibitors on wild-type and C797S-mutant EGFR, and their ability to compete with osimertinib for binding to the kinase domain of EGFR. The different fourth-generation inhibitors show various selectivities for the various EGFR mutants and differences in their ability to spare wild-type EGFR. Profiling results of the three fourth-generation EGFR inhibitors in the osimertinib-resistant cell lines and on a panel of more than one hundred human cancer cell lines will be presented.

#4669 Differential preclinical activity of Bruton tyrosine kinase inhibitors (BTKis) against *BTK* resistance-associated mutations.

M. S. Davids[1], I. E. Ahn[1], J. J. Riehm[2], M. Acar[2], V. Girardi[2], S. Patel[2], T. Gururaja[2], J. Woyach[3], L. T. Lam[2], E. Szafer-Glusman[2];
[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, [2]AbbVie, North Chicago, IL, [3]Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Differences in profiles of acquired mutations of resistance to BTKis might have implications for treatment sequencing. We evaluated preclinical activity of BTKis (ibrutinib [Ibr], acalabrutinib [Acala], zanubrutinib [Zanu], and pirtobrutinib [Pirto]) against multiple clinically relevant *BTK* mutations and report on the clinical impact of *BTK* C481S in patients (pts) treated with Ibr.
Methods: Inhibition of kinase activity by BTKis was evaluated in a cell-free kinase activity assay (Nanosyn). Cell-killing activity on CRISPR-generated *BTK* mutant knock-in TMD8 cells was assessed after 3 days of BTKi treatment. Time from first detection of C481S mutation to progressive disease (PD) was evaluated in pts treated with Ibr with previously untreated (n=247) or relapsed/refractory (R/R; n=172) CLL using pooled data from 5 clinical trials.
Results: In vitro kinase activity was highest for Ibr compared with Acala or Zanu against C481S (Ibr IC_{50}: 26.3 nM; Zanu: 84.8 nM; Acala: 338 nM) and T474I (Ibr: 1.2 nM; Zanu: 4.4 nM; Acala: 43.6 nM). Ibr maintained cell-killing activity against all tested *BTK* mutants, whereas limited activity was seen with Acala against C481S and A428D; with Zanu against C481S, L528W, and A428D; and with Pirto against T474I, L528W, V416L, and A428D (Table). In pts treated with Ibr, C481S was detected prior to clinical PD in 3 previously untreated pts and in 26 pts with R/R CLL; median (range) time from first detection of C481S to PD in these pts was 17.0 mo (11.2-34.3) and 10.0 mo (2.6-35.7), respectively.
Conclusion: This study demonstrates activity of Ibr against all evaluated *BTK* variants, which are associated with resistance to covalent and noncovalent BTKis. Clinical data shows that pts who develop C481S mutations continue to derive benefit from Ibr for several months before PD. Together, these data suggest a role for Ibr in the treatment of pts with a broad spectrum of *BTK* variants.

Table. Cell-killing activity of BTKis against wild type and mutant BTK

EC_{50} (nM)	***BTK***					
	Wild type	**C481S**	**T474I**	**L528W**	**V416L**	**A428D**
Ibr	0.6	414.0	1.9	181.4	0.5	205.3
Acala	3.9	2973.8	43.3	3.5	106.3	3000.0
Zanu	0.7	2322.0	11.7	3000.0	0.6	1726.0
Pirto	8.2	12.6	2727.5	3000.0	1898.0	3000.0

#4670 KS18, an Mcl-1 inhibitor, triggers cell death and enhances the therapeutic efficacy of venetoclax in bortezomib-resistant multiple myeloma cells.

O. Al Odat[1], O. Aloudat[2], E. Nelson[1], T. Budak-Alpogan[3], S. Jonnalagadda[1], Y. Chen[4], M. Pandey[2];
[1]Rowan University, Glassboro, NJ, [2]Cooper Medical School of Rowan University, Camden, NJ, [3]Cooper University Hospital, Camden, NJ, [4]College of Science and Mathematics, Rowan University, Glassboro, NJ

A critical clinical challenge in the management of multiple myeloma (MM) is the development of both innate and acquired resistance to the treatment with bortezomib. Our prior research showed that the overexpression of the anti-apoptotic Bcl-2 family protein Mcl-1 can result in resistance to the chemotherapy drugs bortezomib and venetoclax. In order to overcome the issues posed by resistance, this study investigates the possibility of a small chemical called KS18, a novel Mcl-1 inhibitor. KS18 outperforms other Mcl-1 inhibitors such as S63845, VU661013, and AZD5991, according to the findings of our research, which shows that it is extraordinarily effective against MM cells that have become resistant to bortezomib. We establish the selectivity of KS18 through tests employing Mcl-1 knock-down (KD), and we find that it is both effective and efficient. In addition, we used immunoprecipitation (IP) and protein-protein interaction analysis (PPIs) to investigate the dynamic connections that exist between Mcl-1 and pro-apoptotic proteins. The KS18 therapy exhibits an outstanding ability to cause complete apoptosis, as seen by the remarkable 88.8% apoptosis rate recorded in MM patient samples. Not only does KS18 restore apoptosis in bortezomib-resistant MM cells, but it also synergizes with venetoclax to enhance the apoptotic response. This is an important finding. It has been demonstrated through both *in vitro* and *in vivo* research that KS18 can re-sensitize MM cells to the effects of bortezomib, which represents a potential step forward in the treatment of the disease. In bortezomib-resistant MM cells, treatment with KS18 led to a remarkable 92% reduction in colony formation compared to untreated controls. *In vivo* experiments that were performed on mice models that were resistant to bortezomib provide additional evidence that KS18 is effective. The extraordinary reduction in tumor weight of 55% that occurred as a direct result of treatment with KS18 at a dose of 1 mg/kg for a period of 15 days exemplifies the powerful anti-resistance characteristics of this compound. These intriguing findings highlight the potential value of KS18 as an adjunct to therapies aimed at overcoming bortezomib resistance in MM and other associated cancers. Bortezomib-resistant malignancies provide a challenge for patients, but additional research into the clinical value of KS18 holds the potential to improve treatment outcomes and broaden the range of therapeutic alternatives available to these patients.

#4671 Efficacy and mechanism of mebendazole for ovarian cancer therapy.

R. Rai[1], D. Penta[1], D. Dey[1], D. Benbrook[1], L. Wang[2], M. Bieniasz[2], L. Dockery[1];
[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

Introduction: Ovarian cancer (OvCa) is the most lethal gynecological malignancy. Although most OvCa patients initially respond to frontline platinum-based therapies with approximately 80% of patients experiencing remission, approximately 75% of those women experience a recurrence with only approximately 50% of patients alive 5 years following diagnosis. There is a critical need to develop novel therapeutic agents or methods to overcome chemoresistance and toxicities experienced with conventional chemotherapy regimens used for OvCa patients. Repurposing drugs is a promising strategy to safely and more rapidly evaluate potentially effective treatment regimens. Over the past two decades, Mebendazole (MBZ), an anti-parasitic drug, has gained much attention in oncology due to its favorable biosafety profile and potent anti-cancerous activity seen in several human malignancies. Therefore, we examined the efficiency and mechanism of MBZ against OvCa.

Methods: The *in vitro* efficacy of MBZ was evaluated in cisplatin-resistant (CPR) and parent (WT/sensitive) OVCAR-8 cell lines as well as in ascites samples collected from chemo-resistant OvCa patients by using 2D and/or 3D cell viability assay and invasion assay. The *in vivo* efficacy of MBZ was assessed in orthotopic animal models, utilizing CPR-OVCAR8 spheroids, and patient-derived xenograft (PDX) animal models with specimens from chemo-resistant ovarian cancer patients. Molecular mechanisms were investigated through western blot and immunofluorescence analysis.

Result: Our results confirmed that MBZ efficiently decreased cell viability, spheroid size, and the invasion ability of OvCa cell lines and ascites samples. OvCa cells treated with MBZ demonstrated downregulation of proliferation markers and upregulation of apoptosis markers indicating inhibition of cell proliferation and induction of apoptosis. Mechanistically, MBZ inhibited the Wnt/β-catenin signaling pathway by downregulating the expression and nuclear localization of β-catenin and epithelial-mesenchymal transition (EMT) markers. Preclinical studies showed that MBZ at 50 mg/kg/day dose for 28 days significantly reduced tumor growth in PDXs and orthotopic tumor models without any evidence of toxicity.

Conclusion: Collectively, our study strongly supports the therapeutic potential of MBZ against OvCa particularly, which warrants further clinical studies.

#4673 Genome-scale metabolic models identify gene targets that enhance drug response of drug-resistant breast cancer cells.

H. Jung[1], J. Lim[1], H. Ryu[2], Y. Kim[1], H. Kim[1];

[1]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, [2]Seoul National University Hospital, Seoul, Korea, Republic of

Adaptive drug resistance poses a significant therapeutic challenge in treatment of breast cancer patients. Metabolic reprogramming in cancer cells is one of the major mechanisms associated with drug resistance. In this study, we aim to identify gene targets that enhance the drug response of drug-resistant breast cancer cells through downregulation. We hypothesized that metabolic perturbation in drug-resistant breast cancer cells could revert their metabolic features to those of drug-sensitive cells. To predict such gene targets, we used a computational model known as a genome-scale metabolic model (GEM). A GEM simulates the entire metabolic reaction fluxes of a cell under varying genetic and/or environmental conditions. We specifically targeted two engineered MCF7 breast cancer cell lines: one resistant to doxorubicin and the other to paclitaxel. First, we generated proteome data from drug-sensitive and drug-resistant MCF7 cell lines, and used them to construct the cell-specific GEMs. Subsequently, single-gene knockout simulation was conducted using these cell-specific GEMs. The initial list of the gene knockout targets was subjected to pathway analysis involving proteome and metabolome data to finalize the gene targets. The final gene targets were expected to lead to metabolic features similar to those of drug-sensitive MCF7 upon the downregulation. *In vitro* experiments using inhibitors were conducted to validate these predicted gene targets. This study provides a computational approach that can also be applied to other types of drug-resistant cancer cells.

#4674 Reserpine analog modulates transport function of ABCG2.

S. Ohnuma[1], S. Kokubo[1], N. Sugisawa[1], M. Murakami[2], Y. Hatsuzawa[1], M. Kobayashi[1], T. Kajiwara[1], H. Suzuki[1], H. Karasawa[1], K. Watanabe[1], T. Doi[3], S. V. Ambudkar[2], T. Kamei[1], M. Unno[1];

[1]Tohoku University Hospital, Sendai, Japan, [2]National Cancer Institute, National Institutes of Health, Bethesda, MD, [3]Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan

Backgrounds: Reserpine is an agent that is used for the treatment of hypertension. ABCG2 also known as breast cancer resistance protein (BCRP) is a member of the ABC transporters associated with multidrug resistance (MDR). Our high-throughput screening assay has revealed that reserpine analog inhibits transport function of ABCG2.

Aim: To investigate the effect of reserpine analog on ABCG2 function.

Results: Flow cytometry assay showed that reserpine analog blocked the efflux of Pheophorbide a (PhA: fluorescent substrate of ABCG2) from ABCG2-expressing HCT-116/BCRP colon cancer cells in a concentration-dependent manner. Furthermore, cell proliferation assay (MTS assay) revealed that 5 and 10 μM reserpine analog sensitized HCT-116/BCRP cells to SN38 with IC50 value 0.61 + 0.12 μM and 0.22 + 0.036 μM, respectively. Finally, reserpine analog did not stimulate ABCG2-mediated ATP hydrolysis, but rather inhibited it (concentration required for 50% inhibition = 2.7 μM), suggesting that reserpine analog might prevent conformational changes required for ATP hydrolysis.

Conclusion: Reserpine analog could be developed as a potent modulator to overcome ABCG2-mediated MDR in cancer cells.

#4675 Reduction in NSCLC tumorigenesis by targeting sphingosine kinase 2.

Ayesha Khan, Bamby Dieng, Namrata Dube, Mohammad Fazle Alam, Neelu Puri

University of Illinois College of Medicine (Rockford), Rockford, IL

Lung cancer will account for 21% of US cancer deaths in 2023 with 238,340 cases and 127,070 deaths. Treatment with EGFR-TKI (epidermal growth factor receptor tyrosine kinase) inhibitors initially decrease tumor growth, but often leads to TKI resistance. According to studies, non-small cell lung cancer (NSCLC) tumors express more SphK2 (Sphingosine kinase 2) than normal lung tissue and patients with overexpression have worse survival chances. However, SphK2's role in TKI resistance is unclear. We hypothesize that inhibiting/downregulating SphK2 could reduce tumorigenicity and overcome ER (Erlotinib) and OR (Osimertinib) resistance. We studied the expression of SphK2 in both drug-resistant (OR/ER) and drug sensitive (parental) H358, H2170, H3255, and PC9 NSCLC cell lines using Western blotting, qRT-PCR, and immunofluorescence. H3255OR cells were also bioprinted with GelMA hydrogel using an R-Gen 200 bioprinter to mimic the physiological tumor environment and treated with SphK2 siRNA or ABC294640 (SphK2i). Immunoblotting was done to analyze changes in the expression of SphK2 in H358 (WT-EGFR) and H3255 (mutant EGFR- L858R) parental and OR-resistant cell lines. Results indicated a 1.5-1.8-fold upregulation of SphK2. Increased SphK2 gene expression was observed using qPCR in TKI-resistant H3255OR (4.3-fold), PC9ER/OR with mutant EGFR (E746-A750del) (1.8-3.3-fold), and H2170ER/OR with WT EGFR (1.3-1.5-fold) compared to parental cells. Immunofluorescence studies showed increased fluorescence of SphK2 in H3255OR (2.6-fold), H358 ER (2.4-fold) and OR cells (2.3-fold) compared to parental cells. Spheroids formed from single cancer cells can "re-create" the growth of a tumor. The spheroid count of H3255OR was reduced by 73.98% and 56%, respectively, when SphK2i was added to the 3D-cell culture with Matrigel, compared to the diluent and OR alone ($p \leq 0.01$). We used 3D bioprinting to precisely stack cells on biological scaffolds to recreate lung tumors from patients and boost the therapeutic efficacy of these findings. When bioprinted spheroids of H3255OR were treated with SphK2i in combination with OR, the number of spheroids per microscopic field were reduced by 87.3% compared to OR alone. Bioprinted H3255OR spheroids treated with SphK2 siRNA and OR revealed a 75.8% and 84% reduction of spheroid count, respectively, compared to treatments with siRNA alone or OR alone ($p \leq 0.05$). This data supports the hypothesis that SphK2 suppression or downregulation can assist in mitigating oncogenesis. We also used H3255OR transwell migration assays to examine how SphK2 inhibition affects cell migration. Combining OR with SphK2i resulted in a 94.7% and 91.4% decrease in cell migration compared to diluent and OR alone ($p \leq 0.01$). In H358OR-resistant cells, combining OR with SphK2i resulted in a 94.97% inhibition compared to diluent ($p \leq 0.01$). These results suggest that targeting SphK2 could be a valuable approach for treating lung cancer.
[A.K. and B.D. contributed equally to this work.]

#4676 11α-O-2-methylbutanoyl-12β-O-tigloyl-tenacigenin B (MT2) is a novel paclitaxel chemosensitizer to inhibit growth in Taxol non-resistant and Taxol resistant cancers.

Ka Ming Cheng[1], Gui yun Wu[2], Kowk Kuen Cheung[1], Xiao-Ling Shen[2], Ying-Jie Hu[2], **Ki Lui**[3]

[1]Department of Rehabilitation Sciences, Hong Kong Polytechnic University, Hunghom, Hong Kong,[2]Science and Technology Innovation Center, Guangzhou University of Chinese Medicine, Guang Zhou, China,[3]School of Nursing and Health Studies, Hong Kong Metropolitan University, Ho Man Tin, Hong Kong

11α-*O*-2-methylbutanoyl-12β-*O*-tigloyl-tenacigenin B (MT2) is a single molecule isolated from a traditional Chinese Medicinal herb *Marsdenia tenacissima* (MT). Recently, our group has isolated a few single molecules from the MT herb, they have shown significant anti-tumor activity in vitro and MT2 has the highest potential among all. We have performed MTT viability assay and clonogenic assay to demonstrate that MT2-alone is non-cytotoxic, but the cytotoxicity of the paclitaxel+MT2 combination treatment was more significant than that of paclitaxel, a microtubule stabilizing chemotherapeutic agent. The underlying mechanism of such growth inhibition is contributed by the down-regulation of the pro-survival signaling and up-regulation of the apoptotic signaling such as an increase in cleaved caspase 3 and decrease in anti-apoptotic Bcl-2 proteins when cancer cells are co-treated with MT2+paclitaxel. More importantly, intraperitoneal administration of the combination treatment 5 times of MT2+paclitaxel (30mg/kg, 8mg/kg) has a more significant anti-tumor effect than the paclitaxel-alone (8mg/kg) or MT2-alone (30mg/kg) treatments using the wild-type hepatic HepG2 xenograft model in nude mice. Besides the wild-type HepG2 cancer cells, we have further demonstrated that MT2 is able to resensitize paclitaxel-resistant HepG2 cancer cells by inhibiting the activity of p-glycoprotein (Pgp), a key drug efflux transporter in chemotherapy resistance cancer cells. Also, the combination treatment has shown a significant anti-tumor effect in HepG2/DOX Pgp-overexpressed xenograft in nude mice. Taken together, MT2 is a novel chemosensitiser in combination use with paclitaxel to treat cancer. It enhances cancer apoptosis by suppressing the anti-apoptotic and survival signaling pathways in cancer cells.

#4677 Characterizing resistant and metastatic phenotypes to pharmacological ascorbate in pancreatic cancer.

A. N. Pope, B. R. O'Leary, J. Du, G. R. Buettner, M. D. Henry, J. J. Cullen;
Carver College of Medicine, University of Iowa, Iowa City, IA

Background and purpose: Pharmacological ascorbate (P-AscH) is a prooxidant that oxidizes to produce high levels of hydrogen peroxide. It is currently being investigated as an anti-cancer neoadjuvant for pancreatic cancer (PC). In phase I clinical trials, P-AscH has generated encouraging results in terms of efficiency and safety. However, 50% of patients do not respond to P-AscH suggesting that resistance occurs in a subset of patients. We have generated PC cell lines resistant to P-AscH to characterize mechanisms of resistance.
Methodology: PANC-1 and MIA PaCa-2 PC cell lines were treated with a stepwise progression of increasing concentrations of P-AscH until 10-fold IC_{50} concentration was fully tolerated (AscR, ascorbate resistant) as determined by clonogenic survival. Once resistance was achieved, various redox enzyme protein expression and activity were measured to determine their role in resistance to P-AscH. Proliferation and cell cycle analysis were conducted on resistant and sensitive cells. An RNA sequencing screen was conducted as an unbiased approach to identify potential candidates crucial for resistance. Finally, phenotypes associated to increased metastatic potential, including collagen invasion and in vivo tumor colonization were explored for characterization.
Results: PANC-1 and MIA PaCa-2 AscR cells developed unique mechanisms to tolerate high levels of P-AscH. PANC-1 AscR cells almost exclusively rely on catalase to detoxify H_2O_2 generated during P-AscH treatments, while MIA PaCa-2 AscR cells do not. It is interesting to note that not every redox enzyme was upregulated in response to P-AscH treatments, including GPx1/4. The AscR cell lines also differed in growth rates. PANC-1 AscR cells developed a faster proliferation rate, whereas MIA PaCa-2 AscR cells significantly decreased their growth. This is consistent with a shortened G1/G0 cell cycle phase and an accumulation in G2/M, respectively. The RNA sequencing screen revealed a metastatic signature in association with resistance to P-AscH, including upregulation of the PI3K/AKT axis. We observed a significant increase in collagen matrix invasion, as well as metastatic colonization in vivo. Additionally, we have observed increased expression of active AKT in both AscR cell lines, indicating a potential mechanism for the increased metastatic phenotype.
Conclusion: Our findings demonstrate distinct mechanisms for AcsR cells to tolerate high doses of P-AscH. Although catalase has demonstrated to be a key factor in controlling redox flux, it may not be necessary for all cell types. Not only can P-AscH resistance alter redox enzyme expression, but we have also observed substantial increase in metastatic potential to drive invasion and tumor colonization. In summary, our data indicate a potential route for PC to tolerate high levels of P-AscH and may explain how some patients do not respond to this treatment regimen.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets, Technologies, and Drug Delivery Systems
Poster Session

#4681 Unlocking the anticancer potential of calix[4]arene-based Cu(I) ionophores *in vitro* and *in vivo*.

P. Lelievre[1], C. Nogier[1], N. Renier[2], J.-L. Coll[1], I. Jabin[2], L. Sancey[1], H. Valkenier[1], A. Deniaud[3], **B. Busser**[1];
[1]Institute for Advanced Biosciences, Grenoble, France, [2]Universite libre de Bruxelles, Bruxelles, Belgium, [3]CEA Grenoble, Grenoble, France

Introduction: Cuproptosis is a novel programmed cell death pathway triggered by increased intracellular Copper (Cu) levels. This process offers promising avenues for cancer therapy and underscores the pivotal role of Cu-targeting molecules, such as chelators and ionophores. Despite the progress made, there is still a critical need for novel molecules capable of disrupting copper homeostasis within cancer cells.
Methods: We developed and patented a novel class of Cu(I) ionophores characterized by calix[4]arene structures. The anticancer effects of these compounds were evaluated through proliferation assays (IC50), cell cycle assays, and the mechanisms of cell death were explored, including apoptosis, senescence, autophagy, and cuproptosis. To elucidate the mechanisms of action, we conducted proteomic and phosphoproteomic analyses in three different lung adenocarcinoma cell lines (A549, H322, and PC9). Intracellular concentrations of Zn, Fe, and Cu were determined by Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Animal experiments were conducted on nude mice bearing subcutaneous A549 lung cancer xenografts.
Results: Our lead compound, Cuphoralix, demonstrated potent cytostatic effect across a panel of 60 cancer cell lines. This effect was attributed to an early and irreversible blockade of the cell cycle initiation at 24 hours post-treatment. Cuphoralix treatment did not induce senescence or apoptosis. Proteomic analyses confirmed the differential regulation—both upregulation and downregulation—of over 500 proteins and phosphopeptides following treatment with Cuphoralix. Notably, Cuphoralix treatment resulted in decreased expression levels of proteins implicated in cell cycle progression and DNA replication. We discovered that Cuphoralix induced cuproptosis and autophagy, as evidenced by the overexpression of LC3B-II. Intracellular Cu level was significantly increased after treatment with Cuphoralix, suggesting the initiation of cuproptosis. In vivo, the toxicity of liposomal Cuphoralix was assessed following three intravenous injections / week for 4 weeks. Animal weights remained stable, with no observed toxicity or signs of neurological or functional impairment. The anticancer efficacy of Cuphoralix, both alone and in combination with other treatments, was corroborated in vivo by measuring the volumes of subcutaneous xenografts.
Conclusions: Our novel Cu(I) ionophore, Cuphoralix, has demonstrated significant potential in inducing cuproptosis and disrupting copper homeostasis, presenting a novel approach to cancer therapy. The compound's capacity to initiate an early and irreversible cell cycle blockade and to modulate the expression of key proteins underscores its therapeutic promise. The profound in vitro and in vivo anticancer effects observed encourage further development and investigation of cuproptosis as a targeted cancer treatment strategy.

#4682 Membrane protein expression and activity following inhibition of B-cell receptor-initiated signaling by WBMP-4, a therapeutic antibody for leukemia/lymphoma.

R. S. Welt[1], D. Kostyal[2], V. Raymond[3], J. M. Lobo[1], S. Welt[1];
[1]Welt Bio-Molecular Pharmaceutical, Briarcliff Manor, NY, [2]ARDL, Akron, OH, [3]Biogent Consultants, LLC, Armonk, NY

The B-cell Receptor (BCR), comprising membrane Ig (mIg) and CD79a/b, controls normal signaling in B-cells, but dysregulation of this signaling is the dominant driver of leukemia/lymphoma. The class-specific mIg subunit of the BCR is a rational drug target for B-cell malignancies. It plays a critical role in the functioning of these cells, and allows for restricted targeting of only B-cells expressing an Ig class, offering a more tumor-specific approach than current pan-B-cell treatments. We developed a first-in-class antibody, WBMP-4, to the mIgM-BCR, which inhibits cell growth and induces apoptosis via widespread down-regulation of tyrosine kinase activity. Given the potent inhibition of intracellular signaling induced upon WBMP-4 binding to the mIgM-BCR, we expect that translation of membrane proteins will be impacted. Here we investigate the expression and phosphorylation profile of cell surface proteins following treatment of malignant B-cells with WBMP-4.

Using western blot and flow cytometry, we measure levels of CD79a/b, CD19, CD20, CD21, CD22, CD32a, CD81, and CXCR4 at 6, 24, and 48 hours after low (5ug/mL) and high (20ug/mL) dose WBMP-4 treatment, as compared to control, untreated Burkitt lymphoma (CA46) cells. We analyze phosphorylation levels of those surface proteins that serve as kinases in this system (CD79a/b, CD19, CXCR4, etc.). Using these same methods, we also examine the expression and phosphorylation of key B-cell transcription factors (e.g. NF-kB, c-MYC, STAT5, PAX5, EBF1, FOXO, and BCL-2).

Preliminary analyses show a complete absence of CD79a protein (western blot), and decreased phospho-kinase activity of CD79b (Pamgene phosphokinase array) following treatment of Burkitt lymphoma cells with WBMP-4, as compared to untreated cells. While the effect of an antibody binding to mIg may be most pronounced for CD79a/b relative to other proteins, as mIg and CD79a/b form a complex, we expect that the absence of CD79a/b is a result of WBMP-4-induced mIgM inhibition modulating downstream signaling and transcription factor activity. By examining cell surface markers, we may gain insight into how WBMP-4 impacts a cell's interaction with the tumor microenvironment, and this information is valuable for diagnostic and patient monitoring purposes, and to determine drug combination strategies. This work will be considered in the context of our ongoing research on WBMP-4's inhibition of intracellular signaling pathways, and the resulting biologic effects, and will contribute to the continued development of WBMP-4 by providing an understanding of the effects achieved (cell growth inhibition, cell differentiation, apoptosis) at different dosages and if these effects are maintained over time. As a novel, efficacious, and low toxicity treatment strategy for B-cell leukemia and lymphoma, WBMP-4 has significant clinical potential.

#4683 Suppression of ARL6ip1 inhibits malignant phenotypes of human colorectal cancer cells in vivo and > in situ.

Y. Lin, S. Karnan, H. Ito, K. Umezawa;
Aichi Medical Univ., Nagakute, Japan

Introduction: Conophylline is an alkaloid isolated from the leaves of the Thai plant, *Ervatamia microphylla*. We isolated conophylline as an inhibitor of K-Ras functions and an activator of pancreatic β-cell differentiation. It ameliorates various disease models in animals, including cancer, diabetes mellitus, NASH, and hepatic cirrhosis. On the other hand, its molecular target was determined to be ADP-ribosylation factor-like 6-interacting protein 1 (ARL6ip1) using a conophylline-biotin conjugate. ARL6ip1 is located in the endoplasmic reticulum (ER) membrane, and conophylline binds to the cytoplasmic portion of ARL6ip1. Known functions of ARL6ip1 include inhibition of apoptosis, inhibition of glutamate transporter, and modulation of the ER structure. Previously, we knocked out ARL6ip1 in human colon carcinoma cells by CRISPR-Cas9 and found that either deletion of ARL6ip1 or addition of conophylline inhibited migration, invasion and tumorigenicity in cultured cancer cells. In the present research we have studied the in vivo anticancer effect of conophylline and ARL6ip1 knockout, and the mechanism of anticancer activity in cultured cells.

Materials and Methods: Conophylline was isolated from the leaves of *Ervatamia microphylla*. We employed HCT116 and DLD1 cell lines as human colorectal cancer cells. Cellular migration was measured by a wound-healing assay. The activity of Akt was measured by the phospho-Akt antibody. BALB/cSlc-nu/nu mice were used for the animal experiment.

Results: Colon adenocarcinoma tissue microarray comparing tumor and adjacent normal tissues revealed that ARL6ip1 expression was significantly higher in cancer than in normal tissues. Intraperitoneal administration of conophylline and knockout of ARL6ip1 both inhibited the growth of HCT116 in mice. Neither influenced the bodyweight of animals. Conophylline and deletion of ARL6ip1 both inhibited the migration. Rescue of ARL6ip1 canceled the effect of ARL6ip1 deletion on migration in HCT116 and DLD1 cells. As the mechanism, either conophylline or ARL6ip1 knockout inhibited the Akt activity, which was canceled by the rescue of ARL6ip1 in both cell lines.

Conclusion: ARL6ip1 was found to be highly expressed in the tumor tissue in colorectal cancer. CRISPR-Cas9 knockout of ARL6ip1 showed a similar anticancer activity as treatment with conophylline in the animal experiment. It is likely that the anticancer activity of conophylline would be mediated by Akt. Thus, ARL6ip1 would be a useful molecular target for the treatment of cancer.

#4684 A comprehensive platform for identification of KRAS-specific synthetic lethal targets using patient-derived cells.

M. Dulęba[1], E. Zimoląg[1], J. Szuszkiewicz[1], M. Serocki[1], J. Szklarczyk[1], O. Dracz[1], Z. Kurzejamska[1], D. Coelho[1], M. Combik[1], O. Bryzghalov[1], J. Krawczyk[1], A. Stachowicz[1], M. Mikula[2], K. Brzozka[1], R. Dziadziuszko[3], T. Rzymski[1], **A. Mazan**[1];

[1]Ryvu Therapeutics, Krakow, Poland, [2]Maria Skłodowska-Curie Institute of Oncology, Warsaw, Poland, [3]Medical University of Gdańsk, Gdańsk, Poland

Colorectal cancer (CRC) remains a global health concern, constituting a large portion of cancer incidence and mortality. Despite advances in comprehending the genetic and epigenetic landscape of CRC and progress achieved in developing KRAS-specific inhibitors poised for clinical evaluation, a significant unmet medical need persists. This underscores the necessity for innovative therapeutic interventions in this field, as effective therapeutic strategies targeting specific molecular vulnerabilities are currently lacking. Our study aims to address this gap by focusing on the identification of synthetic lethal (SL) inhibitors specific to the KRAS pathway. We have established a platform utilizing human intestinal stem cell (hISC)-derived CRC model cells, patient-derived xenografts (PDXs), and clinical samples for genomic and functional analyses. Employing CRISPR/Cas9 technology, we introduced common CRC mutations into hISCs, generating isogenic CRC model cells with diverse mutational backgrounds including KRAS G12D. Additionally, we developed PDXs from CRC patients and collected biopsy samples from primary and metastatic tumors. Through RNA-seq and whole-exome sequencing (WES), we identified molecular signatures and pathways associated with different mutational variants. Our innovative platform enables high-throughput screening, incorporating both small molecule screening and CRISPR/Cas9 dropout screening with a genome-wide library on CRC model cells. Notably, our focus on KRAS-specific SL inhibitors distinguishes our approach, aiming for targeted therapies tailored to specific CRC subtypes. Validation of driver mutations, such as APC, KRAS, and TP53, in patient-derived material showcased the relevance of our model. High-quality screening results, meeting industry-standard QC criteria, allowed us to identify essential and tumor suppressor genes critical for CRC. Importantly, the use of normal hISCs enabled the identification of genes crucial only for transformed cells. The platform serves as a powerful tool for target discovery and validation in CRC, emphasizing the significance of primary material-derived cells. Beyond CRC, our findings have broader implications for other cancer types and personalized medicine approaches. By focusing on the identification of KRAS-specific SL inhibitors, our research contributes to the development of novel therapies for CRC, addressing the urgent need for targeted interventions in this heterogeneous malignancy.

#4685 The identification of new therapeutic targets in mucinous ovarian carcinoma.

S. Petrella, M. Colombo, M. Marabese, C. Grasselli, A. Panfili, I. Craparotta, M. Barbera, G. Cassanmagnago, M. Bolis, G. Damia;
Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy

Background: Epithelial ovarian cancer (EOC) is the second cause of death among gynaecological cancersworldwide. Mucinous ovarian carcinoma (mEOC) accounts for 3-5% of all EOCs, and when diagnosed at anadvanced stage its prognosis is very poor mainly for its limited chemosensitivity. PLK1 is a member of thewell-conserved serine/threonine kinase family, that plays a key role in the progression of mitosis, in the G2/Mcheckpoint regulation, DNA damage replication, stress response, and cell death pathways. mEOC has beenshown to be sensitive to PLK1 inhibition both with siRNA and small molecule inhibitor (onvansertib). Giventhis background and the need for new therapeutic approaches in mEOC, the purposes of this work were toidentify new therapeutic targets in mEOC using CRISPR/Cas9 lentivirus libraries and to find synthetic lethalpartners with the PLK1 inhibitor onvansertib.
Methods: We used three different mucinous cell lines: MCAS,EFO27, TOV2414, overexpressing Cas9 gene. We evaluated the Cas9 expression through Western Blotanalysis, and the Cas9 activity through a Fluorescent Activated Cell Sorter- based-GFP assay. We used twodifferent lentiviral gRNAs Libraries (Bassik Library Human CRISPR Deletion Library - Apoptosis and cancer(Addgene #101926)/Drug targets, kinases, and phosphatases (Addgene #101927)). The EFO27 Cas9 cells wereused for the screening experiment. Cells were infected with the lentiviral libraries at MOI of 0.3 and put inpuromycin selection. Six days after puromycin addition (Time point 0) 30x10^6 cells were collected forsequencing. The remaining 30x10^6 cells were split in two: control cells and cells treated with a subtoxic doseof onvansertib (IC30). After 7 days (Time point 1) 30x10^6 cells for each condition were collected forsequencing. The infection of libraries was performed alone and in combination with sub-toxic onvansertibtreatment, to identify genes important for mucinous carcinoma cell survival, and those genes in syntheticlethality with onvansertib.
Results: Bioinformatic analyses comparing control cells (time 1 vs time 0) andPLK1 treated and non -treated cells (time 1) allowed the generation of a gene ranking list, including genesinvolved in survival of EFO27 cells like ZC2HC1C, RPA2, POLE3, KIN, TUBG1, SMC2, CDC26, CDC42, HOXA9,TAF10, DCLRE1C, SENP1, MRPS31, COPS2; and genes in synthetic lethality with PLK1 treatment, like JUND,CARD9, BCL2L2. Validation experiments are ongoing and will be presented and discussed.
Conclusion: Using a CRISPR-based approach, we identified genes that either alone or in combination with PLK inhibitioncould have therapeutic value in mEOC.

#4686 Identification of ART3 as a novel synthetic lethal partner of the BRCA1 mutation in breast cancer.

H. Neiger[1], X. Pei[2], A. Nguyen[1], W. Wang[1], E. L. Siegler[1], J. Zhou[1], K. Lau[1], A. Tan[1], **Y. Shi**[3];
[1]California Northstate University, Elk Grove, CA, [2]City of Hope, Duarte, CA, [3]California Pacific Medical Center Research Institute, San Francisco, CA

Breast cancer (BC), the most prevalent malignancy in women, ranks fourth in cancer mortality as of 2022. Mutations in the BRCA genes significantly elevate BC risk and are associated with markedly reduced survival compared to non-carriers. These genes are crucial in homologous recombination, a mechanism essential for error-free DNA repair. Despite advancements, treatment options for BRCA mutation-driven cancers remain limited. Synthetic lethality (SL) has emerged as a promising strategy, with poly(ADP-ribose) polymerase inhibitors (PARPi) being the first developed drugs based on this principle. However, PARPi's effectiveness is limited, as nearly 40% of BRCA-mutated BCs are unresponsive, and resistance often develops in initial responders. Therefore, novel mutation-specific targeted therapies are urgently needed. In this study, we employed the novel computational method 'Mining Synthetic Lethals (MiSL)' to analyze TCGA pan-cancer primary tumor data, identifying ART3 as a potential SL partner of the BRCA1 germline mutation. Our approach focused on the intersection of genetic interactions and cancer vulnerabilities, providing a unique insight into SL relationships. siRNA-mediated silencing of ART3 in BRCA1-mutated cells consistently led to decreased cell viability, apoptosis induction, and G2/M cell cycle arrest. Following stable transfection with an inducible ART3 shRNA construct, we confirmed significant reduction in cell viability in BRCA1-deficient cells through colony formation assays. RNA sequencing of ART3 knockdown cells revealed transcriptional changes in genes involved in cell cycle progression, apoptosis, and growth and proliferation pathways compared with control cells. Immunofluorescent staining revealed increased DNA damage foci with decreased DNA repair in ART3 knockdown BRCA1-deficient cells. In conclusion, our study identifies ART3 as a novel SL partner of the BRCA1 mutation in BC. This discovery paves the way for developing new therapeutic strategies for BRCA1-mutated breast cancers and novel chemoprevention approaches for individuals carrying germline BRCA1 mutations. Future research will focus on further elucidating the molecular mechanisms underlying this SL interaction and exploring its therapeutic potential in clinical settings.

#4687 Primary study on the anticancer role of BAM15 in lung cancer cells.

M.-y. Zhang, Y.-N. Wang, Y.-F. Zhou, S.-C. Wang, S.-J. Mai, H.-Y. Wang;
State Key Laboratory of Oncology in South China, Guangdong Provincial Clinical Research Center for Cancer，Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Lung cancer remains the leading cause of cancer-related death worldwide. Non-small cell lung cancer (NSCLC) accounts for about 80-85% of all lung cancer cases. BAM15, a mitochondrial uncoupler, is a potential therapeutic agent for many diseases, including obesity, diabetes, nonalcoholic fatty liver disease, Sepsis and cancers. However, there is no report on the anti-tumor role of BAM15 in NSCLC.
Methods: To investigate the direct anti-cancer effects of BAM15 in NSCLC, we examined its inhibitory role on cell proliferation of NSCLC cells using the Cell Counting Kit-8(CCK8), colony forming assays and EdU staining assays. The impact of BAM15 on the cell cycle and cell apoptosis of NSCLC cells was analyzed by flow cytometric. A xenotransplanted NSCLC model in mice were used to test the anticancer role of BAM15.
Result: Using the CCK8 assay, we found that the inhibitory role of BAM15 on the proliferation and colony formation of NSCLC cells is dose-dependent. The half maximal inhibitory concentration (IC50) values for cell proliferation were 2.71, 4.74, and 9.50 μM for A549, PC9, and H1299 NSCLC cells, respectively. The EdU staining assay demonstrated that BAM15 treatment significantly inhibited DNA synthesis in NSCLC cells. Flow cytometric analysis revealed that BAM15 arrested cell cycle at G2 phase in NSCLC cells and caused a striking increase in the percentage of apoptotic cells in NSCLC cells. The xenotransplanted NSCLC experiment indicated that BAM15 could significantly suppressed the growth of NSCLC tumors compared with the control tumors.
Conclusions: Our study demonstrates that BAM15 significantly inhibits cell proliferation and promotes apoptosis in NSCLC cells, indicating that BAM15 is a potential therapeutic candidate for the treatment of NSCLC.

#4688 EC359, A new therapeutic drug for the treatment of low grade serous ovarian cancer.

Y. Lyons[1], W. C. Arnold[1], B. Ebrahimi[1], B. Santhamma[2], E. R. Kost[1], H. B. Nair[2], S. Viswanadhapalli[1], R. K. Vadlamudi[1];
[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Evestra Inc., San Antonio, TX

Background: Ovarian cancer (OCa) is the deadliest of all gynecologic cancers in the United States. About 10% of all cases of serous ovarian cancer have the unusual histology named low-grade serous carcinomas (LGSOC), that has a distinct clinical behavior with a unique molecular landscape. LGSOC is characterized by a younger age at diagnosis, indolent progression, and chemotherapy resistance. BRAF and KRAS mutations occur in 33% and 35% of LGSOC cases, respectively. LGSOC is frequently detected when the malignancy is in advanced stage and LGSOC relapses in about 70% of patients with advanced disease. Therefore, new targeted therapies are required. Since LGSOC uniquely expresses mutations of either BRAF or KRAS, and because Leukemia Inhibitor Factor (LIF) expression is induced by oncogenes such as KRAS, we reason that the LIF/LIFR axis represents a unique target for treating LGSOC. The objective of this study is to test the utility of blocking LIF/LIFR axis using LIFR inhibitor EC359 in treating LGSOC.
Methods: The expression of LIF and its receptor LIFR was profiled using multiple established LGSOC cells and primary LGSOC model cells. The effects of EC359 on LGSOC cells were evaluated using cell viability, colony formation, and apoptosis assays. Mechanistic investigations were conducted with Western blotting, reporter assays and RT-qPCR analysis. The *in vivo* efficacy of LIFR inhibitor EC359 as a targeted therapy was investigated using LGSOC cell-based xenografts.
Results: Western blot analysis confirmed expression of LIFR and LIF in established LGSOC and primary LGSOC cells and functional autocrine loop of LIF/LIFR signaling. The treatment with the LIFR inhibitor EC359 significantly reduced LGSOC cell viability, cell survival, and increased apoptosis. The activation of downstream LIFR signaling including STAT3, mTOR, AKT, and p42/44 MAPKs markedly decreased by EC359 treatment. EC359 enhanced the efficacy of trametinib, a currently used medication of LGSOC. EC359+trametinib as a combination therapy showed more efficacy over monotherapy of EC359 or trametinib in reducing cell viability and colony formation. Using cell-based xenograft and PDX models, we demonstrated that the EC359 at 5mg/kg dose significantly reduced the LGSOC xenograft growth compared to the vehicle control.
Conclusions: Together, our findings support the existence of LIF/LIFR autocrine loops, and EC359 is a viable treatment option for LGSOC.

#4689 4HF CancerDataMiner platform accelerates target discovery and evaluation.

H.-H. Fiebig, A.-L. Peille, M. Schmitz, V. Vuaroqueaux, T. Metz;
4HF Biotec GmbH, Freiburg, Germany

For the management of metastasized cancer, tumor-targeted chemotherapies with improved therapeutic index are urgently needed. Over the last 25 years, antibody drug conjugates (ADCs) targeting cancer-associated proteins have emerged as a promising new treatment modality. While the first ADCs were registered for the treatment of acute leukemias and lymphomas, more recently at least six ADCs were approved by the FDA for solid tumors. Despite these successes, clinical development of ADCs remains a risky exercise as evident from the failure of more than 20 pivotal clinical phase III trials. A narrow therapeutic index due to excessive toxicity of potent payloads, little therapeutic activity, and difficulties in chemistry, manufacturing, and controls were among the limiting factors. Meanwhile, ADC technology and production have advanced substantially. More than 100 ADCs are currently in clinical development in approximately 600 clinical trials, with some of the investigated ADCs being close to approval. While issues related to ADC linkers and payloads have been extensively investigated and many problems have been solved, the choice of molecular targets for ADCs remains challenging. This is, in part, due to a lack of information about candidate targets: while knowledge about generally accepted cancer targets such as ERBB2 is abundant, data about many novel targets is still scarce. In particular, reliable information about expression in normal tissues, subcellular localization and protein function is often missing. 4HF Biotec has established the CancerDataMiner, an *in-silico* platform dedicated to cancer data mining by integrating large OMICS datasets that are connected and aligned. It allows molecular analyses of all human genes in >12,000 tumor samples and >14,000 normal tissues, using proprietary tools and widgets for visualization and statistics. Target evaluations are performed at the DNA, RNA and protein levels and employ complementary tools such as pathway analysis and literature search to obtain a comprehensive picture of candidate targets. Using this approach, we recently reviewed the molecular targets of all ADCs that either have already received approval or are in clinical development. As proof-of-concept for the CancerDataMiner, here we analyze targets of ADCs and compare our findings with the clinical data obtained for those ADCs. The profiles of selected ADC targets will be discussed, among them CD79B and CD33 for hematologic malignancies and FOLR1 and Claudin 18.2 for solid cancers. We will demonstrate that proteins with very diverse profiles can make good ADC targets. In conclusion, the 4HF CancerDataMiner is a platform which has proven its value for the identification and characterization of cancer-associated targets for ADC development for all tumor types.

#4690 SC-2882, a novel QPCTL inhibitor, with anti-tumor activity in solid tumor models.

J. Mullenders, M. Scheepstra, M. R. Faas, A. B. Galler, B. Evers, J. U. Wuerthner;
Scenic Biotech B.V., Amsterdam, Netherlands

Background: SC-2882 is an orally administered first-in-class small molecule inhibitor of glutaminyl-peptide cyclotransferase like (QPCTL). QPCTL is an intracellular enzyme that modifies several proteins containing an N-terminal glutamine or glutamate, resulting in pyroglutamylated amino acids. Pyroglutamylation can alter protein function in different ways and dependent on context. Key substrate proteins include the “don’t eat me” signal protein CD47 and several chemokines (CCL2 and CCL7) (Nat Med 2019, Nat Imm. 2022). Previously, we have shown activity of SC-2882 in a murine model of diffuse large B-cell lymphoma (Di Siervi, 2023). Here we report for the first time, the evaluation of SC-2882 in several preclinical mouse models for solid tumors.
Methods: Potency of SC-2882 was evaluated in a cell-based assay in several human and mouse tumor cell lines: SIRPα binding to CD47 in response to increasing concentrations of SC-2882 was measured in a flowcytometry-based assay. Several syngeneic mouse tumor models were evaluated for their response towards SC-2882 as a single agent and in combination with either a murine anti-PD-L1 antibody or cisplatin. Animals were dosed orally with SC-2882 once daily for the duration of the experiment.
Results: In all human and mouse cancer cell lines tested, SC-2882 was able to reduce SIRPα binding to CD47 significantly. This reduction was equivalent to the reduction observed in QPCTL genetic knockouts created in the same cell line. In the same experiments, no differences in CD47 expression were observed. From anti-tumor efficacy studies, we learned that SC-2882 was well tolerated in mice as a single agent and in combination with anti-PD-L1 or cisplatin for at least 4 weeks (this was the maximum period tested). No clinical signs or changes in body weight were observed, even over prolonged periods of treatment. Tumor growth inhibition and tumor shrinkage by SC-2882 was observed in 5 different syngeneic mouse tumor models. In two out of these five models, SC-2882 was able to reduce tumor growth as a single agent. In the other three models, tumor growth inhibition was observed in combination with either anti-PD-L1 or cisplatin.
Conclusions: SC-2882 is an orally administered small molecule inhibitor with a favorable PK profile. Preclinical studies show that SC-2882 was well tolerated in mice. In several mouse tumor models, SC-2882 reduced tumor growth in either single agent treated animals or in combination with anti-PD-L1 or cisplatin. SC-2882 is currently in IND enabling studies and scheduled to enter the clinic in 2024.

#4692 A novel ceramide synthase 2 agonist and its implication in triple-negative breast cancer therapy.

H. Alatawi[1], N. Koo[1], I. Mahmud[1], H. Nair[1], A. Singh[2], T. J. Garrett[1], A. K. Sharma[2], S. Hong[1], **S. Narayan**[3];
[1]University of Florida, Gainesville, FL, [2]University of Florida, Hersey, PA, [3]Narayan (Individual), Gainesville, FL

Based on the biological/molecular markers, breast cancer can be classified into five subgroups: Luminal A (ER+/PR+/HER2-), Luminal B (ER+/PR-/HER2- or ER+/PR+/HER2+, triple-positive), ER-/PR-/HER2+, and ER-/PR-/HER2- (triple-negative). Significant progress has been made in treating hormone-responsive and HER2-expressing breast cancer. However, the targeted therapies are limited for triple-negative breast cancer (TNBC) due to lack of well-defined druggable targets. Additionally, all breast cancer subtypes can quickly develop resistance to current treatments. Thus, there is an urgent need for therapeutic strategies targeting pathways common to all subtypes, irrespective of receptor status. In this effort, we have synthesized a novel biisoquinoline-derivative, DH20931 (US Patent ID: US9914733B2) that induces cytotoxicity in breast cancer cells, including TNBC cells. The spatial molecular modeling and enzymatic assays show that DH20931 interacts with and stimulates ceramide synthase 2 (CerS2) activity, reduces the growth of hormone-responsive, HER2-expressing, and TNBC cells in monolayer and 3D spheroid culture models. DH20931 treatment increases the level of very long chain fatty acid (VLCFA) containing ceramides, induces lipotoxic endoplasmic reticulum (ER) stress, and ATF4/CHOP/PUMA pathway of apoptosis. Based on Swiss-ADME analysis, DH20931 possess all the properties of a druggable molecule and obeys the Lipinski-rule-of-five. Thus, DH20931 can be developed as a novel targeted therapeutic agent independent of ER, PR and HER2 status that potentially may reduce the morbidity and mortality for women with breast cancer.

#4693 A Phase 1b study of BYL719 (Alpelisib) in combination with androgen receptor inhibitor (enzalutamide) in patients with androgen receptor (AR)-positive and PTEN-positive metastatic breast cancer.

M. Karuturi[1], T. Fuji[2], N. Ueno[3];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]National Caner Insttitute, Bethesda, MD, [3]University of Hawaii Cancer Center, Honolulu, HI

Background: Novel combination therapies treatment of Hormone Receptor (HR)+/HER2- metastatic breast cancer, with a high incidence of AR expression, remains to be a priority in modern-day clinical trials. The PI3K pathway, a crucial regulator of cell processes, has been closely linked to AR signaling, with the interplays between the AR and PI3K pathways leading to emerging interest in exploring combination that target both pathways. Several studies have hinted at concordance between AR expression and PI3K pathway aberrations in breast cancer. therapies.
Methods: We conducted a phase 1b clinical trial of BYL719 in combination with enzalutamide for patients with AR-positive (defined as ≥ 1% of nuclear staining) , PTEN-positive (defined as >0% of nuclear staining), HER2-negative metastatic breast cancer (MBC). The primary objective was to determine the recommended dose of the 2 drugs for a phase II study (RP2D), in addition to the toxicity/safety profile of the combination. A conventional 3+3 dose escalation design was applied.
Results: A total of 18 patients were enrolled, with 17 ultimately treated (12 in dose-finding and 5 in dose-expansion). The median age was 57 (28-77 y/o). Two of the 17 were classified as having metastatic TNBC, and the remainder ER and/or PR+ MBC. Patients received a median of 2 prior endocrine therapies (range 0-5) and a median of 2 prior chemotherapies (range 0-4). Dose-limiting toxicities (DLTs) established a dose of BYL719 of 200 mg in combination with enzalutamide 160 mg. 4 patients experienced DLTs at the higher dose of BYL719 of 250 mg PO daily (4 with a maculopapular rash ranging from grade 1-3, 1 additionally with allergic reaction and lung infection categorized as grade 3). Three patients experienced SAEs, 2 at a higher dose of BYL 719 (fever, maculopapular rash, infection, allergic reaction) and 1 at the 200 mg dose, thought to be unrelated. The most common AEs attributed to enzalutamide included anemia (6 total, 3 grade 3, 3 grade 2), headache (6 total, 4 grade 1, 2 grade 2), and nausea (6 total, 3 grade 1, 3 grade 2). The most common AEs attributed to alpelisib included diarrhea (8 total, 5 grade 1, 2 grade 2, 1 grade 3), hyperglycemia (14 total, 7 grade 1, 4 grade 2, 3 grade 3) and rash (7 total, 1 grade 2, 6 grade 3). Clinical benefit rate was observed at 16 weeks, 6.7% partial response, 26.7% stable disease, and 60% progressive disease. Overall survival in the total cohort was 19.4 month (95% CI 4.11-NA), with a median time to progression of 2.07 months (95% CI 1.81-NA).
Conclusions: The Phase 1b study of BYL719 in combination with enzalutamide provides valuable insights into the safety and tolerability of the combination in AR/PTEN-positive MBC, including RP2D. Further studies are needed to evaluate their treatment efficacy fully.

#4694 In charge: Targeting neddylation of UBE2M for anticancer therapy.

A. G. Batrouni[1], J. P. Matson[1], A. L. Mota[1], A. Ravi[1], M. O'Hara[1], M. D. Smith[2], J. C. Smith[3], V. K. Vishnudas[1], A. Thakurta[1], S. Gesta[1], M. D. Nastke[1]; [1]BPGbio Inc., Framingham, MA, [2]University of Tennessee, Knoxville, TN, [3]Oak Ridge National Laboratory, Oak Ridge, TN

Post-translational modification of proteins with ubiquitin and ubiquitin-like molecules orchestrates a vast number of processes in the cell. Consequently, post-translational modification pathways are considered major targets for therapeutic intervention of many diseases, including cancers. Neddylation is a post-translational mechanism like ubiquitination, but instead of ubiquitin, NEDD8 is conjugated to protein targets via an E1-E2-E3 multi-enzymatic cascade. Neddylation is upregulated in multiple cancer types and the development of therapeutics targeting neddylation pathways are gaining increasing popularity. UBE2M, one of the two E2 neddylation conjugation enzymes, takes part in two types of reactions: transthiolation-transfer of NEDD8 from a thioester to a thiol group and aminolysis-transfer of NEDD8 from a thioester to an amino group. These activities require both a 26-residue N-terminal docking peptide and a conserved E2 catalytic core domain, which is the basis for the transfer of NEDD8. Here, we describe findings in the quest to understand the UBE2M interaction with NEDD8 and effects on cancer cells by modifying UBE2M at the N-terminal docking peptide or at the catalytic site. Cancer cells were transfected with ΔN or catalytic site UBE2M mutant constructs and analyzed by immunoprecipitation for charging of NEDD8 onto UBE2M. The catalytic site mutants are deficient in charging (C111A) or discharging (C111S) of UBE2M by NEDD8, which leads to a decrease in neddylation of downstream substrates, such as CULLIN family members. Elimination of the N-terminal docking peptide by introduction of catalytically competent ΔN UBE2M mutant constructs resulted in reduced reaction kinetics. Structural modeling suggests that the loss of the N-terminal docking region likely weakens protein-protein interactions between UBE2M and the UBA3-APPBP1 E1 complex. Interestingly, ΔN UBE2M mutants were observed to be slightly charged with NEDD8, but appeared to have a defect in NEDD8 discharge, resulting in reduced neddylation of substrates. Moreover, further phenotypic evaluation of UBE2M mutant transfected cancer cells revealed a divergence in phenotypic effect: while both mutant types led to a deficiency in NEDD8 charge or discharge from UBE2M, only the manipulation of the active site of UBE2M led to a DNA re-replication phenotype with subsequent cell death. These observations reveal the complexity of the neddylation cascade and raise the question if slowing down discharge of NEDD8 from UBE2M is a more viable therapeutic option than slowing down the charging of UBE2M.

#4695 Effect of fully human anti-PTGFRN antibody drug conjugate on head neck cancer cells and patient derived xenografts.

J. Marquez[1], J. Dong[1], M. Oshimura[2], J. Hayashi[3], **G. Serrero[1]**;

[1]A&G Pharmaceutical, Inc., Columbia, MD, [2]Trans Chromosomics, Inc., Yonago, Japan, [3]Precision Antibody, Columbia, MD

Prostaglandin F2 Receptor Negative regulator, or PTGFRN, also known as FPRP is a 175 kDa transmembrane protein associated with metastatic characteristics of certain cancer types and a member of the tetraspanin family. PTGFRN expression is undetectable to low in normal tissues whereas it is elevated in several cancers such as head and neck, mesothelioma and medulloblastoma. PTGFRN has also been reported to be upregulated in many different types of cancer, increasingly so in metastatic cancer cells, compared to their non-metastatic counterparts PTGFRN expression has been reported to be a poor prognostic factor for glioblastoma making it a potential novel cancer therapeutic target. We have previously shown that PTGFRN is an internalizable cell surface protein making it suitable for targeting by antibody drug conjugate (ADC). We have developed fully human monoclonal antibodies to PTGFRN by immunizing humanized transgenic TC mice with human PTGFRN. Within 60 days from the start of immunization we were able to select several fully human anti-PTGFRN monoclonal antibodies that were examined by several functional assays that included flow binding, internalization, affinity determination and cell killing as antibody drug conjugates. Several monoclonal antibodies were selected and evaluated for their ability to inhibit tumor formation in several cancers. Selected antibodies were then conjugated to duocarmycin by a cleavable linker. The present study proposed to examine the effect of one such anti-PTGFRN ADC on head and neck cancer cell lines and patient derived xenografts that had been analyzed for their PTGFRN expression by western blot analysis using anti-PTGFRN antibody. Cells lines and PDX that were positive for PTGFRN expression were used to examine the effect of anti-PTGFRN ADC on their in vitro and in vivo proliferation. The data show that anti-PTGFRN ADC inhibits tumor formation in a dose-dependent fashion. These data also establish PTGFRN as cancer druggable target and the selected fully human anti-PTGFRN antibody as an attractive antibody for the development of new antibody drug conjugate in Oncology. These data also emphasize the potential of humanized transgenic TC mice for the development of fully human monoclonal antibodies, thus bypassing the need for humanization and affinity maturation required by other humanized mice or phase display.

#4696 ERBB2 signaling and inhibition in bladder cancer.

C. Caparas-Spaugy, C. Stubben, K. Boucher, B. Feng, A. Atkinson, D. Nix, B. Cairns, S. Gupta;
University of Utah Huntsman Cancer Institute, Salt Lake City, UT

The role of human epidermal growth factor receptor-2 (HER2) protein and the inhibition of its oncogenic signaling pathway, ERBB2, is well defined and found to be beneficial in combination with standard chemotherapies in breast and certain gastro-intestinal cancers. Targeting the ERBB2 pathway has had unclear or inconsistent results in early trials in bladder cancer (BLCA) and the efficacy of its combination with cisplatin, a standard BLCA chemotherapy, is not known. In this study, we identify the transcriptomic oncogenic signatures that correlate with ERBB2 signaling in BLCA, explore how HER2 expression in BLCA cell lines correlates with treatment response *in vitro*, and evaluate the potential of ERBB2 inhibition in combination with cisplatin for BLCA.

We analyzed the tumor transcriptome from the Cancer Genome Atlas (TCGA) study of BLCA with single sample Gene Set Enrichment Analyses (ssGSEA) for Hallmark and Oncogenic gene sets. We performed multiple Pearson correlation analyses of HER2 protein levels and ERBB2 signaling with other signaling pathways in the TCGA BLCA tumors and adjusted the significance for multiple comparisons using the Benjamini-Hochberg method. Immunoblotting was used to assess HER2 protein levels across a panel of bladder cancer cell lines. We then assessed cell viability and colony formation upon exposure to the specific ERBB2 inhibitor, tucatinib. Synergy between cisplatin and tucatinib in BLCA cell lines was evaluated using the Chou-Talalay method.

In the TCGA BLCA dataset, HER2 protein positively correlates with ERBB2 signaling with a Pearson correlation coefficient of 0.45 and an adjusted p-value of 1.73E-17. ERBB2 signaling has multiple significant positive and negative correlations. ERBB2 signaling negatively correlates with the DNA repair gene set with a Pearson coefficient of -0.5 and an adjusted p-value of 1.40E-22. HER2 protein expression varies greatly between bladder cancer cell lines: HT-1197 and UMUC3 have lower HER2 expression, with HT-1376, T24, RT4, 5637, and SW780 showing higher HER2 expression. HT-1197 and RT4 had the lowest IC50s for tucatinib and showed a strong response to low doses of tucatinib in the colony formation assay. Cisplatin and tucatinib have synergetic growth inhibition (combination index <1) at low concentration levels in the HT-1197 and SW780 cell lines.

Multiple oncogenic pathways coexist with ERBB2 signaling in BLCA. The varied response to specific ERBB2 inhibition and the lack of correlation of the response with HER2 protein level in cell lines alludes to alternative oncogenic pathways. A strong negative correlation of ERBB2 signaling with the DNA response pathway in the TCGA BLCA dataset, combined with preclinical evidence of synergy between tucatinib and cisplatin, indicates a potential for development of the combination as a clinical treatment strategy and warrants further study.

#4697 Surface localization of enolase-1 (ENO-1) as an attractive theranostic target in docetaxel-resistant neuroendocrine-like prostate cancer cells.

K. R. Santiago Torres, C. A. Casiano, F. Almaguel, A. Duran, K. Whitley;
Loma Linda Univ. School of Medicine, Loma Linda, CA

Prostate cancer (PCa) is American men's second most common cancer. Although taxane-based chemotherapy is the last line of defense for Metastatic Castration Resistant Prostate Cancer (mCRPC), it invariably fails due to chemoresistance. The protein-specific membrane antigen (PSMA) has been an effective target for the imaging and therapy of mCRPC. Although PSMA radioligand therapy (PSMA-RLT) is a theranostics option for men with advanced PCa, about 30% have a limited response due to neuroendocrine-like PCa (NEPC), which lacks PSMA expression. Enolase (ENO) is a promising theranostic alternative due to its cell surface localization in many human tumors. We observed that chemosensitive PCa cell lines expressing NEPC markers express both ENO-1 and ENO-2; however, docetaxel-resistant NEPC-like cells only express ENO-1 and have a metabolic vulnerability due to the loss of ENO-2. We hypothesize that ENO-1 is expressed on the surface of NEPC-like cell lines and can be targeted with small molecule inhibitors (SMIs) that could potentially be used as theranostics agents. Additionally, we have observed changes in the expression and localization of ENO-1 in NEPC-like cell lines under different glucose concentrations. Our data show that under high glucose conditions, found on metabolically active metastatic tumors, ENO-1 is highly expressed on the cell surface, making it a promising candidate target for theranostics. However, low glucose conditions inhibit the activity of the c-MYC oncogene resulting in ENO-1 downregulation and upregulation of MBP1, the small splice variant of ENO1 that blocks the transcriptional activity of c-MYC. Our efforts to confirm ENO-1 surface expression on NEPC-like cell lines entailed using confocal microscopy, cell fractionation analysis followed by Western blotting, and Flow cytometric cell surface staining. We also evaluated the cytotoxicity of SMIs designed to target ENO-1 in chemoresistant NEPC-like cell lines using MTT viability assays, clonogenic assays, and Hoffman Modulation microscopy imaging. Our long-term goal is to identify an alternative treatment for patients with NEPC by establishing ENO-1 as a novel theranostics target.

#4698 Measuring cellular PARylation to gain insight in PARP / PARG-targeted drug discovery.

C. Pilo, M. Awad, V. T. Baron, F. Martins, J. Mikolosko, S. Plouffe, Z. Tao, K. Zientara-Rytter, H. Zhu, P. Shashkin;
BPS Bioscience, San Diego, CA

Inhibitors of poly (ADP-ribose) polymerases (PARPs) have revolutionized cancer therapy by highlighting the potential of synthetic lethal drugs to target the DNA damage response (DDR) network. More recently, the development of PARG inhibitors was spurred by the discovery that inhibiting PARG (poly (ADP-ribose) glycohydrolase) results in the accumulation of poly ADP-ribose on DDR proteins and induces cell death. Adding PARG or PARP inhibitors to a cell of interest and quantifying the resulting levels of PARylation can provide valuable insight on compound membrane permeability and target engagement in a cellular context. Nevertheless, assessing PARylation (poly-ADP-ribosylation in which multiple ribose units are added in linear or branched forms) in cells is difficult compared to biochemical assays, impeding the progress of candidate drug development. A sandwich ELISA-based assay was developed to analyze the total protein PARylation present in cellular extracts. Experimental protocols were optimized to discern differences in cellular PARylation levels resulting from activating the DDR and from exposure to PARP inhibitors and/or PARG inhibitors. It is worth noting that our assay specifically detects PARylation, measuring the effects associated with PARP family members 1 to 5, as other family members primarily catalyze MARylation (mono-ADP ribosylation in which a single ADP-ribose unit is added). Titration of known PARP inhibitors and PARG inhibitors was performed to validate the assay. 1) PARG inhibitor PDD00017273, used in combination with DNA damaging agent H_2O_2, increased the level of cellular PARylation, exhibiting a similar IC_{50} value across the four cell lines tested. This is consistent with the notion that PARG is the major de-PARylating enzyme in most cells. The potency of other known PARG inhibitors PDD00017272 and PDD00017238 ranked the compounds as expected from published results (PDD00017272< PDD00017273< PDD00017238). 2) Titration of the three PARP1/2 inhibitors Talazoparib, Olaparib and AZD5305, in combination with a DNA damage agent and PDD00017273 inhibitor, shows a dose-dependent reduction in cellular PARylation in HEK293 cells, as expected since PARP1 is activated in response to DNA damage and this activation is blocked by the inhibitors (IC_{50} values, Olaparib = 0.013 µM, AZD5305 = 0.0024 µM, Talazoparib = 0.0016 µM). These IC_{50} are consistent with published values and underscore the usefulness of the assay in measuring dose response effects, allowing accurate determination of compound IC_{50} in living cells. In summary, our optimized experimental cell treatment protocols and ELISA-based assay allow quantification of total cellular PARylation and accurately rank candidate drugs targeting PAR erasers or PAR writers in a high-throughput format, using living cells.

#4699 Evaluating extracellular matrix invasion and cytotoxicity of natural killer cells in a novel co-culture assay.

J. Thyagabhavan Mony, X. Zhang;
Agilent Technologies, Inc., San Diego, CA

Background: The complex tumor microenvironment (TME) in solid tumors presents unique challenges for lymphocytes used in cancer immunotherapy. The extracellular matrix (ECM) in TME can limit the recruitment of lymphocytes and restrict access to cancer cells. This study utilized Matrigel to study the kinetics of natural killer cell invasion and cytotoxicity. We hypothesized that the kinetics of tumor cell killing by the NKs would depend on the distance for invasion and rely on matrix-metalloproteinases (MMPs) for remodeling the ECM.
Methods: Increasing volumes (50-100 µL/well) of Matrigel (6 mg/mL) representing increasing distance for invasion was layered over MCF7-red target tumor cells expressing nuclear-localized mKate2 (red fluorescent protein). NK92 (Creative Bioarray) or eGFP-NK92 (BPS Bioscience) were seeded over the solidified Matrigel layer at E:T of 3:1. The broad spectrum MMP inhibitor, Ilomostat (GM6001, 2 µM and 10 µM), was added to the wells to investigate to role of MMPs. Label-free impedance and live cell imaging data was collected in real time on xCELLigence RTCA eSight to evaluate NK cell invasion and cytotoxicity. Percent cytolysis was calculated on the RTCA software from normalized cell impedance readings and imaging data using the formula [(1-(treated/untreated)*100].
Results: Impedance reading increases as the MCF7-red cells settle, attach, and proliferate. The readings plateau as the cells reach confluence. The addition of Matrigel modulates the impedance signature of MCF7 cells. Importantly, Matrigel delays cytolysis by NK92 cells added at 24h. The delay increases with increasing volume of Matrigel representing increasing invasion distance. The time to achieve 60% killing with respect to controls (KT60) was 67, 76 and 89 hours for 50, 75 and 100 µL/well, respectively. Consistent with the role of MMPs in invasion, percent cytolysis calculated independently from normalized impedance readings and live cell imaging data confirmed both delayed and reduced target cell killing by GFP-NK92 cells in the presence of Ilomostat. Interestingly, only a few GFP-NK92 were detected by live cell imaging when there was increased target cell death. These included highly active NK cells that made multiple contacts with different MCF7 red targets in clusters suggesting serial killing activity.
Conclusions: The observations that only a few NK92 cells are detected during the killing of susceptible target cells and that cytolysis is not abrogated by the inhibition of MMPs suggest a potential role for distal effectors like cytokines, independent of invasion. This is a novel 2.5D assay that demonstrates the potential of RTCA eSight platform for studying the invasion and cytotoxicity function of various immune cells through both real-time impedance recording and live-cell time-lapse imaging simultaneously. (For Research Use Only. Not for use in diagnostic procedures. RA45236.3472453704)

#4700 Induced phenotype targeted ADC by using caspase enzymatic cleavable peptide linker to overcome tumor heterogeneity.

H. Lee[1], B. Kim[1], H. Chang[2], S. Kim[3], Y. Byun[1];

[1]Seoul National University, Seoul, Korea, Republic of, [2]University of Ulsan College of Medicine, Seoul, Korea, Republic of, [3]Pharosgen Co., Seoul, Korea, Republic of

Antibody-drug conjugates (ADCs) have ushered in a new era of precision cancer therapy, and the caspase-3-cleavable linker has demonstrated its potential as a game-changing addition to the ADC toolkit. The DEVD peptide, specifically cleaved by caspase and lysosomal enzymes, in combination with the KG peptide, provides the necessary flexibility to achieve targeted cancer cell apoptosis. This research explores the key attributes and actions of the linker, aiming to highlight its potential for revolutionizing ADC therapy. The caspase-3-cleavable linker operates through caspase-3 activation during apoptosis. After targeting cancer cells with specific antigens, the ADC is internalized into the cells, and the linker is cleaved by caspase-3, releasing the drug and initiating apoptosis. The specificity of caspase-3 extends the drug's effect to neighboring cells, even those lacking the target antigen. This cascade effect ensures the continuous activation of ADCs until all cancer cells are eradicated. Firstly, it overcomes tumor heterogeneity by activating the drug outside of the cell. Traditional bystander killing effects rely on internalization followed by drug release and penetration of neighbor cancer cells. However, this linker's unique mechanism ensures that the drug is activated by caspase-3 outside the cell without the need for internalization, effectively targeting all cancer cells within the tumor tissue. This is achieved through the induced phenotype targeting effect (IPTE), which involves caspase-3 cleavage of the linker, inducing a phenotype in the tumor tissue that targets all cancer cells, regardless of their specific markers. Secondly, it maintains therapeutic efficacy even as the target antigen decreases. Current targeted therapies face a challenge as target antigens may diminish during treatment, leading to reduced drug effectiveness. However, the unique mechanism of the linker ensures that the drug continues to be activated as long as there is caspase-3 secretion, resulting in continuous activation of ADCs in the tumor, with a feedback amplification loop that ensures therapeutic efficacy until all cancer cells are eliminated. Lastly, the linker's superior physicochemical properties allow for a maximum drug-to-antibody ratio (DAR). Its hydrophilic nature enables independent drug conjugation, increasing therapeutic potential and mitigating aggregation issues. This innovation addresses the current limitations in ADC conjugation technologies. In summary, the caspase-3-cleavable linker represents a significant leap forward in the field of ADCs. Its unique attributes offer promising prospects for more effective and targeted cancer treatments. This linker is poised to revolutionize the landscape of targeted cancer therapy, bringing us one step closer to the dream of eradicating cancer cells with precision and efficiency.

#4701 A novel microtubule disruptor exerts broad anticancer efficacy with a tolerable safety profile.

H. Lelie[1], I. Brandsma[2], G. Hendriks[2], L. R. Cavedine[3], B. A. Epkins[3], S. M. Garner[3], A. J. Cook[3], M. Renganathan[3], Y. Zhao[3], A. J. King[3], P. Y. Chan[4], A. Risinger[4], **M. Koutsioumpa**[1];

[1]Australis Pharmaceuticals, Inc., Simi Valley, CA, [2]Toxys B.V., Oegstgeest, Netherlands, [3]Eurofins Discovery, St. Charles, MO, [4]University of Texas Health Science Center at San Antonio, San Antonio, TX

Initial evaluation of the prenylated hydroxy-stilbene isolated from bee propolis, AUS_001, in the NCI 60 human cell line anticancer screen showed significant growth inhibitory effects with the most robust being observed in leukemia, central nervous system and breast cancer cell lines. The aim of the current study was to further assess the potency of AUS_001 *in vitro* and investigate its safety profile and mechanism of action. A commercially available cell-based profiling screen (OncoPanel®) identified significant AUS_001-induced growth inhibition in 273 out of 280 cancer cell lines with a concentration causing 50% cell growth inhibition in the range of 0.021-0.94 µM, while non-neoplastic cells required an average of 20x higher concentration to generate similar efficacy. These findings indicate that AUS_001 exerts a high degree of potency across 30 cancer types with a selectivity for cancer versus normal cells. Maximum tolerated dose studies in mice illustrated that orally administered AUS_001 is well tolerated at doses 4 times greater than those that conferred antitumor efficacy, with no myelosuppression or other overt toxicities observed. Predictive toxicology and safety screening indicated that AUS_001 exerts a strong safety profile as evidenced by absence of mutagenic potential in the Ames test using up to 100 µM drug doses and low hERG-blocking liability with a half-maximal inhibitory concentration of 65 µM. Notably, AUS_001 is a poor substrate of the drug efflux transporter, P-glycoprotein 1 (Pgp), as it does not inhibit drug-stimulated Pgp ATPase activity and retains efficacy in high Pgp-expressing models *in vitro*. Subsequently, the effects of AUS_001 were explored in the ToxTracker® assay, consisting of a panel of mammalian stem cell lines that contain fluorescent reporters for the exploration of DNA damage, oxidative stress, and protein damage using flow cytometry. Robust activation of the Rtkn genotoxicity reporter under low cytotoxicity conditions, in combination with accumulation of cells in G_2/M phases of the cell cycle within 4 h and an increase in aneuploid cells after 24 h of drug treatment, suggested an aneugenic mode of action, typically caused by tubulin-targeting agents or mitotic kinase inhibitors. Biochemical tubulin polymerization assays then revealed that AUS_001 acts as a direct tubulin destabilizing agent and monitoring microtubule dynamics in GFP-tubulin reporter cells provided evidence that AUS_001 blocks microtubule assembly. Our studies have elaborated the mechanism of AUS_001 as an inhibitor of tubulin polymerization. The favorable safety profile of AUS_001, along with its ability to circumvent Pgp-mediated multidrug resistance, provides potential for efficacy against multiple cancers where microtubule destabilization is proven to be an effective target.

#4702 MediLink's TMALIN ADC linker technology: Tumor microenvironment specific extracellular and intracellular double cleavage mechanism for better efficacy and expanded target space.

T. Xue[1], L. Xiao[1], Q. Liu[1], S. Song[1], A. Shan[1], X. Zhang[1], S. Stann[2], **J. Cai**[1];
[1]MediLink Therapeutics (Suzhou) Co., Ltd., SuZhou, China, [2]MediLink Therapeutics USA, INC., Boston, MA

Antibody-drug conjugates (ADC) are a type of the fastest growing anticancer drug modalities. However, the traditional ADC technologies constrain on therapeutic development, requiring overexpressed targets, high internalizing antigens and efficient intracellular processing. To this end, MediLink's TMALIN platform was developed, with an irreversible pyrimidine coupling anchor and a valyl dipropyl-lysyl glycinamide-methylene (-VK*G-$NHCH_2$-O-) cleavable sequence. The TMALIN platform is featured as a high hydrophilicity linker-payload, remarkable stability in circulation, coupled with an efficient payload release mechanism which is achieved through the cleavage both extracellularly in the tumor microenvironment and intracellularly within lysosomes. A site-specific and homogeneous conjugation using TMALIN platform provides highly stable ADC in circulation. It is evidenced by less than 2% payload drop-off after a 21-day incubation in plasma under physiological conditions in vitro. This feature is observed in over 7 ADCs developed using the TMALIN platform. Additionally, the high stability was also illustrated by the pharmacokinetic profiles in NHP studies and clinical trials, with the overlapped curves of ADC and TAb in all TMALIN platform-based ADCs. Apart from the stability, a battery of *in vitro* and *in vivo* studies showed the linker-payload efficiently releases the payload in both tumor cells and the tumor microenvironment. Due to the high stability in circulation and efficient cleavage within tumors, the TMALIN platform ADCs have shown promising efficacy and good safety windows in preclinical studies. In xenograft mouse models, including those with low antigen expression, these ADCs have demonstrated tumor regressions and good tolerability. This highlights the potential of the TMALIN platform in improving the efficacy of ADCs and expanding their therapeutic applications. Furthermore, favorable safety profiles have been observed in clinical trials and/or pivotal non-human primate (NHP) studies for ADCs developed using the TMALIN platform. No drug-related adverse effects in organs were identified including the lungs, liver, or kidneys for those ADCs. In summary, the TMALIN platform addresses the unmet need of ADCs by releasing the payload extracellularly in tumors and tumor microenvironments on top of the known intracellular lysosomal cleavage mechanisms. This enables the advancement of ADC development, and has the potential to expand the field of ADC therapy and improve patient outcomes.

#4703 Automated 42 PDX 3D *in vitro* tumor models of the TME screen immuno-oncology and targeted compounds and biologics for antitumor effects and MOA.

B. Xue[1], C. Harrod[1], L. Le[1], J. Schuler[2], **K. C. Hribar**[1];
[1]Cypre Inc., San Francisco, CA, [2]Charles River Laboratories, Freiburg im Breisgau, Germany

High throughput screening has been widely utilized for its efficiency in testing novel therapeutic agents. However, the conventional screening using 2D culture of cancer cell lines lacks the biological complexity of the tumor microenvironment or the immune compartment which limits their application in testing immune-oncology therapies. Particularly with the passing of the FDA Modernization Act 2.0, it is critical to create more biologically relevant 3D in vitro models that can be used to reduce, refine and ultimately replace preclinical animal models. Here we have developed a highly automated 3D high throughput screening platform comprised of 42 patient-derived xenograft models in coculture with fibroblasts in engineered extracellular matrix hydrogels that resemble tumor stromal microenvironment. The PDX models cover a diverse range of tumor and histological types including NSCLC, CRC, gastric, TNBC, RCC, bladder, ovarian, melanoma, pancreatic, and others. Moreover, PBMCs or other immune cells can be incorporated into the system for evaluating immuno-oncology drugs. The panel has been tested against chemotherapy drug cisplatin and the immunotherapy biologic, Solitomab, an EpCAM/CD3 bispecific antibody. The endpoint analyses for antitumor effects include the dose response of tumor size and tumor cell death percentage based on high content imaging analysis. In addition, immune cells and supernatant in the IO assay can be recovered from the wells and used for flow cytometry profiling and cytokine assays. In summary, the novel 42-PDX panel described here offers a unique and powerful tool for rapidly generating preclinical data and a better understanding the drug activity at the pharmacology stages, opening the door for faster and more human relevant drug discovery for cancer patients.

#4704 Biochemical and cell-based assay platforms for development of RAF inhibitors against human cancers.

J. Wu, Y. Wan, S. Liang, P. Gallagher, L. Liang, C. Loch, H. Ma;
Reaction Biology Corporation, Malvern, PA

The RAF protein kinases are key intermediates in cellular signal transduction, functioning as direct effectors of the RAS GTPases and as the initiating kinases in the ERK cascade. In human cancer, RAF activity is frequently dysregulated due to mutations in the RAF family members (ARAF, BRAF, and CRAF) or to alterations in upstream RAF regulators, including RAS and receptor tyrosine kinases. The first and second generations of RAF inhibitors have yielded dramatic responses in malignant melanomas containing BRAF mutations; however, their overall usefulness has been limited by both intrinsic and acquired drug resistance. In addition, cancers with hyperactive RAS exhibit intrinsic resistance to these drugs. In particular, issues related to the dimerization of the RAF kinases can impact the efficacy of these compounds and are a primary cause of drug resistance. We have established biochemical HotSpot™ kinase assay, NanoBRET™ and NanoBIT™ cell assay platforms for High Through Screening of kinase inhibitors. Here, we demonstrate that the 3rd generation of pan-RAF inhibitors LY3009120, LXH254, and Belvarafenib inhibit ARAF, BRAF, CRAF, BRAF(V600E), and CRAF(R391W) kinase activity in biochemical HotSpot™ assay. Our NanoBRET™ target engagement and NanoBIT™ cellular assay data show that LY3009120, LXH254, and Belvarafenib bind to KRAS(G12C) primed BRAF and CRAF, and block BRAF and CRAF dimerization. Furthermore, our results show these inhibitors can block the downstream ERK phosphorylation in cellular HTRF assay and induce caspase-3/7 activation in Western blot assay in the triple negative breast cancer MDA-MB-231 cells. Taken together, our results indicate the biochemical HotSpot™ kinase activity assay, and NanoBRET™ target engagement and NanoBIT™ cellular assays can serve as great platforms to facilitate RAF drug discovery against human cancers.

#4705 Repetitive membrane potential oscillations enhance metformin's antiproliferative effect in glioblastoma stem cells.

Ivan Verduci, Gaetano Cannavale, **Guido Rey**, Francesca Cianci, Alessandro Fantin, Michele Mazzanti

University of Milan, Milano, Italy

Glioblastoma (GB) is the most common and lethal brain tumor and there is a general agreement that GB stem cells (GSCs) are primarily responsible for its high aggressiveness and recurrence. It was recently reported that GSCs are enriched in the transmembrane form of CLIC1 protein (tmCLIC1) and its inhibition was shown to impair tumor growth both *in vitro* and *in vivo*. IAA94 hampers tmCLIC1 function but could not be used in clinics. However, tmCLIC1 is also sensitive to metformin, the most used drug to treat type-2 diabetes. Metformin has been demonstrated to have the same effect as IAA94 in *in vitro* experiments, resulting in an antitumoral action on cancer cells. Moreover, GB orthotopic mouse model treated with metformin shows a 50% survival compared to control animals, even if metformin concentration in the mice brain resulted in the nanomolar range. In this scenario, the main aim of this work is to enhance the effect of metformin able to reach the brain, improving its antitumoral activity in GB. The interaction between metformin and tmCLIC1 occurs only when this protein is in its open state. TmCLIC1 has the peculiarity of being a voltage-dependent ion channel that opens at depolarized voltages. Thus, our strategy is to apply electromagnetic field (EMF) stimulation to induce repetitive membrane depolarization, increasing metformin-tmCLIC1 binding. Our results show that EMF stimulation induces the close-to-open transitions of tmCLIC1, resulting in a 10-fold decrease of the operative concentration of Metformin. This was verified initially *in vitro* with GSC culture and spheroids model and afterward confirmed also in an *in vivo* model. The project's long-term goal is to combine transcranial stimulation and metformin administration in patients as an adjuvant therapy able to target cells that are resistant to chemotherapy and drive tumor relapse.

#7249 Enhancing mRNA- lipid nanoparticles formulations to improve transfection efficiency in macrophages and dendritic cells in cancer immunotherapy.

Yasir Alshehry, Matthew Fernandez, Raneem Aldaqqa, Asma Al-Terawi, Douglas Sweet, Sandro da Rocha

Department of Pharmaceutics and Center for Pharmaceutical Engineering and Sciences, Virginia Commonwealth University, Richmond, VA

Cancer poses a global health challenge, driving the quest for innovative therapies. Messenger ribonucleic acid (mRNA) lipid nanoparticles (LNPs) are a promising strategy in cancer immunotherapy. However, a major obstacle lies in efficiently transfecting immune cells like macrophages and dendritic cells (DCs) with LNPs. This study seeks to improve cancer immunotherapy by optimizing mRNA-LNP formulations. Therefore, we systematically evaluated three components of LNPs, namely ionizable lipids, phospholipids, and sterols, and fine-tuned the components and their molar ratios. A comprehensive screening process was conducted to determine the efficiency of LNPs, involving in vitro experiments on macrophages and DCs, as well as in vivo assessments. Among six ionizable lipids assessed in different cell lines (RAW264.7 and DC2.4), SM-102 significantly enhanced the transfection efficiency in macrophages and DCs. Subsequently, we evaluated these LNPs in an in vivo setting. We quantified the bioluminescence signal after administering LNPs loaded with luciferase mRNA. The results demonstrated a significant increase in luciferase expression when using SM-102 and ALC-0315 lipids. To validate this finding, we conducted a T cell response study, which revealed an increased percentage of CD8+ T cells with SM-102-based LNPs compared to other formulations. Having identified SM-102 as a potent ionizable lipid, we proceeded to evaluate three phospholipids in vitro. The results indicated a significant enhancement in transfection efficiency with DOPE lipids compared to DSPC. Consequently, we selected DOPE as the phospholipid for subsequent screening. Lastly, we explored different types of sterols with varying molar ratios in macrophages and DC cells. Our findings unveiled a notable improvement in mRNA delivery, particularly in DCs, when the molar ratio of β-sitosterol was increased to 19.5%, while concurrently decreasing the molar ratio of cholesterol to 19% within the same formulation. It is noteworthy that the addition of β-sitosterol alone led to reduced transfection efficiency in DCs but resulted in a significant enhancement in macrophages. Lastly, we evaluated the top four formulations in vivo, and the results demonstrated a significant increase when β-sitosterol was added to the formulation with cholesterol, at molar ratios of 19.5% and 19%, respectively. Overall, altering lipid composition and their molar ratios profoundly impact mRNA-LNP transfection. The optimized formulations, comprising SM-102, DOPE, and cholesterol with or without β-sitosterol, outperformed the alternatives. These refined formulations hold promise for clinical applications, potentially enhancing passive therapeutic agent delivery into macrophages and DCs, offering promising prospects for advancing cancer immunotherapy.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Other Cellular Mechanisms for Anticancer Drug Action
Poster Session

#4708 Potency and selectivity of ERBB2-targeting antibody drug conjugates in vitro.

A.-L. Peille[1], K. Holtorf[2], P. Anton Garcia[1], N. Obier[2], D. Feger[2], T. Metz[1], S. Dempe[2], H.-H. Fiebig[1], J. Ehlert[2], V. Vuaroqueaux[1];
[1]4HF Biotec GmbH, Freiburg, Germany, [2]Reaction Biology Europe GmbH, Freiburg, Germany

Previously we have reported on the relevance of the joint ProLiFiler and Cancer DataMiner platforms when studying the antitumor efficacy of novel antibody-drug conjugates (ADCs), such as Sacituzumab govitecan. In this study, we use our platforms to investigate and compare the selectivity of two FDA-approved Trastuzumab-based ADCs targeting ERBB2: Kadcyla, the first-in-class ADC employing a microtubule inhibitor bound via a non-cleavable linker, and Enhertu, which combines a topoisomerase inhibitor with a protease-cleavable linker. We performed a cell proliferation and survival assay using the ProLiFiler™ (Reaction Biology) to characterize the in vitro antitumor effects of Enhertu, Kadcyla, and their individual cytotoxins, deruxtecan & mertansine on 160 human cancer cell lines (CLs). The resulting data were uploaded to 4HF´s Cancer DataMiner platform for data analysis. First, we confirmed high potency and limited selectivity of mertansine, as it displayed an IC_{50} < 250 nM (mean: 27.3 nM) in 95% of cell lines (CLs). A COMPARE analysis confirmed that mertansine data correlated best with those of other microtubule inhibitors in our drug databases (e.g., MMAE, Spearman rho = 0.79, p=9.6E-27). Conversely, a paired analysis showed that CLs were less sensitive to Kadcyla than to mertansine except for CLs overexpressing ERBB2. The 160-CL panel included a total of nine CLs (six mammary, two gastric, one ovarian) with strong ERBB2 overexpression (Affymetrix data >10), mostly associated with ERBB2 gene amplification; seven of them were the most sensitive CLs to Kadcyla (IC_{50} < 6 nM). Focusing solely on breast cancer cell lines (breast cancer is the approved indication for Kadcyla), we observed a strong correlation between sensitivity to Kadcyla and ERBB2 expression (Spearman r = -0.78, p = 0.003). Interestingly, in line with published data, the ERBB2-overexpressing cell lines SNU-216 (stomach cancer) and JIM-T1 (breast cancer) were less sensitive to Kadcyla. In non-ERBB2-amplified CLs, Kadcyla sensitivity did not correlate with ERBB2 expression levels. Focusing on ERBB2-negative CLs such as hematological CLs, we unexpectedly observed consistent cell inhibition (mean IC_{50} =33 nM) with Kadcyla, suggesting that the ADC was cleaved, and the payload released into the medium. Overall, this study has demonstrated the relevance of our platforms to study and compare newly developed ADCs. Cytotoxic activities recorded for conjugates and free payloads, along with molecular data for the test cell lines, provides insight in the mode of action of conjugates and their target cell populations and hence can support the development of ADCs. Investigations are underway with Enhertu and its payload deruxtecan, and results will be compared with those obtained for Kadcyla and mertansine.

#4709 The RAS^{MULTI}(ON) inhibitor RMC-7977 blocks downstream MAPK and PI3K pathway activation in KRAS^{G12X} mutant cancers.

P. S. Bapat, K. Seamon, A. Gould, D. Wildes;
Revolution Medicines, Inc., Redwood City, CA

Oncogenic RAS binds to multiple effector proteins to activate downstream signaling pathways, including the MAPK and PI3K axes. While RAS-mediated MAPK activation has a well-validated role in driving cancer progression, the contribution of PI3K activation has been more difficult to assess. Understanding the degree to which different KRAS-mutant genotypes stimulate PI3K activity may inform biomarker and combination strategies for RAS inhibitors currently undergoing clinical evaluation.RMC-7977 is a RAS^{MULTI}(ON) inhibitor that targets GTP-bound RAS(ON) and blocks effector protein binding. RMC-7977 exhibits similar potency for wild-type and oncogenic mutant RAS and is a powerful preclinical tool, representative of the investigational RAS^{MULTI}(ON) inhibitor RMC-6236, for comparing how RAS-mutant genotypes differ with respect to signal activation. MAPK signaling proceeds through a protein phosphorylation cascade that is readily detectable using standard cell biology methods, but PI3K is a lipid kinase whose activity is not amenable to protein characterization techniques. An assay of phosphatidylinositol (3,4,5)-trisphosphate (PIP3) was developed to directly measure the activity of PI3K in the context of RAS inhibition.In isogenic LIM1215 cell lines expressing different KRAS^{G12X} mutants (KRAS^{G12D}, KRAS^{G12V}, KRAS^{G12C} and KRAS^{G12R}), RAS inhibition by RMC-7977 completely suppressed PI3K activity in cells with wild-type KRAS and KRAS^{G12D}, had a moderate inhibitory effect in KRAS^{G12C} and KRAS^{G12V}, and had no effect in KRAS^{G12R}. To confirm that this inhibition is dependent on a direct interaction between RAS(ON) and PI3K, CRISPR engineering was used to introduce mutations in *PIK3CA* to perturb the RAS-binding domain. In cells with disrupted RAS-PI3K interactions, the basal levels of PIP3 are significantly reduced and no longer change in response to treatment with RMC-7977.Based on the isogenic cell line results, KRAS^{G12D} and KRAS^{G12R}-mutant pancreatic cancer cell lines were profiled for their response to RAS inhibition. RMC-7977 decreased the levels of MAPK signaling in both KRAS^{G12D} and KRAS^{G12R} genotypes, but PI3K activity was only inhibited in KRAS^{G12D} lines. MEK inhibitors only inhibited MAPK signaling and had no effect on PI3K activity in either genotype. The simultaneous inhibition of MAPK and PI3K signaling by RMC-7977 led to deeper suppression of cyclin D levels and a more pronounced G1 cell cycle arrest as compared with MAPK inhibitors.We demonstrate that the coupling between RAS activation and PI3K signaling varies between oncogenic mutants, with KRAS^{G12D} showing the greatest degree of PI3K stimulation. In KRAS^{G12D}-mutant pancreatic cancer cell lines, a RAS^{MULTI}(ON) inhibitor suppresses both PI3K and MAPK signaling. These preclinical results may be used to inform potential, rational, mechanism-based combination treatment strategies for RAS(ON) inhibitors.

#4710 The polymeric AMD3100 based drug PAMD-Ch17 induces its anti-leukemic effects in a CXCR4 independent mechanism.

C. Lam, J. Chinmay, E. Kapoor, S. Tang, S. Romanova, D. Oupicky, K. Hyde;
University of Nebraska Medical Center, Nebraska, NE

Background: Acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) are devastating blood cancers associated with 5-year survival rates of ~50% each in adults. We recently developed a new class of polymeric drugs called PAMDs based on the CXCR4 inhibitor AMD3100 (plerixafor). PAMDs have the potential to be more effective and less toxic therapeutics than the standard of care high-dose chemotherapy. We tested one variant (PAMD-Ch17), and found that unlike AMD3100, PAMD-Ch17 has several novel anti-leukemic effects. To understand the potential mechanism(s) for these new activities, we performed the following study.

Methods: To test the role of CXCR4 in PAMD-Ch17's activities, we generated *CXCR4* knockout cells via Crispr/Cas9. We used PrestoBlue, 7-AAD, and Annexin V staining to assay viability and apoptosis. To identify pathways deregulated by PAMD-Ch17, we performed whole transcriptomic sequencing (RNA-Seq). To investigate if PAMD-Ch17 mediates its activities by inducing oxidative stress, we performed SeaHorse assays, and dihydroethidium (DHE), Mitosox, and Bodipy C11 staining. To investigate whether PAMD induces programmed cell death pathways, we used ferrostatin and deferoxamine to inhibit ferroptosis, necrostatin-1 against necroptosis, and Z-VAD-FMK against apoptosis.

Results: We found that PAMD-Ch17 induces cell death in a dose dependent manner in human AML and ALL cell lines and, mouse primary leukemia cells, but not healthy mouse bone marrow cells. Surprisingly, PAMD-Ch17 induces equivalent levels of cell death in both wild type and CXCR4 knockout Jurkat cells, indicating that the only known target of the polymer is not required for its anti-leukemic effects. By RNA-Seq, we found altered expression of genes related to mitochondrial function, suggesting that PAMD-Ch17 could be targeting the mitochondria. To test this, we performed SeaHorse assays and found that PAMD-Ch17 induces a significant decrease in mitochondrial respiration. Consistent with this, we found that PAMD-Ch17 induces a significant increase in superoxide production, as well as lipid peroxidation. Using inhibitors of programmed cell death pathways, we found that preventing necroptosis, apoptosis, or ferroptosis caused only subtle effects on PAMD-Ch17 induced cell death, implying that the polymer's anti-leukemic activity is likely not entirely dependent on these pathways.

Conclusions: These results indicate that PAMD-Ch17 induces cell death in leukemia cells but not healthy bone marrow via a CXCR4 independent mechanism. We also found that PAMD-Ch17 induces reactive oxygen species, potentially explaining its selectivity for leukemia cells compared to healthy blood cells. Continued investigation of PAMD-Ch17 will not only further development of this new class of drugs, but also provide much needed insight into leukemia biology.

#4711 Evaluation of effect of autophagy inhibition by SAR405, a selective Vps34 inhibitor, on proliferation of pleural mesothelioma cells.

Y. Kuwabara, K. Sakai, S. Ishi, S. Yokosuka, M. Abe, T. Takahashi, Y. Kawano, H. Nishimura, M. Toda-Sasaki, Y. Kobayashi-Ogawa, S. Kikuchi, Y. Hirata, H. Kyoyama, G. Moriyama, N. Koyama, K. Uematsu;
Saitama Medical University Saitama Medical Center, Saitama, Japan

Pleural mesothelioma is a poor prognostic malignancy because the efficacy of therapies remains limited; thus, there is an urgent need to elucidate the pathophysiology leading to newer treatment modalities. Macroautophagy (hereafter referred to as autophagy) is an intracellular degradation system in which cytoplasmic components are degraded by the lysosome. Autophagy plays pivotal roles in various physiological processes, including adaptation to starvation, preimplantation embryonic development, elimination of intracellular pathogens, and regulation of innate and adaptive immunity. In cancer cells, autophagy may have the potential to function protectively for the cells and, alternatively, to work suppressively. It can promote tumor growth in established cancers through autophagy-mediated intracellular recycling, providing substrates for metabolism and maintain that the functional pool of mitochondria. On the other hand, it may lead to a cytotoxic effect called autophagy-dependent cell death. Several reports have demonstrated that autophagy has cytoprotective effects on pleural mesothelioma cell lines. In this study, we assessed effects of inhibition of autophagy using SAR405, which specifically inhibits Vps34 in an early step of autophagy, on pleural mesothelioma cells. Additionally, we investigated whether SAR405 could enhance the growth suppression induced by cisplatin in these cells. Mesothelioma cell lines, including NCI-H28 (H28), NCI-H2452 (H2452), and MSTO-211H (211H), were cultured with 0.1-50 μM SAR405 or 1.0-5.0 μM cisplatin for cell viability analysis using water-soluble tetrazolium salt-8, and cell cycle analysis. For the assessment of autophagy, a plasmid, pMRX-IP-GFP-LC3-RFP-LC3ΔG, was stably transfected into mesothelioma cells. Transfected cells generate GFP-LC3-RFP-LC3ΔG, and it is cleaved into GFP-LC3 and RFP-LC3ΔG by inherent ATG4. GFP-LC3 levels are decreased by autophagy activation, while RFP-LC3ΔG serves as an internal control. SAR405 dose-dependently suppressed cell viability, accompanied by a significantly increase in the proportions of cells in the G2/M phase. The IC50 of SAR405 at 72 hours was 11.5 μM for H28, 16.7 μM for H2452, and 14.9 μM for 211H. SAR405 inhibited autophagy 24 hours after treatment at 2.5 μM for H28 and 211H, and at 5.0 μM for H2452. Furthermore, cisplatin induced autophagy at 5.0 μM for H28, 0.5 μM for H2452, 1.0 μM for 211H. The combination of 2.5-10 μM SAR405 and 0.5-5.0 μM cisplatin exhibited additive or synergistic effects on cell growth inhibition in all plural mesothelioma cell lines. In conclusion, Vps34 inhibition by SAR405 suppressed cell growth in pleural mesothelioma cells, accompanied by autophagy inhibition. The combination of SAR405 and cisplatin resulted in a synergistic inhibition of cell proliferation.

#4712 GPCR panel establishment and application in drug discovery.

X. Wang, N. Sui, D. Hu, Z. Zhang, **T. Bing**;
ICE Bioscience, Inc., Beijing, China

G protein-coupled receptors (GPCRS) are the largest family of membrane proteins of cell surface receptors. It can be activated by various stimuli and play an important role in various physiological and pathological processes such as cell growth, proliferation, differentiation, metabolism, and homeostasis. Abnormal regulation of GPCR is associated with various human diseases, such as metabolic diseases, cardiovascular diseases, and eye diseases. G protein contains three subunits: α, β, and γ, which form a trimer. When extracellular ligands are bound to GPCRs which activate G protein and GTP phosphorylates Gα subunits, leading to the dissociation of Gα subunits from the trimer and dissociation from the β and γ subunits. In addition, Gα different subtypes of Gαs, Gαi and Gαq have different biological effects after activation, Gαs-coupled receptors activate adenylyl cyclase (AC) to increase cAMP. In contrast, Gαi-coupled receptors activated adenylyl cyclase (AC) to inhibit cAMP. Gαq coupled receptors promote phospholipase C (PLC) to produce IP3, and IP3 can increase intracellular Ca^{2+} concentration. GPCR Panel With high general availability, which provides over 150 GPCR targets, covering wide families like 5-Hydroxytryptamine, adrenoceptors, Acetylcholine, dopamine, glucagon, and opioid receptors and having the selectivity of multiple species. It can conduct similar GPCR poly-link interaction and screening, used to study new GPCR drug development technology, detect the expression properties of GPCR receptors, reveal new GPCR structure and function, and screen GPCR drugs. We also constructed different assay platforms, including cAMP assay, Ca2+ flux assay, IP3 assay, β-arrestin recruitment assay and reporter assay to detect the different second messengers produced by G protein submits and GPCR-mediated multiple signaling pathways. This research constructed stable cell lines expressing GPCRs and provided related assays, which could be used to detect compounds' effects on GPCR targets successfully. In addition, the GPCR panel was applicable to both activating and inhibitory models, and the establishment of this platform provides a powerful tool for drug development of GPCR-related targets.

#4713 Chlorpromazine affects glioblastoma bioenergetics by interfering with pyruvate kinase M2: A route for drug repurposing in glioblastoma.

C. Abbruzzese[1], S. Matteoni[1], P. Matarrese[2], M. Signore[2], B. Ascione[2], E. Iessi[2], A. Gurtner[1], A. Sacconi[1], A. Pace[1], V. Villani[1], A. Polo[3], S. Costantini[3], A. Budillon[3], G. Ciliberto[1], **M. G. Paggi**[1];

[1]IRCCS Regina Elena National Cancer Institute, Rome, Italy, [2]Istituto Superiore di Sanita, Rome, Italy, [3]Istituto Nazionale Tumori-IRCCS-Fondazione G. Pascale, Naples, Italy

Glioblastoma, the most common and deadly brain tumor, remains a critical unmet medical need due to the limited effectiveness of current treatments. Drug repurposing has recently emerged as a promising strategy to improve glioblastoma outcomes. Antipsychotic drugs, with their established safety profile and potential to disrupt tumor-neuron interactions, have drawn particular attention. Among these, chlorpromazine, a well-tolerated medication included in the 2021 WHO Model List of Essential Medicines, holds promise due to its therapeutic effects in psychiatric disorders stemming from its non-specific interference with various CNS neurotransmitter receptors. Our recent studies have demonstrated chlorpromazine's ability to inhibit several molecular and cellular processes in glioblastoma cells, suggesting its potential as a novel treatment option for this challenging disease.To elucidate chlorpromazine's mechanism of action as a potential anticancer drug, we employed two proteomics approaches: Reverse-Phase Protein microArrays to evaluate its impact on signal transduction pathways and Activity-Based Protein Profiling followed by mass spectrometry to identify novel molecular targets.Our data revealed that chlorpromazine significantly modulates major signal transduction pathways and implicates pyruvate kinase (PK) M2 as a drug target. PKM2, a PK variant characteristic of many cancers, plays a crucial role in orchestrating metabolic alterations, exemplified by the Warburg effect – the high glucose consumption and lactate production by cancer cells even under oxygen-rich conditions. PKM2 functions as a tetramer in the glycolytic pathway, while its dimeric form acquires nuclear localization, protein kinase activity, and interacts with various transcription factors, contributing to its pro-tumorigenic activity.Consistent with its ability to target PKM2, chlorpromazine promoted PKM2 tetramerization in glioblastoma cells, leading to significant alterations in glioblastoma energy metabolism. Notably, RPE-1 non-cancer neuroepithelial cells showed a reduced response to the drug. Additionally, silencing PKM2 diminished the effects of chlorpromazine. 3D modeling revealed that chlorpromazine interacts with the PKM2 tetramer at the same site involved in binding other small-molecule activators that stabilize the PKM2 tetramer.These findings suggest that chlorpromazine counteracts the Warburg effect and, consequently, malignancy in glioblastoma cells, while sparing non-cancerous RPE-1 cells. This preclinical evidence supports the rationale behind our recently completed multicenter Phase II clinical trial investigating the role of chlorpromazine in glioblastoma treatment. The study is registered as EudraCT #2019-001988-75 and ClinicalTrials.gov Identifier #NCT0422444.

#4714 Mechanisms by which the Rac & Cdc42 inhibitor MBQ-167 overcomes the adverse effects of paclitaxel in TNBC.

Nilmary Grafals-Ruiz[1], Patricia Sanchez-Orive[2], Anamaris Torres-Sanchez[3], Ailed Cruz-Collazo[1], Derealise Garcia-Almedina[2], Stephanie Dorta-Estremera[4], Suranganie Dharmawardhane[1]

[1]Biochemistry, University of Puerto Rico - Medical Sciences Campus, San Juan, PR,[2]Natural Sciences, University of Puerto Rico - Rio Piedras Campus, San Juan, PR,[3]Biology, University of Puerto Rico - Rio Piedras Campus, San Juan, PR,[4]Microbiology and Medical Zoology, University of Puerto Rico - Medical Sciences Campus, San Juan, PR

Triple-negative breast cancer (TNBC) is the most aggressive, recurrent, and metastatic type of BC. Since there are limited targeted therapies available, the standard treatment is taxane-based chemotherapy, which still results in recurrence and metastasis. Therefore, we developed MBQ-167, a clinical-stage Rac/Cdc42 inhibitor that reduces tumor progression and metastasis in TNBC mouse models. In vitro studies show that PXL increased Rac activation, which MBQ-167 reduced in combination with PXL. In mouse models of TNBC, we found that PXL increases metastasis and that MBQ-167 prevents it. Therefore, this study aimed to identify potential mechanisms to explain the antimetastatic effects of MBQ-167 in combination with PXL. Previous studies suggest that PXL may act as an agonist to the Toll-Like 4 Recceptor (TLR4) and activate NfkB signaling to promote metastasis. We hypothesize that MBQ-167 chemosensitizes TNBC cells to PXL and reduces metastasis by blocking Rac/Cdc42 and TLR4/NF-kB signaling. Treatment of SCID mice with orthotopic MDA-MB-468 TNBC tumors with MBQ-167, PXL, or the combination increased lung metastases in mice treated with PXL, which MBQ-167 suppressed. Flow cytometry of spleens harvested from the mice with or without tumors demonstrated increased M2 immunosuppressive macrophages (F480+, CD206+) compared to M1 macrophages (F480+, CD206-), where macrophage differentiation has been implicated with TLR4 signaling. To determine the role of TLR4 signaling, we treated MDA-MB-231 cells stably expressing scrambled or TLR4 shRNA with MBQ-167, PXL, or the combination. Treated cells were evaluated for cell viability, apoptosis, migration, mammosphere assay, and NF-kB p65 activation. Results show that MBQ-167 reduced cell viability stem-cell-like features and increased apoptosis comparable to vehicle or PXL. TLR4 knockdown (kd) did not change cell viability, apoptosis, or migration in vehicle-treated cells. However, TLR4 kd further reduced the decreased cell viability and increased apoptosis in response to MBQ-167, PXL, or the combination, indicating that PXL effects on cell growth are at least partially dependent on TLR4. PXL treatment did not affect cell migration in the control cells but reduced migration in TLR4 kd cells. TLR4 kd exacerbated the inhibitory effects of MBQ-167 or the combination. MBQ-167, but not PXL, reduced LPS-induced (i.e., TLR4-regulated) NfkB translocation to the nucleus, with a similar effect as the combination. Therefore, MBQ-167 may prevent PXL-induced metastasis by partially inhibiting the NF-kB pathway in TNBC tumors and reducing inflammation and immunosuppression from M1 and M2 macrophages *in vivo*.

#4715 Azathioprine and Z36 induced cell death in human colorectal cancer HCT-116 and HCT-15 cells.

Y. Tahir Ali, M. Fatima, M. Ahmed, H. Siddiqi, A. Hussain, **M. Rehman**;
Aga Khan University, Karachi, Pakistan

Rationale and Objectives: Cancer accounts for a huge global health burden and is the third highest cause of death across the globe. Cancer cells are known to have higher basal reactive oxygen species (ROS) levels, owing to their higher metabolism and proliferation. Higher basal ROS in cancer cells made them susceptible to exogenous ROS stimuli that lead to cell death. Therefore, in the present study, we have analyzed the effects of Azathioprine, a glutathione (GSH) inhibitor and an intracellular ROS producer. The effect of Azathioprine was analyzed alone or in combination with a BCL-2 family protein inhibitor Z36, on human colorectal cancer cell lines HCT-116 and HCT-15.

Methods: The effects of the drugs have been investigated using various methods including cell viability assay, DNA fragmentation assay, and Annexin V-FITC/PI apoptosis assay. In addition, morphological changes evident in cell death were detected by Giemsa staining. Combination dosage for drug synergistic effects was computed through the use of CompuSyn software. Western blot was performed to detect changes in the expression of cell death-related proteins following drug treatments.

Results and conclusion: Azathioprine at a dose of 5 μM has been demonstrated to induce cell death in both HCT116 and HCT15 cells in a concentration and time-dependent manner. On the contrary, Z36, a novel BCL_{XL} inhibitor, has demonstrated similar cell viability results at an even lower dose of 2.5 μM. When both drugs were combined at lower doses, no significant effects were observed on the cell viability of either cell line, demonstrating that the combined treatment has no synergistic or additive effects. This suggests that both drugs do not augment each other and might induce cell death via upregulation of ROS using a similar mechanism.

#4716 First-in-class peroxiredoxin 3 (PRX3) inhibitor RSO-021 triggers mesenchymal-to-epithelial transition in mesothelioma.

T. Messier[1], V. Gibson[1], D. J. Seward[1], E. Y. Baitei[2], P. Jordan[2], C. Poile[2], J. Dzialo[2], A. Bzura[2], K. Kutywayo[2], A. Nakas[3], G. N. Naumov[4], D. A. Fennell[2], **B. Cunniff**[1];

[1]Larner College of Medicine at The University of Vermont, Burlington, VT, [2]University of Leicester and University Hospitals of Leicester, Leicester, United Kingdom, [3]University Hospitals of Leicester, Leicester, United Kingdom, [4]RS Oncology, Cambridge, MA

Mesothelioma, a lethal cancer associated with asbestos exposure, lacks effective drug therapy particularly in the relapsed treatment setting. Epithelial-to-mesenchymal transition (EMT) confers an aggressive sarcomatoid phenotype capable of invasion, metastasis, and drug resistance. Pharmacological targeting of EMT could favorably alter the progression and treatment of mesothelioma. We identified a geospatial transcriptomic gradient between adjacent epithelioid and sarcomatoid regions in patient-derived biphasic mesotheliomas involving hypoxia tolerance, TGF-β, mitochondrial oxidative phosphorylation, and EMT. Mesothelioma cells rely on buffering of mitochondrial oxidative stress through the expression and activity of mitochondrial peroxiredoxin 3 (PRX3), which is covalently inactivated by the first-in-class inhibitor RSO-021, now under investigation in the phase 1/2 MITOPE clinical trial (NCT05278975). To better understand the pharmacodynamics of RSO-021, transcriptomic profiles of drug sensitive and resistant biphasic mesothelioma cell lines were generated. Differential analysis revealed that RSO-021 induced up-regulation of ROS response and apoptosis signaling, while down-regulating TGF-β and EMT markers, WNT signaling, and TEAD target genes. Additionally, we observed altered expression of the mesothelioma specific EMT genes Col5A2, mesothelin and VISTA. Resistance to RSO-021 conferred significant proliferative defects and was reversible upon RSO-021 removal, however the down-regulation of EMT genes was conserved, suggesting an irreversible mesenchymal-to-epithelial transition. In summary PRX3 is a clinically actionable drug target, inhibition of which correlates with EMT modulation. This activity suggests a mechanism to alter mesothelioma progression and prevent the emergence of the most aggressive mesothelioma phenotype.

#4717 Small molecule modulation of PP2A selectively induces oncogenic cytotoxicity through chronic and irreversible integrated stress response.

R. A. Avelar, R. Gupta, G. Carvette, F. da Veiga Leprevost, J. Colina, J. Teitel, G. Narla, A. DiFeo;
University of Michigan, Ann Arbor, MI

High-grade serous cancer (HGSC) is the most lethal gynecological malignancy and accounts for approximately 70% of all ovarian carcinomas. Despite recent advancements in drug discovery and a deeper understanding of the genetic mechanisms that drive HGSC oncogenesis, the mortality rate has remained stagnant over the past three decades, with a 5-year survival rate below 30%. Due to the prevalence of homologous recombination defects (HRD) in over 50% of HGSC tumors, the clinical management of patients harboring these genetic vulnerabilities has vastly relied on PARP inhibitors (PARPi). Nonetheless, about 80% of these patients ultimately relapse with refractory resistant and more aggressive disease, having no effective therapeutic alternatives currently available. Therefore, there is an urgent need for novel targeted therapies to be tailored towards the treatment of HGSC. Recently, we unveiled that 95% of HGSC tumors present with a widespread loss-of-heterozygosity in genes essential to form the tumor suppressor Protein Phosphatase 2A (PP2A) heterotrimer, second only to *TP53*. These deleterious alterations have been established to inhibit PP2A function, preventing it from counteracting oncogenic signatures that drive tumorigenesis. Our studies revealed that a Small Molecule Activator of PP2A (SMAP) synergizes with PARPi to induce synthetic lethality in HGSC cells while displaying favorable tolerability profiles in normal tissues. Mechanistically, SMAP activates distinct translational responses and stress signatures depending on the cellular context, driving selective oncogenic cytotoxicity through a chronic and irreversible integrated stress response (ISR), independent of PERK activation. In malignant contexts, SMAP-mediated activation of PP2A specifically drives the dephosphorylation of TFE3 to transcriptionally activate ATF4 and CHOP. Consequently, as cancer cells are incapable of activating adaptive homeostatic recovery mechanisms in response to SMAP, chronic ISR is induced, ultimately leading to cell death. Conversely, non-transformed cells leverage their intrinsic ISR plasticity to adapt, thereby restoring basal functions that allow cell survival under SMAP-mediated stress conditions. Collectively, our data highlights a new role of PP2A in HGSC and further underscore SMAP's selective cytotoxicity in cancer cells, independent of oncogenic genetic vulnerabilities or HRD profiles, by leveraging ISR plasticity and intrinsic adaptive homeostatic mechanisms. Thus, this class of PP2A modulators holds tremendous promise for broader therapeutic applications across diverse patient populations and tumor histological subtypes beyond HGSC, while mitigating standard-of-care therapy-associated toxicity.

#4718 Reclaiming a dirty drug: What is the context of vulnerability to arsenic trioxide in glioblastoma?.

C. Shaffer IV[1], N. Tang[1], Y. Hao[1], K. Fink[2], G. Snipes[2], B. Mickey[2], M. Berens[1];
[1]TGen (The Translational Genomics Research Institute), Phoenix, AZ, [2]Baylor Scott & White Research Institute, Dallas, TX

Glioblastoma (GBM) is the most prevalent type of malignant tumor within the central nervous system. There is a growing demand to develop and adapt new therapeutic options in order to combat the five-year survival rate of 6.8% and improve patient quality of life. Arsenic trioxide (ATO) is the standard of care for myelodysplasia and relapsed or refractory acute promyelocytic leukemia. While currently being classified to have an idiopathic mechanism of action, two specific cytotoxic consequences of ATO have emerged: MNK1 activity and oxidative stress. Across six GBM PDX models a 20-fold difference in sensitivity manifests, indicative of underlying innate sensitivity or resistance to ATO. To correlate this to the proposed mechanisms of action, we observed ATO's effect on MNK1 activity through eIF4E phosphorylation and glutathione (GSH) levels following treatment. A subset of GBM models exhibited a marked upregulation of eIF4E phosphorylation following treatment with 2 uM ATO. Of the six models, three were chosen to undergo further testing to observe whether this upregulation showed a consistent dose-dependent relationship across the models and correlated with vulnerability to ATO. Combination therapy with the MNK1 inhibitor, ETC-206, displayed mild to moderate synergy on overall cell viability and strong synergy when observing its effects on the glioma stem cell population. This preferential effect on the GSC populations suggests that MNK1i based combination strategies may show greater effectiveness *in vivo* than indicated by our previous *in vitro* studies. Nutraceuticals targeting GSH synthesis, Chrysin and Silibinin, displayed a 0.95 to 1.4-fold decrease in ATO IC_{50} values across all 6 models. To observe whether each nutraceutical impacted GSH levels consistently across all of the tested models, we measured GSH levels following treatment for each individual compound and their combination treatments. These findings further implicate MNK1 activity and cellular response to oxidative stress as markers of ATO sensitivity, however they are not the sole determinates of response. Understanding of the mechanism of action for idiopathic compounds may allow for the discovery of molecular signatures of sensitivity, improving patient selection for clinical trials and the development of new combination approaches to combat resistance in other tumor types.

#4719 Modulation of HR-HPV viral protein E7 by SHetA2 in cervical cancer.

J. Garland[1], S. Hussain[2], D. M. Benbrook[1];
[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [2]ICMR-National Institute of Cancer Prevention & Research, Noida, India

Introduction: The purpose of this study is to determine the effect of the chemotherapeutic sulfur heteroarotinoid A2 (SHetA2) on high-risk human papillomavirus (HR-HPV) proteins and the modulation of cell survival and proliferation in cervical cancer. Cervical cancer is caused by persistent HR-HPV infection. HR-HPV tumorigenesis is driven by its early 6 and 7 (E6, E7) oncoproteins, which increase cell proliferation and survival. Cellular pathways regulated by E6 and E7 are counter-regulated by the investigational new drug SHetA2, which is currently in phase 1 clinical trial for advanced and recurrent cancers. SHetA2 disrupts complexes of 70-kDa heat shock protein (HSP70) family members, hsc70, GRP78, and mortalin, with their client proteins. We hypothesized that SHetA2 reduces E6 and E7 levels and their binding to HSP70 chaperones in association with the reduction of cervical cancer cells and tumor growth.
Methods: SHetA2 effects on specific genes and proteins in HR-HPV-positive cervical cancer cell lines and xenograft tumors were assessed by western blot, quantitative polymerase chain reaction, immunofluorescence ligation assays, and coimmunoprecipitation assays.
Results: SHetA2 significantly reduced E6 and E7 mRNA, and protein levels of E7 and the E7-regulated p16, but not E6 in cervical cancer cells and xenograft tumors. MG132 inhibition of proteasome function attenuated the E7 reduction. HSP70/hsc70 proteins bound E7 and SHetA2 disrupted these complexes.
Conclusions/Implications: SHetA2 reduces E7 proteins in cervical cancer cells through a mechanism that involves proteasomal degradation in association with disruption of HSP70/E7 complexes, p16 reduction, and decreased cell and tumor growth. This is the first demonstration of HSP70/E7 complexes. SHetA2-induced release of E7 from HSP70s could be causing increased susceptibility of E7 to proteasomal degradation. This data supports the development of SHetA2 and HSP70 inhibitors for cervical cancer.

#4720 Effects of removing heat and nourishing yin prescription on malignant phenotype and PI3K/AKT signaling pathway of human esophageal carcinoma cells.

F. Si[1], W. Zhao[1], G. Si[2], X. Song[1];
[1]Henan University of Chinese Medicine, Henan, China, [2]Peking University Third Hospital, Beijing, China

Introduction: Esophageal carcinoma (EC) ranks eighth in the incidence of malignant tumors and the sixth mortality worldwide. This study aims to screen out the Chinese herbs with strong inhibitory effects on the proliferation of four kinds of EC cells EC9706, EC-1, TE-1 and Eca109 from 366 Chinese herbs produced in Henan Province, and study the effect of composed Removing Heat and Nourshing Yin Prescription(RHNYP) on the proliferation, migration, invasion and PI3K/AKT signaling pathway of four EC cells.
Methods: MTT and orthogonal design was applied to screen out the best effective Chinese herbs and determine the optimal dosage ratio of prescription on EC9706, EC-1, TE-1, Eca109 cells from 366 Chinese herbs alcohol extracts, the effects of this prescription on the proliferation, migration, invasion, clone formation, cell cycle and apoptosis of four EC cells were investigated by MTT, RTCA, soft agarose colony forming test, flow cytometry and western blot analysis. Then exploring the effects of RHNYP on EC related signaling pathways and key genes expression by western blot and RT-PCR assay.
Results: Rhizoma Fagopyri Dibotryis(Jinqiaomai), Rhizoma Anemarrhenae(Zhimu), Asparagus Cochinchinensis(Tiandong), and Carpesium Abrolanoides Linne(Heshi) were screened out and composed Removing Heat and Nourshing Yin Prescription(RHNYP) according to their efficacy and orthogonal design. RHNYP could obviously inhibit the proliferation of EC9706, TE-1, EC-1, ECa109 cells with dose-effect and time-dependent manner. IC50 values of Jinqiaomai, Zhimu, Tiandong, Heshi in RHNYP for EC9706 cell were 27.639μg/ml, 40.015μg/ml, 9.044μg/ml, 11.208μg/ml respectively; for EC-1 cell were 24.575μg/ml, 56.991μg/ml, 9.361μg/ml, 13.584μg/ml respectively; for TE-1 cell were 23.534μg/ml, 25.862μg/ml, 6.788μg/ml, 8.911μg/ml respectively; for ECa109 cell were 33.990μg/ml, 33.604μg/ml, 19.873μg/ml, 15.227μg/ml respectively. RHNYP could effectively inhibit the proliferation, migration, invasion, cloning ability, cell cycle and reduce apoptosis of four EC cells. PI3K/AKT/mTOR pathway had closely relationship with the occurrence and development of EC and RHNYP could effectively regulate the proteins expression on the pathway. CDCK3, KIF4A and RAD51AP1 genes were negatively correlated with the overall survival of EC patients and RHNYP could significantly inhibit their expression in four EC cells.
Conclusion: RHNYP can effectively inhibit EC cell proliferation, migration, invasion and cell cycle, induce apoptosis, which may be related to the regulation of PI3K/AKT/mTOR pathway.

#4721 Cell death induction via CB2 receptor and TRPV receptor in cannabichromene (CBC) treated human pancreatic cancer cells.

Y.-N. Hwang, **K.-C. Kim**;
Kangwon National University, Chuncheon, Korea, Republic of

Cannabichromene (CBC: $C_{21}H_3O_2$, M.W.: 314.46g) is one of the most abundant nonpsychotropic phytocannabinoids extracted from Hemp species (*Cannabis sativa),* and can extract using either a hexane/florisil extraction method. Phytocannabinoids contain Δ9-tetrahydrocannabinol (Δ9-THC), cannabidiol (CBD), cannabigerol (CBG), cannabichromene (CBC), and other compounds. CBC can cause strong anti-inflammatory effects in animal models of edema through non-CB receptor mechanisms, but there is little pharmacological study in cancer disease models. In this study, we investigated the molecular mechanism on anti-cancer activity of CBC treatment in human pancreatic cancer cells. MTT assay was performed to determine concentrations for inducing pharmacological effects of CBC in human pancreatic cancer cells. FACS and Annexin V/PI staining analysis showed the increase dead cells by CBC treatment, and Western blot analysis also showed the changes in expression of cell death related proteins by CBC. Moreover, CBC treatment increased expression of CB2 receptor and TRPV receptor, but the anti-cancer effect was restored by double inhibition with SR144528 for CB2 receptor and capsazepine for TRPV receptor, respectively. mRNA-seq analysis showed that 1206 genes were upregulated and 1145 genes were down-regulated by CBC treatment, indicating that some of ferroptosis related genes (HMOX1, CHAC1, GPX4 and NFE2L2) were regulated by CBC treatment. qPCR analysis showed that those genes are increased by CBC treatment in time dependent manner. It was also confirmed that HMOX1 protein expression was increased using Western blot analysis. Therefore, we suggest that CBC induces multiple cell death mechanism including ferroptosis via CB2 receptor and TRPV receptor in human pancreatic cancer cells.

#4722 Enhanced phenotypic screening: A kinetic, multiplexed approach to analyzing drug effects using Incucyte® Live-Cell Analysis System.

K. McBain[1], G. Lovell[1], J. Trigg[1], N. Bevan[1], D. Appledorn[2];
[1]Sartorius, Royston, United Kingdom, [2]Sartorius, Ann Arbor, MI

Phenotypic screening is a valuable tool for analysis of the complex mix of effects that drug treatment has on cells. Traditionally image-based screening uses fixed cells stained with reagents at a pre-chosen end point, however our technique combines kinetic, label-free readouts with non-perturbing fluorescence reporters to enable information-rich quantification of compound effects. A549 lung cancer cells were treated with a library of over 800 FDA-approved drugs while images were acquired in the Incucyte® Live-Cell Analysis System every two hours for four days. Cell growth and viability were measured using label-free readouts of confluence and dead cell count while cell cycle, cell death and Akt pathways were investigated using multiplexed fluorescent readouts. Cytotoxicity was measured using label-free Incucyte® AI Cell Health Analysis Software Module which uses two neural networks to segment individual cells and classify them as live or dead. Assay robustness was quantified using the time course of positive and negative controls (camptothecin and vehicle, respectively). Z' reached a maximal value >0.9 between 48h and 72h; at 72h 4.4% of the compounds within the library induced >50% cell death. Correlation between % Live cells and % Confluence indicated 3 types of effect: cytotoxic (low viability, low confluence), cytostatic (high viability, low confluence), and none (high viability, high confluence). Morphological changes were observed in a multitude of wells with 29 compounds inducing cell enlargement >1800 μm^2, suggesting induction of senescence. Hits from fluorescent readouts were identified as the compounds which perturbed the quantified readout more than 3 standard deviations away from the mean value of the vehicle. Mechanisms of cell death were examined by correlative analysis of the total dead cell population (label-free cell death identification), caspase-active (caspase 3/7-reagent positive) and Annexin V positive cells. This enabled rapid identification of compounds which induced apoptosis by caspase-independent pathways, including the serotonin-selective reuptake inhibitor Sertraline. Kinetic plots of cell cycle stage (% S|G2|M or G1) revealed contrasting mechanisms. Mycophenolic acid induced cell cycle arrest, observed as a consistent increase in the percentage of cells in G1 over time. However flumazenil displayed repeated, transient peaks in the percentage of cells in S|G2|M over the same 72h period, indicating synchronisation behavior. Incucyte® Live-Cell Analysis System as a phenotypic screening platform provides valuable kinetic data from cells within the physiologically relevant environment of a standard incubator. Label-free readouts yield direct cellular information and can be combined with fluorescent data to provide vastly more information than a single endpoint readout.

#4723 Target engagement sheds light on difference in drug efficacy in breast cancer cell lines.

Tomas Friman, Tuomas Tolvanen, Merve Kacal, Victoria Brehmer, Stina Lundgren, Laurence Arnold, Daniel Martinez Molina

Research & Development, Pelago Bioscience AB, Solna, Sweden

Breast cancer is a serious disease that affects millions of women worldwide, and 700,000 people succumb to the disease annually. Breast cancers are divided into several functional subgroups based on molecular characteristics and growth pattern: Luminal A and B, HER2 positive (HER2+) and triple negative. The subgroups are important from a clinical perspective as they partially guide treatment strategies. In this study we wanted to investigate the difference in target engagement with four drugs indicated for treatment of different types of breast cancer: Alpelisib, Neratinib, Vinorelbine, and Docetaxel. Five different human breast cancer cell lines were included, representing Luminal A (MCF-7, T-47D), HER2+ (SK-BR-3, BT-474), and triple negative (BT-20). We used CETSA® (CEllular Thermal Shift Assay) coupled to mass spectrometry detection to assess proteome wide changes in protein thermal stability in intact breast cancer cell lines. CETSA is unique as a target engagement detection modality as it allows for target engagement assessment in intact cells with unaltered drug molecules. Also, as biology is intact in live cells it is possible to follow compound induced downstream signaling or phenotypic events that result in changed thermal stability of proteins. In addition to assessing protein thermal stability with CETSA, which is a short treatment of 1 h, we also subjected cells in culture to prolonged drug exposures, ≤72 h, in order to measure viability. This was done to correlate early changes in protein thermal stability to the viability phenotype that manifested later. In general, responses both in protein thermal stability and cell viability was heterogenous among the cell lines. The most homogenous response in viability was observed for the Phosphatidyl Inositol 3' kinase inhibitor Alpelisib, which reduced viability to 20 - 40% in all cell lines. In contrast, partial resistance was shown to the other drugs by at least one of the cell lines. For Alpelisib, the amount and type of proteins that were thermally shifted correlated with the effect on viability. The covalent HER2 inhibitor Neratinib was most effective in inhibiting viability in HER2+ cells and proteins of the HER2 pathway were thermally shifted in these cells, which was not observed for the other cell lines. Viability of the other cell lines were also affected by Neratinib, but only at higher concentrations. Both microtubule inhibitors induced thermal stabilization of tubulins, but that did not always translate into efficacy in the viability assay. However, sensitive cell lines showed thermal shifts of tubulins at lower concentrations of compound. In oncology drug development it is important that effects on viability are driven by on-target efficacy and not by off-target effects. Here we show the benefit of connecting knowledge of target engagement and phenotypic readouts; what targets are engaged, at which concentrations, and what is the corresponding phenotype.

#4724 Optimizing 500 pooled PRISM cell lines for a 10-day assay to elucidate viability effects and mechanism of action for slower-acting therapeutics.

M. Ronan, B. C. Ip, E. Nguyen, U. Widocki, T. Sangpo, A. Kalathungal, N. Diaz-Gallegos, A. Fazio, A. Golabi, M. Naim, A. Bino George, Y. Liu, M. Kocak, R. Puram, M. G. Rees, J. Roth;
Broad Institute of MIT and Harvard, Cambridge, MA

PRISM (Profiling Relative Inhibition Simultaneously in Mixtures), using DNA-barcoded cell lines cultured as ~25 cell line pools, has been an effective drug discovery screening platform to rapidly test large numbers of potential therapeutics on over 900 different cancer cell lines. However, the conventional 5-day assay may be too short to offer the resolution needed to identify the full cellular response for slower-acting therapeutics such as those directed against epigenetic pathways. Here, we describe development of the PRISM 10-day extended assay with ~500 adherent solid tumor cancer cell lines to overcome this challenge. We found that the ranges of cell line growth rates within the standard PRISM pools were too large and not amenable for a long-term assay beyond 6 days—after 10 days of growth, slower cell lines dropped below the limit of barcode detection as faster cell lines overtook the pools. We therefore regenerated pools to reduce the range of growth rates within a pool. We show that this re-pooling, coupled with seeding density optimization, enables recovery of > 98% of cell lines at day 10 in vehicle-treated wells, with acceptable data variability. The average estimated number of cell doublings across our cell lines, 7, is significantly greater than the number of doublings in the PRISM standard 5-day assay (~3 doublings). Importantly, we observe greater drug effects on day 10 versus day 6 when cells are treated with slow-acting DNA methyltransferase inhibitors such as decitabine; this also results in increased sensitivity to identify cellular biomarkers underlying differential response. In summary, we have successfully engineered a PRISM 10-day assay in ~500 adherent cell lines, where the extended duration can be beneficial in elucidating the effects and mechanism of action for epigenetic drug candidates.

#4725 Phenotypic single-cell analysis of nuclear stress responses in drug-treated prostate cancer cells.

E. Batnasan, M. Karkkainen, S. Koivukoski, P. Ruusuvuori, **L. Latonen**;
University of Eastern Finland, Kuopio, Finland

Chemotherapy with anti-cancer drugs aims to stop the growth of cancer cells either by killing them or by stopping them from dividing. The different specificities in inducing cellular damage responses are incompletely understood currently and may underlie the preferential effectiveness of anti-cancer drugs against different types of cancer cells. Better understanding and tools to measure drug-induced phenotypes *in vitro* may aid in assessing cellular heterogeneity of responses, determining potential effectiveness, estimating amount and types of adverse effects, and predicting likelihood of surviving populations for residual disease. To measure the types and extent of nuclear stress responses to cancer drugs, we studied nuclear organelle, namely nucleolar and Cajal body, phenotypes to drug-induced stress in prostate cancer cells. We utilized organelle-specific markers NPM, Fibrillarin, Coilin, and SMN1 in immunofluorescence staining to determine suitable markers for nuclear organelle stress. We used three different prostate cancer cells lines representing different biological types of advanced prostate cancer (AR positive, AR negative, and expressing AR transcript variant). Based on initial assessments, NPM and coilin immunostaining were selected for automated phenotypic analysis screening for drug effects. Using AI-assisted nuclear segmentation and feature-based single-cell phenotypic analysis, we demonstrated quantitative effects on nuclear morphology, nucleoli, and Cajal bodies with drug treatments. A proof-of-principle study with platinum-based chemotherapeutic agents in clinical use demonstrated heterologous responses to the platinum drugs that are associated with prostate cancer cell types with different AR status. Further, we have defined the corresponding quantitative responses for androgen deprivation therapy (ADT) drugs enzalutamide and bicalutamide in AR-positive prostate cancer cells. Our findings evidence variability of prostate cancer cells' response to chemotherapy and have implications in future therapy regimen considerations. Furthermore, we have developed a fluorescence light microscopy-based method to assess nuclear stress response phenotypes in prostate cancer cells that can be used for high throughput drug screening.

#4726 Identification of efficacy biomarkers for therapies targeting miR-10b.

A. Halim, N. Al-Qadi, S. K. Mondal, E. Kenyon, N. Savan, H. Mackie, A. Moore;
Michigan State University, East Lansing, MI

Breast cancer stemness is one of the drivers of metastatic spread and presents a key target in the battle against metastatic disease, especially in triple-negative breast cancer (TNBC). Existing treatment options for TNBC are limited due to recurrence and resistance, representing a major unmet clinical need. MicroRNA-10b (miR-10b) is one of the major drivers of breast cancer cell migration and invasion. In our earlier studies, we discovered that miR-10b is also responsible for metastatic cell viability. With the goal of translation of this finding to the clinic, we developed a novel therapeutic, or "nanodrug," that targets miR-10b, consisting of antisense anti-miR-10b oligonucleotides conjugated to magnetic nanoparticles (MN) that serve as delivery vehicles. Administration of the nanodrug in mice bearing metastatic MDA-MB-231 TNBC tumors prevents the development of metastases and stops the growth of pre-existing metastases. Additionally, combination treatment with adjuvant doxorubicin induced a stable regression of metastases in immunocompromised and immunocompetent mouse models of metastatic TNBC. A limitation of our previous studies is the lack of understanding of the molecular basis for the therapeutic effect of MN-anti-miR10b. To address this gap in knowledge, we performed RNA sequencing on MDA-MB-231 cells treated with the nanodrug or controls. Functional enrichment analysis of differentially expressed genes (DEGs) between cells treated with the nanodrug versus controls (PBS or bare MN) identified a significant overrepresentation of genes associated with cell differentiation. It has been suggested that miR-10b confers stem cell-like properties such as self-renewal and drug resistance onto cancer cells. Our RNA sequencing findings led us to hypothesize that MN-anti-miR10b functions by inhibiting these stem-like cancer cell (CSC) features that are critical to cancer survival. Here, we present preliminary data showing that miR-10b is overexpressed in MDA-MB-231 cells expressing a CSC-associated surface marker phenotype (CD44+/CD24-, compared to CD44-/CD24- cells) and that this trend is not universal among other miRNAs. Furthermore, we found that the nanodrug interferes with the ability of cells to assemble as spheroids, a property associated with CSCs. With our recent observation that the nanodrug inhibits miR-10b in metastases *in vivo* in as little as one dose after 72 hours, our next steps are to determine whether the cell differentiation-associated DEGs identified in RNA sequencing results can be used as biomarkers of nanodrug efficacy *in vivo*. Understanding the changes in gene expression induced by MN-anti-miR10b as a function of time will be critical for guiding treatment regimens in future preclinical and clinical trials.

#4727 Large scale drug response comparison across different neuroblastoma cell model systems.

S. Park[1], **E. Liu**[1], A. Los[1], B. Seashore-Ludlow[1], P. Ostling[1], J. Molenaar[2], O. Kallioniemi[1], J. Stenman[1], K. Karlsson[1];
[1]Karolinska Institutet, Stockholm, Sweden, [2]Princess Maxima Centre, Utrecht, Netherlands

Traditionally neuroblastoma research has predominantly used 2D cell lines, which, despite their simplicity, often fall short in mirroring the physiological complexity of actual tumors. Recently, 3D models like patient-derived tumor organoids (PDO) and patient-derived xenografts (PDX) have emerged as superior alternatives, offering more realistic predictions of patient treatment responses. This study aims to discern the differences in drug response between conventional 2D cell lines and the more advanced 3D neuroblastoma models - specifically, patient-derived organoids (nPDO) and patient-derived xenograft organoids (nPDXO). Employing high-throughput drug screening of 528 cancer drugs, we evaluated the drug responses across traditional 2D cell lines, nPDOs, and nPDXOs. Additionally, focused experiments with 29 selected drugs were conducted to determine the influence of culture topology on drug efficacy. The findings were compared to a study by Hansson et al.[1] that used nPDXO. Our study discovered a pronounced difference in drug sensitivity between 2D cell lines and 3D models, with 3D models showing heightened sensitivity. Interestingly, 2D cell cultures had a more heterogenous drug response compared to 3D models. The drug response correlation between nPDOs and nPDXOs was relatively high (Spearman ~0.8), indicating consistent responses across these models. Our comparison underscores the impact of model system choice on drug response studies in neuroblastoma. The study highlights important differences in drug response between neuroblastoma 2D and 3D cell culture models. However, only subtle differences were found between PDO and PDX-derived organoid lines, despite differences in treatment centers and media compositions. This suggests that while the choice of cell culture topology greatly impacts drug response, PDO and PDX derived lines can largely be used interchangeably for drug screening experiments.

#4728 Circ-EGFR enhances cetuximab efficacy by regulating miR-942-3p/GAS1 signaling axis in colorectal cancer.

S. Sui[1], C. Xu[1], Y. Li[1], W. Wei[2], J. Maurel[3], M. Li[4], A. Goel[1];

[1]Beckman Research Institute of The City of Hope, Monrovia, CA, [2]Harvard Medical School, Boston, MA, [3]Hospital Clinic of Barcelona, Barcelona, Spain, [4]the Second A, Dalian, China

Background: Cetuximab, an epidermal growth factor receptor (EGFR)-targeting IgG1 monoclonal antibody (mAb), results in beneficial, yet limited, clinical improvement in metastatic colorectal cancer (mCRC) patients with wild-type (WT) KRAS gene. Numerous studies have shown that circRNAs are aberrantly expressed in tumors and play crucial roles in tumor growth and metastasis in various human malignancies, including colorectal cancer (CRC). One such circRNA, circ-EGFR, has been identified as having associations with tumor progression and chemotherapy response in diverse cancer types. However, exploring the functional role and underlying mechanisms of circ-EGFR in the context of the response to EGFR-targeted therapy may offer new therapeutic avenues for mCRC.

Methods: The expression level of circ-EGFR (hsa_circ_0080229) was evaluated in cetuximab-sensitive and resistant RAS and BRAF WT CRC cell lines by using real-time quantitative reverse transcription polymerase chain reaction (RT-qPCR). The biological function of circ-EGFR was investigated by loss- and gain-of-function assays in cultured cells and an animal model. The potential targets of circ-EGFR were identified through in-silico analysis, and the circ-EGFR/miR-942-3p/GAS1 axis pathway was verified using the luciferase reporter assay and RT-qPCR. The association of circ-EGFR expression with clinical prognosis in mCRC patients with different cetuximab responses was analyzed by Kaplan-Meier survival analysis.

Results: The expression of circ-EGFR was remarkedly higher in sensitive (DiFi and SW48) compared with resistant cell lines (CaCO2 and SNU-C1) after exposure of cells to cetuximab (sensitive vs. resistant: $p < 0.001$). Biologically, genetic depletion of circ-EGFR significantly enhanced cell proliferation, migration [DiFi: sh-circ-EGFR vs. shNC: Foldchange (FC) = 1.97, $p < 0.001$; SW48: FC = 1.96, $p < 0.001$], and invasion (DiFi: sh-circ-EGFR vs. shNC: FC = 2.23, $p < 0.001$; SW48: FC = 1.78, $p < 0.001$) after 24-48 hours of cetuximab treatment in DiFi and SW48 cell lines, and its overexpression suppressed tumor growth *in vivo* under cetuximab treatment. Mechanically, we identified circ-EGFR as a sponge for miR-942-3p to regulate the expression of Growth Arrest Specific 1 (GAS1), which promoted sensitivity to cetuximab treatment in CRC. Notably, our findings identified circ-EGFR as a promising therapeutic indicator in clinical applications.

Conclusion: Our study illustrated that circ-EGFR plays a vital role in affecting cetuximab efficacy by regulating the miR-942-3p/GAS1 axis in CRC. This holds promise for improving patient selection and management in this malignancy.

#4729 Incorporation of the antitumor compound 2OHOA and its metabolite into cell membranes.

R. Beteta-Gobel[1], R. Rodriguez-Lorca[1], P. Fernandez-Garcia[1], P. V. Escriba[1], V. Llado[2];
[1]Laminar Pharma, Inc., Palma de Mallorca, Spain, [2]Laminar Pharma, Inc., Boston, MA

The compound 2-hydroxyoleic (2OHOA) is a bioactive lipid molecule that has demonstrated an anti-tumor effect and high safety in cellular and animal models of glioblastoma multiform (GBM), considered the most aggressive and lethal of primary tumors of the central nervous system. Due to the poor prognosis of patients, with a median survival of 15 months, it is of great importance to develop new therapeutic strategies that improve the efficacy and safety of treatments to achieve complete remission of GBM. Granted orphan designation for the treatment of glioma in both the European Union and the United States, 2OHOA completed a phase I/IIA study on advanced solid tumors in adults (NCT01792310) showing pharmacological efficacy and safety. It is currently undergoing a phase IIB/III clinical trial on glioma patients (NCT04250922) in combination with the standard of care for glioma and a pediatric study on glioma and other solid tumors (NCT04299191).Here, we seek to define the mechanism of action of 2OHOA which is based on Membrane Lipid Therapy, an innovative approach that proposes the use of new molecules designed to modify the composition and lipid structure of the membrane and reverse a pathological lipid state. Therefore, we further investigated the effect of 2OHOA on membrane lipid composition when applied to human glioblastoma cell line by gas chromatography. In addition, we defined the 2OHOA's effect on different components of the cell signaling pathway by Western Blot and PK in glioma patients.Our results demonstrated that 2OHOA is mostly incorporated in glioma cell membranes and poorly integrated in non-tumor cells, which would explain its specific effects and low side effects in GBM treatment. Moreover, we observed that after its incorporation, 2OHOA is metabolized to produce the compound C17:1n-9 by α-oxidation pathway, a key process for its anti-tumor effect in glioma cells. In addition, the C17:1n-9 metabolite impairs cell growth, reinforcing the 2OHOA activity. Finally, we examined this metabolite as a biomarker to predict and trace 2OHOA treatment, studying the pharmacokinetics of glioma patients treated with the drug in phase I/IIA and its accumulation in mice xenograft tumors. In conclusion, 2OHOA shows a different incorporation into cell membranes between tumor cells and non-tumor cells. Moreover, both 2OHOA and its metabolite C17:1n-9 have an antiproliferative effect and exhibit an appealing potential in the treatment of patients that develop GBM with unmet effective therapy.

#4730 Pharmacodynamic determinants of anti tumor activity of SHMT2 inhibitors.

M. J. Schneider[1], C. O'Connor[1], X. Bao[1], M. Nayeen[2], Z. Hou[1], J. Li[1], A. Gangjee[2], L. Matherly[1],
[1]Wayne State University School of Medicine, Detroit, MI, [2]Duquesne University, Pittsburgh, PA

These studies investigate factors that impact the antitumor activity of SHMT2 targeting including drug accumulation, metabolism, expression of one carbon (C1) related enzymes, and tumor hypoxia. Mitochondrial C1 metabolism is upregulated in a variety of cancer types including leukemias and solid tumors. The mitochondrial C1 enzymes serine hydroxymethyltransferase (SHMT) 2 and 5,10-methylene tetrahydrofolate (THF) dehydrogenase 2 (MTHFD2) are among the top 5 overexpressed metabolic enzymes in tumors vs normal tissues in a wide range of tumor types. Thus, SHMT2 and MTHFD2 are potential therapeutic targets for cancer, sparing normal tissues that are less reliant on mitochondrial C1 metabolism. SHMT2 metabolizes serine and THF to produce glycine and 5,10-methylene THF; MTHFD2 metabolizes 5,10-methylene THF to NADH and 10-formyl THF which is converted to formate by MTHFD1L. Thus, mitochondrial C1 metabolism is the principal source of C1 units for cellular biosynthesis and provides the majority of glycine for protein, purine and glutathione synthesis. We previously discovered novel 5-substituted pyrrolo[3,2-*d*]pyrimidine antifolate compounds which exhibit primary inhibition at mitochondrial SHMT2 along with cytosolic SHMT1 and *de novo* purine biosynthesis at glycinamide ribonucleotide and 5-aminoimidazole-4-carboxamide ribonucleotide formyltransferases. The lead compound AGF347 is taken up into cells by the facilitative transporters reduced folate carrier (SLC19A1) and the proton coupled folate transporter (SLC46A1) and like folate cofactors is metabolized to polyglutamate (PG) forms by folylpolyglutamate synthase (FPGS) which promotes retention in cytosolic and mitochondrial compartments and target enzyme engagement. We investigated the impact of folate transporter expression on metabolism to PGs for SHMT2 targeted antifolates. Folate transporter expression inversely correlated with anti-tumor efficacy of SHMT2 targeted antifolates and overexpression of FPGS resulted in dramatically increased sensitivities. However, for pyrazolopyran inhibitors of SHMT2 (e.g. SHIN1) which enter cells by diffusion and are not metabolized to polyglutamates, increased transporter and FPGS levels dramatically decreased anti-tumor activity. As SHMT2 is a target of HIF1α, we studied the impact of multitargeting SHMT2 and purine biosynthesis by pyrrolo[3,2-d]pyrimidine antifolates under hypoxic conditions. Our results establish that multi-targeting SHMT2 and purine biosynthesis preserves anti-tumor activity under hypoxia. Collectively, our results demonstrate that SHMT2 targeted pyrrolo[3,2-*d*]pyrimidine antifolates exhibit increased antitumor efficacies in cells expressing low folate transporter expression and is further enhanced by increased FPGS activity. Additionally, we find multitargeting of SHMT2 and *de novo* purine biosynthesis manifests as antitumor activity even under hypoxic conditions.

#4731 Targeting Lon protease as novel strategy to treat aggressive IDH mutant diffuse malignant astrocytoma.

C. Douglas, **S. Jain**, N. Lomeli, T. Vu, J. Pham, D. A. Bota;
UC Irvine, Irvine, CA

While isocitrate dehydrogenase (IDH) wild-type and mutant malignant astrocytoma (IDH*wt*, IDH*mt*) are diffuse CNS tumors that have a high degree of parallelism with one another, including microvascular proliferation and necrosis, the IDH*wt* tumors clinically presents with a higher tumor grade and thus poorer prognosis and survival rate. Isocitrate dehydrogenase mutation (IDH) hinders the hypoxia response in gliomas and promotes an advantageous reduction in both tumor growth and treatment resistance. Since recurrence is high, adequate characterization and identification of potential novel molecular targets in IDH*mt* mutant diffuse glioma is integral for developing new therapeutic strategies for better control of tumor burden and, thus, improved outcomes. Our previous published work has shown that the hypoxia responsive LONP1 mitochondrial protease is involved in glioma growth and treatment resistance and that LONP1 inhibitors can augment the effect of chemotherapy in IDH*wt* models. Here, we highlight the downstream activity of LONP1 via the NRF2 pathway and how synergistically, along with the IDH mutation, LONP1 overexpression can promote the subsequent proneural to mesenchymal transition (PMT) induced by stress and other tumor microenvironment signals. By characterizing the interplay between LONP1 and IDH mutation in *in-vitro* models, we demonstrate that oxidative stress modulates both PMT and TMZ drug resistance. When translated to an i*n-vivo* patient-derived, intracranial orthotopic xenograft model, LONP1 overexpression is associated with decreased survival.Based on our findings, future clinical translation includes the possibility of using LONP1 as a novel target to optimize the standard of care treatment in IDH mutant diffuse astrocytoma.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance 1
Poster Session

#4736 Evaluate the potential sensitization effect and underlying mechanism of lenvatinib on cisplatin resistance oral squamous cell carcinoma.

Y.-T. Chen[1], Y.-T. Tsai[2], F.-T. Hsu[2], H.-F. Tu[1];

[1]Department of Dentistry, National Yang Ming Chiao Tung University, Taipei City, Taiwan, [2]Department of Biological Science and Technology, China Medical University, Taichung City, Taiwan

Oral squamous cell carcinoma (OSCC) is a prevalent form of cancer that develops in the oral cavity, globally recognized as the eighth most commonly diagnosed cancer. Despite the application of standard surgical techniques or concurrent chemoradiotherapy, the prognosis for OSCC patients remains unsatisfactory. Initially, cisplatin, the primary and most frequently used chemotherapy agent for treating OSCC, demonstrates effectiveness in therapy. Nonetheless, chemoresistance frequently arises, leading to treatment failure, and this is intricately associated with the activation of hypoxia-inducible factor 1α (HIF-1α) signaling. Recent research has brought to light heightened levels of HIF-1α-mediated vascular endothelial growth factor (VEGF) and BCL-2 in OSCC tumor sites, which play crucial roles in regulating angiogenesis and anti-apoptotic processes within cancer cells. Additionally, interventions aimed at targeting anti-apoptotic molecules or augmenting the expression of pro-apoptotic molecules may represent promising strategies to overcome chemoresistance in OSCC. Therefore, HIF-1α/VEGF/BCL-2 axis could be considered a potential target for the development of chemopreventive and chemotherapeutic strategies for OSCC. Lenvatinib is a targeted multi-kinase inhibitor that can inhibit tumor growth and angiogenesis by blocking the activation of vascular endothelial growth factor receptor (VEGFR) 1-3, fibroblast growth factor receptor (FGFR) 1-4, platelet-derived growth factor receptor (PDGFR) α, as well as the proto-oncogenes RET and KIT. However, whether lenvatinib may sensitizes OSCC to cisplatin remains unclear. In our study, we used the MTT assay to prove the cytotoxicity of OSCC cells (SAS and MOC1 cells) was induced by cisplatin and lenvatinib. We employed flow cytometry to verify that the combination of lenvatinib and cisplatin can indeed trigger both extrinsic and intrinsic apoptotic pathways in OSCC cells. Furthermore, our demonstration revealed that the induction of apoptosis pathways by the combination of lenvatinib and cisplatin is associated with mitochondrial-dependent apoptosis and death receptor-dependent apoptosis. Then, transwell invasion and migration assay results proved the inhibition effect of lenvatinib combined with cisplatin in SAS and MOC1 cells. Furthermore, we indicated that the combination of lenvatinib and cisplatin can effectively inhibit angiogenesis and anti-apoptotic mechanisms mediated by the HIF-1α/VEGF/BCL-2 axis in OSCC cells. In summary, our results demonstrate that the combined treatment with lenvatinib and cisplatin enhances the response of OSCC cells under hypoxic conditions. Additionally, it aims to mitigate the negative impact of hypoxia on cisplatin's therapeutic effectiveness and increase the sensitivity of OSCC cells to cisplatin.

#4737 The combination of the BET inhibitor JQ1 and gemcitabine induces regressions in gemcitabine resistant patient-derived xenograft models of pancreatic cancer.

A. L. Miller, S. C. Fehling, E. J. Brown, E. O. Heard, T. L. Gamblin, R. B. Vance, **K. J. Yoon**;
University of Alabama at Birmingham, Birmingham, AL

Efforts to develop targeted therapies for drug resistant tumors have been relatively unsuccessful. The 5-year survival for patients with advanced pancreatic cancer is ~3%. Gemcitabine is usually combined with nab-paclitaxel as a standard of care for treatment of locally advanced or metastatic pancreatic ductal adenocarcinoma (PDAC). However, no chemotherapeutic regimens thus far evaluated have been curative. We developed the first PDAC patient-derived xenograft (PDX) models in which resistance against gemcitabine was acquired *in vivo*. We used RNA-seq and ingenuity pathway analysis to compare expression profiles of paired parent vs gemcitabine resistant PDX models. This comparison suggested a previously unreported mechanism for gemcitabine resistance, involving aberrations of cholesterol biosynthesis and lipid metabolism pathways. We also made the unexpected observation that gemcitabine-resistant PDAC models derived from primary tumors have high levels of 3-hydroxy-3-methylglutaryl-CoA synthase 2 (HMGCS2), an enzyme essential to cholesterol biosynthesis and rate limiting in ketogenesis. Notably, the BET bromodomain inhibitor JQ1 decreases HMGCS2 levels; and BET inhibitors + gemcitabine exert synergistic cytotoxicity in gemcitabine-resistant PDAC cells. We determined that the BET bromodomain inhibitor JQ1 + gemcitabine induces regressions of two *in vivo* gemcitabine-resistant tumor models which we developed directly from primary human tumor tissue. These mechanism-based studies suggest that inhibiting HMGCS2 represents a novel approach to therapy for PDAC. We propose that combining gemcitabine with agents that decrease levels of HMGCS2 comprises effective treatment for patients with drug resistant PDAC.

#4738 Overcoming therapy resistance in rhabdomyosarcoma by targeting the PI3K-MAPK pathway.

Y. Wang, E. Chen;
Univ. of Washington School of Medicine, Seattle, WA

Rhabdomyosarcoma (RMS) is a devastating pediatric cancer. There has not been any significant change in the treatment options for the last 4 decades, especially for relapsed or advanced disease. There is an urgent need to identify alternative treatment options to improve survival outcomes of RMS patients. RMS is comprised of two major subtypes as defined by the presence or absence of PAX3/PAX7-FOXO1 gene fusion. Fusion-negative RMS (FN RMS) is characterized by alterations in the RAS-PI3K-MAPK pathway in >90% of the cases. However, the role of the PI3K-MAPK pathway in therapy resistance and disease relapse remains poorly characterized. We have generated two FN-RMS lines, RD and SMS-CTR, with resistance to the standard-of-care chemotherapeutic agent, vincristine, through long-term culturing in incrementally increased concentrations of the drug. By RNA sequencing, vincristine-resistant RD and SMS-CTR cells demonstrated increased expression of genes in the RAS-PI3K-MAPK pathway compared to the parental lines. We hypothesize that increased activity of the PI3K-MAPK pathway contributes to therapy resistance in FN RMS. To test the hypothesis, we first showed that targeted disruption of PIK3CA by shRNA inhibited the cell growth of vincristine-resistant FN RMS cells. The same cells also showed increased sensitivity to the MEK inhibitor, trametinib, as well as the PIK3Cα inhibitor, alpelisib, compared to the parental cells. We then showed that zebrafish FN-RMS tumors treated with the combination of vincristine and alpelisib significantly inhibited tumor growth compared to the treatment with each agent alone. Through integrative analysis of RNA sequencing and ATAC-seq data, we identified MYOD1 and NFATC2 as among the top candidate upstream regulators. Targeted disruption of either MYOD1 or NFATC2 by CRISPR/Cas9 reduced cell growth of vincristine-resistant FN RMS cells and altered expression of the genes in the PI3K-MAPK pathway, implicating MYOD1 and NFATC2 in driving abnormal activity of this pathway. To assess the relevance of our findings in the clinical settings, we showed that selective components in the PI3K-MAPK pathways are up-regulated in 3 matched primary-recurrence/metastasis paraffinized tissue samples of human FN RMS by the NanoString GeoMx Digital Spatial Profiler (DSP) platform. Our findings indicate that targeting the PI3K-MAPK pathway is a promising targeted therapy option for overcoming therapy resistance in RMS.

#4739 Targeting resistance to BET inhibitors in Fusion-Positive Rhabdomyosarcoma.

M. Cassandri[1], E. Ferraro[1], L. D'Archivio[1], F. Aiello[1], H.-C. Chou[2], Y. K. Song[2], B. E. Gryder[3], J. S. Wei[2], S. Sidoli[4], R. G. Hawley[5], R. Rota[1], F. Locatelli[1], J. Khan[2], **S. Pomella**[1];

[1]Bambino Gesu Children's Hospital, Rome, Italy, [2]National Institute of Health, National Cancer Institute, Bethesda, MD, [3]Case Western Reserve University School of Medicine, Cleveland, OH, [4]Albert Einstein College of Medicine, New York, NY, [5]GW Cancer Center, Washington DC, DC

Rhabdomyosarcoma (RMS) is the most frequent pediatric soft tissue sarcoma. Fusion-positive (FP-)RMS expressing the oncogenic chimeric transcription factor (TF) PAX3-FOXO1 (P3F) is at high risk of recurrence. FP-RMS cells show survival dependency on P3F. Despite P3F, as a TF, is considered undruggable, we and others demonstrated that P3F levels/functions can be epigenetically modulated. The BET protein and epigenetic reader BRD4 binds super-enhancers (SEs) to foster oncogenic transcription in cancer. We showed that P3F rewires the RMS enhancer landscape by recruiting BRD4 on oncogenic SEs. Accordingly, JQ1, a BET inhibitor (BETi) shuts down P3F functions halting tumor growth in vitro and in vivo. Therefore, BRD4 inhibition in FP-RMS results in a tumor subtype-specific vulnerability. Nonetheless, as for other targeted therapies, cancer cells can acquire resistance to BETi, thus, we investigated whether FP-RMS cells could develop BETi resistance. Therefore, we established resistant cells from two sensitive FP-RMS cell lines chronically exposed to escalating doses of JQ1, as a model of naturally acquired resistance. Our data show that the two established FP-RMS cell lines, acquired resistance by increasing JQ1 IC50 over the sensitive cells both in 2D and 3D settings. Compared to the sensitive ones, both the resistant cell lines show cross-resistance to other monovalent and bivalent BETi and degraders. Resistant cells also maintain the ability to form colonies in a clonogenic assay and to invade in a 3D Matrigel assay in the presence of JQ1. Moreover, conversely to sensitive cells, JQ1 treatment is unable to down-regulate P3F, MYCN and BCL2 (P3F target) levels in resistant cells. Furthermore, integration of transcriptomic and proteomic data reveals differentially modulated subset of genes/proteins among which MYCN and P3F targets, suggesting a restored activity of the TFs circuitry in resistant cells. Accordingly, MYCN silencing completely halts growth of resistant cells. In line, MYCN protein levels are reduced by JQ1 in a dose-dependent manner in sensitive but not in resistant cells and its half-life is 3 folds longer in resistant than in sensitive cells. Being MYCN protein stability affected by specific post-translational modifications among which the phosphorylation at Ser62 by ERKs, we evaluated the expression of phosphorylated MYCN and the activated form of ERK (pERK) and found both of them increased in resistant cells. In agreement, resistant cells are more sensitive to MEK-ERKs pathway inhibition, showing a lower IC50 of Trametinib (MEKi) compared to sensitive cells. Moreover, Trametinib and JQ1 co-treatment downregulates MYCN protein levels in resistant but not in sensitive cells, suggesting that ERKs overactivation could participate to BETi acquired resistance by stabilizing MYCN, thus representing an acquired vulnerability. The study has received funding from Ministero della Salute to SP.

#4740 Acid ceramidase inhibition enhances venetoclax sensitivity in preclinical models of acute myeloid leukemia.

J. Ung[1], S.-F. Tan[1], J. J. P. Shaw[1], T. E. Fox[1], M. Taori[1], D. F. Claxton[2], K. H. Fisher-Wellman[3], M. C. Cabot[3], D. J. Feith[1], T. P. Loughran, Jr.[1]; [1]University of Virginia School of Medicine, Charlottesville, VA, [2]Pennsylvania State University College of Medicine, Hershey, PA, [3]East Carolina University, Greenville, NC

Acute myeloid leukemia (AML) is an aggressive hematologic malignancy in urgent need of improved therapeutic strategies. AML blasts frequently rely on the anti-apoptotic protein, Bcl-2, for survival. The specific Bcl-2 inhibitor, venetoclax (VEN), is FDA-approved in combination with low-dose cytarabine (LDAC) or azacitidine for patients unfit for intensive induction chemotherapy. Unfortunately, responses are transient due to upregulation of compensatory survival proteins (e.g., Bcl-xL or Mcl-1) or resistance characterized by reprogrammed mitochondrial bioenergetics. Our research aims to improve current AML treatments and understanding of AML pathogenesis by targeting dysregulated sphingolipid metabolism. Ceramides are tumor-suppressor sphingolipids that mediate therapy-induced cell death. Sphingolipid dysregulation that results in decreased ceramide content and/or enhanced ceramide catabolism is an emerging AML hallmark. We've previously shown that acid ceramidase (AC), a ceramide catabolizing lysosomal enzyme, is overexpressed in AML and contributes to drug resistance. Here, we demonstrated that AC inhibition enhanced VEN cytotoxicity. Combining the AC inhibitor/ceramide analog, SACLAC, with VEN resulted in synergistic lethality in multiple AML cell lines in cell viability and apoptosis assays. Genetic inhibition of AC also improved VEN cytotoxicity. The SACLAC+VEN combination achieved Bliss scores (SynergyFinder 2.0) between 22 and 32 in cell lines, which indicate a highly synergistic combination. SACLAC+VEN efficacy was comparable to the FDA-approved combination of VEN+LDAC when tested in 67 primary AML patient samples. Pharmacological inhibition of AC also increased the efficacy of the VEN+LDAC combination. Mechanistically, the observed synergistic lethality was independent of changes to Bcl-2, Mcl-1, and Bcl-xL protein levels. Combined AC and Bcl-2 inhibition resulted in synergistic ceramide accumulation, integrated stress response (ISR) activation, and caspase-dependent apoptosis characterized by impaired mitochondrial function. Pretreatment with the pan-caspase inhibitor, zVAD-FMK, or ISR inhibitor, ISRIB, significantly rescued cell death. Ongoing studies aim to further characterize mitochondrial impairment and ISR activation induced by inhibiting AC and Bcl-2. Taken together, these results detail the first report of ISR activation and mitochondrial defects elicited by combined AC and Bcl-2 inhibition as contributory to cytotoxic impact (mechanism) and warrant additional studies of AC inhibitors with frontline AML therapeutics.

#4741 Targeting sorafenib-resistant HCCs by protein X-armed T cell immunotherapy.

M.-H. T. Ngo, M. Chen, P.-C. Lan, K.-H. Chuang, Y.-H. Huang;
Taipei Medical University, Taipei, Taiwan

Hepatocellular carcinoma (HCC) is the most common type of liver cancer globally, ranking fourth according to the World Health Organization's GLOBOCAN database. Sorafenib and lenvatinib are single-drug therapies used for advanced HCC, but only around 30% of patients benefit from them, and drug resistance typically develops within a few months. Our previous study has demonstrated the specific IL-6-IGF-1R-YAP signaling in regulating the stemness expressions, tumor metastasis, and drug-resistance of the sorafenib resistant HCC (2015 Clinical Cancer Res, 2019 J Exp Clinical Cancer Research, 2021 Cancers, 2023 Cancers). In advance our previous study, this study aims to develop a novel immune therapeutic strategy for sorafenib-resistant HCC treatment. We found, when compared to peri-tumor tissues, the immunohistochemical staining showed a high co-expression of both protein X and PD-L1 in liver tumor tissues (6.25%, n=32 versus 28.125%, n = 64, respectively). To further confirm this observation, we used in vitro cell line models with sorafenib-naïve HCCs (HepG2215_N, Hep3B_N, Huh7_N, and PLC5_N) and sorafenib-resistant HCCs (HepG2215_R, Hep3B_R, Huh7_R, and PLC5_R) in this study. As PD-L1 on tumor cells can dampen T cell cytotoxicity, we generated CD3/protein X bispecific antibodies, which can bind to both CD3 and protein X, and coupled them to T cells (Arm-T cells) and normal T cells (N-T cells). We tested their cytotoxic effects on sorafenib-resistant HCCs using the sorafenib-resistant HepG2215_R cells, co-cultured with Arm-T cells and N-T cells for 24 hours. Our results showed that Arm-T cells exhibited a significantly stronger cytotoxic effect on sorafenib-resistant HepG2215_R cells, with several notable findings: (1) The binding time of Arm-T cells to HepG2215_R cells was significantly longer than that of N-T cells (248.9 ± 146.6 minutes, n=23 versus 28.3 ± 13.49 minutes, n=24); (2) The cytotoxicity of Arm-T cells was significantly higher than that of N-T cells (29.7 ± 2.3% versus 13.6 ± 3.3%); and (3) The secreted levels of INFγ and TNFα by Arm-T cells were significantly higher than those of N-T cells (138.1 ± 7.2 ng/ml and 34.6 ± 0.7 ng/ml versus 31.4 ± 2.5 ng/ml and 3.6 ± 1.1 ng/ml, respectively). These findings were also consistent when using Hep3B-R cells (data not shown). To summarize, our study shows that Arm-T cells possess strong cytotoxic abilities against sorafenib-resistant HCC. These findings have implications for developing effective immuno-therapeutic strategies for patients with sorafenib-resistant HCCs.

#4742 Targeting the RNA-binding protein LARP1 overcomes therapeutic resistance in ovarian cancer.

A. M. Elsayed, P. Amero, E. Bayraktar, A. K. Sood, G. Lopez-Berestein, **C. Rodriguez-Aguayo**;
UT MD Anderson Cancer Center, Houston, TX

La-related protein 1 (LARP1) is an RNA-binding protein that plays a pivotal role in regulating mRNA on a post-transcriptional level. Overexpression of LARP1 has been detected in multiple cancers substantiating the critical role of LARP1 as a driver for cancer progression. This study aims to investigate the downstream target pathways regulated by LARP1 and to determine the impact of LARP1 targeting on the resistance to cisplatin and olaparib therapy in ovarian cancer (OC). Analysis of The Cancer Genome Atlas OC dataset, reverse phase protein array, *in vitro* functional and mechanistic experiments, and a xenograft OC mouse model using OVCAR8 cell line were executed. Our results revealed that overexpression of LARP1 is negatively correlated with progression-free survival in OC patients. Furthermore, LARP1 knockdown using two independent small interfering RNAs (siRNAs) suppressed cell growth, invasion, and migration, and ameliorated cisplatin resistance *in vitro*. Mechanistic analyses identified AXL as a target of LARP1 and this finding was further supported clinically in which co-overexpression of LARP1 and AXL is associated with poor prognosis in OC. Furthermore, LARP1 knockdown resulted in reduced phosphorylation of mTOR, AKT, and SRC with no significant effect on FAK. *In vivo*, administration of 1,2-dioleoyl-sn-glycero-3-phosphatidylcholine (DOPC) nanoparticles loaded with LARP1-siRNA suppressed tumor growth and improved the response to cisplatin and olaparib in a xenograft OC mouse model. In conclusion, LARP1 acts as an oncogenic RNA-binding protein in OC, and targeting LARP1 may represent an innovative therapeutic approach for ameliorating resistance to chemotherapy and targeted therapy in OC.

Keywords: RNA-binding proteins; cisplatin resistance; olaparib resistance; chemotherapy resistance; LARP1; ovarian cancer.

#4743 Targeting a novel TWIST1-Hexokinase II pathway to overcome MET TKI resistance in NSCLC.

P. H. Rumde[1], K. R. Cargill[1], V. Kumar[1], P. Devadassan[1], J. Chen[1], L. McGraw-Sapp[1], X. Wu[1], S. Dacic[2], R. Bao[1], B. Sivakama[1], E. S. Goetzman[1], S. Agnihotri[1], S. J. Mullett[1], S. G. Wendell[1], L. P. Stabile[1], T. F. Burns[1];

[1]University of Pittsburgh, Pittsburgh, PA, [2]Yale School of Medicine, New Haven, CT

Non-small cell lung cancer (NSCLC) is the most common primary tumor to metastasize to the brain, with up to 40% of NSCLC patients developing brain metastases (BM). These BM portend a poor prognosis, even when extracranial disease is well-controlled. While targeted therapy and immunotherapy have improved lung cancer survival, there are no therapies specifically targeting NSCLC BM. Our lab identified a significant enrichment of *MET* amplification in lung adenocarcinoma (LUAD) BM (16%) compared to primary NSCLC (3%) and liver metastases (5%). MET, a receptor tyrosine kinase, and its ligand, hepatocyte growth factor (HGF), promote proliferation, epithelial-mesenchymal transition (EMT), angiogenesis, and metastasis. Although MET tyrosine kinase inhibitors (TKIs) are approved for use in *MET*altered NSCLC, half of patients with *MET* alterations fail to respond or inevitably acquire TKI resistance. We have found that MET pathway activation by *MET* alterations leads to increased expression of TWIST1, an EMT transcription factor required for tumorigenesis in MET-dependent NSCLC. Together, the HGF/MET/TWIST1 axis promotes cancer survival and metastasis. We found that *MET* amplified BM had distinct transcriptional signatures reflecting increased glycolysis. A similar shift toward glycolysis was observed in the *MET* amplified metastatic LUAD cell line (H1993) compared to the *MET* wild type primary LUAD line (H2073) derived from the same patient. Furthermore, LUAD cell lines with high MET expression demonstrated increased expression and activity of glycolytic enzymes, as well as increased susceptibility to glucose deprivation and glycolytic inhibitors (2DG, PFK158, AT-101, V-9302). Conversely, treatment of *MET* amplified cells with MET TKI, capmatinib, reduced glycolysis and oxidation phosphorylation to the levels observed in *MET* wild type LUAD lines. Activation of the MET pathway with HGF or TWIST1 overexpression specifically increased the mRNA and protein expression of the key glycolytic enzyme, Hexokinase II (HK2), compared to other glycolytic pathway proteins. Conversely, inhibition of the MET pathway with capmatinib or the TWIST1 inhibitor, harmine, decreased HK2 protein expression through a MYC-independent pathway. However, TWIST1 was required for MET-dependent transcriptional upregulation of HK2. Remarkably, in two novel *MET* altered models (cell line and patient derived xenograft) of acquired MET TKI resistance, TWIST1 and HK2 expression were increased at the time of resistance. Both models remained sensitive to pharmacologic inhibition of either TWIST1 or glycolysis at the time of acquired resistance to MET TKIs. These findings suggest that continued upregulation of the TWIST1-HK2 axis is required for acquired MET TKI resistance. In summary, these studies suggest a targetable, metabolic reprogramming in *MET* altered LUAD BM mediated through a novel TWIST1-HK2 pathway.

#4744 Overcoming MK1775 resistance in upper gastrointestinal cancers with combined WEE1 and CHK1 inhibition.

K. Thangaretnam, M. Islam, H. Lu, D. Peng, N. Bhat, M. Soutto, E.-R. Wael, Z. Chen;
University of Miami, Miami, FL

Background: Upper gastrointestinal cancers (UGC), encompassing esophageal and gastric cancers, rank among the top causes of cancer-related deaths globally, with esophageal cancer being the sixth and gastric cancer the fourth leading cause. Esophageal adenocarcinoma (EAC), predominant in the western world, shares histopathological and molecular characteristics with gastric cancer (GC). Despite these similarities, treatment challenges persist, exemplified by the limited efficacy of the WEE1 inhibitor MK1775 in clinical trials due to drug resistance. Our study investigates novel mechanisms underlying this resistance in UGC.

Methods and results: RNA sequencing and immunohistochemistry staining demonstrated notable overexpression of WEE1 in over two hundred human EAC and GC samples compared to normal tissues. Concurrently, Western blot analysis revealed a positive correlation between WEE1 and CHK1 overexpression across 16 UGC cell lines. To categorize UGC cells based on their sensitivity to MK1775, we conducted ATP-glo cell viability assays, determining their half-maximal inhibitory concentration (IC50) values. Utilizing nuclear-cytosol separation, our data intriguingly uncovered, for the first time, that in MK1775-resistant cells, MK1775 treatment induces the abnormal translocation of phosphorylated CHK1 (p-CHK1) from the nucleus to the cytoplasm, a shift not observed in MK1775-sensitive cells. Further analysis through Western blot suggested that the cytoplasmic presence of p-CHK1 might trigger the activation of oncogenic STAT3 following MK1775 treatment. This activation appears to stimulate the expression of genes that promote cancer cell survival and drug resistance by enhancing cell survival and inhibiting apoptosis. Notably, combining the WEE1 inhibitor with the CHK1 inhibitor CHIR124 effectively inhibited CHK1 kinase activity and abrogated STAT3 phosphorylation, DNA binding, and transcriptional activity in UGC cells. Our findings strongly indicate that a combined therapy of WEE1 and CHK1 inhibitors could be a promising strategy to overcome MK1775 resistance in UGC cells. Our ongoing research will employ human-derived UGC organoids, patient-derived xenografts (PDXs), and human tissue samples to further validate these findings.

Conclusions: Our study underscores the potential of combining WEE1 and CHK1 inhibitors to effectively combat MK1775 resistance in UGC, offering a promising direction for improved treatment strategies and patient outcomes in these challenging malignancies.

#4745 A novel combination therapy targeting RAF, MEK and FAK to overcome skin cutaneous melanoma treatment resistance.

S. Lubrano[1], F. Faraji[2], R. Cervantes-Villagrana[1], S. Ramirez[3], N. Arang[1], A. Officer[1], D. C. Rigiracciolo[1], P. Y. Anguiano Quiroz[1], A. Bacchiocchi[4], R. Halaban[4], S. Coma[5], S. Holmen[6], C. Martini[7], J. Pachter[5], A. Aplin[8], **J. Gutkind**[1];

[1]UCSD Moores Cancer Center, La Jolla, CA, [2]University of California, San Diego School of Medicine, La Jolla, CA, [3]La Jolla Institute for Immunology, La Jolla, CA, [4]Yale School of Medicine, New Haven, CT, [5]Verastem Oncology, Boston, MA, [6]University of Utah School of Medicine, Salt Lake City, UT, [7]University of Pisa, Pisa, Italy, [8]Thomas Jefferson University, Philadelphia, PA

Metastatic melanoma is the most aggressive malignancy of the skin and $BRAF^{V600E}$ mutation is the most common genetic alteration in skin cutaneous melanoma (SKCM). Despite the advent of immune checkpoint inhibition (ICI) immunotherapy, only 40% of patients show long-term responses. As such, combined therapy with BRAF and MEK inhibitors (BRAFi + MEKi) remains the standard of care for $BRAF^{V600E+}$ SKCM. In the present study, transcriptome analysis of $BRAF^{V600E+}$ SKCM tumors derived from patients revealed that activation of extracellular matrix signaling, including focal adhesion signaling, is highly enriched in patients who experienced disease progression on BRAFi + MEKi therapy. Consistent with these results, we found increased activation of focal adhesion kinase (FAK) in human $BRAF^{V600E+}$ SKCM A375 cells treated with BRAFi, MEKi or the RAF/MEK clamp avutometinib. Mechanistically, we discovered that avutometinib-mediated inhibition of the RAF/MEK/ERK pathway decreased RhoE/Rnd3 expression, thereby unleashing RhoA/FAK/AKT signaling. Thus, we hypothesized that FAK activation represents a resistance mechanism to BRAFi + MEKi and that FAK inhibition (FAKi) might overcome resistance to BRAFi/MEKi. Indeed, avutometinib demonstrated synergistic antiproliferative and proapoptotic activity when combined with FAKi in human $BRAF^{V600E+}$ SKCM A375 cells. Importantly, we found that the combination of FAKi + avutometinib overcame resistance to BRAFi + MEKi in SKCM xenografts and patient-derived cells from SKCM-resistant lesions. Finally, we showed that while $BRAF^{V600E+}$ SKCM YUMM 1.7 syngeneic tumors failed to respond to ICI therapy, avutometinib ± FAKi inhibited tumor growth. We observed that tumors treated with avutometinib as single agent eventually developed resistance and escaped growth inhibition, but those treated with combined avutometinib and FAKi displayed durable treatment responses, often with complete tumor regression. These findings provide a rationale for the clinical development of avutometinib with defactinib (FAKi) in patients with $BRAF^{V600E+}$ cutaneous melanoma following progression on BRAFi + MEKi and/or ICI therapy.

#4746 PIM kinase inhibition synergizes with a MERTK inhibitor to treat osimertinib resistant *EGFR*-mutant non-small cell lung cancer.

D. Yan[1], X. Wang[2], S. V. Frye[2], H. Earp III[3], D. DeRyckere[4], D. K. Graham[4];
[1]Emory University, Atlanta, GA, [2]Chemical Biology and Medicinal Chemistry, Chapel Hill, NC, [3]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC, [4]Aflac Cancer and Blood Disorders Center, Children's Healthcare of Atlanta, Atlanta, GA

There is an unmet need for effective treatment in the setting of acquired osimertinib resistance in EGFR-mutant non-small cell lung cancer (NSCLC) patients and MERTK tyrosine kinase is a potential therapeutic target in this context. Treatment with the MERTK inhibitor MRX-2843 was sufficient to abrogate downstream PI3K-AKT and MAPK-ERK signaling, cell expansion, and colony formation in osimertinib-resistant EGFR-mutant NSCLC cell lines, suggesting dependence on MERTK signaling for tumor cell proliferation/survival. Further, two structurally distinct PIM kinase inhibitors, SGI-1776 and PIM447, provided synergistic inhibition of cell expansion and colony formation in osimertinib-resistant cell line cultures when combined with MRX-2843 treatment. Mechanistically, treatment with MRX-2843 in combination with either PIM kinase inhibitor decreased downstream PI3K-AKT and MAPK-ERK signaling more effectively than single agents. Furthermore, knockdown of PIM kinases (PIM1, 2, 3) using nine sets of siRNAs led to various changes in expression of TAM receptor family members (TYRO3, AXL, MERTK), indicating a role for PIM kinases in regulation of TAM kinase expression. These studies suggest a novel treatment strategy for osimertinib-resistant EGFR-mutant NSCLC using a first-in-class MERTK kinase inhibitor that is currently under evaluation in multiple Phase I clinical trials.

#4747 Novel targets for BRAF^{V600E} and BRAF^{V600E}RAC1^{P29S} drug resistant melanoma.

C. Uribe-Alvarez, D. Araiza-Olivera, A. Cannon, J. Chernoff;
Fox Chase Cancer Center, Philadelphia, PA

The most common mutational drivers in malignant melanoma are the oncogene *BRAF*$^{V600E/K}$ (60%), *NRAS*$^{Q61L/R}$ (30%) and the RHO GTPase RAC1$^{P29S/L}$ (9%). BRAF$^{V600E/K}$ melanoma standard of care comprises the use of checkpoint inhibitors (CPIs) such as anti-PD1 or anti-CTLA-4 in combination with targeted therapies against BRAF and MEK kinases. BRAF mutant melanomas develop intrinsic, acquired, or after treatment resistance to BRAF and MEK inhibitors : around half of targeted therapy combination treatments with anti-PD1 and 70% with anti-CTLA-4 will be unsuccessful due to melanoma intrinsic resistance. Among other causes, intrinsic drug resistance can be associated with additional genome mutations, such as the activating Rac1^{P29S} mutation present in 6% of patients with BRAF positive melanoma. A deeper understanding on the biology, progression, and tumor microenvironment of drug resistant melanomas is needed to aid in the search of novel targets and to increase the effectivity of proposed treatments.

We generated 3 sets of isogenic BRAF^{V600E} and BRAF^{V600E}/RAC1^{P29S} cell lines by transfecting 501mel, 451Lu and YUMM1.7 cell lines with Rac1^{P29S}. We then exposed them for 3 months to increasing concentrations of PLX4720 to generate drug resistant cell lines (DR). Rac1^{P29S} -transfected and PLX4720 resistant cell lines had an increase in the Mek/Erk signaling pathway. A differential analysis using a kinome and an epigenome drug screening library in the 501mel cell lines (501mel, 501mel Rac1^{P29S}, 501mel-DR, 501mel Rac1^{P29S} -DR) showed that BRAF^{V600E}/RAC1^{P29S} and the DR melanoma cell lines growth can be inhibited with mTor, PI3K, cdk9 and BRD4 inhibitors. BRD4 is an epigenetic regulator that recruits P-TEFb to stimulate RNA polymerase II elongation. BRD4 also interacts with SMAD3 and CDK9 to regulate transcription through eIF4G increasing oncogenic c-Myc and increasing Mek/Erk signaling pathways. We tested 501mel, 451Lu and YUMM1.7 isogenic cell line series against Rapamycin to confirm mTORC1 as an effective target. Drugs that target different subunits of the eIF4F complex (CR-1-31-B, Ribavirin and Briciclib) also decrease BRAF^{V600E}/RAC1^{P29S} and the DR melanoma cell lines growth specifically. Furthermore, silencing of eIF4A1 and Raptor genes reduces cell growth in the BRAF^{V600E}/RAC1^{P29S}, and the DR cells when compared to the parental cell lines. Silencing Rictor had no effect on cell growth on any cells. When tested in a syngraft model, CR-1-31-B and rapamycin reduced tumor size when using YUMM1.7, YUMM1.7- RAC1^{P29S} and YUMM1.7 RAC1^{P29S}-DR cell lines. Next, we sought to investigate the effect of inhibiting mTOR and eiF4F in the PD-1/PD-L1 axis in tumor cells and tumor associated dendritic cells and macrophages, and how targeting these modifies the tumor microenvironment.

#4748 Aronia berry overcomes gemcitabine resistance by regulating the MYD88/NF-kB/P-glycoprotein pathway in pancreatic ductal adenocarcinoma.

Y. Li[1], C. Xu[1], H. Han[2], A. Goel[1];

[1]Beckman Research Institute of The City of Hope, Monrovia, CA, [2]The Translational Genomics Research Institute, Phoenix, AZ

Background: Pancreatic ductal adenocarcinoma (PDAC) is lethal, which is partly due to the limited efficacy of Gemcitabine (Gem)-based chemotherapy, resulting from the development of acquired resistance to this regimen. Aronia berry extract (ABE) is a natural source of phenolic compounds known for its anti-cancer properties. Previous research has highlighted the ability of ABE to help overcome chemoresistance to conventional chemotherapies in various cancers. In this study, we interrogated the ability of ABE to overcome Gem-resistance (Gem-R) in PDAC and identify specific pathway(s) responsible for this anti-cancer efficacy. Methods: We performed a series of in-vitro experiments in Gem-R cells to evaluate the synergistic effect of combined treatment with Gem and ABE. Furthermore, we conducted a genomewide transcriptomic analysis to identify the critical regulatory pathways associated with chemoresistance and potential therapeutic targets of ABE in Gem-R PDAC cells. The cell culture findings were validated in patient-derived 3D organoids. Results: The combined treatment with ABE and Gem in Gem-R cells exhibited significant synergistic anticancer effects on cell viability, proliferation, migration, and invasion. The transcriptomic analysis revealed that the NF-κB signaling pathway was associated with Gem-R ($p<0.05$), with a significant upregulation of MYD88. Additionally, MYD88 was significantly associated with overall survival in PDAC patients in the TCGA cohort (HR=1.58, P=0.045). The MYD88/NF-κB signaling is associated with chemoresistance as it can upregulate the efflux transporters like P-glycoprotein (P-gp). Our results confirmed that combined treatment inhibited the NF-κB signaling pathway by suppressing MYD88 and downregulating P-gp expression to overcome Gem-R. Finally, the combined treatment demonstrated superior anti-cancer activity in 3D organoids by reducing both their number and size (P<0.05). Conclusion: We provide novel insights into the potential of ABE in overcoming Gem-R in PDAC cells by targeting the MYD88/NF-κb/P-gp axis, which offers a safe and inexpensive approach for improving therapeutic outcomes in this fatal malignancy.

#4749 Acrivon predictive precision proteomics (AP3) uncovers mechanism of resistance to ACR-368, a clinical-stage CHK1/2 inhibitor, and identifies rational combination treatment.

H. Nilsson[1], L. Shi[2], M. E. Jakobsson[1], J. Baddour-Sousounis[2], S. Rafiei[2], U. Muralitharan[1], Z. Best[2], V. Siino[1], F. J. Santana[2], I. Arribas Diez[1], K. Singh[2], P. Lombardo[2], W. Dahlberg[2], S. Kumar[2], A. Youssef[2], R. Improgo[2], C. Xu[2], J. Jung[2], J.-M. Lee[3], A. Murshid[2], M. Shipitsin[2], J. V. Olsen[4], K. Masson[2], D. A. Proia[2], C. Wigerup[1], P. Blume-Jensen[2];

[1]Acrivon Therapeutics, Lund, Sweden, [2]Acrivon Therapeutics, Watertown, MA, [3]National Cancer Institute, Bethesda, MD, [4]University of Copenhagen, Copenhagen, Denmark

ACR-368 (prexasertib) is a clinically advanced CHK1/2 inhibitor which has demonstrated durable activity across a proportion of patients with advanced solid tumors. Genomic biomarkers have proven unsuccessful in predicting response to ACR-368, limiting its clinical success. Using AP3, we previously developed a response-predictive proteomics-based test for ACR-368 (ACR-368 OncoSignature) for the identification of patients sensitive to ACR-368 monotherapy treatment as demonstrated in blinded preclinical studies. A Phase 2 clinical trial is ongoing where patients are treated with ACR-368 monotherapy based on OncoSignature-predicted sensitivity (NCT05548296). Here, we demonstrate the utility of AP3 for the identification of a key druggable resistance mechanism to ACR-368 and how to overcome that with low dose gemcitabine (gem), providing OncoSignature negative patients with a new potential therapeutic option. Five ovarian cancer cell lines were rendered durably resistant to ACR-368 by culturing in the presence of clinically relevant concentrations of ACR-368. Matched parental and ACR-368 resistant cell line pairs were profiled using AP3 mass spectrometry. Comprehensive pathway reconstitution and kinase activity analyses were performed to identify drug resistance mechanisms in an unbiased manner. Downregulation of DNA damage repair pathway activity was causally linked to the ACR-368-resistant phenotype, suggesting agents that restore replication stress around the CHK1/2 signaling axis may re-sensitize to ACR-368. To test this, a panel of ovarian cancer cell lines with intrinsic or drug-induced resistance to ACR-368 were screened for cell growth inhibition by ACR-368 combined with gem. Gem synergized with ACR-368 in 12/13 cell lines at low doses (1-40 nM). Moreover, Western blot analysis demonstrated protein markers of replication stress were induced by low dose gem (3-30 nM), suggesting a correlation between gem-induced replication stress and synergy with ACR-368. Comet assays showed that DMSO, gem (3 nM), or ACR-368 (100 nM) had minimal impact (4.4%, 4.5%, and 11.4%, respectively) on % comet tail DNA in ACR-368 resistant cells, while the gem combination led to 35% comet tail DNA ($p<0.001$). Finally, in a human tumor xenograft mouse model, low dose gem demonstrated a dose-dependent increase in replication stress markers (Cyclin E, pCHK1 S345) from 0.3-3 mg/kg, which allometrically scales to 1-10 mg/m2 in humans. These data supported a dose escalation Phase 1b/2 clinical study of low dose gem with ACR-368 to evaluate the efficacy and safety of the combination in ACR-368 OncoSignature negative patients (NCT05548296). This shows the potential of AP3 for unbiased elucidation of actionable drug resistance mechanisms and rapid clinical implementation in our trials, which have recently confirmed clinical activity.

#4750 The MNK inhibitor EB1 sensitizes AR-V7 positive castration-resistant prostate cancer to enzalutamide.

S. Garcia-Ortega[1], L. Suarez-Cabrera[1], J. Morote[1], O. Mendez[1], M. Cano-Galietero[2], E. Muro-Blanc[1], J. I. Borrell[3], A. Santamaria[1], S. Ramon y Cajal[1], S. Hummer[1];

[1]Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, [2]Spanish Biomedical Research Network Centre in Oncology (CIBERONC), Madrid, Spain, [3]IQS School of Engineering, Barcelona, Spain

Introduction: Resistance to androgen receptor signaling inhibitors (ARSI) like Enzalutamide is frequent in castration resistant prostate cancer (CRPC). The mechanisms driving drug resistance include the overexpression of androgen receptor (AR) and the presence of splice variants like androgen receptor splice variant 7 (AR-V7). Clinical studies (PROPHECY) have demonstrated that AR-V7 positive CRPC patients treated with Enzalutamide show poorer overall survival and thus lack an effective targeted line of treatment. Recently, AR signaling and the regulation of protein translation via the translation initiation factor 4E (eIF4E) and MAPK-interacting kinases (MNKs) have been shown to depend on each other and targeting eIF4E has been proposed to increase the efficacy of ARSI.
Objectives: We have recently described EB1 as the first in class non-ATP competitive inhibitor of MNK1/2 (Bou-Petit et al. JMC, 2022) and have now tested its applicability in CRPC. In this work we describe the impact of EB1 on the efficacy of Enzalutamide treatment in CRPC.
Methodology: Cell lines 22RV1 and LNCaP-95 were used as AR-V7 positive models of CRPC. Effects of EB1 and Enzalutamide alone and in combination on cell growth were studied through crystal violet assay. Drug combination Index was calculated following Chou-Talalay method using CompuSyn Software. Cell death was studied through propidium iodide (PI) staining. AR transcriptional activity was assessed through RT-qPCR of AR canonical target genes like PSA. A head-to-head study with eFT-508 (Tomivosertib, eFFECTOR Therapeutics, Inc.) as the most advanced Type I MNK inhibitor was performed. Lastly, spheroids obtained through centrifugation in ultra-low attachment plates were used for validating drug interaction in 3D growth and viability studies. Spheroid viability was assessed through PI and Calcein AM staining as well as MTT assay.
Results: In vitro results demonstrate strong to moderate synergistic inhibition of cell growth through the induction of cell death by the combination of Enzalutamide and EB1 in AR-V7 positive CRPC cell lines, as well as reduction of AR transcriptional activity (PSA). Drug combination also reduced growth and viability of spheroids, indicating good tumor penetrating properties in 3D models and giving in vitro proof-of-concept for in vivo applications. Furthermore, drug synergy with Enzalutamide could only be observed with EB1 and not with Type-I MNK inhibitors like eFT-508, indicating that MNK1/2 functions beyond its kinase activity might be relevant for cancer progression.
Conclusion: Here we demonstrate that the novel MNK inhibitor EB1 shows promising in vitro results, which cannot be obtained with Type-I MNK inhibitors. The combination of EB1 with the standard of care Enzalutamide provide a novel therapeutic opportunity for the treatment of CRPC, particularly in AR-V7 positive patients.

#4751 The antiviral, Daclatasvir, downregulates Tribbles 2 pseudokinase and reverses enzalutamide resistance in prostate cancer.

J. Monga, R. Guddeti, C. Rogers, S. Gadgeel, D. Chitale, **J. Ghosh**;
Henry Ford Health System, Detroit, MI

Background: FDA-approved enzalutamide is commonly prescribed for advanced prostate cancer. However, enzalutamide-resistant prostate cancer (ERPC) invariably develops, which leads to aggressive, lethal disease. Recently, we found that the Tribbles 2 (TRIB2) pseudokinase is overexpressed in ERPC cells and confers resistance to enzalutamide by promoting lineage plasticity to neuroendocrine differentiation. Though TRIB2 emerged as an excellent molecular target for ERPC, suitable inhibitors are not commercially available for effective targeting.

Methods: Compounds were tested using a luciferase-tagged TRIB2 fusion protein-based assay system. Binding of drugs with TRIB2 protein was analyzed by thermal shift assays and by advanced computer-based homology modeling. Degradation of TRIB2 protein was measured by Western blot. Drug effects on re-sensitization of ERPC cells and synergy with enzalutamide were determined through cell viability and apoptosis assays. To gauge the *in vivo* effects of Daclatasvir (DCV), ERPC tumor xenograft-bearing mice were treated with varying doses of DCV via oral gavage. Tumor growth was calculated by measuring volumes and molecular markers in tumors were analyzed by immunohistochemistry.

Results: By designing a luciferase-tagged TRIB2 fusion protein-based assay system, we screened a library of about 1,600 FDA-approved compounds and found that DCV, effectively inhibits the TRIB2-luciferase activity (more than 70% inhibition in 24 hours at 10 micromolar) but does not inhibit the activity of free luciferase. Notably, DCV directly binds to pure TRIB2 protein, leading to its destabilization and a reduction in the half-maximal melting temperature *(Tm)* from 41^{o}C to 37^{o}C, as confirmed by thermal shift assays. Interestingly, we found that DCV degrades TRIB2 proteins via activation of proteasomes and re-sensitizes ERPC cells to enzalutamide. DCV downregulates the master neuronal transcription factor, BRN2, and the stemness factor, SOX2, and synergizes with enzalutamide at lower, sub-lethal doses to decrease the viability of prostate cancer cells by inducing apoptosis. Finally, DCV was found to effectively inhibit the growth of ERPC tumors and decrease the protein level of TRIB2 in mice when delivered via oral gavage.

Conclusion: These findings indicate that DCV effectively downregulates TRIB2 both *in vitro* and *in vivo* and suggest that further testing of DCV may help design an innovative therapeutic approach for management of enzalutamide-resistant, aggressive, lethal prostate cancer.

#4752 Enhancer of zeste homolog 2 inhibitors overcome glucocorticoid resistance in acute lymphoblastic leukemia by augmenting pro-apoptotic signaling.

M. Dalal[1], J. Yi[2], J. Li[3], A. Shobh[1], D. DupereRicher[1], R. Bennett[1], J. Licht[1];
[1]University of Florida College of Medicine, Gainesville, FL, [2]Baylor College of Medicine, Houston, TX, [3]Thomas Jefferson University, Philadelphia, PA

Introduction Relapsed acute lymphoblastic leukemia (ALL) portends a poor prognosis. Glucocorticoids (GCs) are a central component of a multi-agent regimen to treat ALL. GCs mediate ligand-dependent global transcriptional changes activating feedback loop that increases GC receptor (GR) expression and pro-apoptotic signaling. GC resistance is a common mechanism in relapsed/refractory ALL. Altered function of Enhancer of Zeste Homolog 2 (EZH2), a histone methyl transferase (HMT), including increased expression and activating mutations have been reported in ALL. Previously, EZH2 inhibitors have been shown to increase GC efficacy in non-ALL B-cell lymphoid malignancies including non-Hodgkin lymphoma. Furthermore, EZH2 inhibitors reversed GC resistance and increased efficacy of GCs in an ALL subtype with an activating point mutation in an HMT called nuclear set domain 2. Overcoming GC resistance by novel therapeutic strategies may help improve outcomes in relapsed/refractory ALL.

Hypothesis EZH2 inhibitors may enhance GC efficacy by augmenting downstream effects of GCs.

Methods We performed in-vitro studies of EZH2 inhibitors, EPZ-6438 and CPI-1205, at graded doses in GC resistance human-derived B-cell (SUPB15) and T-cell (SUPT1, KOPTK1, PEER) ALL cell lines followed by graded doses of dexamethasone (dex). Cell viability was performed using CellTiter-Glo assay. Induction of apoptosis was measured with Annexin V flow cytometry. Pro-apoptotic BIM mRNA and protein levels were measured using real-time PCR and immunoblot. Global H3K27me3 protein levels were assessed using immunoblot.

Results GC resistant B-cell ALL and T-cell ALL treated with EZH2 inhibitors for 3-7 days followed by the addition of dex for 48-72 hours led to decreased cell viability and increased apoptosis of the ALL cells compared to cells treated with vehicle (DMSO) and dex alone. EZH2 inhibitors on their own did not cause apoptosis. SynergyFinder revealed Bliss synergy scores between 23- 31 in B-cell ALL and T-cell ALL cell lines with greater than 10 considered a synergistic drug interaction. Immunoblotting of cells treated with EZH2 inhibitors alone showed an increase in pro-apoptotic protein, BIM. BIM level was further enhanced when dex was added in combination with EZH2 inhibitors compared to vehicle and dex alone suggesting that EZH2 inhibitors were augmenting BIM expression. Further assessment of the mechanism of how EZH2 inhibitors lead to improved GC efficacy will be performed by integrating transcriptomic and epigenomic profiling in the presence and absence of EZH2 inhibitors. Furthermore, in-vivo testing of EZH2 inhibitors in patient derived xenografts will be performed.

Conclusion EZH2 inhibitors can overcome GC resistance in ALL posing as a potential novel therapeutic agent to treat relapsed/refractory ALL.

#4754 Targeted inhibition of the HNF1A/SHH axis by triptolide overcomes paclitaxel resistance in non-small cell lung cancer.

P. Li, L. Li, L. Yang, L. Liu, **X. Zhao**;
The Second Hospital of Shandong University, Jinan, China

Paclitaxel resistance is commonly associated with a poor prognosis in non-small cell lung cancer (NSCLC) patients, and there are no promising pharmacological treatments for paclitaxel resistance. Here, we constructed human NSCLC-derived paclitaxel-resistant cell lines as an effective tool to explore the mechanisms of chemoresistance. We discovered that triptolide, a monomer compound extracted from Tripterygium wilfordii Hook F, was able to reverse paclitaxel resistance by reducing ABCB1 expression in vivo and in vitro. Through high-throughput sequencing, we found that the SHH-initiated Hedgehog signaling pathway played an important role in this process. More importantly, triptolide could directly target HNF1A, a transcription factor of SHH, and inhibited HNF1A/SHH expression, ensuing in attenuation of Hedgehog signaling. Clinically, we found a positive correlation between HNF1A and SHH expression in both NSCLC tumor tissue microarrays and cancer network databases. These findings illuminated a novel molecular mechanism through which triptolide effectively targets and inhibits HNF1A, thereby impeding the activation of the Hedgehog signaling pathway and reducing the expression of ABCB1. This finding indicated the potential clinical application of triptolide and provided promising prospects in targeting the HNF1A/SHH pathway as a therapeutic strategy for NSCLC patients with paclitaxel resistance.

#4755 Extracellular GRP78 inhibition reverses drug and immune resistance in cancer cells.

D. J. Davidson, J. Zelek, E. Stolarik, M. Thigpen, A. Davidson, DPT;
Creative BioTherapeutics, Gurnee, IL

CBT300 was created from Creative BioTherapeutics' discovery that drug resistant recurrent cancer cells up-regulate a survival pathway that results in the expression of extracellular Glucose-Regulated Protein 78 (ecGRP78) in the tumor microenvironment (TME). This TME ecGRP78 binds to cancer and immune cell surfaces, which induces a cascade of events to increase drug resistance, immune suppression, and cancer stem cell (CSC) formation. CBT300 targets surface bound ecGRP78 that has been found on breast, lung, ovarian, prostate, melanoma, multiple myeloma, colon, pediatric and adult brain tumors. We can now show that inhibition of ecGRP78 can a) induce apoptosis of drug resistant tumor cells, b) eliminate drug and immune resistance showing synergistic effects with chemotherapy and immunotherapy, c) decrease the amount of chemotherapy about 90% in combination with CBT300. Recent publications show that ecGRP78 is found on many types of tumor cell surfaces but not on normal cell surfaces. In fact, cell surface bound ecGRP78 is important for many aspects of cancer development, including cell survival, proliferation, chemoresistance, angiogenesis, metastasis formation, immune suppression, and stem cell formation. Recently, it has been shown that increased ecGRP78 expression in metastatic breast cancer, glioblastoma and multiple myeloma patients was significantly associated with later stage, increased distant metastasis, increased aggressiveness, shorter disease-free survival, and decreased overall survival. In studies to help understand how ecGRP78 causes tumor progression and drug and immune resistance, we discovered a novel ecGRP78 binding transmembrane protein on TNBC, and brain cancer cells called Receptor Tyrosine Kinase Orphan Receptor-1 (ROR1). Using the GRP78 binding domain from ROR1 and a human Fc domain, we created a biologic fusion protein that is a potent and specific ecGRP78 inhibitor called CBT300. We now show that CBT300's elimination of csGRP78 destabilizes and removes oncofetal proteins ROR1, and Cripto, and checkpoint protein PD-L1 from tumor cell surfaces resulting in reversal of chemoresistance, reduction in immune suppression, inhibition of stem cell phenotype and increased tumor cell apoptosis. Our results with CBT300 demonstrate proof of concept data in vitro and in vivo for our novel ecGRP78 inhibitor on several drug resistant cancers demonstrating the potential to provide a major advance in the treatment of drug resistant cancers either alone or in combination with lower doses of chemotherapy. Exploiting a novel mechanism of action with a non-toxic, efficacious and cost effective biologic therapy that has shown increased survival in recurrent cancers will bring new hope for these patients.

#4756 Targeting DNA topoisomerase II to manage acquired resistance to third generation EGFR tyrosine kinase inhibitors in the treatment of EGFR mutant NSCLC.

Z. Chen[1], K. A. Vallega[1], D. Wang[1], Z. Quan[2], S. Fan[2], Q. Wang[3], T. A. Leal[1], S. S. Ramalingam[1], **S.-Y. Sun**[1];
[1]Emory University, Atlanta, GA, [2]The Second Xiangya Hospital, South Central University, Changshai, China, [3]Henan Cancer Hospital, Zhengzhou, China

Development of effective strategies to manage the inevitable acquired resistance to osimertinib, a 3rd generation EGFR inhibitor with proven clinical efficacy in prolonging survival of patients with EGFR mutant (EGFRm) non-small cell lung cancer (NSCLC), is an urgent and critical area of unmet need in the clinic. Effort toward this direction led us to find that the DNA topoisomerase II (Topo II) inhibitors, doxorubicin and etoposide (VP-16), but not other chemotherapeutic agents, synergistically decreased the survival of osimertinib-resistant cell lines when combined with osimertinib. The combination of osimertinib with either doxorubcin or VP-16 effectively induced DNA damage and apoptosis in osimertinib-resistant cells, suppressed the growth of osimertinib-resistant tumors, and delayed the emergence of acquired resistance to osimertinib. Mechanistic studies found that osimertinib as well other EGFR-TKIs effectively decreased Topo IIα levels in EGFRm NSCLC cells by facilitating its proteasomal degradation and induced DNA damage; these effects were lost in cell lines with osimertinib acquired resistance that possessed elevated basal levels of Topo IIα. In the majority of EGFRm NSCLC tissues relapsed from EGFR-TKI treatment, Topo IIα levels were substantially increased. Enforced expression of ectopic *TOP2A* genes in sensitive EGFRm NSCLC cells conferred resistance to osimertinib in inducing DNA damage and apoptosis, whereas knockdown of *TOP2A* in osimertinib-resistant cell lines restored their responses to undergo osimertinib-induced DNA damage and apoptosis. Together, these results reveal a previously undiscovered essential role of Topo IIα modulation in regulating the responses of EGFRm NSCLC cells to osimertinib, providing scientific rationale for targeting Topo II to manage acquired resistance to osimertinib and possibly other third generation EGFR-TKIs, thus warranting clinical validation of this strategy. (This study was supported by NIH/NCI R01 CA223220 and UG1 CA233259 and Emory Winship Cancer Institute lung cancer research pilot funds).

#4757 Combining PARP inhibitor with TACC3 inhibition overcomes PARP inhibitor resistance in ovarian cancer.

Y. Wu[1], Q. Wang[2], C. Deng[3], M. Li[1], **Y. Xiao**[1];

[1]Peking University Third Hospital, Beijing, China, [2]Peking University, Beijing, China, [3]Peking University People's Hospital, Beijing, China

The treatment of ovarian cancer (OC) presents a significant challenge due to the emergence of resistance to poly (ADP-ribose) polymerase inhibitors (PARPi). Transforming acidic coiled coil containing protein 3 (TACC3) belongs to the TACC family, characterized by its coiled-coil domains. TACC3 plays a crucial role in cell division, particularly in the formation and stability of the mitotic spindle, which is essential for proper chromosome segregation. Mutations or changes in TACC3 have been associated with various cancers, making it an increasingly attractive target for anticancer therapy in recent years. Here, we demonstrated a significant upregulation of TACC3 in OC, correlating with adverse clinical outcomes. Notably, PARPi-resistant OC cells exhibited a marked sensitivity to TACC3 inhibition. This was evidenced by the induction of spindle defects and mitotic catastrophe in PARPi-resistant cells upon TACC3 suppression, achieved either genetically or pharmacologically. Moreover, we explored the therapeutic efficacy of combining TACC3 inhibitor with PARPi, specifically BO-264 with olaparib or niraparib. This combination exhibited a synergistic effect, markedly reducing cell viability in vitro and tumor growth in PARPi-resistant tumor xenograft models. Our study suggests a promising new method for treating ovarian cancer, especially for those resistant to current PARPi treatments, by simultaneously targeting TACC3 and PARPi, enhancing treatment efficacy and potentially improving patient outcomes.

#4758 Targeting cellular pH as a novel therapeutic strategy in CDK4/6 inhibitor resistant breast cancer.

E. R. Scheidemann, D. M. Demas, A. N. Shajahan-Haq;
Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Cyclin dependent kinase 4 and 6 inhibitors (CDK4/6i) are part of standard of care therapy in combination with antiestrogens for the treatment of metastatic estrogen receptor positive (ER+) breast cancer. Of the three major CDK4/6i, only ribociclib and abemaciclib, but not palbociclib, have shown significant improvement in overall survival in the clinic. However, resistance to CDK4/6i is prevalent and advanced metastatic ER+ breast cancer remains incurable. Other studies have focused on cell cycle or growth factor alterations in resistant tumors but targeting these pathways have not been clinically validated. Beside inhibiting the cell cycle, CDK4/6i are known to induce lysosomes in sensitive cells but the role of lysosomes in CDK4/6i resistance remains elusive. Recently, we have shown that CDK4/6i resistant breast cancer cells gain metastatic potential relative to sensitive cells and this is potentially due to deregulated lysosomes, which can be targeted with lysosome destabilizers. Here we show that all three CDK4/6i induce rapid lysosomal acidification in sensitive cells, which suggests a role of cellular pH in CDK4/6i-mediated cell death. However, in resistant cells, lysosomal acidification following CDK4/6i treatment was diminished. Therefore, we hypothesize that cellular pH is tightly regulated in CDK4/6i resistant cells and this pathway can be targeted to inhibit cell viability. Interestingly, protein levels of carbonic anhydrase IX (CA9), an important regulator of cellular pH, is significantly elevated in resistant cells. Increased CA9 levels correlate with impaired overall survival in breast and other cancers. Small molecule inhibitor of CA9, S4 or clinical-grade SLC-0111, inhibits growth of resistant cells when combined with CDK4/6i plus antiestrogens. Thus, our study highlights the role of pH changes in CDK4/6i resistant breast cancer and offer therapeutic strategies to treat this incurable disease.

#4759 Targeting slow-cycling persisters in EGFR mutant non-small cell lung cancer.

M. Thiruvalluvan[1], S. Billet[1], Z. Liu[2], J. Lownik[1], G. Gonzales[1], H. Kim[1], A. L. Villamejor[1], L. Milshteyn[1], K. Sankar[1], E. M. Posadas[1], J. Lopategui[1], S. You[1], K. Reckamp[1], N. A. Bhowmick[1];

[1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Radiation Effects Research Foundation, Hiroshima, Japan

Activating mutations in the epidermal growth factor receptor (EGFR) gene in non-small cell lung cancer (NSCLC) patients are associated with clinical benefit in the metastatic and adjuvant settings when treated with EGFR inhibitors, such as osimertinib. Despite its dramatic efficacy, most patients are partial responders and refractive disease leave limited treatment options. The objective was to dissect the mechanism of osimertinib resistance in EGFR mutant NSCLC models to identify a means of re-sensitization. Imaging mass cytometric analysis of 76 NSCLC patients demonstrated EGFR expression was inversely correlated to CD105 membrane expression. CD105 is a transforming growth factor beta (TGF-β) family co-receptor that promotes bone morphogenic protein (BMP) signaling and inhibits TGF-β signaling. Significant elevation in cell surface CD105 by osimertinib was furthered by EGFR knockdown in two NSCLC lines with EGFR activating mutations. These lines were subjected to a program of increasing osimertinib concentrations to generate isogenic resistant lines. Heterogeneous drug-tolerant persister cells had significantly higher mutational load, increased CD105 cell surface expression as well as greater expression of bypass signaling factors such as ERK, PI3K, and BMP ligands compared to their parental counterparts. Single cell RNA-seq analysis of parental NSCLC revealed a small population of cells that shared elevated endothelial and pyrimidine metabolism, with a slow-cycling signature that was enriched in the osimertinib-resistant cells. Combining osimertinib with a CD105 neutralizing antibody, carotuximab, reduced the slow-cycling population and restored osimertinib sensitivity in resistant cell lines. The knockdown of CD105 had a more pronounced decrease in cell viability when combined with osimertinib. The osimertinib-resistant lines demonstrated more condensed chromatin and glycolytic state compared to the respective parental lines by ATAC-seq and Single Cell ENergetIc metabolism profiling, respectively. The addition of carotuximab reversed the chromatin and metabolic reprograming of osimertinib resistance. Carotuximab was discovered to initiate CD105 interaction with EGFR and its dominant active variant, EGFRv3. Ultimately, combination therapy of carotuximab and osimertinib resulted in significantly reduced tumor expansion compared to mice treated with either drug alone. Paradoxically, the small tumors from combination therapy had greater mitosis compared to the larger tumors of the osimertinib single agent treated mice. Inhibition of CD105 with carotuximab can overcome resistance to osimertinib and inhibit NSCLC tumor progression. This is a first-in-class pre-clinical foundation for a novel synthetic lethality treatment strategy resulting from the observation of global changes in EGFR-antagonist resistance as opposed to individual mutations identified in tumor subpopulations.

#4760 Inhibition of FASN postpones development of resistance to BRAF inhibitors in colorectal cancer.

M. Geisen, J. weber-Tessmann, C. Kelson, D. He, C. Wang, A. Faisal, J. Kolesar, Y. Zaytseva;
University of Kentucky, Lexington, KY

Introduction: Mutations in proto-oncogene BRAF occur in about 10-15% of CRC patients and $BRAF^{V600E}$ is the most common. For patients who undergo BRAF-targeted therapy, resistance develops 4-6 months after treatment initiation and results in more aggressive disease. We found that development of resistance to BRAF inhibitors (BRAFi) is associated with an increase in lipid metabolism and expression of fatty acid synthase (FASN). FASN is a key enzyme of lipid synthesis overexpressed in CRC. Therefore, our hypothesis is that inhibition lipid metabolism via FASN will postpone development of resistance to BRAFi.
Methods: We established CRC cells resistant to PLX8394, a novel BRAFi. To evaluate differences in parental and resistance cells, CellTiterGlo 2.0, PrestoBlue, CytoSelect™ Invasion Assay, Triglyceride Assay, Seahorse XF, and confocal microscopy were used. Combination of PLX8394 and TVB3664 or C75 (FASN inhibitors) was tested on cell viability, colony formation, and synergy studies in parental and BRAFi resistant cells.
Results: The development of resistance to BRAFi promotes cellular proliferation and increases cyclin D and survivin expression *in vitro* and *in vivo*. BRAFi resistance is also associated with an increase in invasive properties and loss of E-cadherin expression. Metabolic changes include an increase in lipid metabolism, oxidative phosphorylation, and triglycerides storage. RNAseq and western blot analysis show significant upregulation of FASN in BRAFi resistant cells. Using cell viability and soft agar colony formation assays, we show that combined PLX8394 and TVB3664 treatment leads to a significantly higher decrease in cell viability and colony formation as compared to each drug alone in parental cells but not in BRAFi resistant cells. The calculation of a Bliss synergy score confirms that combination treatment with C75 and PLX8394 has synergetic effect in $BRAF^{V600E}$ cells. To further confirm that FASN contributes to resistance to BRAFi, we show that HT29 FASN shRNA cells are more susceptible to PLX8394 treatment as compared to control cells. Importantly, our data show that the long-term treatment with PLX8394 in combination with TVB3664 postpones development of resistance to BRAFi as compared to cells treated with PLX8394 alone.
Conclusion: Our study demonstrates that resistance to BRAFi is associated with a significant increase in proliferation, metastasis, and lipid metabolism. We demonstrate that combination of FASN inhibitors and BRAFi postpones development of resistance in $BRAF^{V600E}$ cells. However, FASN inhibition does not sensitize cells to BRAFi in already resistance cells, suggesting that this approach cannot be used to overcome acquired resistance to BRAFi. In summary our data suggest that an addition of TVB3664 at the beginning of BRAF treatment regimen could be an efficacious treatment strategy for $BRAF^{V600E}$ CRC patients.

#4761 Understanding three-drug combinations: optimizing scheduling while avoiding toxicity.

M. Stoddard[1], **L. Yuan**[1], D. Van Egeren[2], A. Chen[3], D. Bottino[4], A. Chakravarty[1];
[1]Fractal Therapeutics, Inc., Lexington, MA, [2]Stanford University, Palo Alto, CA, [3]Columbia University, New York, NY, [4]Takeda Pharmaceuticals, Cambridge, MA

The promise of combination therapies in managing tumor resistance is constrained by the therapeutic window (the difference between efficacious and toxic doses). We have sought to understand the impact of dose scheduling on the emergence of resistance, using a mathematical model-based approach linking pharmacokinetics (PK) to a parsimonious evolutionary model of tumor growth incorporating the emergence of drug resistance. Here, we analyze the potential of a three-drug combination to minimize toxicity while preventing the emergence of resistance. We simulated eight tumor subpopulations representing resistance to one, two or three hypothetical drugs, using an exponential growth model with growth penalties based on drug concentrations. We used the model to simulate the effects of pairs of antagonistic, synergistic, and additive drugs on the growth of sensitive and resistant populations in a tumor. Final tumor volume and resistant population were used to compare the efficacy of various drug schedules. We assumed an overlapping neutropenia-like toxicity as the dose-limiting toxicity for the three drug combination, which we have previously shown to be proportional to the peak moving average drug concentration over 18 days. Final tumor volume and peak toxicity were used to compare the effectiveness of various dosing strategies and interaction combinations. Synchronous dosing results in the greatest drug interaction effect between any two drugs. When all interactions between the three drugs are either antagonistic or synergistic, the greatest effect is observed when all drugs are dosed simultaneously. The drugs are most toxic when all three are dosed simultaneously or nearly simultaneously. Our work shows that time sensitivity—that is, the magnitude of the changes in efficacy associated with small changes in schedule—varies with phase offset. Scheduling is most time sensitive when all drugs are dosed simultaneously or nearly simultaneously; dosing of two drugs simultaneously is less time sensitive. Three-drug combinations are an effective means of preventing complete resistance. While simultaneous dosing of two or more drugs confers the greatest efficacy, such simultaneous dosing results in greater peak toxicity because of higher simultaneous drug concentrations. A potential compromise is the simultaneous dosing of two of the three drugs, which results in an intermediate toxicity. Dosing of two drugs simultaneously is also less time sensitive, advantageous in a practical sense as it is more robust to patient dosing error. While the approach used here is based on hypothetical drug properties, it provides a framework that is readily applicable to real-world drug combinations, with the potential for practical insights to guide the framing of the Target Product Profile for three-drug combinations.

#4762 Tumor treating fields (TTFields) increase cancer cell membrane permeability and improve sensitivity to doxorubicin in vitro and in vivo.

B. Koltun, **T. Voloshin**, T. Kan, C. David, L. Koren, Y. Porat, A. Volodin, N. Kaynan, A. Klein-Goldberg, R. Paz, B. Brant, Y. Barsheshet, E. Zemer-Tov, A. Haber, M. Giladi, U. Weinberg, Y. Palti;
Novocure Ltd, Haifa, Israel

Background: Tumor Treating Fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression. While the mechanism of action of TTFields has been associated with an antimitotic effect and impaired DNA damage repair mechanisms, the application of TTFields has also been shown to increase the membrane permeability of glioblastoma cells. The current study examined whether increased cell membrane permeability is relevant in other tumor types and may be leveraged to facilitate uptake of the anticancer agent doxorubicin (DOX).
Methods: Breast mammary carcinoma (4T1), breast adenocarcinoma (MCF-7), uterine sarcoma (MES-SA), lung fibroblasts (MRC-5), and brain endothelial (HBMVEC) cells were treated with TTFields using the inovitro™ system. Intracellular 7-aminoactinomycin D (7-AAD) accumulation and cell count were measured using flow cytometry to determine membrane permeability and cytotoxicity, respectively. TTFields (300 kHz) together with DOX were applied to 4T1 cells DOX-sensitive (4T1-S) and DOX-resistant (4T1-R, generated by repeated DOX exposure of the 4T1-S cells), followed by flow cytometry analysis of DOX accumulation (24 h treatment) and cell survival using cell count (72 h treatment). For proof of concept, mice were orthotopically inoculated with 4T1-S cells, followed by TTFields treatment for 72 h and injection of DOX (5 mg/kg) 24 h before ending TTFields treatment. DOX fluorescence was measured by flow cytometry in single-cell tumor suspension and whole tumor in vivo imaging system (IVIS). For the efficacy studies, mice were orthotopically inoculated with 4T1-S or 4T1-R cells. Tumors were allowed to grow, and then the mice were treated with TTFields (300 kHz) or sham-heat continuously for 8 days, with DOX (1 mg/kg for 4T1-S cells; 5 mg/kg for 4T1-R cells) or vehicle 2- and 6-days following treatment initiation. Tumor volumes were measured using caliper.
Results: TTFields increased 7-AAD accumulation in cancer but not normal cells. Maximal TTFields-induced cellular permeability was identified at 300 kHz for 4T1 cells, whereas TTFields-induced cytotoxicity was the highest at 150 kHz. The application of TTFields allowed DOX accumulation to the same extent in both DOX-resistant and DOX-sensitive cells and sensitized both cell types to DOX cytotoxicity. A 2- to 3-fold higher DOX accumulation was observed in tumors isolated from mice treated with TTFields relative to control mice. Significantly lower tumor volume was observed in mice treated with TTFields and DOX relative to control or mice treated with DOX alone.
Conclusions: TTFields increased cancer cell permeability, resulting in enhanced intracellular accumulation of DOX. Concomitant treatment with TTFields and DOX can improve treatment efficacy in DOX-resistant tumors and sensitize DOX-sensitive tumors to lower DOX concentrations.

PREVENTION / EARLY DETECTION / INTERCEPTION: Biomarkers and Molecular Targets for Cancer Prevention
Poster Session

#4765 Tumor, serum and plasma metabolome in patients with high-grade bladder cancer.

M.-M. Tsamouri[1], A. Karthikeyan[2], C. A. Lucchesi[3], B. P. Durbin-Johnson[2], M. A. Dall'Era[1], **P. M. Ghosh**[1];
[1]UC Davis, Sacramento, CA, [2]UC Davis, Davis, CA, [3]VA Northern California, Mather, CA

Introduction: Bladder cancer (BlCa) ranks as the sixth most prevalent cancer in the world. A number of urine based BlCa detection tests have recently been approved for clinical use, including the NMP22 tests and the bladder tumor antigen (BTA) tests for both detection and monitoring of patients with known bladder cancer. The FDA have approved them both for surveillance in BlCa only in conjunction with cystoscopy. Unfortunately, the sensitivity and specificity of these tests are poor, and cannot distinguish between aggressive and non-aggressive tumors. This project aims to identify alternate markers that can overcome these drawbacks.
Methods: We characterized the global metabolome of 47 bladder tumors retrieved by radical cystectomy (RC) or TURBT, including 14 specimens with matching plasma and serum samples. All specimens were subjected to untargeted metabolomic approaches with gas chromatography- time-of-flight mass spectrometry (GC-TOF MS) to profile primary metabolites, hydrophilic interaction liquid chromatography MS (HILIC-QTOF MS) to profile biogenic amines, and liquid chromatography charged surface hybrid MS (LC-CSH-QTOF MS) to characterize complex lipids. Differentially expressed metabolites were analyzed with respect to grade, stage, metastases, and the use of neoadjuvant chemotherapy. For selected metabolites, area under the ROC curve (AUC) is calculated as % sensitivity vs. 100% specificity. Expression of highly discriminatory metabolites were then validated in the plasma and serum samples to determine which forum would provide greater specificity.
Results: We first assembled a discovery cohort of 33 patients who did not have matching blood specimen for primary metabolites, biogenic amines and complex lipids. Comparison of high vs low grade tumors yielded two lipids, a sphingomyelin (SM (d38) and a phosphatidylcholine PC(p-38), that were significantly different (adjusted p-value<0.05, $\log_2$fold change>2.5). These results were validated in the 14-sample cohort with matching plasma and serum of which the latter showed significant correlation between tumor and plasma (Spearman R=0.872, adj p=0.03).
Conclusions: Our results indicate that certain sphingomyelins and phosphatidylcholines may be useful as plasma markers of high grade BlCa. Further analyses are required to evaluate whether these markers are more discriminatory compared to existing urinary markers.

#4766 Androgen deprivation in mice is linked with cognitive impairment.

S. S. Verma[1], D. Swain[2], V. Singh[2], E. Shankar[2], Z. Lee[2], S. Gupta[2];
[1]Case Western Reserve University School of Medicine, Cleveland, OH, [2]Case Western Reserve University, Cleveland, OH

Androgens play a neuroprotective role in maintaining the normal physiological functions of the brain. It also plays a pivotal role in prostate cancer development and progression. Advance-stage prostate cancer treatment is primarily based on androgen deprivation therapy (ADT) that blocks the male hormone testosterone. Moreover, prostate cancer patients who undergo ADT develop cognition impairment such as loss of memory, learning, reasoning, and decision-making. Several studies have shown a positive association between ADT and the risk of cognitive impairment. Currently, there are no clinical markers to identify patients at-risk to ADT-mediated cognition. This demands a need for biomarkers that can help distinguish the vulnerability of patients toward cognitive impairment undergoing ADT. We utilized a in-vivo model to identify biomarkers and the impact of ADT in different regions of the brain. Sixteen-week-old BALB/c mice were gavage 50 mg/kg/day of enzalutamide (mimicking ADT) for 5 days per week (0.2 ml of vehicle consisting of 0.5% methylcellulose and 0.025% Tween 20) for a total of 8 weeks. Control animals received 0.2 ml vehicle per day for the same time period. Mice were observed for behavioral changes post-enzalutamide treatment and brain PET scans were generated. The experiment was terminated, the brain was excised for cortex, cerebellum, and hippocampus, and subjected to mass spectroscopic (MS) analysis. Differentially expressed proteins were identified and validated using qRT-PCR in the mice blood. Enzalutamide treatment for 8 weeks resulted in a modest weight gain and lack of attention and letharginess in these mice. Examination of PET scan and H&E sections of mice brain from control group by light microscopy showed a normal morphology of neurons in the cortex. Enzalutamide treatment showed lower neuron density and signs of neuron injury, as well as cytoplasmic swelling of the astrocytes. MS analysis identified a number of differentially expressed proteins that were validated in the blood. These include ABCB10, CAB, DAZAP1, DCU, DERL1, FBXO, MBNL, PUM2, SERL1, SLC8A3, SLC9A, TCF20, VIM, and ZYXIN. Among them, the expression of SLC8A3, PUM2, and SERL1, were significantly higher than others in the enzalutamide-treated group. Taken together, our findings suggest that enzalutamide treatment in mice leads to cognitive impairment like that observed in men on ADT protocol. Our study highlights that blood-based markers can be developed for ADT-mediated cognition which can lead to the identification of new strategies for prevention and early intervention to improve the quality-of-life of patients suffering with advance-stage prostate cancer.

#4767 Changes in the NSE and S100B levels following treatment with peripheral neuropathy-inducing drugs.

P. R. Vontikommu[1], S. Selvakumar[1], U. Natarajan[2], A. Rathinavelu[2];

[1]Rumbaugh-Goodwin Institute for Cancer Research, Nova Southeastern University, Davie, FL, [2]Rumbaugh-Goodwin Institute for Cancer Research, Barry & Judy Silverman College of Pharmacy, Nova Southeastern University, Davie, FL

Neo-adjuvant chemotherapy is considered the standard of care for patients with multiple myeloma (MM). Peripheral neuropathy (PN) is one of the most common chemotherapy-induced side effects that impact 50% of all patients who receive chemotherapy and can lead to discontinuation of drug treatment. Treatment with Bortezomib (BTZ), Cisplatin (CIS), and Vincristine (VIN) has been established as the most common trigger of ChemotherapyInduced Peripheral Neuropathy (CIPN) among cancer patients. Since CIPN can lead to disabling long-term adverse effects, many cancer patients discontinue or limit their treatment regimen once they see signs or symptoms of CIPN. Therefore, it was hypothesized that developing diagnostic/prognostic biomarkers that can accurately predict the onset or progression of CIPN would help to determine the chemotherapy eligibility with the above-mentioned drugs and proactively prepare for protective care. Hence, our initial goal was to elucidate the molecular mechanisms underlying the onset and progression of CIPN that would allow for the identification of suitable biomarkers that can be used for monitoring before or during chemotherapy with BTZ, CIS, and VIN. Initially, we conducted *in vitro* studies to identify the underlying molecular mechanisms activating CIPN related pathways. We used neuronal Schwann cells (RT4), for testing the neurotoxic effects of BTZ, CIS, and VIN that might precede or coincide with the onset of CIPN in an *in vivo* condition. Interestingly, the BTZ treatment was able to significantly reduce the intracellular level of NSE and S100B in RT4 cells compared to the untreated controls, when they were measured using an immunofluorescence assay and Western blot. Furthermore, we conducted an *in vivo* study to determine the CIPN using rats. We used the sciatic nerve (SN) from drug-treated animals to check the S100B level using the ELISA method. Our preliminary results showed that levels of S100B in the SN of Rats were reduced following 8 weeks of treatment with the PN-inducing chemo drugs. We anticipate that this study will enrich our understanding of how chemotherapy medications induce PN in cancer patients and guide us to identify reliable biomarkers (This project was supported by the PFRDG grant of the Nova Southeastern University, Ft. Lauderdale Florida, and the Royal Dames of Cancer Research Inc., Ft. Lauderdale, Florida).

#4768 Differential expression of triptolide gene targets in human papillomavirus positive and negative head and neck squamous cell carcinomas.

W. E. Kamm, L. J. Mortenson, F. G. Ondrey;
University of Minnesota Medical School, Minneapolis, MN

Head and neck squamous cell carcinoma (HNSCC) is the fifth most common cancer in the US. HPV represents a more recent risk factor for which treatment may be individualized. HPV expresses viral E6 and E7 oncoproteins which downregulate wild type p53 and Rb respectively. Triptolide, a derivative of a traditional Chinese medicinal herb, has been shown to inhibit viral E6, thereby reactivating wild type p53. Therefore, triptolide may target HPV positive HNSCC as a putative treatment. To explore this, we compared mutation, methylation, and expression of triptolide gene targets between HPV positive and HPV negative samples from The Cancer Genome Atlas (TCGA) program.

Patient data was queried from the TCGA PanCancer Atlas for HNSCC using cBioPortal. This included a total of 523 patients with 487 meeting inclusion criteria. 415 patients were HPV (-) and 72 were HPV (+).Differences in direct genomic alterations, DNA methylation, mRNA expression, and protein expression of the 34 known triptolide targets were compared between these two groups using the Benjamini-Hochberg Procedure with a significance level of $q < 0.05$. Significant differences of the studied genes ($q < 0.05$) are shown in Table 1. There were no significant differences in protein expression.

Of the 34 known triptolide targets, HPV positive and negative samples show variable enrichment. Triptolide targets exhibit greater methylation and mRNA expression in HPV positive samples supporting triptolide's efficacy in these samples. However, other triptolide targets are the differentially expressed and methylated in HPV negative samples, so the compound may have a beneficial effect in this context as well. Further studies are required to test efficacy of triptolide against HPV positive and HPV negative HNSCC in vitro and in vivo models.

Table 1. Significant genomic differences between HPV (+) and HPV (-) samples shown.

#4769 Phospho-YAP (Ser127) overexpression is associated with sporadic advanced adenomas: The Tennessee Colorectal Polyp Study.

L. Fan[1], X. Guo[1], M. K. Washington[1], J. Shi[1], R. M. Ness[1], Q. Liu[2], W. Wen[1], X. Liu[2], Q. Cai[1], W. Zheng[1], R. J. Coffey[1], M. J. Shrubsole[1], T. Su[1]; [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

About 70-80% of sporadic colorectal cancers (CRCs) harbor APC mutations. Whether specific characteristics of APC mutation or APC-related signaling pathways contribute to tumor initiation, advanced progression, and recurrence in the precancerous lesions remain to be elucidated. This study included145 sporadic precancerous adenomas from the Tennessee Colorectal Polyp Study. Expression of six APC-related proteins (β-catenin, p-YAP, CtBP, EB1, Asef, and N-terminal APC) in adenoma and non-tumor tissues (n=22) were quantitatively detected by immunohistochemistry. Targeted sequencing of APC was done for 108 adenomas. Metachronous adenoma status was obtained from chart review. *YAP*-correlated genes and their functional enrichment analysis were conducted using gene expression data of 326 adenomas from the Gene Expression Omnibus database. We found that nuclear β-catenin and p-YAP overexpression only existed in adenoma tissue, correlated with each other (r=0.26, *P*=0.0018), and associated with APC mutations (*P*=0.05). P-YAP was strongly associated with odds of large adenomas (OR=14.25, 95%CI=3.32-61.18, *P* trend<0.0001), villous growth pattern (OR=58.71, 95%CI=10.49-328.61, *P* trend<0.0001) and advanced adenomas (OR=12.62, 95%CI 4.57-34.86, *P* trend<0.001), and showed a significant interaction with nuclear β-catenin on advanced tumor (OR=16.82, 95%CI 4.41-64.08, *P*<0.0001). After adjusting for selected covariates and mutually adjusting for biomarkers with *P*<0.20 in crude models, p-YAP overexpression remained significantly associated with advanced adenomas (OR=12.31, 95% CI=3.78-40.10, *P* trend<0.0001). YAP-correlated genes were significantly enriched in autophagy, unfolded protein response, and sirtuin pathways with predominantly pro-tumorigenic alterations. APC mutation and selected biomarkers were not significantly associated with metachronous adenoma. In conclusion, p-YAP overexpression might be a promising biomarker for high-risk sporadic adenoma. In addition to its synergistic effect with nuclear β-catenin, p-YAP may play tumorigenic roles through interaction with other cancer pathways in human sporadic adenoma. This study provided new evidence for oncogenic effects of p-YAP in human sporadic adenomas and shed light on the complex network of Hippo, Wnt, and other oncogenic signaling pathways.

#4771 Assessment of Ki67 proliferation index in pre-malignant colonic adenomas: Implication for new biomarker testing to predict metachronous disease (The INCISE project).

G. P. Lynch[1], A. Ammar[1], C. Bigley[1], M. Johnstone[1], J. Jawny[2], H. Morgan[1], J. Hay[3], N. Maka[2], S. McSorley[1], J. Edwards[1];
[1]University of Glasgow, Glasgow, United Kingdom, [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom, [3]The Francis Crick Institute, London, United Kingdom

Approximately 40% of patients are found to have polyps at bowel screening colonoscopy, which are associated with a higher risk of developing future polyps or colorectal cancer. The British Society of Gastroenterology 2020 (BSG20) guidelines stratify patients into high/low risk of metachronous disease, using the size, dysplasia, and number of polyps found at index colonoscopy. This study aims to explore the prognostic significance of Ki67 proliferation percentages in adenomatous polyps, with metachronous disease. Tissue microarray (TMA) was constructed from 1201 index adenomatous polyps with representative cores of basal and luminal adenomatous epithelia. 67% patients were identified as high risk at index colonoscopy. The median time to detect metachronous polyps was 55 months (range 6-72 months) with 56% of patients developing metachronous polyps by the end of follow-up. TMA was stained for Ki67 using immunohistochemistry. Ki67 proliferation percentages in adenomatous epithelia was quantified using QuPath. Data was split into training (n=830) and test (n=371) datasets. The Ki67 proliferation cutpoint was made using Survmine R package using the training dataset. X^2 test was used to study associations with clinicopathological criteria and Kaplan survival analysis was used to assess Ki67 association with metachronous lesions. Ki67 percentages were higher in lumina than in basal adenomatous epithelium (median Ki67 were 63% & 48%; respectively). Total Ki67 percentages were computed by averaging luminal and basal values. Thresholds of 70%, 64% and 59% were employed to classify patients into low/high categories based on luminal, basal or total percentages; respectively. In the training cohort, high luminal, basal or total Ki67 were associated with metachronous lesions (p values 0.032, <0.001 and 0.006; respectively). Other associations were significant between luminal or total Ki67 and location of index polyps (p=0.017 & p=0.044; respectively), histology (p=0.019) and advanced future lesion status (p=0.002 & p<0.001; respectively). In multivariate cox regression analysis, high Ki67 was an independent prognostic factor for metachronous polyps (luminal Ki67 HR=1.28, CI: 1.052-1.560, p=0.014; basal Ki67 HR=1.639, CI: 1.313-2.046, p<0.001; total Ki67 HR=1.344, CI: 1.105-1.635, p=0.003) when adjusted to number of index polyps and BSG20 risk score. BSG20 risk score stratification of patients in terms of metachronous disease was improved when combined with luminal, basal or total Ki67 in the training datasets (all p<0.05). Prediction of metachronous disease by the combined groups was validated in the test cohort for luminal, basal and total Ki67 (all p<0.05). High Ki67 proliferation rates in adenomatous polyps are independently associated with the development of metachronous polyps and may help improve the BSG20 criteria.

#4772 Metabolic phenotype, age acceleration, and obesity-related cancer risk in Women's Health Initiative and Atherosclerosis Risk in Communities cohorts.

Prasoona Karra[1], Garnet L. Anderson[2], Mary C. Playdon[3], Sheetal Hardikar[3], Aladdin Shadyab[4], Kari E. North[5], Anne E. Justice[6], Elizabeth A. Platz[7], Jan Bressler[8], Anna Prizment[9], Weihua Guan[9], Dominique S. Michaud[10], Eric A. Whitsel[11], Brock C. Christensen[1], Lucas A. Salas[1]

[1]Department of Epidemiology, Geisel School of Medicine, Dartmouth College, Lebanon, NH,[2]Division of Public Health Sciences, Fred Hutchinson Cancer Center, Seattle, WA,[3]3Cancer Control and Population Sciences, Huntsman Cancer Institute, Salt Lake City, UT,[4]Herbert Wertheim School of Public Health and Human Longevity Science, University of California, San Diego, CA,[5]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC,[6]Dept. Population Health Sciences, Geisinger Health, Danville, PA,[7]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[8]The University of Texas Health Science Center, Houston, TX,[9]University of Minnesota, Minneapolis, MN,[10]Tufts University School of Medicine, Boston, MA,[11]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC

Introduction: While normal physiologic aging causes metabolic decline, metabolic dysregulation owing to excess nutrient intake, physical inactivity, and obesity may drive accelerated aging. However, the relationship of accelerated aging with metabolic dysfunction across different levels of BMI (i.e., metabolic obesity phenotype) and whether it may mediate the relationship with obesity-related cancer (ORC) risk is not well established.
Methods: To test this hypothesis, we are leveraging existing blood-based DNA methylation (DNAm) data within the Women's Health Initiative (WHI) and the Atherosclerosis Risk in Communities (ARIC) cohorts. Weight, height and blood pressure were measured by trained technicians in the respective cohorts and fasting blood glucose, triglycerides and HDL cholesterol were quatified by standard clinican assays. Metabolic obesity phenotypes are classified as metabolically healthy normal weight (MHNW), metabolically unhealthy normal weight (MUNW), metabolically healthy overweight/obese (MHO), and metabolically unhealthy overweight/obese (MUO) when defined by ATP III criteria. Age acceleration was measured as a residual from regressing pan-tissue Horvath's DNAmAge on chronological age.
Results: The mean baseline age was 64 ± 6.6 years and 54 ± 5.7 year among WHI and ARIC participants, respectively and the age acceleration was measured at an mean follow-up time of 16 years from baseline for WHI and 3.5 years from baseline for ARIC cohort. The outcome of interest, ORC incidence was observed among 474 participants of which 387 were women. The median time for cancer diagnosis from baseline was 25 year and from DNAm measurement was 18.6 years. Of the 4341 (70% women) participants included in the analysis, 23.9% were MHNW, 3.2% MUNW, 39% MHO, and 33.5% MUO. A 31.5% of MHNW, 40.4% of MUNW, 28.7% of MHO, and 35.2% of MUO showed age acceleration. MUNW (OR 1.47, 95% CI: 1.03-2.11) and MUO (OR 1.18, 95% CI: 1.00-1.40) individuals at baseline had increased odds of experiencing age acceleration at a follow-up visit. The risk of all ORC combined was significantly elevated among MUO (HR 1.63, 95% CI: 1.27-2.09) compared to MHNW. Age acceleration at the follow-up visit was not significantly associated with ORC risk (HR 0.91, 95% CI: 0.75-1.11). These analyses were not adjusted for confounders.
Conclusions: MUNW and MUO individuals had increased odds of age acceleration at a follow-up visit. Furthermore, MUO individuals were at an elevated risk of ORC, compared to individuals with MHNW. Accelerated aging does not appear to mediate this association, as accelerated aging was not associated with ORC.

#4773 Interferon regulatory factor 8 (IRF8) as a biomarker for early detection and prevention of axillary lymph node-positive breast cancer.

M. Rossi[1], N. Cruz-Reyes[1], M. L. Stallings Mann[1], B. M. McCauley[2], T. L. Hoskin[2], R. A. Vierkant[2], S. J. Winham[2], A. C. Degnim[2], M. E. Sherman[1], D. C. Radisky[1];

[1]Mayo Clinic, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN

Breast cancer (BC) remains a leading health concern worldwide and is often undetected until the cancer metastasizes. Early detection can limit the need for aggressive treatments and improve prognosis. We analyzed early immune and molecular markers in benign breast disease (BBD) biopsies prior to BC development to identify women at elevated risk of developing node-positive invasive BC, which might direct surveillance and prevention efforts aimed at reducing incidence of this disease. Utilizing the Mayo Clinic BBD cohort, we compared women who developed node-positive BC following their BBD biopsy (cases; n=42) with those who remained cancer-free (controls; n=37), matched on patient age and biopsy date. We used NanoString nCounter system to identify differentially expressed genes (DEGs) between cases and controls. We also developed a multiplex immunofluorescence (mIF) approach using Opal system by Akoya Biosciences for comprehensive marker detection in FFPE tissue, enabling correlation of cells expressing DEGs with innate and adaptive immune cells. Digitized images were segmented, and cell phenotyping, and spatial relationships were compared between cases and controls. Our findings revealed significantly increased expression levels of IRF8 (interferon regulatory factor 8, a factor involved in immune cell differentiation) in controls as compared to cases and found that increased IRF8 expression in cases is correlated with delayed cancer onset. Additionally, controls exhibited higher frequencies of CD4+, CD8+, CD68+, CD20+ and CD11c+ immune cells, and lower frequency of Ki67+ staining, with a notable increase of CD11c+/CD68+ cells, a marker for M1 type macrophages, indicating a pro-inflammatory, antitumorigenic immune microenvironment polarization. Furthermore, our mIF analyses offer new insights into spatial biomarker localization, enhancing prognostic accuracy. Our findings suggest that decreased numbers of immune cells in BBD biopsies may be associated with increased risk of developing axillary node-positive BC. This research underscores the importance of dissecting molecular and immune interactions in BBD for assessing the risk of this disease. Our results have the potential to improve individualized risk assessment, leading to more targeted surveillance and informed screening, potentially reducing BC incidence and mortality through early intervention. This study not only contributes to our understanding of BC pathogenesis but also opens avenues for developing novel preventive strategies.

#4774 Inhibition of pancreatic acinar ductal metaplasia by novel YAP/TAZ inhibitor, CV-4-26.

C. M. Perkins[1], C. Zhou[1], M. Campbell-Thompson[1], Y. Mao[2], K. R. Atanasova[1], J. Jiang[1], R. Ratnayake[1], H. Luesch[1], J. Ali[3], C. Li[1], T. D. Schmittgen[1]; [1]University of Florida, Gainesville, FL, [2]Florida Agricultural and Mechanical University- Florida State University, Tallahassee, FL, [3]Florida Agricultural & Mechanical University- Florida State University, Tallahassee, FL

Current challenges for pancreatic ductal adenocarcinoma (PDAC) treatment include overcoming the disease's fibrous tumor microenvironment with limited cytotoxicity- in which tissue stiffening is believed to occur even pre-disease onset. Acinar to ductal metaplasia (ADM), the transdifferentiation of acinar cells into duct-like cells, is a predisposing event to PDAC development that is also linked to Hippo signaling, a major pathway involved in fibrosis and inflammation. Hippo activation is initiated by the yes-associated protein (YAP) in conjunction with the PDAZ binding motif (TAZ) and TEA domain (TEAD) transcription factor. Thus, the synthesis of the novel covalent TEAD autopalmitoylation inhibitor, CV-4-26, presented an opportunity to therapeutically target ADM. CV-4-26 binds to the TEAD lipid binding pocket, which, in turns, hinders TEAD palmitoylation, thereby leading to the inhibition of the Hippo pathway. Utilizing our 3D organoid p48Cre/+LSL-KRASG12D/+ (KC) mouse model, we demonstrated pronounced phenotypic and molecular inhibition of ADM by CV-4-26, resulting in a conserved acinar phenotype, as well as downregulation of downstream markers of the YAP/TAZ complex. The compound did not reverse ADM to the acinar state once ducts were visibly formed. Yet, CV-4-26 demonstrated a lack of cytotoxicity (up to 25 μM) as determined by Calcein AM staining. Biomechanical measurements of extracellular matrix stiffness acquired through calculations of fluorescent nanoparticle displacement further displayed decreased moduli as a response to inhibition treatment. Moreover, a 56-fold downregulation of collagen (COL1A1, COL1A2) mRNA, markers for PDAC development, was observed. However, less reduction in the collagens and extracellular matrix stiffness was observed in the ADM reversal treatments, corroborating our morphology and gene expression results. Our data suggest that combining CV-4-26 by ADM inhibition with standard of care therapies for PDAC may enhance the penetration of small molecules through the tumor's extracellular matrix.

#4775 Unveiling caveolin-1's crucial role in breast cancer progression and metastasis: A molecular perspective.

R. Begum[1], S. Thota[1], D. Singh[2], N. Chintala[1], A. Pandit[1], B. Sapkota[1], J. Francis[1];
[1]Louisiana State University, Baton Rouge, LA, [2]Indiana University Health, Indiana, IN

Background: Breast cancer, particularly its metastatic form, constitutes a significant portion of oncological mortality. Caveolin-1 (Cav-1), a caveolae structural protein, has been implicated in cellular processes such as proliferation, apoptosis, autophagy, and cellular motility (aberrant in breast cancer). With its dual role as a tumor suppressor and promoter, Cav-1's function in breast cancer pathophysiology requires elucidation for potential therapeutic targeting.
Methods: We utilized a syngeneic mouse model to engineer Cav-1 deficient 4T1 murine mammary carcinoma cells which mirror the characteristics of stage IV breast cancer to investigate Cav-1's role in tumor growth and metastasis. We assessed cellular proliferation and lung metastasis, compared with wild-type controls, and performed molecular analyses to evaluate epithelial and mesenchymal marker expression, stemness-related markers, and autophagy-related gene expression.
Results: Cav-1 ablation corresponded with a marked decrease in tumor proliferation and lung metastasis, indicating a suppressive role in tumor progression. Molecular characterization revealed downregulated epithelial markers (E-cadherin, β-catenin), transcription factors (TWIST1/2), and stem cell markers (NANOG, OCT4, SOX2, c-MYC, SALL4), with concurrent upregulation of the mesenchymal marker vimentin. Enhanced expression of autophagy-related genes (Beclin-1, ATG5, ATG16) was also observed, suggesting a disruption in autophagic pathways.
Conclusion: Our findings underscore the critical role of Cav-1 in breast cancer progression, specifically its function in suppressing metastasis and modulating cellular phenotypes. Targeting Cav-1 could represent a novel therapeutic strategy to mitigate breast cancer growth and dissemination. Further research is warranted to explore the therapeutic potential of modulating Cav-1 in breast cancer treatment.

#4776 The role of angiogenesis in gastric tumorigenesis.

V. Akkanapally, S. BASU;
The Ohio State University, Columbus, OH

Introduction: Gastric or stomach cancer remains one of the most lethal malignancies, with an estimated 1,089,103 new cases and 768,793 deaths worldwide in 2020. In the United States, it is estimated that there were 26,500 new cases and 11,130 deaths from stomach cancer in 2023. Unfortunately, despite improved treatment in recent years, ~65% of gastric cancer patients present with aggressive metastatic disease, and they die within one year of diagnosis. Therefore, the identification of newer and effective therapies to target the precancerous stages of the disease promises possibilities for the prevention of gastric cancer in patients harboring these lesions. Gastric metaplasia and dysplasia are precancerous lesions that often progress to gastric cancer. Since anti-VEGF-A anti-angiogenic agents have shown efficacy in advanced gastric cancer patients, we hypothesized that VEGF-A-mediated angiogenesis has a functional role in the pathogenesis of gastric metaplasia and dysplasia.

Experimental Procedures: The Initial experiments were undertaken in human gastric metaplasia and dysplasia tissues and murine gastric metaplasia and dysplasia tissues collected from a well-established *Helicobacter felis* (*H. felis*) induced murine model of gastric tumorigenesis simulating human patients to detect angiogenesis (CD31/MVD) and identify angiogenic pathways using GeoMx DSP Spatial Proteomics and NanoString nCounter assay. Thereafter, further experiments were undertaken in the *H. felis*-induced murine model of gastric metaplasia and dysplasia, simulating human patients using VEGF-A hypo mice to determine the role of VEGF-A-induced angiogenesis in the progression of these lesions.

Results and Conclusion: Although our results indicated angiogenesis and VEGF-A expression in both human and mouse gastric metaplasia and dysplasia, inhibition in the progression of the precancerous gastric lesions was observed in only 40% of the VEGF-A hypo mice, thereby suggesting that VEGF-A induced angiogenesis might not be the major angiogenic pathway in these precancerous lesions in every patient. A similar phenomenon is also seen in some gastric cancer patients.

#4777 A small-molecule SMUG1 activator enhances repair of 5-hydroxymethyl-2'-deoxyuridine-mediated pyrimidine lesions in DNA.

L. A. McPherson, Y. Gao, S. Adimoolam, S. Suresh, D. L. Wilson, I. Das, E. R. Park, C. S. C. Ng, Y. Jun, J. M. Ford, E. T. Kool;
Stanford University, Stanford, CA

Background: Pharmacological upregulation of DNA repair pathways presents a potentially promising approach for cancer prevention in populations that are genetically high-risk. SMUG1, an enzyme involved in base excision repair, removes uracil and certain oxidized bases from DNA to mitigate adverse genotoxic and mutagenic effects and represents a promising target for cancer therapy. A growing body of evidence suggests that SMUG1 is involved in tumorigenesis, and deficiency of SMUG1 correlates with poor prognosis in several cancers. We hypothesize that upregulation of SMUG1 by a small molecule activator may be a viable strategy for reducing tumorigenesis in at-risk populations. We report on the properties of SU0547 - a SMUG1 activator that was derived from the EGFR inhibitor drug gefitinib - which shows reduced kinase inhibition and potent activation of SMUG1 both in vitro and in human cell lines.
Methods: MTT proliferation assays were used to screen for toxicity and to determine the effect of SU0547 on 5-hydroxymethyl-2'-deoxyuridine (5-hmdU)-treated cell lines. The effect of the compound on SMUG1 expression was determined by Western blot and RT-qPCR while its effect on DSBs via γH2AX expression in 5-hmdU-treated cells was determined by immunofluorescence and Western blot.
Results: SU0547 activates SMUG1 by 347 ± 50% in vitro at 100 nM, with an AC_{50} of 2.55 ± 0.62 μM. We examined whether it can modulate SMUG1 activity in a panel of human cell lines by artificially inducing DNA damage with the native SMUG1 substrate 5-hmdU and treating cells with the activator. In all five human cancer cell lines tested, SU0547 caused the cells to become significantly more resistant to 5-hmdU by factors of 2.1 to 5.3-fold. A series of CRISPR-Cas9 generated SMUG1 KO cell lines showed resistance to 5-hmdU and SU0547 had no effect on these treated cells, confirming that this activator acts on endogenous SMUG1. To determine the effect of the activator on double-strand breaks (DSBs), cells were treated with 5-hmdU with or without the compound and DSBs were visualized and quantitated by examining γH2AX foci. 5-hmdU treatment induced γH2AX foci while SU0547 treatment significantly reduced these foci to near or below baseline levels. These results were confirmed using Western blot quantitation of γH2AX.
Conclusions: We envision that this activator will serve as a useful tool for further studying the role of SMUG1 in mediating 5-hmdU toxicity and will enable the testing of our hypothesis that enhancing DNA repair processes may serve to inhibit mutagenesis and slow progression of pre-neoplastic lesions to invasive cancers associated with genomic instability.

#4778 Development of self-amplifying RNA vaccines targeting prostate tissue-restricted and tumor-associated antigens.

R. H. Shoemaker[1], J. H. Erasmus[2], P. Berglund[2], J. D. Marshall[3], Y. Koboziev[3], B. M. Beckman[3], B. D. Cholewa[1], S. G. Reed[2];
[1]National Cancer Institute, Bethesda, MD, [2]HDT Bio, Seattle, WA, [3]Frederick National Laboratory for Cancer Research, Frederick, MD

Prostate cancer is the most frequent cancer type in men, with increasing incidence at advanced age. As this cancer is frequently slow growing, opportunities for cancer interception exist, particularly among men with low-grade tumors who frequently undergo active surveillance. A well-tolerated vaccine intervention would be ideal for this population. Self-amplifying RNA (saRNA) vaccines built on a replication-deficient alphavirus backbone such as VEEV, offer several advantages for vaccine development. Sequences for relatively large antigens can be encoded and efficiently expressed, at low vaccine doses. Practical and efficient delivery of the saRNA is possible with advanced nanoparticles such as cationic inorganic lipid nanoparticles (LION). Among candidate antigens for a prostate cancer interception vaccine, we selected prostein (SLC45A3), a protein whose natural expression is restricted to the prostate gland and prostate cancer and ERG, a member of the ETS family of transcription factors frequently involved in chromosomal translocations in prostate cancer. We generated saRNA constructs with several design strategies and demonstrated that upon in vitro transfection, both antigens are expressed as assessed by mass spectrometry and Western blot analysis. This was achieved using commercial transfection reagents and LION. Prostein expression was particularly notable in that this eleven-transmembrane protein could be detected in HEK-293 cells using flow-cytometry and cell-surface staining. Nearly 50% of the cell population stained positively. Immunogenicity of the vaccines was tested in mice. Following formulation with LION particles i.m. injection and boosting, saRNAs coding for prostein elicited strong cellular immunity as demonstrated by IFN-γ ELISPOT analysis. Detailed analysis of intracellular cytokine expression indicated a strong CD8 response. saRNAs coding for ERG also showed antigen-specific ELISPOTs. Using commercially available recombinant ERG protein, an ELISA was developed and a strong humoral response to the ERG saRNA vaccine was demonstrated. The saRNA vaccines will be further credentialled with additional preclinical studies including cancer preventive efficacy studies in genetically engineered mouse models of prostate cancer.

#4779 The effects of glutamine deprivation on ovarian cancer initiation and progression.

S. Ferri-Borgogno[1], K. Lu[1], B. T. Gamal[1], C. Au Yeung[1], E. Seeley[2], J. A. Gomez[1], A. Basi[1], J. K. Burks[1], O. Animasahun[3], D. Nagrath[3], S. C. Mok[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Texas at Austin, Austin, TX, [3]The University of Michigan, Ann Arbor, MI

High-grade serous ovarian cancer (HGSC) is the most common subtype of ovarian cancer. Most patients with HGSC are diagnosed at advanced stage diseases. Despite the high response rate to platinum/taxane-based chemotherapy, most of these patients will develop recurrent chemoresistant disease. Recent studies showed the cancer associated fibroblasts (CAFs) in the tumor microenvironment (TME) play an important role in modulating the malignant phenotypes of HGSC. CAFs are primarily responsible for producing factors such as cytokines and growth factors to modify the TME niche to promote the malignant phenotypes of cancer cells. Recently, we have identified a previously unrecognized mechanism in which metabolism of reactive CAFs is reprogrammed through an upregulated glutamine anabolic pathway in HGSC. This dysfunctional CAF metabolism confers atypical metabolic flexibility and adaptive mechanisms in CAFs, allowing them to harness carbon and nitrogen from noncanonical sources to synthesize glutamine in nutrient-deprived conditions existing in the TME. Our preliminary data show that tumors developed from syngeneic fallopian epithelial cell-derived cancer cells injected IP into C57BL/6 mice, which started to be fed with normal diet two weeks before tumor cells injection had significantly higher tumor burden than those fed with the glutamine-deprived diet. Moreover, tumor-bearing mice treated with glutaminase inhibitor for 3 weeks demonstrated significantly lower tumor burden than those treated with the control vehicle. These findings suggest that the interplay between CAFs and HGSC cells enriches glutamine in the ovarian TME; and glutamine depletion can not only suppress ovarian tumor growth but also prevent the development of advanced progressive diseases. In addition to the direct promoting effect of glutamine on the glutamine addicted HGSC cells, increased CAF-derived glutamine can also affect the activity of other stromal cell types such as immune cells in the TME, which subsequently modulate HGSC cell growth. Imaging mass cytometry (IMC) and Mass Spectrometry Imaging (MSI) were performed on serial tissue sections of tissue microarrays generated from the abovementioned murine samples. Mice fed with a glutamine-deprived diet or treated with the glutaminase inhibitor not only have a significantly lower tumor burden but also induced dramatic changes in the cellular and molecular composition within the TME. In particular, mice fed with a glutamine-deprived diet had greater B-cell-related immune response, reduced stemness, and EMT of ovarian cancer cells, and more activated CAFs, which may result in increased stiffness of the ECM and subsequently enhance the malignant phenotype of HGSC cells. Further studies to delineate the molecular mechanisms by which spatial cellular and metabolic profiles modulate HGSC pathogenesis and progression are warranted.

#4780 TRAIL-inducing imipridone ONC201/TIC10 demonstrates anti-neoplastic effects in colonic adenoma-derived organoids.

A. J. Lannigan[1], J. Chan[1], M. Schwermann[1], L. Zhou[1], V. V. Prabhu[2], M. Dame[3], D. Brenner[3], W. S. El-Deiry[1], A. G. Raufi[1];
[1]Brown University, Providence, RI, [2]Chimerix Inc., Durham, NC, [3]University of Michigan, Ann Arbor, MI

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related death inthe United States and screening is the most effective method to reduce mortality. Chemoprevention, which aims to prevent CRC through eradication or prevention of precursor colonic adenomas, represents an alternative strategy to address this problem. The imipridone dordaviprone (ONC201) has been shown to induce apoptosis in cancer cells through both upregulation of tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) and the integrated stress response. More recently, we have shown that ONC201 induces TRAIL and apoptosis in a dose-dependent manner and reduces adenoma formation in the *Apc*$^{min/+}$ CRC mouse model. We hypothesized that ONC201 would similarly enhance human colonic adenoma cell death through both TRAIL-dependent and TRAIL-independent mechanisms. We therefore evaluated the effects of ONC201 in two adenoma-derived organoid lines: one developed from an adenoma obtained from an individual with familial adenomatous polyposis (FAP) and the second from a sessile serrated adenoma (SSA).
Methods: Sensitivity of the FAP and SSA organoid lines to ONC201 was assessed using CellTiter-Glo® luminescent cell viability assay. Organoids were plated in triplicates and treated with ONC201 (concentration ranging from 0 uM to 20 uM). Results were analyzed after 72 hours of incubation. Western blotting was performed on lysates generated from organoids treated with either 1.69 uM DMSO, 1.69 uM ONC201, or 3.38 uM ONC201 for FAP and 1.23 uM DMSO, 1.23 uM ONC201, or 2.46 uM ONC201 for SSA for 0, 24, or 48 hours. Co-culture experiments were performed with the adenoma-derived organoids (dyed using blue CMAC dye) and human NK-92MI cells (dyed with green CMFDA dye) treated with either 845 nM DMSO, 845 nM ONC201, or 1.69 uM ONC201 for FAP and 615 nM DMSO, 615 nM ONC201, or 1.23 uM ONC201 for SSA. Fluorescent images following administration of red live/dead dye were performed using DAPI, FITC, and cherry red channels on ImageXpress® at 0, 24, 48, and 72hours.
Results: ONC201 demonstrated antineoplastic effects in adenoma-derived FAP and SSA organoids. Half maximal inhibitory concentrations (IC50) of ONC201 in FAP and SSA organoids were 1.69 uM and 1.23 uM, respectively. As was noted in rodent studies, the mechanism of action of ONC201 appears to be mediated through modulation of multiple pathways including the TRAIL pathway (TRAIL and DR5 were both upregulated) and the integrated stress response (ATF4 was upregulated). Co-culture with NK cells revealed an increase in NK-mediated organoid cell death. The ability of ONC201 to enhance NK-mediated killing is still being evaluated. Further analysis of the effects of ONC201 on stemness markers and on T-cell-mediated organoid cell killing are currently underway and may reveal other potential biomarkers and chemopreventive strategies for ONC201.

#4781 Evaluation of a TP53 biomarker for lung cancer risk in nasal brushings and peripheral blood.

E. L. Crawford[1], D. J. Craig[1], P. T. Gorman[1], M. Omballi[1], R. Ahmad[1], E. L. Grogan[2], S. A. Deppen[2], **J. C. Willey**[1];
[1]University of Toledo, Toledo, OH, [2]Vanderbilt University Medical Center, Nashville, TN

Background and Purpose: Early detection of lung cancer through annual screening with low-dose computed tomography (LDCT) scans enables potentially curative surgical or stereotactic body radiation therapy (SBRT) treatment and thereby significantly reduces mortality. However, LDCT screening among those currently eligible based primarily on age and smoking criteria yields a large number of false-positive findings and many lung cancers occur among individuals who currently are ineligible. A biomarker that identifies lung cancer risk independent from that caused by age and cigarette smoking might increase specificity and increase the number of people eligible for LDCT screening. Recently we demonstrated that a biomarker measuring TP53 somatic mutations in bronchial brush biopsy specimens from grossly normal airway epithelium was significantly associated with cancer status independent of age and smoking status. Additionally, the TP53 biomarker was synergistic with traditional risk score models (e.g. $PLCO_{M2012}$ risk score). The goal of this pilot study was to test the TP53 biomarker in nasal brush biopsy specimens, a potential surrogate tissue obtained using less invasive collection methods. **Methods:** Nasal brushings from 10 lung cancer and 11 control subjects were collected at the University of Toledo and Vanderbilt University Medical Center under approved institutional protocols. Genomic DNA (gDNA) was extracted with the Qiagen AllPrep DNA/RNA kit using a modified protocol. Amplifiable copies of gDNA were measured using quantitative PCR. For each test a sample comprising 25,000 amplifiable copies of gDNA was combined with 50,000 copies of a TP53 internal standard and a complexity control, then PCR amplified, purified and barcoded. Samples were pooled to create two NGS libraries, each with approximately equal numbers of cases and controls, and sequenced on an Illumina MiSeq (Two V3 flow cells, 2 x 250 paired-end). Bioinformatic analysis was conducted using Qiagen CLC Workbench. Variants were called using the Basic Variant Detection Tool. Poisson Exact Test was utilized to determine the significance of endogenous variants relative to internal standard variants at the same base position and a Bonferroni correction was applied to minimize false discovery. Comparison of variant numbers between cases and controls was conducted using an f-test followed by a paired t-test. **Results and Conclusions:** Consistent with previous results in airway epithelium, in this pilot study the TP53 mutation biomarker measured in nasal brushing was associated with lung cancer ($p=0.0085$). Measurement of the TP53 biomarker in nasal brush specimens in a larger case-control study currently is underway along with a pilot study in gDNA from peripheral blood.

PREVENTION / EARLY DETECTION / INTERCEPTION: Population-Based Screening
Poster Session

#4784 PATHFINDER 2: A prospective study to evaluate safety and performance of a multi-cancer early detection test in a population setting.

K. V. Giridhar[1], M. J. Demeure[2], R. H. Kim[3], J. A. Chen[4], S. Gadgeel[5], D. Kurbegov[6], M. Lopatin[4], R. Matthews[7], M. Matrana[8], C. McDonnell[9], D. Richards[10], B. Rybicki[5], G. Stipec[11], N. Nabavizadeh[12];

[1]Mayo Clinic, Rochester, MN, [2]Hoag Memorial Hospital Presbyterian, Newport Beach, CA, [3]University Health Network, Toronto, ON, Canada, [4]GRAIL, LLC, Menlo Park, CA, [5]Henry Ford Health, Detroit, MI, [6]Sarah Cannon Research Institute, Nashville, TN, [7]Morehouse School of Medicine, Atlanta, GA, [8]Ochsner Clinic Foundation, New Orleans, LA, [9]Sutter Institute For Medical Research, Sacramento, CA, [10]Texas Oncology, Tyler, TX, [11]Long Beach Memorial Medical Center, Long Beach, CA, [12]Oregon Health & Science University, Portland, OR

Background: Multi-cancer early detection (MCED) tests are being established as a novel approach to screen for multiple cancer types with one test. A blood-based MCED test using cell-free DNA targeted methylation patterns to detect a shared cancer signal and predict a cancer signal origin (CSO) has demonstrated feasibility. An initial return of results study (PATHFINDER; NCT04241796) reported performance of a refined version of the MCED test, including a 43.1% positive predictive value (PPV), 98.5% negative predictive value (NPV), 99.5% specificity, and 88.0% CSO accuracy. To build on this work, the PATHFINDER 2 study (NCT05155605) will evaluate safety and performance of the MCED test in larger, more diverse populations.

Methods: PATHFINDER 2 is a prospective, multicenter, interventional study. Participants ≥50 years of age will be enrolled, with specific targets to improve diversity (age, sex, race/ethnicity) and few exclusions due to comorbid conditions. Exclusion criteria include current clinical suspicion of cancer or recent cancer/treatment (within 3 years). Participants will undergo blood draw for MCED testing, followed by return of results (cancer signal detection and CSO) to the investigator and diagnostic evaluations if a cancer signal is detected. A confirmatory PET-CT scan will be performed when CSO-directed workups do not result in a cancer diagnosis. Participants will be followed for approximately 3 years. Primary endpoints include 1) MCED test safety in terms of diagnostic testing triggered by a positive result (number/type of procedures and adverse events) and 2) test performance (PPV, NPV, specificity, sensitivity, CSO accuracy, cancer detection rate and number needed to screen). Secondary endpoints include participant reported outcomes (eg, anxiety), utilization of guideline-recommended cancer screening, and cancer detection rate of confirmatory PET-CT, amongst others.

The study plans to enroll approximately 35,000 participants across North America. Sites were selected based on geographic location, catchment area demographics, and practice setting (academic vs non-academic). Enrollment targets for age, sex and race/ethnicity (White [non-Hispanic] 72%; Hispanic or Latino 11%; African American or Black 11%; Asian, Native Hawaiian or Other Pacific Islander 6%; American Indian/Alaska Native 1%) were derived from US Census data. Strategies to promote diverse recruitment include translation of participant-facing documents across multiple languages, participant and healthcare provider educational material, and site-led community outreach campaigns.

MCED testing is an emerging, potentially paradigm-changing strategy in cancer screening, and PATHFINDER 2 is designed to characterize the safety, performance, and clinical implementation of the MCED test as a screening tool in a broad and representative population.

#4786 Colorectal cancer screening rates among deaf, deafblind, and hard of hearing adults aged 45 to 75 years old.

R. M. Wang[1], S. R. Rao[2], **E. J. Bergeron**[3], E. C. Perrodin-Njoku[3], P. Kushalnagar[3];
[1]University of California at San Diego Health, San Diego, CA, [2]Boston University, Boston, MA, [3]Gallaudet University, Washington, DC

Background: Deaf, deafblind, and hard of hearing (DDBHH) individuals who use American Sign Language (ASL), a subpopulation of the disability, experience disparities concerning cancer screening and cancer-related health outcomes. For this study, we explored colorectal cancer screening rates among DDBHH survey respondents in comparison to rates found in the hearing population.
Materials and Methods: Using the National Cancer Institute Health Information National Trends Survey in ASL (Kushalnagar et al., 2015), we surveyed participants 18+ years old using the Center for Deaf Health Equity at Gallaudet University's database of over 2,500 DDBHH participants from all over the USA, including Hawaii and Puerto Rico. We used the U.S. Preventive Services Task Force (USPSTF) guidelines' age cutoffs to assess adherence to colorectal cancer screenings.
Results: Survey response rate within three weeks of mail out in July 2023 was 12%. A total of 405 DDBHH adult participants answered screening questions for colorectal cancer in ASL and English. Overall, 43.7% self-reported screening adherence for age-eligible (45-75 years) colorectal cancer screening; 54.7% reported never having a colorectal cancer screening. Similarly-aged hearing adults reported 58.7% adherence in the English version of the National Health Interview Survey (NHIS).
Discussion: With the 43.7% adherence rate, the DDBHH community is lagging behind colorectal cancer screenings compared to the general population of hearing adults. Estimating the colorectal cancer screening rates among the DBHH community and understanding the reasons for these existing disparities is important to achieve screening adherence of 68.3%, the target set by the Healthy People 2030. Such research will aid the Center for Deaf Health Equity to actively work with the community to improve strategies to increase colorectal cancer screening.

#4787 Preference for multi-target stool DNA for colorectal cancer screening among Alaska Native people in rural/remote communities.

D. Redwood;
Alaska Native Tribal Health Consortium, Anchorage, AK

Background: The Alaska Tribal Health System is working on increasing colorectal cancer (CRC) screening rates among Alaska Native people, who have the highest CRC rates in the world. Most remote Alaska Native communities are not connected to the road system, which severely limits access to screening colonoscopy. As part of a clinical trial, Alaska Native patients were offered either colonoscopy or the at-home multi-target stool DNA test (mt-sDNA; Cologuard®). Patients had never been offered mt-sDNA before and it was unknown what they would think about the new test option. Both tests were provided at no cost to patients.
Methods: From April 2022 to July 2023, 194 patients who chose mt-sDNA for screening received a follow-up phone survey asking whether they were aware that they could have had colonoscopy instead, their reasons for choosing mt-sDNA, and the factors influencing their choice of mt-sDNA over colonoscopy. Patients answered the survey before receiving results of their mt-sDNA test in order to capture initial screening test preferences.
Results: A total of 115 (59%) Alaska Native patients participated in the survey; 56% men and 44% women. About 70% were ages 45 to 60 years while the remaining 30% were 61 to 75 years old. The majority (80%) were aware that they had the option to undergo colonoscopy for CRC screening instead of mt-sDNA. Key themes for mt-sDNA preference included not having to travel, less time commitment, and greater convenience. Many patients expressed financial concerns arising from the costs of air travel and accommodation required to access screening colonoscopy even though the procedure itself was covered. Additionally, patients highlighted existing obligations such as childcare and work responsibilities which made the use of mt-sDNA at home more appealing. Many respondents also shared negative perceptions of colonoscopy procedure including fear, embarrassment, and discomfort as reasons why they preferred mt-sDNA instead.
Conclusions: These findings demonstrate the multifaceted factors influencing the preference for at-home mt-sDNA CRC screening among Alaska Native individuals. Challenges such as limited access to medical facilities, financial burdens, and personal commitments have significant bearing on the screening decision-making process. Moreover, the emotional aspect of fear and discomfort associated with colonoscopy plays a role in shaping these preferences. CRC screening programs need to be aware of patient needs and preferences when deciding which screening methods to offer to increase screening rates and result in improved colorectal health outcomes.

#4788 Noninvasive longitudinal monitoring of residual disease in chemotherapy-treated colorectal cancer patients.

Alison D. Tang, Rebecca Gupte, Victoria Cheung, Tao Qing, Austin Cauwels, Emily Leff, Kimberly Walter, Ehsan Tabari, Alex Lovejoy, Jimmy C. Lin

Freenome, Inc., South San Francisco, CA

Noninvasive monitoring of cancer shows great promise in assessing therapy response and improving patient outcomes. Recently, various groups have developed methods that detect circulating tumor DNA (ctDNA) in the plasma to measure minimal or molecular residual disease (MRD). Aberrant DNA methylation patterns are a hallmark of cancers, and robust signals can be detected by sensitive ctDNA assays. Here, we present a methylation-based approach for longitudinal monitoring of tumor burden that is tumor-naive, i.e., with no reliance on prior characterization of tumor molecular characteristics. We assess the effectiveness of our approach in a cohort of colorectal cancer (CRC) patients receiving chemotherapy with or without additional targeted agents.
Longitudinal blood samples were collected from patients (n = 57) while on therapy, which averaged 4.9 months, for a total of 239 sample collection time points (median per patient = 5). Based on RECIST status, 16 patients were classified as complete responders (CR) at the end of treatment.
We generated plasma cell free DNA-derived libraries for methylation sequencing targeting regions relevant to CRC. Next, we computed a disease burden score for each sample and related these scores to clinical response (CR vs. non-CR). We trained a classifier on an independent cohort of CRC and healthy donor plasma cfDNA samples, and used this classifier to check for residual disease at the end of treatment for each of our 57 patients. The classifier detected residual disease in only 3/16 CRs (19%) but 35/41 non-CRs (85%).
Two of the non-CR patients were initially assessed as CRs at earlier time points. In both cases, our method successfully detected residual disease at or prior to the CR assessment and consistently showed residual disease in all follow up samples. This suggests improved sensitivity relative to RECIST and highlights the potential of using noninvasive blood tests for continuous monitoring of CRC patients receiving therapy.*Authors contributed equally to the work

#4790 Hospitalization as an opportunity to improve lung cancer screening in high-risk patients.

E. M. Nielsen, J. Zhang, J. Marsden, C. Bays, W. P. Moran, P. D. Mauldin, L. A. Lenert, B. A. Toll, A. D. Schreiner, M. Heincelman;
The Medical University of South Carolina (MUSC), Charleston, SC

Background: Lung cancer screening with annual low-dose computed tomography (LDCT) in high-risk patients with exposure to smoking reduces lung cancer-related mortality, yet the screening rate of eligible adults is low. As hospitalization is a critical moment to engage patients in their overall health, it may be an opportunity to improve rates of lung cancer screening. Prior to implementing a hospital-based lung cancer screening referral program, this study assesses the association between hospitalization and completion of lung cancer screening.
Methods: A retrospective cohort study of evaluated completion of at least one LDCT from 2014-2021 using electronic health record data using hospitalization as the primary exposure. Patients aged 55-80 who received care from a university-based internal medicine clinic and reported cigarette use were included. Univariate analysis and logistic regression models evaluated the association of hospitalization and completion of LDCT. The secondary outcome was completion of any CT of the chest.
Results: Of the 1,935 current smokers identified, 47% had at least one hospitalization, and 21% completed a LDCT during the study period. While a higher proportion of patients with a hospitalization had a LDCT (24%) compared to patients without a hospitalization (18%, $p<0.001$), there was no association between hospitalization and completion of a LDCT after adjusting for potentially confounding covariates (95%CI 0.680 - 1.149). Of cohort patients, 38% completed any CT of the chest and hospitalization was associated with increased odds of receiving chest CT imaging in the adjusted model (OR 1.72; 95%CI 1.37 - 2.17).
Conclusions: In a cohort of patients at risk for lung cancer, only 1 in 5 completed lung cancer screening with LDCT and hospitalization events were not associated with LDCT completion. A hospitalist driven lung cancer screening program has the potential to increase the suboptimal rates of lung cancer screening in high-risk patients.

#4791 Characterizing interventions to reduce disparities in lung-cancer screening uptake by state Medicaid expansion status: A scoping review.

M. J. Reid, C. Washington, M. Wheeler, L. Adkins, D. Braithwaite, R. Salloum;
University of Florida College of Medicine, Gainesville, FL

Background: Lung cancer is the leading cause of cancer-related deaths in the United States, and yet, lung cancer screening rates remain persistently low. Many interventions are being developed to address the low rates of lung cancer screening (LCS), including interventions that address the additional barriers faced by historically marginalized racial and ethnic populations as well as low-income and rural populations. However, the impact of Medicaid expansion on the types of interventions developed in non-expansion states and the efficacy of those interventions is not well understood.
Methods: A research librarian conducted searches in MEDLINE via PubMed, Web of Science, and Embase. Results were screened and evaluated for eligibility by three reviewers in Covidence. Data was extracted from included studies after full-text review and analyzed using both a thematic analysis and a descriptive numerical summary of studies. The chosen framework was based on scoping review guidelines by Levac et al. and Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for scoping reviews (PRISMA-ScR).
Results: Of 4696 studies found through the initial search, 53 met inclusion criteria. This includes 34 studies in Medicaid expansion states (M) and 17 studies in non-Medicaid expansion states (NM). Two additional studies compared interventions implemented in a Medicaid expansion state to a similar intervention implemented in a non-expansion state. Studies in both groups were primarily focused on addressing disparities by race and ethnicity (M=74%; NM=65%), with fewer studies focusing on rurality (M=9%; NM=12%), income (M=9%; NM=0%), or multiple disparities (M=9%; NM=24%). In non-expansion states, the most common interventions were patient navigation (29%) and community outreach (24%). While in Medicaid expansion states, the most common interventions were EHR algorithms (24%) and decision aids (21%). The intervention setting for both Medicaid expansion and non-expansion states were most commonly in a hospital/health system (M=53%; NM=47%) or community setting (M=24%; NM=47%). Interventions in both groups typically showed some improvement in uptake of LCS, though the degree of impact was variable between studies.
Conclusion: Due to continued barriers to access posed by inadequate insurance coverage, there is a critical need for interventions to reduce disparities in lung cancer mortality in states that have not expanded Medicaid. Interventions focused on patient navigation and community outreach have been effective in multiple settings in these states and could fill that gap.

#4792 Nationwide patterns of incidence and surveillance of second primary lung cancer among long-term lung cancer survivors using SEER Medicare data.

Chloe C. Su[1], Eunji Choi[2], Julie T. Wu[3], Allison W. Kurian[1], Michelle C. Odden[1], Manisha Desai[4], Leah M. Backhus[5], Heather A. Wakelee[6], Ann N. Leung[7], Joel W. Neal[6], Summer S. Han[2]

[1]Epidemiology and Population Health, Stanford University School of Medicine, Palo Alto, CA,[2]Quantitative Sciences Unit, Stanford University School of Medicine, Palo Alto, CA,[3]Veterans Affairs Palo Alto Healthcare System, Palo Alto, CA,[4]Biomedical Data Science, Stanford University School of Medicine, Palo Alto, CA,[5]Department of Cardiothoracic Surgery, Stanford University School of Medicine, Palo Alto, CA,[6]Division of Oncology, Stanford University School of Medicine, Palo Alto, CA,[7]Department of Radiology, Stanford University School of Medicine, Palo Alto, CA

Background: With advances in screening and therapy, the number of lung cancer (LC) survivors is rapidly increasing, with over half a million as of 2019. Prior studies demonstrated that the incidence of second primary lung cancer (SPLC) among LC survivors is 4-6 times that of initial primary lung cancer (IPLC) in the general population. However, the incidence of SPLC and surveillance strategies using computed tomography (CT) have not been examined in long-term LC survivors with over 5-year survival. We aim to estimate SPLC incidence among long-term survivors and the effectiveness of annual surveillance CT exams.
Methods: We used data from SEER-Medicare with a cohort of 1,232,338 LC patients from the SEER cancer registry followed till death or last follow-up, who were also enrolled in Medicare in 1999-2020. The study cohort included 12,948 patients who were long-term survivors (≥ 5-year survival from IPLC) by age 65, received curative therapy for IPLC, and were continuously enrolled in Medicare 1 year prior to 5 years after IPLC diagnosis. The primary outcome was the 10-year cumulative SPLC incidence accounting for competing risk of death in the full study cohort and by receipt of surveillance CTs post-5-year survival, defined using detailed billing and LC-related ICD codes. To qualify as surveillance CTs, two annual CTs 9-18 months apart is required. Cox regression was used as exploratory analysis to examine the association between LC-specific survival (LC as cause of death) and the receipt of two CTs post-5-year survival as a binary variable, adjusting for SPLC diagnosis, age, sex, marital status, race, IPLC stage, income, education, and poverty.
Results: Of 12,948 long-term LC survivors, 46% (n=6,015) were male, 90% (n=11,476) had early-stage disease, 77% (n=9,945) had undergone surgery for initial curative treatment, and 3.8% (n = 486) received two surveillance CTs initiated within 18 months post-5-year survival. The 10-year cumulative incidence of SPLC was 5.06% [95% CI: 5.00-5.12%] in the SEER cohort but was substantially higher among long-term LC survivors at 13.6% [13.0-14.2%]. Those who received two annual surveillance CTs after 5-year survival had a significantly higher 10-year SPLC incidence (23.3% [19.4 - 27.2%]) than those who received one or no CT (13.2% [12.6 - 13.8%]). The adjusted hazard ratio of the association between LC-specific survival and receipt of two CTs was 0.67 [0.59-0.80, $p < 0.0001$].
Conclusions: The high cumulative risk of SPLC among long-term LC survivors warrants tailored surveillance strategies. Our exploratory analysis showed a high SPLC detection rate among those who received two annual surveillance CTs vs. those who did not, with significantly higher LC-specific survival in the former. Future work will include extensive analysis accounting for time-varying exposure of multiple surveillance CTs using rigorous causal inference methods.

#4793 Effects of treatment delays on lung cancer survival.

P. Guzman Montero[1], S. Segura Cordero[2];
[1]National Cancer Institute, Bethesda, MD, [2]Universidad Internacional de las America, San Jose, MD

Background: Previous studies have established a link between treatment initiation delays and reduced overall survival in individuals diagnosed with lung cancer. These delays are often influenced by diagnostic complexities, logistical hurdles, and patient-related factors. However, the association between treatment delays and survival outcomes has yet to be extensively investigated using data from a large national cohort. This study aims to fill this research gap and provide unique insights into the relationship between treatment delays and lung cancer survival by utilizing data from a substantial national cohort.
Methods: The study population consisted of 3,723 lung cancer patients participating in the NCI PLCO Cancer Screening Trial. Cox Proportional Hazards (PH) Regression analyses examined the time between cancer diagnosis and treatment initiation using several measures including intervals from tumor doubling/stage progression time models by Spratt et al. (1964) and Detterbeck et al. (2008). Analyses controlled for patient and clinical characteristics including age, sex, race/ethnicity, smoking status, histopathologic type, cancer stage, and treatment modality. Data analysis was conducted using Microsoft Excel, STATA, and IBM SPSS software.
Results: PH Regression analyses demonstrated a clear association between longer time intervals from diagnosis to treatment initiation and increased risk of mortality. Patients with time intervals exceeding 20 days exhibited a hazard ratio (HR) for mortality of 1.21 ($p < 0.001$, 95% confidence interval [CI] 1.1158-1.3176). The Spratt tumor progression model, considering intervals exceeding 88 days, revealed a HR of 1.22 ($p = 0.03$, 95% CI 1.0146-1.4885). On the other hand, the Detterbeck model, which considered intervals exceeding 118 days, did not show a statistically significant association with increased mortality risk. Furthermore, PH analysis identified cigarette smoking status, marital status, and tumor grade as significant predictors of mortality risk.
Conclusions: Data from a large national cohort study indicate that delays in lung cancer treatment initiation have detrimental impacts on survival. Treatment initiation shortly after diagnosis had the most significant differential impact on mortality risk. Timely initiation of treatment is of utmost importance and should be prioritized in lung cancer care. By addressing factors contributing to treatment delays, it is likely possible to improve the survival rates of patients with lung cancer.

#4794 Impact of prior upper endoscopy on gastric cancer stage and survival.

S. Wagner[1], J. S. Ferris[1], J. Soddano[1], J. Yoon[2], S. D. Rustgi[1], H. Zylberberg[1], J. Yang[1], Y. Huang[3], L. Chen[3], C. Hur[1];
[1]Columbia University Irving Medical Center, New York, NY, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]Columbia University College of Physicians and Surgeons, New York, NY

Background: While gastric cancer (GC) incidence in the US has decreased, 5-year survival remains at 34.5%. Early diagnosis offers curative or treatable options, yet many cases are detected at an advanced stage with poor prognosis. In high-incidence East Asian countries with established screening programs, endoscopic screening demonstrates stage shift towards early GC diagnosis and reduced GC-related mortality. Analyses of these programs have reported benefit of endoscopic screening up to 36 months prior to diagnosis. This study explores the impact of esophagogastroduodenoscopy (EGD) in this timeframe on GC stage at diagnosis and survival in an older US population.

Methods: The SEER-Medicare database was queried from 2000 to 2017 for patients 68 years of age or older with histologically confirmed GC with continuous Medicare enrollment for at least 36 months prior to GC diagnosis. We excluded patients with prior cancer history and those diagnosed by autopsy or death certificate. Medicare claims files were searched for EGD claims 6-36 months prior to GC diagnosis. We excluded claims in the 6 months prior to diagnosis to avoid capturing potential diagnostic EGD. We defined the exposed group as patients with an EGD claim 6-36 months prior to GC diagnosis (Prior EGD) and the unexposed group as patients with no EGD claim in this period (No Prior EGD). Propensity score analysis balanced baseline differences for patients with and without Prior EGD using covariates sex, age and year of diagnosis, race and ethnicity, rural/urban, comorbidity, SES, and marital status. The primary outcome was in situ/local-stage GC (early) at diagnosis compared to regional/distant-stage (advanced). Secondary outcomes were 5-year overall and GC-specific survival. The adjusted odds of having in situ/local-stage GC diagnosis compared to regional/distant-stage was estimated using logistic regression, and survival analysis was done using the Kaplan-Meier method.

Results: In 10,572 patients with GC (57.5% male, mean age 78.8 years), 16.4% had Prior EGD (n=1,736). Patients with Prior EGD had a significantly higher proportion of GC diagnosed in local stage compared to patients with No Prior EGD (45.7% vs. 30.2%, $p < 0.001$). After controlling for confounders, Prior EGD group had two-fold increased odds of GC diagnosis at early-stage compared with No Prior EGD (OR=1.99, 95% CI: 1.88-2.10). Compared with No Prior EGD, Prior EGD was associated with higher overall survival (5-year survival 32.1% vs. 22.7%, $p<0.001$) and GC-specific survival (5-year survival 46.0% vs. 31.1%, $p\leq0.001$), both driven by early-stage disease.

Conclusions: Our analysis demonstrates that EGD up to 36 months prior to the diagnosis of GC is associated with earlier stage at diagnosis and improved overall and GC-specific survival. This study of an older population suggests that endoscopic screening may be beneficial even in a low-incidence country such as the US and warrants further study.

#4795 Social capital and screening mammography rates in the United States.

Tracy Huang, Christine Ekenga

Emory University, Rollins School of Public Health, Atlanta, GA

Background: Social capital may play a role in screening mammogram utilization by influencing individuals' access to information and providing social support for healthy behaviors. However, few studies have examined associations between community-level social capital and screening mammography use. The purpose of this study was to examine the association between county-level social capital and screening mammography rates in the United States (U.S.).
Methods: We conducted a cross-sectional study of social capital and screening mammography rates across 2,613 U.S. counties for 2014. We obtained county-level data on (1) screening mammography rates for female Medicare enrollees aged 67-69 years and (2) social capital (Penn State Social Capital Index). Multivariable regression models were used to evaluate associations between social capital quartiles and mammography screening rates. Models were adjusted for county-level socioeconomic, demographic, and access to care factors.
Results: Average county-level screening mammography rates were 60.5% ± 8.3% (range 26%-88%). Across all U.S. counties, social capital was associated with county-level mammography rates, after adjusting for covariates ($p < 0.001$). This association did not vary by urban-rural classification. In analyses by region, associations between social capital and screening mammography rates were strongest in the West region ($p<0.001$).
Conclusions: In this nationwide study, social capital was significantly associated with screening mammography. Our findings suggest that there are regional variations in the association between social capital and mammography rates. The relationship between social capital and cancer screening behaviors warrants further investigation, particularly in the U.S. West.

#4796 Improving cancer screening performance for women with dense breast tissue.

M. Smith, M. Wang, A. Carson, B. Lee, M. Salmans, B. Leatham;
Genece Health, Inc., San Diego, CA

Breast cancer is the most common cancer in women in the United States. To reduce mortality, screening by mammography in females is recommended by the United States Preventive Services Task Force, successfully reducing mortality by 15 - 32% in women aged 40 - 69 years. This is partially due to the high compliance rate (60 - 80%) among the candidate population. Mammography increases early-stage disease detection, which is correlated with better outcomes. While mammography has been largely successful, this screening method has limitations. Overall, mammography has false-negative and false-positive rates estimated at 12 - 20% and 7 - 12%, respectively. Consequently, annual mammograms result in 50 - 60% of women having a false-positive result within a 10-year span. Additionally, high breast density, found in approximately 50% of females over the age of 40, increases susceptibility to false positive and negative results. For this reason, in 2023 the FDA required that dense breast tissue status, an independent risk factor for cancer, be disclosed to mammogram recipients. The subsequent diagnostic pathway for women with dense breast tissue is not well defined for the care provider. Alternative imaging options have performance issues or are less accessible. Here we describe a liquid biopsy test to complement mammography in women with dense breast tissue to help resolve ambiguity in results. Blood from early- and late-stage breast cancer patients was prospectively collected in Streck cfDNA BCT Devices (n=100) or retrospectively acquired (n=100); and blood from presumed normal samples was collected (n=200). cfDNA was extracted and converted into libraries for low-pass whole genome sequencing (LP-WGS). Sequenced reads were analyzed to generate fragment end-motif and size (FEMS) and fragment coverage dataframes for classification using Genece Health's proprietary analysis pipeline and machine-learning (ML) algorithm. 150 breast cancer samples distributed across stages and 150 presumed normal samples were selected to create a training cohort. Performance was tested using a 5-fold cross validation strategy. The best performance was observed using a convolution neural network (CNN) ML model with >80% sensitivity when specificity was set at 85%. The remaining 50 breast cancer samples and 50 presumed normal samples were used as an external test set. The performance in this cohort was comparable to the training cohort, with both specificity and sensitivity >80%. Genece presents an early proof of concept breast cancer screening liquid biopsy assay that uses LP-WGS fragmentomics and ML to detect cancer from a single blood sample. Continuing development with additional cohorts and optimization will yield even greater performance. The Genece liquid biopsy test has the potential to be paired with mammography, especially in women with dense breast tissue, to improve screening sensitivity, specificity, and overall outcomes.

#4797 Impact of COVID-19 pandemic on breast cancer screening and diagnosis stage in a large midwestern United States academic medical center.

K. J. Johnson, R. Waken, C. P. O'Connell, D. Brown;
Washington University in St. Louis, St. Louis, MO

Background: Access to breast cancer screening mammogram services decreased in association with the COVID-19 pandemic. There is also evidence for increases in late-stage breast cancer diagnoses. Our objectives were to determine: 1) the COVID-19-affected period on mammogram screening, 2) the proportion of pandemic-associated missed or delayed mammogram screening visits overall and by race/ethnicity and age group, and 3) evidence for pandemic-associated shifts in diagnosis stage.
Methods: Screening mammogram encounter data between 1-1-2019 and 12-31-2022 were extracted from EPIC for females ≥ 40 years old for the screening analysis. We used Bayesian state space models to describe weekly screening mammogram counts, modeling an interruption that phased in and out from 3-1-2020 to 9-1-2020. We used the posterior predictive distribution to simulate differences between a predicted, uninterrupted process and the observed screening mammogram counts. Breast cancer diagnoses at ≥ 21 years from the tumor registry between 12-1-2018 and 11-30-2021 were included in the stage analysis. We used logistic regression models to estimate late-stage diagnosis odds comparing matched three-month periods during the pandemic to before the pandemic.
Results: A total of 319,492 encounters among 146,644 women were included. Model-estimated screening mammograms dropped by 98.8% (95% CI 95.1 to 100) between 3-15-2020 and 5-24-2020, returning to pre-pandemic levels or higher after this period. Drops in screening mammogram encounters did not vary significantly by race/ethnicity or age group ($p > .75$). Among 4,669 breast cancer diagnoses, we found no significant differences in the odds of late-stage diagnoses for any period vs. the same period before the pandemic (Table).
Conclusions: These data suggest a short-term pandemic effect on screening mammograms. Evidence for increases in late-stage diagnoses is limited. These results may inform future pandemic planning.

OR (95% CI)	Period comparison
1.19 (0.74 to 1.91)	3/2020 to 5/2020 vs. 3/2019 to 5/2019
1.05 (0.69 to 1.60)	6/2020 to 8/2020 vs. 6/2019 to 8/2019
1.14 (0.73 to 1.78)	9/2020 to 11/2020 vs. 9/2019 to 11/2019
0.92 (0.60 to 1.41)	12/2020 to 2/2021 vs. 12/2019 to 2/2020
1.08 (0.71 to 1.65)	3/2021 to 5/2021 vs. 3/2019 to 5/2019
0.89 (0.59 to 1.33)	6/2021 to 8/2021 vs. 6/2019 to 8/2019
1.31 (0.84 to 2.04)	9/2021 to 11/2021 vs. 9/2019 to 11/2019

#4798 MRI screening for brain metastases (BrM) versus SYMptom-directed brain imaging for patients with triple negative (TN) or HER2+ metastatic breast cancer (MBC): An ad-hoc interim analysis of a randomized phase II pilot study.

K. J. Jerzak[1], M. Shum[1], G. Pond[2], O. Freedman[3], G. Chandhoke[3], T. Conrad[1], P. Brastianos[4], G. Stanisz[5], A. Sahgal[1], E. Warner[1];
[1]University of Toronto, Toronto, ON, Canada, [2]McMaster University, Toronto, ON, Canada, [3]Lakeridge Health, Oshawa, ON, Canada, [4]Harvard Medical School, Boston, MA, [5]Sunnybrook Research Institute, Toronto, ON, Canada

Background: Patients with HER2+ or TN MBC are at high risk of developing BrM, but the role of MRI screening for early detection of asymptomatic BrM has not yet been established.
Methods: We conducted a multicentre phase II pilot study, which randomized patients with TN or HER2+ MBC to 1 year of BrM screening (contrast enhanced brain MRI at baseline, 4, 8, and 12 months) versus a control arm of symptom directed brain imaging (MRI only if symptoms of BrM develop). The primary goal was to determine the feasibility of a future randomized trial of BrM screening versus symptom-directed imaging in this patient population. Key inclusion criteria were age ≥18; TN MBC diagnosed ≤12 weeks prior to study entry or HER2+ MBC with no restrictions regarding time of diagnosis; no symptoms of BrM or known asymptomatic BrM; ECOG ≥ 1 and no MRI contraindications. Overall (EORTC QLQ BN20) and neurologic-specific (FACT-BR tools) quality-of-life as well as cancer-related anxiety (NCI PRO-CTCAE) were assessed at baseline, 6 and 15 months. Criteria rendering a future trial “not feasible” were defined a-priori as: <30% of eligible patients enroll in the study, <50% complete the study protocol, and/or >50% of patients allocated to the control arm during the 1 year study period are screened for asymptomatic BrM with CT or MRI.
Results: Between 2018 and 2023, 44 patients from 3 participating centres enrolled in the study. Thirty-five participants (80%) had HER2+ and 9 (20%) had TN MBC. Of the 22 patients randomized to each of the study arms; 3 patients (8%) in each arm withdrew prior to study completion. Reasons for withdrawal included claustrophobia (n=3) or discontent with their randomised arm (n=3) or follow-up requirements (n=1). Metrics regarding the proportion of eligible patients who enrolled in the study were only collected from the Sunnybrook Odette Cancer Centre site; of 91 patients approached, 38 (42%) enrolled in the study. Within the 12-month study period, the incidence of BrM among patients in the screening arm was n=3 (14%) versus n=4 (18%) in the control arm. To-date among patients in the study arm, 11 (50%) completed the 12-month screening protocol, 5 (23%) remain on study and 6 (27%) did not complete the protocol due to either death or early study withdrawal. Among patients in the control arm, 10 (45%) completed 12-month follow-up, 4 (18%) remain on study and 8 (36%) did not complete follow-up due to either death or early study withdrawal. In total, 13 patients (59%) in the control arm had brain imaging, 4 in the absence of neurological symptoms.
Conclusion: A large randomized trial to investigate the utility of MRI-based surveillance for asymptomatic detection of BrM in the proposed patient population is likely feasible, although episodic brain imaging in the control arm was common. Analysis of patient reported outcomes is ongoing.

#4799 Hidden epidemics: The gender divide in HCV and cancer screenings among the unhoused.

Talal Al-Assil[1], Claire Kalina[1], Madison Laird[1], Nataly Dawood[1], Raven Riordan[1], Neya Suresh Kumar[1], Ryan Olivier[1], Cheryl Dickson[2], Gitonga Munene[3]

[1]Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI,[2]Department of Diversity, Equity, and Inclusion, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI,[3]Department of Surgery, Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI

Background & Methodology: In the United States, the unhoused population experiences disproportionately higher rates of cancer incidence and mortality—double that of the general populace. Despite these startling statistics, there is a notable dearth of research on this topic within medical literature. Our medical student-led pilot study aimed to bridge this knowledge gap by evaluating the uptake of cancer screenings and identifying the barriers faced by the unhoused in Southwest Michigan. Our objective was to enhance the understanding of cancer care disparities and identify factors that hinder access to cancer screenings for this marginalized group. Utilizing questionnaires distributed in homeless shelters, we collected data on the prevalence and impediments to screenings for hepatitis C virus (HCV), and lung, breast, colon, and cervical cancers in a local community.

Results: The study encompassed 143 participants, revealing that women reported a shorter median duration of homelessness (5 months) than men (18 months). The primary barriers to cancer screening were access to services and lack of awareness, rather than insurance coverage. Gender disparities were evident in HCV screening, with an overall rate of 55%; however, willingness to screen was higher among women (83%) compared to men (49%). Colon cancer screening showed no significant gender disparity, standing at 45% uptake. The prevalence of smoking was high at 78%, yet a higher proportion of men were amenable to lung cancer screening. Interestingly, Pap smear uptake surpassed national averages, while mammogram rates were below expected at 40%.

Discussion & Conclusion: While the discrepancies between genders may not be immediately apparent, our data shows that developing targeted interventions and tailoring the delivery of adequate cancer screenings to the unhoused require consideration of gender as a key factor. Women's perceived barriers differ slightly from men's, and generally-speaking, they undergo more cancer screenings per year compared with men. The reluctance among male participants to engage in HCV screening has been observed in other studies as well and as our study demonstrates, it may be related to informational barriers. Although preliminary, our findings shed light on the critical health care issues faced by the unhoused and serves as a steppingstone towards improving our understanding on their challenges in hopes of improving their health outcomes. Comprehensive research is imperative to unravel the complex causes of these gender-based discrepancies. In the interim, the implementation of a navigator social worker system could prove beneficial in facilitating the unhoused with the logistics of screening processes, overcoming transportation hurdles, and reinforcing the importance of ongoing health management.

#4800 Reducing health disparities for prostate adenocarcinoma by integrating multi-omics data via a multi-modal transfer learning approach.

L. Li, J. Wang, S. Wan;
University of Nebraska Medical Center, Omaha, NE

Prostate adenocarcinoma (PRAD) is the most common subtype of prostate cancer, which is the second leading cause of cancer death in American men. Although significant progress has been made to improve PRAD prognosis, existing studies indicated that Black American men have disproportionately high incidence and mortality rate in prostate cancer compared with non-Hispanic White American men. With artificial intelligence (AI) and machine learning (ML) being increasingly applied to PRAD research and clinical decision-making, PRAD data disparities would introduce bias to AI/ML models and further enhance negative impacts on healthcare towards underrepresented groups. Transfer learning has shown potential to reduce racial disparities in PRAD. However, its performance may be deteriorated due to: (1) its model requires large-scale training samples which are difficult to obtain in clinical settings, and (2) it only uses single-omics data without integrating multi-omics information. To address these concerns, we propose to develop a multi-modal transfer learning model to integrate multi-omics data for reducing health disparities. Specifically, we first investigated two multi-modal ensemble methods, Pearson Correlation Coefficient (PCC) based patient-pairwise similarity, and variational autoencoder (VAE) to integrate different types of omics data. Then, we leveraged a transfer learning model based on domain adaptation to pre-train the model on the majority group (White Americans) and fine-tune the model using the minority group (Black Americans). To further address the imbalanced data among ethnic groups, we explored implementing a data augmentation method, Synthetic Minority Oversampling Technique (SMOTE), to increase the size of minority group data. We evaluated our model on multi-omics data (mRNA, miRNA and methylation) of PRAD from The Cancer Genome Atlas (TCGA) database. Results suggested that our proposed approach achieved better performance of reducing health disparities for Black Americans compared with the mixture model and the independent model as well as the conventional transfer learning model in predicting progression-free interval (PFI) prognosis for PRAD patients. Furthermore, we also demonstrated that SMOTE alleviated the data imbalanced problem and improved the performance of the prognosis classification for ethnic minority groups. In summary, our results demonstrated that our proposed multi-modal transfer learning approach could effectively reduce the performance gap between majority and minority groups in PRAD prognosis, thereby mitigating health disparities. We expect that our proposed multi-model transfer learning framework can be customized and extensible to reduce health disparities in other types of cancer.

#4801 Clinical polygenic model to stratify risk of any, metastatic, and fatal prostate cancer in a randomized controlled trial of precision screening.

A. M. Dornisch[1], R. Karunamuni[1], K. N. Maxwell[2], J. Lynch[3], I. P. Garraway[4], A. Kibel[5], C. A. Brunette[6], M. E. Danowski[6], K. M. Lee[3], S. L. DuVall[3], J. M. Gaziano[7], B. S. Rose[8], R. L. Hauger[8], J. L. Vassy[7], T. M. Seibert[8];

[1]UC San Diego, La Jolla, CA, [2]University of Pennsylvania, Philadelphia, PA, [3]VA Salt Lake City Healthcare System, Salt Lake City, UT, [4]Greater Los Angeles Veterans Affairs Healthcare Center, Los Angeles, CA, [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [6]Veterans Affairs Boston Healthcare System, Boston, MA, [7]VA Boston Healthcare System, Boston, MA, [8]VA San Diego Healthcare System, San Diego, CA

Introduction: Lifetime risk of prostate cancer (PCa) is strongly associated with three factors: ancestry, family history, and genetics. We previously developed a polygenic hazard score (PHS) for PCa comprised of 290 common genetic variants (PHS290). When accounting for family history and ancestry (self-reported or genetically determined), PHS290 remained a powerful independent predictor of age at PCa diagnosis, metastatic PCa diagnosis, and PCa death. Additional variants associated with PCa susceptibility or benign elevation of prostate-specific antigen (PSA) have since been published. Here, we evaluate their impact on lifetime risk predictions for metastatic and fatal PCa and develop an updated polygenic score. This score will inform the design of the Prostate Cancer, Genetic Risk, and Equitable Screening Study (ProGRESS, ClinicalTrials.gov ID NCT05926102), a nationwide randomized controlled trial evaluating precision PCa screening in the VA healthcare system.

Methods: We utilized a machine learning approach to update the PHS. Over 450 variants associated with PCa, aggressive PCa, benign prostatic hyperplasia, or benign PSA elevation were evaluated for inclusion. First, we identified pairs of variants with highly correlated genotype (defined as $R^2 > 0.95$) and utilized univariable Cox proportional hazards models (using age at diagnosis of PCa) to exclude one variant from each pair. We then evaluated all remaining candidate variants for inclusion in a new PHS using a LASSO-regularized Cox proportional hazards model. We combined the new PHS with clinical predictors (ancestry and family history) to create a comprehensive, quantitative polygenic score in a diverse, population-based cohort of n=590,750 (Million Veteran Program). Both self-reported and genetic ancestry (based on 2,309 ancestry informative markers) were assessed. We estimated hazard ratios (HRs) to compare men with high versus low polygenic score and evaluated absolute predictions of any, metastatic, and fatal PCa.

Results: The updated polygenic score included 356 variants, as well as family history and genetic ancestry. When comparing the highest to the lowest quintile of the population for polygenic score, the HRs for any PCa, metastatic PCa, and fatal PCa were 5.6, 5.8, and 5.2 respectively. These HRs are all greater than those achieved with PHS290, which yielded 5.2, 4.9, and 4.4 respectively. Risk stratification improved within each ancestry group, including within the >100,000 participants of African ancestry—a group known to have elevated risk of fatal PCa. Absolute risk prediction was accurate for both metastatic and fatal PCa.

Conclusion: The polygenic score accurately predicts risk of metastatic and fatal PCa in multiple ancestry groups. A clinical polygenic model has potential utility for precision PCa screening and will now be evaluated prospectively in the ProGRESS trial.

#4802 Accuracy of the GALAD serologic model in the diagnosis of hepatocellular carcinoma in Ghanaian patients.

Y. A. Nartey[1], J. Yang[2], T. Zemla[3], J. Ayawin[4], S. Osei Asibey[5], M. El-Kassas[6], S. A. Bampoh[7], A. Duah[8], A. Agyei-Nkansah[9], Y. A. Awuku[10], M. Yeboah Afihene[11], H. Yamada[12], J. Yin[13], A. Plymoth[14], L. R. Roberts[3];

[1]Cape Coast Teaching Hospital, Cape Coast, Ghana, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Mayo Clinic, Rochester, MN, [4]Komfo Anokye Teaching Hospital, Kumasi, Ghana, [5]Kumasi Technical University, Kumasi, Ghana, [6]Helwan University, Helwan, Egypt, [7]Greater Accra Regional Hospital, Accra, Ghana, [8]University of Ghana Medical Center, Accra, Ghana, [9]University of Ghana Medical School, Accra, Ghana, [10]University of Health and Allied Sciences, Ho, Ghana, [11]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [12]FUJIFILM Corporation, Tokyo, Japan, [13]Moffitt Cancer Center, Tampa, FL, [14]European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden

Background: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related mortality worldwide. In sub-Saharan Africa, HCC is the second most common cancer in men and the sixth in women. African patients present with HCC at a young age and at advanced stage of disease. Improved surveillance can increase early HCC detection. The GALAD score has good sensitivity in the diagnosis of HCC in Asia, Europe and North America, however, it has not been validated in an African cohort. The aim of this study was to assess the performance of the GALAD score in the diagnosis of HCC in Ghanaian patients.

Methods: Clinical data from patients with cirrhosis (n=93) or HCC (n=78) from out-patient hepatology clinics at 3 teaching hospitals in Ghana were abstracted, and serum samples analyzed. A logistic regression model predicting HCC status based on GALAD score was constructed to obtain the Receiver Operating Characteristics (ROC) curve for GALAD. The area under the curve (AUC) with 95% confidence interval was calculated and used to assess the performance of the GALAD score in surveillance for HCC.

Results: The median AFP (5010.2 vs. 3.4), L3% (28.3 vs. 0.3) and DCP (507.6 vs. 0.2) levels were all significantly higher among HCC cases than the controls ($p<0.0001$). The median GALAD score was also higher among HCC patients (8.0 vs. -4.1, $p<0.0001$). The AUC of the GALAD score in the diagnosis of HCC was 0.86 (95% CI 0.79 - 0.92). At a cut-off value of -0.37, the GALAD score had a sensitivity of 0.81 and a specificity of 0.86. In a re-fit of the logistic regression model, the most significant factors in the GALAD model in our cohort were AFP-L3% and log(DCP). The AUC of the new GALAD model after model selection was 0.89.

Conclusion: The GALAD score can be used to detect HCC in Ghana and has the potential to improve HCC surveillance in low-resource settings in sub-Saharan Africa.

#4803 Cancer screening, knowledge, and fatalism among Chinese, Korean, and South Asian residents of New York City.

I. I. Curro[1], C. A. Teasdale[1], L. Wyatt[2], Y. Yusuf[2], V. Foster[2], S. Sifuentes[2], P. Chebli[2], J. A. Kranick[2], S. C. Kwon[2], C. Trinh-Shevrin[2], M. N. LeCroy[2];
[1]The City University of New York Graduate School of Public Health and Health Policy, New York, NY, [2]NYU Grossman School of Medicine, New York, NY

Background: Asian New York City (NYC) residents have the lowest screening rates by race across cancer type. Past studies indicate heterogeneity within the Asian American population, yet few have examined differences in screening uptake and related factors among Asian ethnic subgroups in NYC. Further, cancer screening knowledge and cancer fatalism have been found to impact cancer screening uptake, and effects vary by race, ethnicity, immigration status, and cancer type.
Objective: Our study aimed to examine differences in cancer screening uptake, knowledge, and fatalism among Chinese, Korean, and South Asian NYC adults and to examine the effects of cancer screening knowledge and cancer fatalism on cancer screening uptake.
Methods: We used data from NYU Langone Perlmutter Cancer Center's Cancer Community Health Resources and Needs Assessment survey. The survey was developed and distributed in 10 languages in collaboration with 23 community partners. Data were collected from NYC adults with recruitment strategies focused on immigrant and non-English language preference communities from Oct. 2021 - Dec. 2022. Multivariable logistic and multinomial regression analyses were used to examine differences in breast, cervical, and colorectal cancer (CRC) screening uptake; breast and CRC screening knowledge; and cancer fatalism between Chinese, Korean, and South Asian (Bangladeshi, Pakistani, Asian Indian, and Nepali) adults; and to examine the effects of breast and CRC screening knowledge on breast and CRC screening uptake and cancer fatalism on breast, cervical, and CRC screening uptake (n=1,045). Analyses were restricted by age and sex using United States (U.S.) Preventive Services Task Force guidelines.
Results: The sample was 60.0% female with a mean age of 45.7 years; 83.1% of participants were born outside of the U.S., 49.9% of participants were Chinese, 22.8% were Korean, and 27.3% were South Asian. Korean women had 0.52 (95%CI: 0.31, 0.88) times lower odds of Pap test uptake than Chinese women; South Asian adults had 0.44 (95%CI: 0.24, 0.80) times lower odds of CRC screening uptake than Chinese adults. Korean adults had 1.68 (95%CI: 1.17, 2.41) times higher odds of knowing the correct age to begin having mammograms compared to Chinese adults; South Asian adults had 0.66 (95%CI: 0.46, 0.94) times lower odds of knowing the correct age to begin CRC screening compared to Chinese adults. Korean adults had a 0.39 (95%CI: 0.25, 0.63) and 0.22 (95%CI: 0.13, 0.37) times lower odds of some and high cancer fatalism, respectively, compared to Chinese adults. No associations were found between cancer screening knowledge or cancer fatalism and cancer screening uptake.
Conclusions: Our study adds to the current literature on the diversity of cancer needs, beliefs, and behaviors among Asian Americans. The findings indicate the need for ethnic-specific cultural tailoring for future cancer screening interventions.

#4804 Prevalence of anal HPV infection in women attending a gynecology and colposcopy clinic: Assessing the potential impact of HPV vaccination..

A. Dominicci-Maura[1], A. P. Ortiz[2], J. Romaguera[3], F. Godoy-Vitorino[1];
[1]University of Puerto Rico - Medical Sciences Campus, San Juan, PR, [2]Comprehensive Cancer Center - University of Puerto Rico, San Juan, PR, [3]School of Medicine, University of Puerto Rico - Medical Sciences Campus, San Juan, PR

Human papillomavirus (HPV) accounts for over 80% of anal cancer cases. In the effort to prevent HPV-related cancers, the 9-valent HPV vaccine emerged as a crucial intervention, targeting HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58; the previous 4-valent (types 6,11,16,18) and 2-valent (types 16, 18). This study involved 213 women aged 21-50 attending gynecology and colonoscopy clinics in San Juan, Puerto Rico. The study assessed anal HPV prevalence and analyzed vaccination status-related differences. Anal swabs were collected for HPV testing using the ATILA AmpFire, targeting 17 HPV types. This method identified 15 high-risk HPV types (16, 18, 31, 33, 35, 39, 45, 51, 52, 53, 56, 58, 59, 66, and 68) and two low-risk HPV types (6 and 11). Prevalence of any HPV, HR-HPV, and LR-HPV, and of specific HPV types were calculated by overall and vaccination status. Differences were assessed for statistical significance ($p<0.05$) using Fisher's exact or Pearson $\chi 2$ test. The mean age of women was 36.0 ± 5.9 years. Overall, 19.7% (n=44) had received the HPV vaccine; among them, 52.2% (n=23) had received the 4-valent vaccine, 2.3% had received the 2-valent vaccine, 2.3% had received the 9-valent vaccine, and 43.2% were uncertain about their specific HPV vaccine type. The prevalence of anal HPV infection was 68.5% for any HPV, 61.5% for HR-HPV, and 15.0% for LR-HPV. The most prevalent HR-HPV types were HPV 56 (13.2%), HPV 68 (11.7%), and HPV 66 (11.2%). There were no statistically significant differences in the prevalence of any HPV, HR-HPV, and LR-HPV between vaccinated and unvaccinated women. The most common HR-HPV type among vaccinated were HPV 66 (20.5%), HPV 31 (18.2%), HPV 56 (15.9%), while the most common among unvaccinated women were HPV 56 (12.4%), HPV 68 (12.4%), and HPV 16 (12.4%). Additionally, when evaluating as a grouped variable, the HPV genotypes covered by the 4-valent, unvaccinated women had a significantly higher prevalence of these types as compared to those vaccinated (28.9% vs. 13.6%, respectively, p-value =.03). The unvaccinated women showed a lower prevalence for HPV types covered by the 9-valent vaccine compared to the vaccinated cohort (43.2% vs. 45.5%). However, this difference was not statistically significant. We found a high prevalence of anal HPV among these women, with lower prevalence of 4-valent and 2-valent HPV types among vaccinated women, evidencing the pivotal role of HPV vaccination. Future research should assess the 9-valent vaccine's long-term effectiveness against more HPV types. Funding: Research Centers in Minority Institutions (RCMI), University of Puerto Rico (NIMHD # 2U54MD007600-36), and CAPAC Research Training Program (NCI #R25CA240120).

#4805 Identifying neighborhood hot spots of HPV-associated cancers for targeted interventions of HPV vaccination uptake in underserved communities of South Florida.

M. Lee[1], S. Parrott[2], R. Kaiser[1], R. Vyas[1], D. Gabuzda[1], A. Vazquez[1], D. Flores Quetant[1], N. Elliott[1], V. Bethel[1], A. Rivera[1], B. Mahal[1], R. Balise[1], E. Franzmann[1], E. Kobetz[1];

[1]University of Miami Miller School of Medicine, Miami, FL, [2]University of Miami, Miami, FL

Background: Although the incidence of cervical cancer in the US has declined, the incidences of other HPV-associated cancers are on the rise. HPV vaccination is an important primary prevention strategy for reducing the burden of HPV-associated cancers. In South Florida (population over 6 million), the percentage of adolescents aged 13-15 years who completed the recommended HPV vaccine series is 54%, which lags significantly behind the Healthy People 2030 target of 80%. In addition, vaccination disparities exist in South Florida by races/ethnicities and sexes, with non-Hispanic black males having the lowest rate at 27%. To address HPV cancer disparities, we performed a geospatial analysis on the incidence of HPV-associated cancers by sex and races/ethnicity to identify communities in South Florida with high incidence of HPV-associated cancer to target interventions that may improve HPV-vaccine uptake via community outreach and engagement.

Methods: The average annual (2010-2019) incidence of HPV-associated cancers in women (cervical, oropharyngeal, vulva, vaginal, and anal) and men (oropharyngeal, penile, and anal) were calculated for Hispanics, Non-Hispanic Whites (NHWs) and Non-Hispanic Blacks (NHB) at the census tract level across South Florida using data from the Florida Cancer Data System (FCDS), the state incident cancer registry. Geospatial hot spot analyses were used to identify clusters of census tracts with high HPV cancer incidence by sex and race/ethnicity. Socioeconomic and cervical screening data of the hot spots were analyzed to identify other neighborhood risk conditions that may be associated with high HPV cancer risk.

Results: For Hispanics and NHBs in South Florida, census tract hot spots for male and female HPV cancers appear to overlap in low-income neighborhoods; however, hot spots for NHW males are mostly in medium to higher income areas and do not overlap with hot spots observed for NHW females, likely given that NHW females generally report higher cervical screening rates.

Conclusion: There is a positive association between male and female HPV cancer incidence in Hispanic and NHB communities of South Florida, justifying the need for increased HPV vaccination and screening programs in these neighborhoods. While increasing cervical screening rate in the hot spot neighborhoods is urgent for cervical cancer control, increasing gender-neutral HPV vaccination uptake in these communities will not only reduce the incidences of male HPV cancers but also help to accelerate cervical cancer elimination by reducing HPV infection.

#4806 The potential impact of a Von Hippel-Lindau clinical care center for patients at the University of Illinois Chicago.

N. Hippalgaonkar[1], K. Drabek[1], A. Aseem[1], T. Maga[1], L. Balay[1], V. Pan[1], P. Ganschow[2], K. Tawagi[1], N. Awati[1], N. Reizine[1];
[1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois Cancer Center, Chicago, IL

Introduction: Von Hippel-Lindau (VHL) is an inherited autosomal dominant cancer syndrome causing early-onset tumors in various organs. It poses high risks of renal cell carcinoma, hemangioblastomas, pheochromocytomas, and paragangliomas among others. VHL can be clinically diagnosed based on the Danish, international, or Dutch guidelines, or through molecular diagnosis by identifying a pathogenic variant in the VHL gene. There is now an FDA-approved HIF-2 alpha inhibitor that is effective for the treatment of VHL-related manifestations, and the identification of eligible patients is paramount to receive this benefit. In addition, the screening recommendations for VHL are extensive and result in significant burden on patients. We suspect that VHL is under-diagnosed in the clinical setting, and we further hypothesize that this burden may contribute to care gaps and disparities in access to VHL-related care.
Methods: This is a single-institution, retrospective study conducted at the University of Illinois Health and Hospitals System (UIH). We assessed the prevalence of patients with VHL-related tumors by examining ICD diagnosis codes from 2010 to 2023. Additionally, we analyzed the subset of these patients who underwent germ-line genetic testing. Furthermore, we examined our cohort of VHL patients more closely to explore the burden of VHL-related care. We examined the time to germ-line genetic and cascade testing from first clinical touchpoint at UIH, as well as the total number of clinical departments accessed at UIH. Demographics, clinical characteristics, germ-line genetic testing results, and information on clinical visits were also collected from those with a molecular or clinical diagnosis of VHL.
Results: We found 9,875 patients with at least one VHL-associated tumor. Among them, 1,379 had two or more VHL-associated tumors, with <2% undergoing germline genetic testing. We identified 10 individuals diagnosed with VHL. Of the ten patients, 30% were black, 30% were white, and 40% self-identified as other. Age of onset for VHL-related screening ranged from 10 to 37 years. All patients diagnosed with VHL underwent germ-line genetic testing, with 60% opting for cascade testing of at-risk family members. Patient care was fragmented, with on average, each VHL patient seeking care from five different UIC clinical departments (range 1-11) and receiving care from multiple separate institutions (range 1-4).
Conclusion: Our data revealed that most patients with VHL-associated tumors did not receive genetic testing, demonstrating a potential missed opportunity for early diagnosis and interventions to improve outcomes for VHL-related disease. Furthermore, our data highlights the clinical burden of VHL, and supports the potential impact of a coordinated care program for these patients.

#4807 Gaucher disease treatment reduces the progression of smoldering myeloma.

R. Shukla[1], A. Parekh[2], V. Leshchenko[1], K. Barley[1], D. Vatti[3], D. Verina[1], M. Balwani[1], S. Parekh[1];
[1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Ardsley High School, New York, NY, [3]New york university, New York, NY

Background: Gaucher disease (GD), a hereditary condition characterized by glucocerebrosidase deficiency, results in the impaired degradation of glucocerebroside (GL1) and its deacetylated form, lyso-GL1 (LGL1). This leads to the accumulation of these substrates primarily in the bone marrow (BM), liver, and spleen. Notably, individuals with GD face an increased risk of plasma cell dyscrasias (PCD) by approximately nine-fold. We present two compelling cases of the regression of smoldering multiple myeloma (SMM) following GD treatment, substantiated by biochemical evidence of lipid-reactive clonal paraproteins (PP) in both patients.

Methods: Peripheral blood samples were obtained with IRB approval from patients with concurrent SMM and GD at the Icahn School of Medicine at Mount Sinai. Utilizing C-18 beads coupled with gly-sphingosine-coated liposomes and Sphingosine-1 phosphate bead liposome-based pulldown, we established the binding of glycolipids to serum PP.

Results: In a 66-year-old male, hepatosplenomegaly and pancytopenia revealed compound heterozygous N370S/V394L mutations and reduced β-glucosidase activity, confirming Type 1 GD. Laboratory findings included substantial pancytopenia (WBC 2.5 k/μL, Hgb 12.1 g/dL, platelet 44 k/μL) and myeloma markers (M spike 1.58 g/dL, monoclonal IgA λ). A BM biopsy indicated 30% λ-restricted plasma cells. PET-CT showed hepatosplenomegaly without FDG avid lytic lesions, consistent with SMM. Imiglucerase enzyme therapy improved GD biomarkers, decreased hepatosplenomegaly, and blood count improvement (WBC 4.7 k/μL, Hgb 13.6 g/dL, platelet 66 k/μL). Notably, myeloma burden significantly reduced (M-spike 0.94 g/dL, IgA 1373 g/dL and free lambda 26.1 mg/L). Similarly, a 41-year-old female with mild fatigue, Hgb levels of 10.9 g/dL, a platelet count of 169 k/μL, M spike of 0.9 g/dL, IgG κappa on immunofixation, and IgG levels at 1730 mg/dL, indicating SMM. GBA analysis showed homozygous N370S mutation and reduced beta-glucosidase activity consistent with Type 1 GD. Substrate reduction therapy with eliglustat alleviated fatigue, reduced GD biomarkers, normalized cytopenias, and gradually decreased myeloma markers. Laboratory results indicated an M spike of 0.5 g/dL, IgG levels at 1295 mg/dL, and free kappa at 31.3 mg/L. To explore the interaction between clonal immunoglobulins (Ig) and lyso-lipids, we utilized Gly-sphingolipids (see methods) and demonstrated a robust interaction with IgA (patient 1) and IgG (patient 2) paraprotein by western blotting.

Conclusion: Our experimental findings confirm specific clonal Ig binding in SMM and GD patients and demonstrate potent and timely benefits from addressing GD in managing SMM patients. This holds significance amid ongoing clinical trials exploring aggressive interventions for SMM, including bispecific and CAR-T therapies.

#4808 Small intestinal leiomyosarcoma in a young adult.

A. A. Guo, B. H. Bentley, A. L. Ellington, H. Lu, W. C. Lippert;
Wake Forest University School of Medicine, Winston Salem, NC

Objectives: • Outline the epidemiology of leiomyosarcoma•Identify the immunohistochemistry of a leiomyosarcoma

Introduction: Primary small intestinal malignancies are rare malignancies as compared with other malignancies of the gastrointestinal tract. Here, we present a case of a jejunal leiomyosarcoma in a young adult.

Case Presentation: A 23-year-old Caucasian male with GERD presented with five months of abdominal pain, intermittent nausea with non-bloody emesis, and a 20-pound weight loss. Presenting vital signs were within normal limits. Physical exam revealed conjunctival pallor with epigastric tenderness to palpation. Serology demonstrated iron deficiency anemia, hemoccult positive stool, negative CEA, CA19-9, and AFP tumor markers. HIV antigen antibody and EBV-PCR were non-reactive. CT of the abdomen and pelvis revealed markedly thickened heterogenous jejunal loop in the left hemiabdomen with associated mesenteric adenopathy and small volume pelvic ascites. EGD with push enteroscopy revealed a single, malignant appearing and ulcerated mass in the proximal jejunum. PET-CT showed a hypermetabolic, multilobulated, ill-defined mass involving multiple loops of jejunum. He underwent exploratory laparotomy with resection of a proximal jejunal mass (10x8 x7 cm), mesenteric lymphadenectomy, and a jejunojejunostomy creation. Pathology demonstrated leiomyosarcoma (pT2aN0MoG3), and he was initiated on cyclophosphamide and doxorubicin.

Discussion: Primary small intestinal malignancies are rare malignancies with an incidence of less than 5% of all GI malignancies. 56 cases of GI leiomyosarcoma in adults were identified between 2000-2012 with a peak incidence between 55-59 years of age (Aggarrwal 2012). Leiomyosarcomas are soft tissue sarcomas arising from bones, tendons, blood vessels, or muscles with a spectrum of disease ranging from low-grade cutaneous lesions to aggressive lesions of internal organs with significant potential for metastasis (Pipe 2002). Diagnosis is based on immunohistochemical positivity for SMA, desmin, and h-caldesmon, and negativity for CD117, CD34, and DOG1.1, notably lacking *KIT* and *PDGFRA* mutations (Aggarwal 2012). Treatment involves surgical resection and a cost benefit analysis of adjuvant chemotherapy with (Reynolds, 2014). This case of a 23 year old, without significant risk factors, diagnosed with a jejunal leiomyosarcoma presents as one of the youngest cases ever to be reported and emphasizes the importance of recognizing the cancer in a broader range of the adult population.

#4812 Evaluating racial and ethnic differences in advanced-stage laryngeal cancer treatment and outcomes in Florida: Unmasking the inequities.
C. J. Washington, C. Lattimore, D. Braithwaite, K. Fredenburg, S. Karanth;
University of Florida, Gainesville, FL

Purpose: To evaluate the association between race/ethnicity, treatment, and mortality among individuals with advanced-stage laryngeal cancer in Florida.
Methods: We obtained data from the Florida Cancer Data System (FCDS) on non-Hispanic (NH)-White (the reference group), Hispanic, and NH-Black patients with advanced-stage (regional and distant) laryngeal cancer from 2009 to 2020. Sociodemographic factors were obtained from FCDS (age, marital status, and insurance) and the United States Census at the county level (education, household income, and rurality). Treatment strategies included chemoradiation, surgery followed by chemoradiation, chemotherapy, radiation, surgery, and surgery followed by chemotherapy. The primary outcome was overall mortality. Multivariable Cox proportional hazard models were used to calculate hazard ratios (HR) and 95% confidence intervals (95% CI) and to examine the association of race/ethnicity with treatment and survival, while adjusting for sociodemographic factors.
Results: There were 4,522 participants with advanced-stage laryngeal cancer (57.9% <65 years, 79.5% male, 75.4% NH-White, 13.1% Hispanic, and 11.5% NH-Black) included in the analysis. Compared to NH-White patients, NH-Black patients were less likely to be married, have private insurance, and live in an urban county. Moreover, NH-Black individuals were less likely to receive chemoradiation alone and were more likely to receive surgery followed by chemoradiation. Government insurance was highly associated with chemoradiation receipt. In age-adjusted models, NH-Black patients with advanced-stage laryngeal cancer had a higher risk of death compared to NH-White patients (HR: 1.19; 95% CI: 1.06, 1.32), while Hispanic patients had a lower risk of death compared to NH-White patients (HR: 0.80; 95% CI: 0.71, 0.89). After adjusting for sociodemographic factors, there was no statistically significant difference in overall mortality in NH-Black patients compared to NH-White patients (HR: 1.07; 95% CI: 0.96, 1.20). However, among individuals who received chemoradiation, NH-Black patients had a higher risk of mortality, even after adjusting for sociodemographic factors, compared to NH-White patients (HR: 1.27; 95% CI: 1.04, 1.55).
Conclusions: Among patients with advanced-stage laryngeal cancer in Florida, NH-Black patients experienced a higher risk of overall mortality compared to other racial and ethnic groups, but this discrepancy was primarily among those who received chemoradiation, even after accounting for sociodemographic factors. This study emphasizes the urgency of expanding laryngeal cancer care access for NH-Black individuals and investigating possible biological variations in their response to chemoradiation and subsequent survival outcomes.

#4813 Demographic, treatment, and survival patterns in Hispanic vs. non-Hispanic patients with lymphoplasmacytic lymphoma/Waldenstrom macroglobulinemia: A national retrospective analysis from the National Cancer Database.

Maria Elena Fierro[1], Heidi Latiolais[2], Qianquian Liu[3], Joel Michalek[4], Adolfo Enrique Diaz Duque[5]

[1]Internal Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX,[2]Hospital Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX,[3]Epidemiology and Biostatistics, University of Texas Health Science Center at San Antonio, San Antonio, TX,[4]University of Texas Health Science Center at San Antonio, San Antonio, TX,[5]Hematology-Oncology, Mays Cancer Center UT Health San Antonio MD Anderson, San Antonio, TX

Background: Lymphoplasmacytic lymphoma (LPL) is a rare type of non-Hodgkin B cell lymphoma. Waldenstrom macroglobulinemia (WM) is a form of LPL that presents with overproduction of IgM monoclonal protein. The understanding and treatment of LPL/WM has improved. However, few studies analyze LPL/WM in Hispanic (HI) patients specifically. This study aims to evaluate demographics, treatment, and survival patterns in HI vs. Non-Hispanic (NH) patients with LPL/WM.

Methods: Data were analyzed on LPL/WM patients in the US reported to the NCDB from 2004-2019. Demographic and treatment characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare overall survival (OS) between HI and NH. Multivariate analysis and propensity score matching were performed with adjustment for age, stage, co-morbidity score, insurance status, type of facility and great circle distance (GCD).

Results: 17,915 patients were identified. 92% were NH, 3% were HI. Most patients were male in both NH and HI ($p = 0.120$). The median age at diagnosis for HI was 68 vs. 71 for NH ($p < 0.001$). Most HI and NH were white (87% HI, 91% NH $p < 0.001$). More HI were uninsured (8% HI, 1% NH $p < 0.001$) and were less likely to have government sponsored insurance (60% HI, 66% NH $p < 0.001$). Regarding income, most NH (42%) were in the $63,000+ bracket while most HI were in the $48,000-$62,999 bracket. Regarding education, reported in percent quartiles with no high school degree, most HI (41%) were in the > 21% bracket while most NH (35%) were in the 7-12.9% bracket ($p < 0.001$). Most HI (43%) were treated at academic/research programs; most NH were treated at comprehensive community cancer programs (38.4%, $p < 0.001$). Regarding comorbidities score, 9% of HI scored ≥ 2 vs 8% of NH (p 0.029). Regarding GCD, the median distance in miles between the patient's residence and the hospital that reported the case, HI lived at a median of 6.7 miles vs 9 miles for NH ($p < 0.001$). Regarding treatment, 68% of HI were given treatment vs. 62% of NH ($p < 0.001$). There was no difference in mortality between HI vs. NH (30 day mortality $p = 0.322$; 90 day mortality $p = 0.217$). On survival analysis, the survival probability at 2, 5 and 10 years of HI vs NH were 81% vs 83%, 69% vs 68%, and 52% vs 46%, respectively. The median survival time (MS) was 10.6 years for HI vs 9 years for NH. There was no OS difference between HI vs. NH ($p = 0.47$). On multivariate analysis, there were no independent variables associated with better or worse OS. The propensity matched analysis showed no MS difference between HI vs NH (8.96 y vs. 8.74 y).

Conclusion: We identified ethnic differences in age, race, insurance, education, income, location of treatment, GCD, staging, and treatment patterns. However, there was no statistically significant ethnic difference in MS or OS.

#4814 Pediatric radiation treatment adherence in LMIC.

A. Joseph[1], A. Akinsete[2], U. Fakile[3], C. Agbakwuru[1], L. Keno[4], O. O. Adisa[3], A. Oladipo[1], O. Fagbemide[1], M. Habeebu[1], W. Ngwa[5];
[1]NSIA - LUTH Cancer Center, Lagos University Teaching Hospital, Lagos, Nigeria, [2]University of Lagos, Lagos, Nigeria, [3]Lagos University Teaching Hospital, Lagos, Nigeria, [4]Johns Hopkins University School of Medicine and The University of Scranton, Baltimore, MD, [5]Johns Hopkins University School of Medicine, Baltimore, MD

Background: Radiation therapy plays a significant role in the treatment of pediatric cancer. However, there have been documented challenges and difficulties encountered by patients while accessing care for cancer and it has been postulated that travel distance contributes to treatment breaks and abandonment.
Objectives: The objective of this study was to determine the prevalence of treatment breaks, assess the travel burden of patients receiving radiotherapy for pediatric cancers at a high-volume center in Nigeria and to determine the impact of travel burden on treatment breaks and treatment completion.
Materials and Methods: A retrospective cross-sectional study design was utilized. Data was extracted from the electronic medical records of all pediatric patients referred to the center for radiation therapy between June 2019 and June 2023. Data was analyzed using Microsoft Excel and the results were presented in descriptive statistics. Association between data were analyzed using chi-square test with the level of significance (p) set at <0.05. **Results:** A total of 210 pediatric cancer patients were enrolled with an average age of 10.9 years. Children aged 0-14 years accounted for 69.05% while 30.95% were between the age of 15 and 19 years. Brain tumors were the most predominant diagnosis, representing 28.10% of cases. Treatment intent was predominantly radical or curative (81.69%). 61.43% (129) of the patient population came from the within the state with an average travel distance of 19.3 km. Of all the 210 patients, 44.29% of patients did not commence RT. The reasons for this were mostly financial constraints but were not explored in this study. Of those who did commence RT, 54.70% had breaks, and 45.30% did not have breaks. Also, 75.21% of patients completed their treatment; however, 24.79% were unable to complete their treatment. Travel distances varied, with the average distance to the treatment center being 165.3 km and the median at 28.5 km. The study categorized travel distance into quartiles: short (0-16 km), medium (>16 km to 28.5 km), long (>28.5 km to 302 km), and very long (>302 km to 1387 km). Chi-square test did not reveal a significant association between travel distance and treatment completion (p=0.57), nor between travel distance and treatment breaks (p=0.20).
Conclusion: These findings highlight the complex interplay of demographic factors, disease profiles, and socioeconomic barriers affecting treatment continuity and completion among pediatric oncology patients in a resource-limited setting. These findings suggest that in this low - resource context, other variables such as socioeconomic status and financial barriers may play a more pivotal role than travel distance in treatment commencement, adherence and completion. As such, more detailed investigation of the obstacles through a comprehensive and targeted strategy could lead to more favorable outcomes in pediatric cancer radiation therapy adherence.

#4815 Time to lung cancer treatment in West Virginia and patient survival.

A. R. Lumadue[1], **S. O. Nduaguba**[2];
[1]West Virginia University School of Pharmacy, Morgantown, WV, [2]Mary Babb Randolph Cancer Center and School of Pharmacy at West Virginia University, Morgantown, WV

Background: Patients from rural areas typically have poor access to healthcare. Studies have shown varying results on the relationship between time to lung cancer treatment and patient survival. We aimed to examine the association of rurality with timely receipt of lung cancer treatment and survival in West Virginia (WV).
Methods: A retrospective study was conducted using WV Cancer Registry data to identify persons diagnosed with NSCLC in WV between 1993 and 2021 who received treatment (surgery, radiation, systemic therapy, other). Participants were classified by rurality (rural vs non-rural), and time to treatment from diagnosis was dichotomized as early treatment (<35 days) or delayed treatment (≥35 days). Descriptive statistics and survival analysis (with univariate and multivariate Cox regression controlling for age, sex, race/ethnicity, marital status, Charlson comorbidity index, cancer stage, and treatment type) were used to address study objectives.
Results: Of 10,463 participants, 678 (6.5%) were rural residents. The majority were male (58.1%), married or partnered (59.9%), and non-Hispanic white (97.5%). 61% received early treatment. 45%, 38%, and 16% received systemic therapy, surgery, and radiation, respectively. There were significantly more non-Hispanic white (99.6% vs 97.3%, p<0.004) patients residing in rural areas compared to non-rural areas, and fewer rural residents were diagnosed at stages 1 (29.4% vs 34.3%) or 2 (10.0% vs 11.6%) (p<0.5). Rurality was not associated with time to treatment but was associated with 9% increase in hazard of death (HR=1.09, 95% CI=1.00-1.18, p<0.05). Significant covariates associated with increasing hazard of treatment included being male (HR=1.08, 95% CI=1.04-1.13, p<0.0001) and cancer stage (HR range=1.19-2.38, while being Black and receiving surgery (0.43, 0.30-0.62, p<.0001), radiation (0.48, 0.33-0.68, p<.0001), or systemic therapy (0.33,0.23-0.47, p<.0001) (compared to other treatment) were each associated with reduced hazard of treatment. Significant covariates associated with hazard of death include increasing age (HR=1.01, 95% CI= 1.01-1.02, p<.0001), increasing CCI (HR=1.07, 95% CI=1.05-1.09, p<.0001), being male (HR=1.21, 95% CI=1.16-1.26, p<.0001), increasing cancer stage (HR range=1.58-4.79) while being married (HR=0.92, 95% CI=0.88-0.96, p<.001), receiving surgery (HR=0.16, 95% CI=1.11-0.22, p<.0001), radiation (HR=0.34, 95% CI=0.24-0.49, p<.0001), or systemic treatment (HR=0.17, 95% CI=0.12-0.24, p<.0001), and delayed treatment (HR=0.82, 95% CI=0.78-0.85, p<.0001) were each associated reduced hazard of death.
Conclusion: Rurality affects lung cancer outcomes in WV increasing risk of death for NSCLC patients by 9%.

#4816 Racial disparities in adjunctive supportive care medication use in pancreatic cancer patients.

Olga M. Trejos Kweyete[1], Yi Guo[2], Sherise C. Rogers[2], Lisa Scarton[2], David L. DeRemer[2], Chardae L. Whitner[3], Diana J. Wilkie[2], John M. Allen[1]

[1]University of Florida, Orlando, FL,[2]University of Florida, Gainesville, FL,[3]University of Florida, Jacksonville, FL

Background: Beyond its well-known lethality, pancreatic cancer (PC) is associated with a wide variety of physical and psychological complications. These complications collectively lead to an increase in symptom burden experienced by patients with PC, as compared to other cancer types, leading to lower health-related quality of life (HRQoL) and worsened clinical outcomes. Reducing symptom burden is often achieved through the use of supportive care medications (SCM). Racial disparities have been described in the use of pain and psychiatric medications but limited research has explored potential disparities in access to and utilization of other SCM among diverse racial and ethnic groups. The goal of this study was to illustrate the presence of racial/ethnic disparities in the treatment patterns of supportive care medications in end-of-life care of PC patients

Methods: We used data from the Surveillance, Epidemiology, and End Results (SEER)-Medicare-linked database from 2005 to 2017. Participants were identified using ICD9 and ICD10 diagnostic codes. Patients diagnosed with PC and have died in 2005-2007 with more than 1 year of Medicare enrollment before death were included. Logistic regression models to assess the association between use of supportive care medications and race, adjusting for covariates (sex, race, age, marital status, education, income, residence, CCI, year of diagnosis of PC, cancer stage).

Results: After the application of the inclusion/exclusion criteria, 74,309 patients were included in the final analysis (White: 72.53%, Black 11.01%, Hispanic 9.60%, Asian/Pacific Islander 6.58%) Racial and ethnic disparities in the use of multiple SCM drug classes were identified. The results are summarized in Table 1.

Conclusion: Disparities in the use of SCM were found in patients with PC. Minorities had significantly less use of sleep aids and headache aids, and increased use of cognitive aids and appetite stimulants. AAs also had lower uses of anti-emetics.

	AA		**Hispanic**		**Asian**	
SCM Drug Class	**aOR**	**95% CI**	**aOR**	**95% CI**	**aOR**	**95% CI**

#4817 Patterns and predictors of opioid dispensing among older cancer patients from 2008 to 2015.

Y. Chen[1], Y.-E. Shin[2], S. Spillane[1], M. Shiels[1], A. Coghill[3], L. Enewold[1], R. Pfeiffer[1], N. Freedman[1];

[1]National Cancer Institute, Rockville, MD, [2]Seoul National University, Seoul, Korea, Republic of, [3]Moffitt Cancer Center, Tampa, FL

Introduction: Understanding factors associated with opioid dispensing in cancer patients is important for developing tailored guidelines and ensuring equitable access to pain management. We examined patterns and predictors of opioid dispensing among older cancer patients from 2008 to 2015.

Methods: We analyzed data from the Surveillance, Epidemiology, and End Results (SEER) database linked to Medicare claims. We included the most common cancer types among patients aged 66-95 years. Opioids dispensed within 30 days before and 120 days after cancer diagnosis were assessed. We used logistic regression models to examine trends, adjusted odds ratios (aORs), and 95% confidence intervals (CIs) for opioid dispensing, considering patient demographics, geography, cancer stage, comorbidities, and treatment options.

Results: A total of 211,759 cancer patients aged 66-95 years were included in the study. Moreover, opioid dispensing increased from 16.4% within 30 days pre-diagnosis to 59.8% within 120 days post-diagnosis. Variations were observed across cancer types, with the largest increase among female breast cancer patients (74.9%, n=44,544). We observed significant increases over calendar time in opioid dispensing within120 days post-diagnosis in both women (p=0.02) and men (p=0.001). For all cancers combined, non-Hispanic Black men had a significantly lower likelihood of receiving opioids during the 120 days post-diagnosis (aOR=0.9, 95% CI=0.8-0.9) compared to non-Hispanic White men. Factors such as pre-diagnosis opioid dispensing, age, geography, cancer stage, comorbidities, and type of cancer treatment were associated with opioid dispensing during the 120 days post-diagnosis. Surgery had the strongest association, with men undergoing surgery being 4.4 times more likely to receive opioids within 120 days post-diagnosis (aOR=4.4, 95% CI=4.2-4.6), while women had an odds ratio of 2.7 (95% CI=2.6-2.8). Chemotherapy and radiotherapy were also positively associated with opioid dispensing, though the associations were less pronounced. Moreover, compared to urinary bladder cancer, patients with kidney cancer (women, aOR=1.6, 95% CI=1.5-1.8; men, aOR=1.7, 95% CI=1.5-1.8), lung cancer (women, aOR=1.4, 95% CI=1.3-1.5; men, aOR=1.5, 95% CI=1.4-1.6), and female breast cancer (aOR=1.8, 95% CI=1.6-1.9) were more likely to receive opioids within the 120 days post-diagnosis.

Conclusion: This population-based study reveals significant variations in opioid dispensing among cancer patients over age 65 across cancer types and demographic and clinical factors. Further research is needed to address disparities and optimize opioid dispensing in older cancer patients, ensuring tailored guidelines and improving patient care.

#4818 Cancer disparities in Chile: Unveiling the impact of educational disparities and regional variances on mortality rates.

Paz Cook[1], Fabio Paredes[2], Jorge Jimenez de la Jara[3]

[1]Center for Cancer Prevention and Control (CECAN), Santiago, Chile,[2]Estadisticas, Pontificia Universidad Catolica de Chile, Santiago, Chile,[3]Salud Publica, Pontificia Universidad Catolica de Chile, Santiago, Chile

Differences in education not only influence our access to good-quality and timely healthcare but also impact our ability to make healthy decisions, access nutritious food, and inhabit healthy and safe physical and psychological environments. Consequently, these factors have contributed to an increase in cancer incidence and mortality among individuals with lower levels of education. To assess the mortality rate based on education, we utilized census data and the national mortality register, comparing the cancer mortality rate between those with more than 12 years of education and those with less than 8 years. We employed a Poisson regression model, with the number of deceased individuals as the dependent variable and age, along with gender, region of residence, and education level as covariates. The natural logarithm of the population served as an offset. The exponential of the estimated betas in this regression represents the Relative Index of Inequality (RII), comparing individuals with a low educational level to those with a high educational level. We conducted the analysis using SPSS version 17.0 and SAS version 9.4, considering values with p-values less than or equal to 0.05 as significant, with a confidence interval of 95%. Our findings indicate that two cancer sites are particularly affected by these educational differences, gallbladder (RII(95%CI): 5.43 (4.0-7.5)) and gastric (RII(95%CI): 4.09 (3.5-4.8)) with additional disparities when comparing by gender (RII gallbladder in women (95%CI): 7.06 (5.0-10.9)). Interestingly, even though Chile is a relatively small country, there are significant variations of mortality by geographical region (RII(95%CI): 1.3 (1.1-1.5) to 3.1 (2.3-4.0)), in terms of magnitude and cancer sites, suggesting the influence of environmental factors. The results of this study should serve as a basis for decentralization and the development of a cancer policy that considers territorial differences in resource allocation and plans specific screening and early detection strategies tailored to the epidemiologic and sociodemographic profile. We also conducted a mortality analysis comparing education levels across age intervals. Our findings reveal that, up to the age of 60, mortality is significantly higher among individuals with less than 8 years of schooling. However, beyond the age of 60, the group with higher mortality comprises individuals with 9-12 years of education. This suggests that they may be more capable of affording health services and accessing screening and diagnosis compared to the less educated group but are still diagnosed at later stages when curative treatment is not feasible. In addition, this group has the highest tobacco consumption in the country.

#4820 Comparison of Black and White patients in treatment for papillary thyroid cancer in an equal access health system.

Y. L. Eaglehouse, S. Darmon, C. D. Shriver, K. Zhu;
Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD

Introduction: In the U.S., Black patients with papillary thyroid cancer (PTC) are less likely to receive treatment than non-Hispanic White patients. Access to care and insurance status may be related to these disparities. We aimed to compare Black and White patients in receipt of cancer care for PTC in the equal access Military Health System.

Materials and Methods: We used the MilCanEpi database to identify a cohort of men and women aged 18 or older who were diagnosed with PTC between January 1, 1998 and December 31, 2014. Patients were assessed for treatment by surgery (e.g., lobectomy, thyroidectomy), adjuvant radioactive iodine (RAI), or active surveillance. Treatment appropriate for risk status (low-risk or high-risk) was compared between non-Hispanic White and Black patients using multivariable logistic regression and expressed as adjusted odds ratios (aOR) with 95% confidence intervals (CIs).

Results: Among 3,511 patients with PTC, 65.0% White and 65.5% Black received surgical treatment (aOR 0.97, 95% CI 0.80-1.18 for Black vs. White). For patients with low-risk PTC, overall receipt of either surgery or active surveillance (aOR 0.86, 95% CI 0.67-1.10 for Black vs. White) was similar between races. For patients with high-risk PTC, overall receipt of surgery (aOR 1.19, 95% CI 0.71-2.01) or adjuvant RAI (aOR 1.44, 95% CI 0.60-3.44) was similar for Black compared to White patients.

Conclusions: In an equal access health system, there were no overall racial differences in receipt of surgical treatment for PTC. Further, in analysis by risk status, there were no significant racial differences in receipt of active surveillance for low-risk PTC nor receipt of adjuvant RAI for high-risk PTC. This suggests the role of access to care in reducing racial disparities in treatment for PTC observed in the general U.S. population.

Funding and Acknowledgement: The authors thank the Joint Pathology Center (JPC) for providing the DoD cancer registry data and the Defense Health Agency (DHA) for providing the MHS data repository (MDR) data. This project was supported by the Murtha Cancer Center Research Program (MCCRP) of the Department of Surgery, Uniformed Services University of the Health Sciences (USUHS) under the auspices of the Henry M. Jackson Foundation for the Advancement of Military Medicine (HJF, Inc.), grant numbers HHU0001-16-2-0014 and HU0001-18-2-0032 awarded to C.S.

#4821 Lung cancer survival disparities by ethnicity in Guam, 2001-2020.

C. Aurienne, L. J. Dulana, R. Teria, G. Badowski;
University of Guam, Mangilao, GU

Background: Lung cancer is the leading cause of cancer-related deaths in Guam, with a significantly higher mortality rate compared to the United States (46.9 vs 40.2 per 100,000), despite a lower incidence rate (50.9 vs 52.6 respectively, for the years 2013-2017). There are significant ethnic disparities in lung cancer incidence and mortality rates, with CHamoru (indigenous people) and Micronesian (immigrants from other Micronesian Islands) populations being disproportionately affected compared to other ethnic groups. This study aims to assess lung cancer survival rates in Guam and explore how demographic and other factors impact these rates.

Methods: This study included 1171 patients diagnosed with invasive lung cancer and reported to the Guam Cancer Registry from 2001-2020. Five-year and 10-year survival rates were calculated using the Kaplan-Meier method and were compared using the log-rank test across different ethnic groups: CHamoru (N = 613), Filipino (N = 245), Asian (N = 74), Micronesian (N = 110), and Caucasian (N = 82). The Cox proportional hazards regression was used to investigate the effects of sex, age, year of diagnosis, ethnicity, lung cancer staging, and cancer treatment status on the risk of all-cause mortality.

Results: Mean age at diagnosis was 65.75 years. Of the cases, only 10.8% were identified at an early stage, 43.1% at a late stage, and 46.0% unstaged. Significant differences in the 5-year and 10-year survival rates were found across ethnic groups. CHamoru had the lowest 5-year (15.6%) and 10-year survival rates (13.2%) followed by Micronesian (18.7% and 17.2%, respectively). All-cause mortality was higher among CHamoru (HR = 1.54, 95% CI: 1.28, 1.85) and Micronesian (HR=1.51, 95% CI: 1.15, 1.98) compared with Filipino after adjusting for age, sex, year of diagnosis, staging, and cancer treatment status. There were no statistically significant differences in all-cause mortality between Asian and Caucasian patients and Filipino patients. Cancer staging also indicated a significantly higher hazard rate for late-stage patients (HR = 1.78, 95% CI: 1.41, 2.25) and un-staged patients (HR = 1.51, 95% CI: 1.18, 1.94) compared to early-stage patients. Additionally, patients who did not receive any treatment (HR = 1.46, 95% CI: 1.22-1.74) and those with unknown treatment status (HR = 1.40, 95% CI: 1.17-1.68) experienced higher hazard rates than those who received at least one form of treatment.

Conclusion: The predominance of late-stage or unstaged diagnoses in this study highlights a significant gap in early lung cancer detection in Guam. Survival rates for the CHamoru and Micronesian populations are notably lower than those observed in the U.S. These findings underscore the critical need for expanded lung cancer screening initiatives in Guam to facilitate earlier diagnosis and potentially improve survival outcomes.

#4822 Disparities in receiving non-surgical therapy impact outcomes in non-metastatic gastric cancer in Louisiana.

C. D. Hartupee, K. Maupin, D. M. Danos, O. Moaven;
Louisiana State University Health Sciences Center, New Orleans, LA

Background: Given the history of evolving medical therapies and advancements in cancer treatments over the last decades, resectable gastric cancer has presented multiple strategies for care. Previous literature indicates historically decreased use of multimodal therapies in minority populations. This study aims to evaluate Louisiana patient populations for rates of definitive treatment, inequities in access to care, and evaluating its impact on the outcomes of minorities and underserved population.

Methods: Patients with non-metastatic primary invasive gastric cancer, with T2-4 or any T status with positive lymph nodes, were identified in the Louisiana Tumor Registry using ICD-O codes and AJCC staging system. Receipt of non-surgical therapy was modeled using logistic regression. Overall survival (OS) was modeled using a Cox proportional hazards model.

Results: The study included 561 patients, of which 37.6% (n=211) did not receive surgical treatment and 16.2% (n=91) did not receive non-surgical therapy. A subset of the cohort received no definitive treatment, (6.8%, n=38). In a demographic only multivariable model, adjusting for age, sex, and race, age 70 and over [OR (95%CI) =0.18 (0.08-0.42), p<0.001] and female sex [OR (95%CI) =0.48 (0.28-0.85), p=0.011] was associated with decreased rates of non-surgical therapy. Black [OR (95%CI) = 0.54 (0.31-0.93), p=0.027] and Hispanic [OR (95%CI) = 0.38 (0.13-1.08), p=0.070] race was associated with decreased receipt of non-surgical therapies. However, after adjusting for domestic partner, insurance status, rurality, area poverty, and surgery status, racial disparities were no longer significant compared to whites: Black [OR (95% CI) = 0.59 (0.33-1.06), p=0.075]; Hispanic [OR (95% CI) = 0.52 (0.17-1.66), p=0.272]. In multivariable analyses, receipt of surgery [HR (95% CI) = 0.3 (0.23 - 0.38), p<0.001) and any non-surgical therapy [HR (95% CI) = 0.43 (0.31 - 0.60), p<0.001) were associated with increased overall survival.

Conclusion: A significant number of patients did not receive all modalities of the multidisciplinary treatment that is recommended for patients with non-metastatic gastric adenocarcinoma. Black patients and females are less likely to receive non-surgical modalities for gastric cancer in Louisiana, which is, at least, partially driven by socioeconomic determinants. Identifying patients with these risk factors is a crucial step in allocating resources to increase access the care and improve outcomes.

#4823 Survival outcomes similar in T-cell/histiocyte-rich large B-cell lymphoma between Hispanics and non-Hispanics within the United States.

I. Mines, D. Urueta-Portillo, Q. Liu, J. Michalek, A. E. Diaz Duque;
The University of Texas Health Science Center At San Antonio, San Antonio, TX

Background: T-cell/histiocyte-rich large B-cell lymphoma (THRLBCL) is a rare variant of large B-cell lymphoma with features that overlap with Nodular lymphocyte-predominate Hodgkin lymphoma (NLPHL). (**Blood** *PMID: 32871584*, **PLoS One** *PMID: 24244368*,**Haematologica** *PMID: 20207840*). Unlike NLPHL, which has a good prognosis. THRLBCL's prognosis is worse (**Leuk Lymphoma** *PMID: 31287335*). Given its rarity and difficulty to diagnose, limited studies explore prognostic factors for it. This study aims to explore clinical, demographic, and survival outcomes differ in Hispanic (HI) versus non-Hispanic (NH) patients with THRLBCL in the United States (US).

Methods: Data were analyzed on THRLBCL patients in the US and reported to the National Cancer Database (NCDB) between 2004 and 2019. Demographic and treatment characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses compared OS between HI and NH. Multivariate analysis and propensity score matching was performed with adjustment for age, stage, co-morbidity score, insurance status, type of facility, and great circle distance.

Results: Of 1252 THRLBCL patients, 7% were HI and 93% NH. 67% of HI were male, compared to 68% of NHHI pts were younger at diagnosis 55 vs 57 (p=0.471); the majority of HI and NH were <65, 64% and 66% respectively (p=0.574)Most of HI and NH were white (88% vs 74%). When examining stage, most of HI and NH were stage (IV) (50% vs 57%) (p=0.600)Regarding insurance type, Government-sponsored was the most prevalent in HI (52%), while private insurance was most prevalent for NH (51%) (p=0.001). The most non-Insured group was HI (11% vs 3%).Regarding Census Median Income (2008-2012), the most prevalent bracket (39.5%) for HI was $48,000 - $62,999, and for NH (31%) $>63,000. Charlson-Deyo Score (comorbidities score), HI had a 10% =/> 2 score, vs NH 7%. Regarding treatment facility type Academic/Research Programs were the most prevalent for HI (44%) and NH (38%).The median distance in miles between the patient's residence and the hospital that reported the case (Great Circle Distance), HI lived at a median of 10 miles, vs NH at a median of 11 miles. On survival analysis, the survival probability at 2, 5, and 10 years of HI vs NH were 83% vs 83%, 77% vs 75%, and 69% vs 62%. The median survival time (MS) was not reached for HI or NH. There was no overall survival difference (OS) between HI/NH (p=0.8). Independently, on multivariate analysis, ethnicity was not associated with worse OS (HR 1.2, CI 0.67-2.17, p=0.54).

Conclusion: The MS and OS between HI and NH with THRLBCL within the US were similar. However, due to the rarity of THRLBCL, the size of both populations was small, which reduces the confidence that there are no
differences in the outcomes of these two populations. Because of this, more data is needed to evaluate further the clinical and socioeconomic factors that play a role in the survival outcomes of THRLBCL.

#4824 Multi-level intervention to increase minority cancer patient enrollment to clinical treatment trials- Study design considerations and baseline characteristics from the ACTWONDER2S Study.

D. E. Rollison[1], R. P. Amorrortu[1], L. N. Fuzzell[1], M. A. Garcia[1], E. S. Tapia-Kwan[1], Y. Zhao[1], S. A. Eschrich[1], B. R. Gore[1], B. S. Mittman[2], N. B. Stanley[1], S. T. Vadaparampil[1];

[1]Moffitt Cancer Center, Tampa, FL, [2]Kaiser Permanente, Tampa, FL

Introduction: Black/African American (AA) and Hispanic cancer patients are underrepresented in cancer clinical trials (CCTs). Disparities stem from multiple factors, thus, comprehensive, multi-level interventions (MLI) are needed. Presented here is a conceptual framework for selecting the appropriate study design for MLIs using ACTWONDER[2]S, a multi-level intervention (MLI) aimed to increase Black/AA and Hispanic patient participation into CCTs, as an illustrative example. Baseline characteristics of the ACTWONDER[2]S target populations are also provided.

Methods: ACTWONDER[2]S integrates community health educator and digital tools into an MLI targeting community residents and physicians in the Moffitt Cancer Center (MCC) catchment area, as well as MCC patients, physicians and CCT coordinators. A literature review of the relative strengths and weakness of 5 candidate designs for MLIs was conducted, and a cluster stratified randomized design was selected. Geospatial analytics were used to identify clusters of census tracts ("priority zones") with high Black/AA and Hispanic populations for intervention deployment. Baseline characteristics of the priority zones were described using US Census data and other sources.

Results: 14 priority zones were identified, which were matched on population characteristics and randomized into intervention (n=7) and control (n=7) zones. There were no statistically significant differences between the intervention and control priority zones in total population size (paired t-test p-value=0.63), proportions of Black/AA (p=0.133) and Hispanic populations p=0.17), and distance (in miles) from MCC (p=0.64). Approximately 35.8% and 16.5% of the intervention priority zones were Hispanic or Black/AA, respectively. Average distance to MCC, cancer cases, referral and CCT enrollment rates were also similar between groups.

Conclusion: Decision frameworks for MLI study design selection are lacking. The framework provided here for ACTWONDER[2]S can be applied to other studies seeking to evaluate MLIs. Furthermore, the randomization of the priority zones produced optimal target populations for testing the efficacy of the MIL within ACTWONDER[2]S.

#4825 Addressing financial toxicity in cancer clinical trial participation: Barriers and facilitators of enrolling in a reimbursement program for out-of-pocket travel costs.

E. Ramos[1], V. Nguyen[2], A. Santaniello[3], D. Dornsife[4], R. G. Johnson[4], P. E. Wileyto[3], R. H. Vonderheide[3], C. E. Guerra[3];
[1]University of Pennsylvania, Philadelphia, PA, [2]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA, [3]Abramson Cancer Center, Philadelphia, PA, [4]Lazarex Cancer Foundation, Danville, CA

Financial toxicity has been associated with adverse outcomes for patients with cancer. Out-of-pocket (OOP) costs contribute to the high financial toxicity (FT) experienced by patients with cancer. Cancer clinical trial (CCT) participants face significant extra OOP expenses presenting a barrier to participation and retention. To address FT in CCTs, the Lazarex Foundation created the Improving Patient Access to Cancer Clinical Trials (IMPACT) Program, a financial reimbursement program (FRP) for OOP travel and lodging costs associated with therapeutic CCT participation. Our study aimed to quantify the FT experienced by patients in CCTs and understand their experience to determine the barriers and facilitators of enrolling in the Lazarex IMPACT Program. Patients enrolled in a CCT were referred to the IMPACT team to determine eligibility. Patients were eligible for IMPACT if they were active on a therapeutic CCT and their household income was less than 700% of the most recent HHS federal poverty guidelines. Patients who enrolled in the program were invited to participate in a brief semi-structured interview via telephone call. We used grounded theory techniques of analysis to identify themes of barriers and facilitators to enrollment in the Lazarex IMPACT program at our cancer center. Table 1 shows the emerging themes from the interviews as barriers and facilitators of enrolling in IMPACT. As a part of the interview process, patients also completed the COST-FACIT questionnaire, a patent reported outcomes measure to evaluate the degree of FT associated with cancer. COST scores in our cohort (n=39) ranged from 14-39.6, mean=27.12, median=27.5; SD=7.96. Following enrollment in the program, patients on average had COST scores indicating low degrees of financial distress. Taken altogether, our results have the potential to inform the development of FRPs for patients with cancer to facilitate their participation in CCTs.

Table 1: Emerging themes from grounded analysis of semi-structured interviews and their frequency

Barrier to enrolling in FRP program.	No. of Participants	Facilitator of enrolling in FRP program	No. of Participants
Patients wanted to be made aware of program earlier in their CCT timeline	4	Enrollment process was easy and straightforward	17
Patients made aware of program after their CCT started	3	IMPACT team contacted patients to offer program	13
CCT Team unaware of program availability	3	Patients learned about the program through their CCT team	8
Patients reported difficulty with technology access and literacy	3	Patients reported sufficient technology access and literacy	4
Patients reported hesitancy sharing financial information	2	Cancer foundation was timely and helpful in enrollment process	2
Patients reported difficulty navigating vast resources at cancer center	1	Cancer Center social workers provided connection to program	1

#4826 Cancer mortality attributable to area-level socioeconomic inequalities in Japan from 2015 to 2020.

Y. Ito[1], T. Nakaya[2], M. Inoue[3], T. Sobue[4], H. Nakagama[3],

[1]Educational Foundation of Osaka Medical and Pharmaceutical University, Takatsuki-shi, Japan, [2]Tohoku University, Sendai-shi, Japan, [3]National Cancer Center, Chuo-ku, Tokyo, Japan, [4]Osaka University, Suita-shi, Japan

Background: In the 3rd Healthy Japan 21 and the 4th National Cancer Plan, the government focused on reducing health inequalities. However, current monitoring of socioeconomic inequalities in cancer is still insufficient to set the targets for the plan. To prioritize strategy aimed at reducing socioeconomic inequalities in cancer mortality, we estimated the population attributable risk fraction (PAF) and excess death due to socioeconomic inequalities, by sex, age group and cancer site.

Method: We used the areal deprivation index (ADI) to establish area-based socioeconomic status. We categorized municipalities to ADI quintile weighted by the size of population, Q1 is the least deprived and Q5 the most deprived group. Excess death due to socioeconomic inequalities was calculated by the difference between observed number of deaths and expected death of Q2 to Q5 group with Q1 as standard population. We used cancer mortality data obtained from vital statistics in 2015-2020.

Results: In total, about 12000 male and 2800 female excess deaths per year due to socioeconomic inequalities were estimated; that is 5.5% and 1.8% as PAF. PAF due to socioeconomic inequalities limited to premature death, less than 75 years old, was estimated as 7.6% in men and 3.3% in women. By age group, the 0-39 years group showed the largest PAF at 15.7% in men and 16.6% in women. In men of all age groups, except 0-39 years, lung cancer was the highest excess death due to socioeconomic inequalities. For women, some cancer sites (breast, ovary, esophagus) showed an opposite association, Q1 was the highest mortality group. Therefore, total excess death was lower than in men. In women of all ages, the highest rate of excess death due to socioeconomic inequalities was gallbladder cancer. For the 0-39 years group, a high rate of excess death in stomach, leukemia, and cervical cancer was observed.

Discussion: Excess death and PAF due to socioeconomic inequalities differed by sex and age group. A greater impact of socioeconomic inequality on cancer mortality was observed in men than in women. Among women, further attention should be paid to areal variation of cancer death related to socioeconomic inequalities, based on the different area-based indices.

#4827 Financial toxicity among cancer survivors during the COVID-19 pandemic.

T. Srivastava, S. Shariff-Marco, S. L. Washington III, C. Miaskowski, J. M. Chan;
UCSF - University of California San Francisco, San Francisco, CA

Background: Financial toxicity (FT), the financial impact of cancer and its treatments on patients' employment, income, and health insurance, can have significant short- and long-term consequences for cancer survivors. With significant increases in cancer survivorship and the changing demographics of the United States, a need exists to identify those most susceptible to FT. This study evaluated FT prevalence during the COVID-19 pandemic and identified factors associated with greater FT risk.

Methods: Data were collected from 1,147 cancer survivors recruited from previous National Cancer Institute-funded studies, from electronic health record searches for patients with cancer diagnoses at University of California, San Francisco (UCSF) and Mount Sinai Medical Center and Columbia University Medical Center in New York City, and the Dr. Susan Love Foundation for Breast Cancer Research. Adults, diagnosed with cancer and proficient in English, completed an online survey via the Research Electronic Data Capture (REDCap) system between May 27, 2020 and February 21, 2021. FT was assessed for the past 14 days using the validated 11-item COmprehensive Score for financial Toxicity (COST) measure. Patients were categorized by score: no FT (COST scores >25), mild FT (14-25), and moderate/severe FT (0-13). Using Pearson's chi-square test of independence, and univariate ordinal logistic regression, the study evaluated sociodemographic and clinical characteristics associated with FT, including age, race and ethnicity, gender, household income, education, marital status, health insurance status, and cancer site.

Results: The COST measure had excellent reliability for the sample (Cronbach's alpha = 0.911). Overall, 9% of respondents reported moderate/severe FT (MSFT), 16% mild. Race/ethnicity, education level, annual household income, cancer site, and years from diagnosis (p-values ≤ 0.035) were associated with FT. Current health insurance coverage was not associated with FT (p=0.456). 18% Black, 13% Asian American, 17% mixed, and 20% other races/ethnicities reported MSFT, while 8% non-Hispanic White and 5% Hispanic respondents reported the same. 31% of survivors with annual household income <$40,000 reported MSFT vs. 7% with ≥$40,000 income. 14% of survivors with less than a college degree reported MSFT vs. 8% amongst those with a college degree or higher. For men, the odds of having FT (mild or MSFT) were 0.60 (95% CI 0.40, 0.90) times that of women. Survivors <50 years old at diagnosis had 7.53 (95% CI 4.09, 13.83) times the odds of FT (mild or MSFT) vs. those aged ≥75 years.

Conclusions: These preliminary analyses from this cross-sectional study characterizes the prevalence and determinants of FT experienced by cancer survivors during the COVID-19 pandemic. The next steps will include multivariable analysis and comparison with pre-pandemic data, to identify those at greatest risk and inform interventions.

#4828 Effect of county-level income and rurality on cardiovascular disease mortality among Asian and Pacific Islander breast cancer survivors in the US, 2000-2018.

K. L. Ho[1], C. Ramin[2], J. Z. Shing[3], K. Taparra[4], J. B. Vo[3];
[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]National Cancer Institute, Bethesda, MD, [4]Stanford Medicine, Palo Alto, CA

Purpose: To examine differences in cardiovascular disease (CVD) mortality by county-level income and rurality for Asian versus Pacific Islander (PI) breast cancer survivors.
Background: Asian and PI individuals experience varying cancer burden, and prior studies have reported disparities in treatment-related CVD mortality among breast cancer survivors by socioeconomic status and race and ethnicity. However, the impact of county-level income and rurality on CVD mortality among Asian and PI breast cancer survivors, separately, are not well described.
Methods: We included 60,184 Non-Hispanic Asian and PI women diagnosed with first primary, invasive breast cancer between 2000-2017 in the U.S. Surveillance, Epidemiology, and End Results program (aged 18-84, survived 12+ months, and received initial surgery). We estimated the hazard ratio (HR) of CVD mortality using Cox proportional hazard models assessing the impact of county-level income (median household income: low = <$75,000; high [ref] = ≥$75,000) and rurality (urban [ref] = metropolitan counties, population ≥ 250,000; rural = nonmetropolitan counties), separately for Asian and PI breast cancer survivors. Models adjusted for continuous age, stage (localized, regional/distant), and year of breast cancer diagnosis (2000-2004, 2005-2009, 2010-2017). We calculated 10-year cumulative CVD mortality for Asian and PI women accounting for competing risks (e.g., non-CVD deaths).
Results: Of 55,602 Asian and 4,582 PI breast cancer survivors, 1,114 Asian and 178 PI women died from CVD through 2018 (median follow-up, Asian = 6.0 years; PI = 5.5 years). PI women had a higher median age at breast cancer diagnosis (57 vs. 55 years) and more advanced stage (37% vs. 33%) than Asian women. Among Asian breast cancer survivors, low county-level income was associated with elevated CVD mortality (HR = 1.17, 95% CI = 1.04, 1.31), but not rurality (HR = 1.20, 95% CI = 0.91, 1.58). For PI breast cancer survivors, there were no significant associations observed for low county-level income (HR = 0.83, 95% CI = 0.60, 1.14) or rurality (HR = 1.11, 95% CI = 0.76, 1.61). At 10 years after breast cancer diagnosis, 1 in 40 Asian women and 1 in 20 PI women died of CVD.
Conclusion: Asian breast cancer survivors living in low-income counties had heightened risk of CVD mortality compared with those living in higher income counties, highlighting potential healthcare access barriers to cancer survivorship care. Although PI women did not experience significant differences in CVD mortality across groups of county-level income and rurality, they had twice as high absolute risk of CVD mortality than Asian women, warranting further investigation. Future studies that disaggregate Asian and PI individuals into more diverse and granular ethnicity groups are needed to understand heterogeneity in breast cancer survivorship outcomes.

#4829 Pre-diagnostic comorbid conditions and survival among black women with ovarian cancer.

Alicia Richards[1], Courtney E. Johnson[2], Anthony J. Alberg[3], Elisa V. Bandera[4], Melissa Bondy[5], Michele L. Cote[6], Theresa A. Hastert[7], Kristen Haller[2], Jeffrey R. Marks[8], Edward S. Peters[9], Paul D. Terry[10], Andrew B. Lawson[11], Joellen M. Schildkraut[2], Lauren C. Peres[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Emory University, Atlanta, GA,[3]University of South Carolina, Columbia, SC,[4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[5]Stanford University, Stanford, CA,[6]Indiana University, Indianapolis, IN,[7]Wayne State University, Detroit, MI,[8]Duke Medical Center, Durham, NC,[9]University of Nebraska Medical Center, Omaha, NE,[10]University of Tennessee, Knoxville, TN,[11]Medical University of South Carolina, Charleston, SC

Introduction: Black women with epithelial ovarian cancer (EOC) have worse survival compared to other racial groups, and the causes of these poor outcomes remain unclear. Compared to other racial groups, Black women are disproportionately affected by comorbid conditions which can adversely impact cancer care and outcomes. Thus, we examined the association of pre-diagnostic comorbid conditions and their associated medications with survival among Black women with EOC.

Methods: Using data from Black women with EOC in the African American Cancer Epidemiology Study, we evaluated the self-reported Charlson comorbidity index (CCI) and three cardiometabolic comorbidities (diabetes mellitus, hypertension, and hyperlipidemia). We also characterized whether women with each cardiometabolic condition were using medication for their condition. Kaplan-Meier survival curves and log-rank tests were used to examine survival by the CCI, each cardiometabolic comorbidity, and medication use. Cox proportional hazards regression models were used to examine the association of comorbid conditions and medications with survival while adjusting for age at diagnosis, stage, histotype, and study site.

Results: Among 592 Black women with EOC, 35% had a CCI ≥2, and the prevalence of diabetes, hyperlipidemia, and hypertension was 19%, 31%, and 62%, respectively. Among women with each cardiometabolic condition, the prevalence of medication use for diabetes, hypertension, and hyperlipidemia was 73%, 78%, and 60%. In bivariate analyses, women with a higher CCI, diabetes, hyperlipidemia, and hypertension had worse survival compared to women without these conditions (P<0.05). However, when adjusting for prognostic factors, only a high CCI (≥2 vs. 0) and diabetes were significantly associated with higher hazard of death (HR=1.36, 95% CI=1.06-1.74 and HR=1.40, 95% CI=1.08-1.81, respectively). Investigating the independent associations of each condition included in the CCI with survival revealed that diabetes was largely driving the association of CCI with survival. When considering medication use, women with diabetes, irrespective of medication use, women with hypertension not on medication, and women with hyperlipidemia on medication had worse survival compared to women without these conditions in bivariate models (P<0.05). Compared to women without diabetes, women with diabetes on medication and women with diabetes not on medication had a statistically significant higher hazard of death in multivariable models (HR=1.39, 95% CI=1.02-1.88 and HR=1.63, 95% CI=1.04-2.57, respectively). No associations with survival were observed when considering medication use for hypertension and hyperlipidemia after adjusting for prognostic factors.

Conclusion: Similar to prior studies among White women with EOC, diabetes, regardless of medication status, was strongly associated with poorer survival among Black women with EOC.

#4830 Predicting drug treatment response in African American lung cancer patients who smoke.

M. Ray[1], I. Osei-Gyening[2], K. Acheampong[3], M. Riebesell[4], **K. A. Mitchell**[5];

[1]Penn State College of Medicine, Hershey, PA, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Bristol Myers Squibb, Princeton, NJ, [4]Lafayette College, Easton, PA, [5]Fox Chase Cancer Center, Philadelphia, PA

Background: Lung cancer is the third most commonly diagnosed cancer in the US and the leading cause of cancer-related death. African Americans (AAs) have higher lung cancer incidence and mortality rates, and lower survival rates, when compared to their European American (EA) counterparts. It is widely known that cigarette smoking is the strongest risk factor for lung cancer development, but it also plays a significant role in clinical outcome. Cigarette smoking after lung cancer diagnosis (up to 30% patients) comes with several risks, including increased secondary tumors and mortality rates (by 20%), as well as poor treatment outcomes (higher radiation and chemotherapy failure and higher drug clearance). There are limited transcriptomic studies that describe molecular characterizations of AA smokers with lung cancer to predict treatment outcomes.

Hypothesis: Cigarette smoking leads to greater drug resistance-related gene expression in AA lung cancer patients.

Methods: mRNA expression changes in an AA (NCI-H2172) and EA (NCI-H1944) lung cancer cell line pair exposed to liquid cigarette smoke condensate (CSC) were profiled. The cell lines were matched based on age (62 years), sex (female), histology (lung adenocarcinoma, LUAD, the most common subtype), and culture properties (adherent). The CSC was derived from Murty Pharmaceuticals and prepared by smoking University of Kentucky's 3R4F Standard Research Cigarette on an FTC Smoke Machine. A total of 500,000 cells per well were treated for one hour under standard incubation conditions (37°C, pH 7.0, 5% CO_2). Cells were pelleted, RNAs were isolated, treated with DNAse-I to remove contaminating genomic DNA, quantified, and sent for bulk mRNA-sequencing (Novogene Co). Three biological replicates and technical triplicates were performed. Partek Flow and Partek Genomics Suite workflows were used to identify population-specific differentially expressed gene (DEG) signatures and pathway enrichment after CSC exposure. DEG were profiled in LUAD tissues from current smokers in an AA and EA TCGA cohort (n = 18 AAs, 86 EAs).

Results: Population-specific gene expression changes were discovered (n = 52 AA DEGs, n = 31 EA DEGs; $P < 0.001$). All of the DEGs were mutually exclusive with no overlap. Some pathways were shared between both populations and others were unique. PI3K/Akt/mTOR signaling pathway enrichment was unique in AA LUAD cells and ECM receptor interactions were distinct in EA LUAD cells. AKT2 (which activates mTOR) had significantly higher expression in LUAD tumor tissues from current AA smokers compared to current EA smokers.

Conclusion: Population-specific PI3K/Akt/mTOR pathway alterations may help explain drug resistance in LUAD tumors from AA patients. PI3K signaling is considered a significant cause of resistance to chemotherapy, targeted therapy, and immunotherapy.

Future Directions: Expose AA and EA LUAD cell lines to CSC and PI3K/Akt/mTOR pathway inhibitors.

#4831 Racialized economic segregation and disparities in late-stage diagnosis, treatment and mortality among patients with non-small cell lung cancer.

P. Shrestha, M. Lian, Y. Liu;
Washington University In St. Louis, St. Louis, MO

Importance: Little is known about the impact of residential segregation on early detection, treatment, and prognosis among patients with non-small cell lung cancer (NSCLC), a predominant type of lung cancers.
Objective: To examine the associations of racialized economic segregation with the risks of late-stage diagnosis, non-adherence to guideline-recommended treatment, and mortality among non-Hispanic White (NHW) patients and non-Hispanic Black (NHB) patients with NSCLC.
Methods: This population-based retrospective cohort study included patients with NSCLC as a first primary malignancy diagnosed at age 20 and older between January 2007 and December 2015, followed through December 2016, and identified from the Surveillance, Epidemiology, and End Results (SEER) dataset released in April 2019. County-level racialized economic segregation was estimated using the Index of Concentration at the Extremes (ICE). We used multilevel logistic regression and multilevel Cox regression accounting for county-level clustering to estimate odds ratios (ORs) for late-stage diagnosis and non-adherence to guideline-recommended treatment, and hazard ratios (HRs) for overall mortality and lung cancer-specific mortality.
Results: Of 203, 441 patients, 85.8% were NHW and 14.2% were NHB. Compared with patients living in the most privileged (lowest ICE quintile—segregated, high-income NHW) counties, patients living in the least privileged (highest ICE quintile—segregated, low-income NHB) counties had higher risks of late-stage diagnosis (OR=1.09, 95% CI: 1.02-1.16; P_{trend} <.001), non-adherence to guideline-recommended treatment (OR=1.28, 95% CI: 1.16-1.41; P_{trend} <.0001), lung cancer-specific mortality (HR=1.10, 95% CI: 1.07-1.14; P_{trend} <.0001), and overall mortality (HR=1.12, 95% CI: 1.09-1.16; P_{trend} <.0001). The association of segregation with treatment underutilization was stronger in NHW patients than NHB patients ($P_{interaction}$ =0.02). There was no significant difference in the segregation-related risk of late-stage diagnosis, lung cancer-specific mortality, or overall mortality between NHW and NHB patients.
Conclusions: Living in segregated, low-income NHB counties was associated with increased risks of late-stage diagnosis, suboptimal treatment, and mortality among patients with NSCLC. Future research should investigate contributors to the adverse impact of residential segregation on lung cancer care and outcomes.

#4832 The impact of neighborhood-level disadvantage on the patient-reported outcomes of primary brain tumor patients.

Z. A. Karim, K. Reinhart, O. Celiku, Y. Kim, H. Miller, E. Vera, J. B. Vo, T. S. Armstrong, M. L. Stockdill;
National Institutes of Health (NIH), Bethesda, MD

There is increased recognition that social determinants of health may impact well-being and health in those with various cancers, but they have not been systematically evaluated in primary brain tumor (PBT) patients. Here, we examined the association between Area Deprivation Index (ADI), a measurement of sociodemographic neighborhood disadvantage, and patient-reported outcomes (PROs) in a cohort of adult PBT patients enrolled in a large National Institutes of Health observational trial (NHS, NCT02851706, PI: Armstrong). We utilized linear regression to assess the relationship between ADI (less advantaged [ADI≥40, n=153, 24%], more advantaged [ADI<40, n=490, 76%]) and patient symptom burden (MDASI-BT), anxiety, and depression (PROMIS Short Forms v1.0 8a). Logistic regression was used to evaluate the association between ADI and health-related quality of life using the 5 dimensions of the EQ-5D-3L. Models were adjusted for age, sex, race/ethnicity, tumor grade, Karnofsky Performance Score (KPS), and tumor recurrence. A sub-analysis stratifying by tumor grade (low, high) was completed. Among 643 PBT patients, the majority resided in more advantaged areas (n=490; 76%) and had high-grade tumors (n=448; 70%). Those who were less advantaged reported more symptom severity (β=1.10, SE=1.05, *P*=0.041), more activity-related interference (β=1.11, SE=1.05, *P*=0.03), and had 4.68 times the odds of having moderate-severe difficulty completing self-care tasks (95% confidence interval [1.46, 14.96], *P*=0.009) compared to those who were more advantaged. KPS was a significant predictor for all three outcomes, and age at diagnosis was significant for PBT symptom severity. Among patients with low-grade tumors, those who were less advantaged reported higher symptom interference (β=1.24, SE=1.10, *P*=0.020), affective symptoms (β=1.24, SE=1.08, *P*=0.007), treatment-related symptoms (β=1.21, SE=1.08, *P*=0.021), general disease symptoms (β=1.26, SE=1.10, *P*=0.016), activity-related interference (β=1.26, SE=1.09, *P*=0.006), mood-related interference (β=1.20, SE=1.09, *P*=0.039), and anxiety (β=1.03, SE=1.02, *P*=0.023), with KPS being a significant predictor for all outcomes except anxiety. Overall, less advantaged PBT patients reported worse symptom severity and activity-related interference, and those with low-grade tumors experienced more affective symptoms, including fatigue, general disease and treatment-associated symptoms, and symptoms of anxiety, but not neurologic or cognitive symptoms. Living in less advantaged areas may lead to barriers to care access, symptom management medications, or other neighborhood resources that could alleviate PBT patient symptom burden but may compound over time for those with poor performance status or low-grade tumors. These results highlight the need for targeted supportive interventions for PBT patients living in less advantaged areas.

#4833 Impact of poverty in surrounding neighborhoods in cancer mortality in the US: A nationwide study among US women.

I. Nwigwe, M. Desjardins, K. Visvanathan;
Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD

Background: Poverty at the individual and county levels is known to lead to worse cancer outcomes. We believe the relationship between poverty and cancer may involve individual-level factors including tumor biology, socioeconomic status, and community measures that alter cancer outcomes such as death. We aim to understand to what extent poverty in the surrounding neighborhood may identify counties at the highest risk of cancer mortality and whether it is modifiable.
Methods: This study used data collected by SEER to examine the association between neighborhood effects of poverty on the top three sites of cancer mortality among women. We included women >= 20 years of age diagnosed with breast, lung, and colorectal cancer between 2005-2009 and 2010-2014 who survived more than one year after diagnosis. We determined county-level neighborhood poverty environments using local spatial autocorrelation (LISA) analysis with Local Moran's I of five-year county-level poverty estimates from the American Community Survey. US counties with poverty estimates above or below the national median were defined as high (H)- or low (L)- poverty counties, respectively. We defined neighborhood poverty environments as H-counties among H-counties (HH), L-counties among L-counties (LL), H-counties among LL-counties (HL), and L-counties among HH-counties (LH). We used a Poisson regression model adjusting for age at diagnosis, race/ethnicity, cancer stage, year of diagnosis, treatment, and cancer type to assess county-level neighborhood poverty environment effects on cancer mortality. We also used stratified analyses to explore the effect of cancer type, stage, and race/ethnicity strata on the association between neighborhood poverty environments and cancer death.
Results: Our analysis includes 36,481 women with 4,740 cancer deaths. In total 7,182 women were in HH counties; 21,112 women were in LL counties; 6,476 women were in HL counties; and 1,711 women were in LH counties. Women in HH, LH, and HL counties had a respective 1.23 [95%CI:1.14,1.32], 1.20 [95%CI:1.05,1.36], and 0.95 [95%CI: 0.88,1.03] relative risk (RR) of cancer death when compared to deaths in LL counties. In our stratified analyses, women with breast cancer in HH and HL counties had higher cancer deaths (RR = 1.21 [95%CI:1.03,1.42] and 1.37 [95%CI:1.13,1.65], respectively) when compared to women with lung cancer. We also observed higher cancer deaths from counties that were LL in 2005-2009 and changed to HH counties in 2010-2014 (RR = 1.60 [95%CI:0.85,2.68]) when compared to unchanged LL counties.
Conclusion: We used LISA spatial clustering to demonstrate the effects HH and LH environments have on cancer mortality. We also demonstrate the impact that changes in neighborhood environments can have on cancer mortality. Our findings suggest that prioritization of resource allocations to HH neighborhoods could improve the burden of women with cancer.

#4834 Racial disparities in pain and psychiatric medication use in patients with metastatic colorectal cancer.

J. M. Allen[1], O. M. Trejos Kweyete[1], Y. Guo[2], S. C. Rogers[2], L. Scarton[2], D. L. DeRemer[2], C. Whitner[3], D. J. Wilkie[2];
[1]University of Florida, Orlando, FL, [2]University of Florida, Gainesville, FL, [3]University of Florida, Jacksonville, FL

Background: In the United States, colorectal cancer (CRC) is a public health concern, as it is the second leading cause of cancer-related death, accounting for over 50,000 deaths annually. In addition to its high mortality, CRC is associated with significant comorbidities including pain and psychiatric symptoms, particularly in late-stage disease. Supportive care medications (SCM) are frequently used for symptom management and improving health-related Quality of Life (HRQoL). Racial disparities in clinical outcomes including HRQoL have been reported in CRC. While racial disparities have been described in the use of SCM for some cancer types, no investigation of SCM use in late-stage CRC have been performed. The purpose of our study was to explore the relationship between SCM use and race/ethnicity in patients with metastatic CRC.

Methods: We used the National Cancer Institute Surveillance Epidemiology and End Results (NCI SEER)- Medicare-linked database to analyze all patients with a CRC diagnosis and a newly initiated outpatient prescription claim for an SCM of interest from 2009-2018. Patients on SCM before cancer diagnosis or who had non-metastatic CRC at diagnosis were excluded. We assessed six SCM classes: opioids, non-opioid analgesics, skeletal muscle relaxants, antidepressants, anxiolytics, and antipsychotics.

Results: After application of inclusion/exclusion criteria, 28, 212 patients were included in the final analysis (White: 72.8%, Black: 12.7%, Hispanic: 9.5%, Asian: 4.6%, Native American: 0.4%). After controlling for socioeconomic factors and compared to non-Hispanic White patients, there were significant differences across multiple SCM drug classes. When considering pain medications, these differences were bi-directional. Black patients were less likely to receive opioids (adjusted Odds Ratio [aOR] 0.86, 95% CI: 0.80-0.93), while Hispanic patients were more likely to receive opioids (aOR: 1.12, 95% CI: 1.03-1.22) and non-opioid analgesics (aOR 1.22, 95% CI: 1.06-1.40). Asian patients were more likely to receive non-opioid analgesics (aOR 1.71, 95% CI: 1.45-2.03), but less likely to receive skeletal muscle relaxants (aOR 0.60, 95% CI: 0.43-0.82). When considering psychiatric medications, decreased use among all racial groups was noted for antidepressants (Black: aOR 0.53, 95% CI: 0.50-0.60; Hispanic: aOR 0.82, 95% CI: 0.75-0.90; Asian: aOR 0.48, 95% CI: 0.42-0.56), and anxiolytics (Black: aOR 0.43, 95% CI: 0.38-0.49; Hispanic: aOR 0.76, 95% CI: 0.67-0.85; Asian: aOR 0.45, 95% CI: 0.37-0.55). Among antipsychotics, only Asian patients had less use compared to non-Hispanic White patients.

Conclusion: Racial disparities in the use of pain and psychiatric medications among patients with late-stage CRC were present, even after controlling for multiple confounders. Further investigation is needed to understand drivers and their impact on HRQoL outcomes.

#4835 Demographic factors and risk of persistent opioid use in a diverse cohort of breast cancer survivors.

L. Chen[1], R. C. Hechter[1], J. Shi[1], Z. Gu[1], M. Brady-Rogers[2], R. T. Chlebowski[3], R. Haque[1];
[1]Kaiser Permanente Research, Pasadena, CA, [2]Alive & Well Women, South Pasadena, CA, [3]The Lundquist Research Institute for Biomedical Innovation at UCLA-Harbor, Torrance, CA

Background: Persistent opioid use (POU), in breast cancer survivors after they have completed active cancer treatment is an emerging area of concern. We examined rates and identified risk with POU in breast cancers survivors in the year after active cancer treatment going forward, and if these risks differed by race/ethnicity.
Methods: We assembled a cohort of female breast cancer survivors diagnosed in 2009-2019 treated for early-stage disease (in situ, local, regional), and had at least two opioid prescriptions after one year of survivorship in a large health plan in southern California. Data were captured from the tumor registry, electronic health records, and pharmacy databases. The primary outcome was POU defined as continuously receiving at least 90 days supplied of opioids during follow-up. Patients were followed through the date once they met POU criteria, died, disenrolled from health plan, or reached study's end (12/31/2021), whichever came first. We calculated rates as the number of patients who experienced POU per 1,000 person-years (PY). We identified the predictors and estimated hazard ratios (HR) associated with POU using multivariable proportional hazard regression and stratified by race/ethnicity.
Results: The cohort included 14,347 breast cancer survivors who used opioids followed for a maximum of 12 years (median: 6.6 years). Overall, the cohort was diverse: 9% Asian/Pacific Islander (API); 14% Black; 22% Hispanic; and 54% White women. Out of 14,347 patients who used opioids, 2,285 (16%) patients developed POU. POU rates was the highest in Whites (36.2 per 1,000 PY) compared other race/ethnicity groups including Blacks, Hispanics, APIs (30.7, 17.3, 10.6 per 1,000 PY, respectively). Patients who developed POU had longer annualized median opioid duration, especially in Black patients (175.0 vs. 5.3 days) and were prescribed stronger opioids (median maximum daily morphine milligram equivalent 83.7 vs 50.0), compared to those who did not develop POU. In adjusted analyses of POU risk, Black (HR, 0.81; 95% CI: 0.72-0.92), API (HR, 0.59; 95% CI, 0.52-0.66), and Hispanic women (HR, 0.59; 95% CI, 0.52-0.66) were less likely to develop POU compared to White women. Patients with older age, Elixhauser Comorbidity Index ≥3, smoking, breast cancer stage (regional); type of opioid (Oxycodone); and who used other psychiatric and pain medications had significantly greater POU risk. In stratified analysis, the POU risk was 2.6 times greater (HR, 2.61; 95% CI, 1.32-5.15) in Hispanic patients aged≥65 vs <40 years. The highest HR was in APIs who were current smokers (HR, 4.26; 95% CI, 1.77-10.29) compared with non-smokers.
Conclusion: The findings suggest that patients who are older, current smokers, with more comorbidities, and diagnosed with higher cancer stage were most vulnerable to developing POU.

#4836 Race differences in symptom burden and medication adherence among women with breast cancer on adjuvant endocrine therapy: A post hoc analysis of a randomized control trial.

X. Hu[1], R. A. Krukowski[1], E. Stepanski[2], L. S. Schwartzberg[3], G. A. Vidal[4], I. Graetz[5];

[1]University of Virginia School of Medicine, Charlottesville, VA, [2]Ovation.io, Cambridge, MA, [3]Renown Institute for Cancer and University of Nevada, Reno, NV, [4]West Cancer Center and Research Institute, Germantown, TN, [5]Emory University, Rollins School of Public Health, Atlanta, GA

Background: Adjuvant endocrine therapy (AET) reduces breast cancer recurrence, but racial differences in nonadherence remains a concern. Differential symptom burden may contribute to disparities in AET adherence.

Method: We conducted a post hoc analysis by race among women with breast cancer starting AET who were randomized in THRIVE Study (NCT03592771) to investigate remote symptom monitoring intervention vs. usual care from 11/2018 to 06/2021. Participants completed surveys at baseline, 6- and 12-month. Outcomes were symptom burden measured by FACT-Endocrine Subscale, and adherence measured by electronically monitored pillbox (>80% Proportion of Days Covered). We estimated symptom differences by race using linear regression with and without adjusting for baseline characteristics. To examine whether symptom burden contributed to racial differences in adherence, we conducted multivariable regression for adherence with and without controlling for symptom burden, and Blinder-Oaxaca decomposition.

Results: Among 102 (34%) Black and 194 (66%) White women who were randomized, retention was 88% at 12-month. Compared to White participants, Black participants were younger (55 vs. 60 years), more likely to be at poverty (10.8% vs. 4.1%), and had lower health literacy (18.9% vs. 13.4%; *p-values*<.01). While symptom burden did not differ by study arm, Black participants had worse symptoms than White at baseline (60.8 vs. 64.5, *p*=.002). This gap became smaller at 6-month (59.7 vs. 61.2, *p*=.30), but diverged again at 12-month (56.9 vs. 61.8, *p*<0.01). Differences at 12-month diminished after controlling for baseline characteristics (-1.6, 95%CI=-4.4 to 1.2). Notably, being at poverty and younger age were associated with higher symptoms. Adherence was lower among Black participants at 6-month (0.69 vs. 0.78, p=.13) and 12-month (0.44 vs. 0.60, p=.014) than White participants. Unadjusted differences in adherence at 12-month (-16.0 percentage points [ppts], 95%CI=-28.9 to -3.3, p=.01) attenuated after adjusting for baseline symptoms, symptom changes to 12-month, and other baseline characteristics (-10.4 ppts, 95%CI=-25.6 to 4.8, p=.18). Lower baseline symptoms were associated with better adherence (0.8 ppts, 95%CI=0.1 to 1.4, p=.03). Decomposition indicates that 9.1 ppts (95%CI=-4.8 to 23.0, 57%) of the difference in 12-month adherence was explained by symptoms and baseline characteristics, and remaining unexplained difference was 6.9 ppts (95%CI=-12.6 to 26.4, 43%).

Conclusion: Our results add to increasing evidence that Black women with breast cancer have lower AET adherence, which may be partially attributed to worse symptoms than White women. These results highlight the need for new strategies to promote equitable symptom management and adherence strategies between Black and White women to reduce disparities in outcomes.

#4837 Perceived discrimination, medical mistrust, and their associations with ovarian cancer mortality among women in the African American Cancer Epidemiology Study.

L. J. Collin[1], C. Johnson[2], M. Akonde[3], M. Kan[2], E. V. Bandera[4], L. Peres[5], A. Alberg[6], T. Hastert[7], J. Schildkraut[2];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Emory University, Atlanta, GA, [3]University of South Carolina, Charleston, SC, [4]Rutgers Cancer Institute, New Brunswick, NJ, [5]Moffit Cancer Center, Tampa, FL, [6]University of South Carolina, Charlston, SC, [7]Wayne State University, Detroit, MI

Background: There are pronounced racial disparities in ovarian cancer mortality wherein Black women are on average 30% more likely to succumb to their disease than White women. Factors that contribute to these disparities are complex and multifactorial. Racial discrimination is hypothesized to affect cancer health disparities through three distinct pathways including the impact on socioeconomic inequities, chronic stress, and restricted access to goods and services. In this study, we examined the role of perceived discrimination and medical mistrust on all-cause mortality among ovarian cancer patients.

Methods: Using data from the African American Cancer Epidemiology Study (AACES), we included 592 ovarian cancer patients who self-identified as Black or African American and completed a telephone interview. Perceived discrimination was measured with a modified version of the 5-question Williams Everyday Discrimination scale. Medical mistrust was measured with the Trust in Physician scale (ranged 0-48 based on a combination of 12 questions). We used Cox proportional hazard models to compute hazard ratios (HR) and 95% confidence intervals (CIs) associating perceived discrimination and medical mistrust with all-cause mortality, adjusting for age, stage, and histotype.

Results: Nearly two-thirds of the cohort passed away by the end of follow-up (mean follow-up 5.5 years, ranging 0.5-12 years). We observed that 231 participants patients (39%) reported experiencing discrimination in at least one of the domains assessed. Reporting any experience of discrimination was associated with lower all-cause mortality (HR=0.78, 95% CI: 0.62, 0.97). In multivariable adjusted models, higher trust in physicians (above vs. below the median of 35) was associated with a decreased risk of mortality (HR=0.87, 95% CI: 0.70, 1.08).

Conclusion: In our preliminary results, we observed an association between any experience of discrimination and better survival, and that a higher trust in physicians was associated with better survival. Further work on this project will try to understand the paradoxical association with perceived discrimination, and evaluate the associations of discrimination and medical mistrust with ovarian cancer treatment, leading to more insight into drivers of racial disparities in ovarian cancer mortality.

#4838 Impact of social determinants of health (SDH) on systemic therapy and survival in young women with breast cancer.

N. J. Reed, F. Ahmed, C. Schepel, L. Hadzikadic-Gusic, J. Fisher, A. R. Tan, A. L. Heeke;
Levine Cancer Institute, Charlotte, NC

Introduction: Health disparities are often influenced by SDH. Breast cancer patients (pts) with negative SDH may experience less access to treatment, which can impact outcomes. This study evaluated the association between SDH, utilization of medical therapy, and outcomes in young pts with early breast cancer.
Methods: We performed a retrospective review of female pts 18-40 years old in the Young Women's Breast Cancer Database at a single institution with non-metastatic breast cancer diagnosed from 2011-2020. Predefined SDH were recorded along with clinical characteristics at diagnosis. Descriptive statistics and logistic regression analyses were performed. Survival analyses were conducted using Kaplan-Meier and Cox Proportional Hazard model.
Results: 1,061 pts were eligible for analysis; 67% were White, 27% Black, 4% Asian, and 3% Other. Additional demographic and clinical characteristics are shown in Table 1. Pts with Medicaid received chemotherapy (chemo) more often than pts with private insurance (OR 2.04, p=0.003), as did self-pay/uninsured pts (OR 1.74, p=0.003). Divorced/separated/widowed pts were more likely to receive chemo than married pts (OR 1.85, p=0.049). Pts living in 1st quartile of area deprivation index (ADI) received chemo less than those in the 4th ADI quartile (OR 0.45, p=0.003). Divorced/separated/widowed pts with HR+ disease were less likely to receive endocrine treatment than married pts (OR 0.48, p=0.039). Worse overall survival (OS) was seen for Black vs White pts (HR 1.72, p<.001); pts with Medicaid or self-pay/uninsured vs privately insured (HR 1.67, HR 1.92; p=0.025); and unemployed vs employed pts (HR 2.49, p<.001) adjusted for chemo use and clinical stage.
Conclusions: Young pts experiencing negative SDH were more likely to receive chemo, less likely to take endocrine therapy if indicated, and suffered from worse OS. These findings may highlight the influence of a pt's social network on access to care and treatment completion.

Table 1: Demographics & clinical characteristics in young women with early-stage breast cancer

Demographic Characteristics				
	Overall, N=1061			
Race	Asian: 40 (3.9 %)	Black or African American: 270 (26.6 %)	Other: 29 (2.9 %)	White or Caucasian: 677 (66.6 %)
Ethnicity	Hispanic or Latino: 86 (8.4 %)	Non-Hispanic or Non-Latino: 939 (91.6%)		
Insurance Type	Private: 824 (77.7 %)	Medicare: 16 (1.5 %)	Medicaid: 145 (13.7 %)	Self-pay/Uninsured: 75 (7.1 %)
Area Deprivation Index (ADI) Quartile*	Q1= 1-25: 215 (20.3 %)	Q2= 26-50: 375 (35.4 %)	Q3= 51-75: 315 (29.7 %)	Q4= 76-100: 155 (14.6 %)
Median Household Income	<45000: 44 (4.1 %)	45000-79,999: 600 (56.6 %)	80000-119,999: 304 (28.7 %)	≥120,000: 112 (10.6 %)
Employment status	Unemployed: 224 (21.1 %)	Employed: 657 (61.9 %)	Unknown: 180 (17.0 %)	
Marital Status	Married: 631 (59.8 %)	Single: 355 (33.6 %)	Separated/ Divorced/ Widowed: 70 (6.6 %)	
Clinical Characteristics				
Clinical AJCC Stage	Stage 0: 149 (14.3 %)	Stage I: 335 (32.1 %)	Stage II: 430 (41.2 %)	Stage III: 129 (12.4 %)
Receptor Status	HR+/HER2+: 174 (19.9 %)	HR+/HER2-: 519 (59.3 %)	HR-/HER2-: 182 (20.8 %)	
Utilization of Chemotherapy	Yes: 702 (67.1 %)	No: 344 (32.9 %)		
Utilization of Endocrine Therapy	Yes: 451 (43.3 %)	No: 590 (56.7 %)		
Recurrence Status	Yes: 111 (10.5 %)	No: 942 (89.5 %)		
Survival Status	Alive: 868 (81.8 %)	Dead: 101 (9.5 %)	Lost to follow-up: 92 (8.7 %)	
*Higher score correlates with greater disadvantage				

#4839 Ethnicity dictates survival benefit in Hispanics diagnosed with diffuse large B-Cell lymphoma survival: A national cancer database analysis.

C. Velez-Mejia[1], E. Toro Velez[1], D. Rosas[2], Q. Liu[1], J. E. Michalek[1], E. Diaz Duque[1];

[1]UT Health Science Center at San Antonio, San Antonio, TX, [2]Memorial Healthcare, Hollywood, FL

Background: Diffuse Large B-Cell Lymphoma (DLBCL) is the most common Non-Hodgkin lymphoma in the United States (US) but there is limited evidence showing ethnic disparities affecting overall survival (OS) (***Blood***10.1182/blood-2022-159201, ***Blood***10.1182/blood-2021-151816). This is the largest nationwide cancer registry analysis evaluating ethnic differences for HI vs Non-Hispanics (NH) with DLBCL in the US.

Methods: Data were analyzed using the National Cancer Database from 2004-2019. Sociodemographic characteristics were compared between ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare OS between HI and NH. Multivariate analysis and propensity score matching were performed with adjustment for age, stage, comorbidity score, and insurance status, type of facility, and great circle distance

Results: 239,391 patients (HI n=18,290, NH n=221,101) were diagnosed with DLBCL. Male sex predominated for both and the majority of patients were Whites. HI were diagnosed at a median age of 62 years (y) vs 68 y for NH [p<0.001]. For HI and NH, most of the patients were diagnosed from 2016-2019.

For both groups, the majority of patients had a Charlson-Deyo Score of 0, stage IV at diagnosis and unknown HIV status. The primary payer at diagnosis was government sponsored for HI and NH. In HI the median income based on the Median Income Quartile for 2000 corresponded to the highest level of >$46,000 and from 2008-2012 it was similarly distributed. For NH, for both time periods the majority of the patient were in the highest bracket. Most patients in the HI and NH were located in metropolitan area and were more likely to be treated at a comprehensive cancer center with a great circle distance (miles) of 7.3 for HI and 9.7 for NH.

The median survival for HI was 11 y vs 6.8 y for NH. The survival probability at 2, 5 and 10 y for HI corresponded to 69%, 61% and 52%, while for NH it was 66%, 55% and 41%, respectively. The OS probability at 10 y was statistically significant favoring HI [p<0.0001]. Independently, on multivariate analysis, not insured status was associated with worse OS (HR 1.2, CI 1.13-1.28, [p<0.01]) and private insurance type was associated with better OS (HR 0.81, CI 0.77-0.84, [p<0.01])

Conclusion: This nationwide cancer registry study identified better OS in HI diagnosed with DLBCL in the US. Both cohorts had similar sociodemographic and clinical results; however, HI were diagnosed at younger age. This finding may not only help to explain a unique trait towards development of cancer at an earlier age, but also an enhanced response to therapy. Regarding median income there wasn't a tendency noted for HI, which support the unique complex interactions in socioeconomic status. Further studies examining intrinsic biologic differences are needed to better understand improved OS for HI, which could also help the rational development of targeted therapies.

#4840 Creating a culturally sensitive manual to increase clinical trial participation among African Americans and African Nationals.

Carolina Aristizabal, Eduardo Ibarra, **Lourdes A. Baezconde-Garbanati**

Keck School of Medicine of USC, Los Angeles, CA

Background: Racial and ethnic minorities are immensely underrepresented in clinical trial studies in the United States. Black/African Americans, Latinos/as, Asians, American Indians, and Pacific Islanders make up roughly 30% of all clinical trials (CT) participation across all race groups. Being inclusive of all populations in CT ensures that everyone has access to modern medicines and treatments, but also, that these latest treatments work and react well to all people.
Methods: We developed a manual on clinical trials with a target focus to African Americans and African Nationals. We hosted two focus groups with Blacks/African Americans in which we found they are more comfortable getting cancer related information through trusted community services, such as coming from churches. We have connected with over 80 Pastors who agreed to collaborate in clinical trials education.
Results: Through outreach and engagement to African American churches in Los Angeles County, we have distributed a copy of this clinical trials educational manual to 90 churches to be disseminated during their services. Our office of Community Outreach and Engagement (COE) regularly attend community health and resource events and provide hard copies of the clinical trials manual at tables/booths designated for our participation. We have attended 50 community events and have disseminated about 1,900 copies of the CT manual so far this year 2023. This manual is also available for free download on our cancer center's website, in which over 100 toolkits have been downloaded within the last year.
Conclusions: By creating a culturally sensitive and adapted educational manual and partnering with trusted services in the community such as faith-based organizations, we can begin to break down barriers to clinical trials participation among all race and ethnic minority groups.

POPULATION SCIENCES: Descriptive Epidemiology and Statistical and Epidemiological Methodology
Poster Session

#4844 Epidemiology of bone and soft-tissue sarcomas: A two-decade analysis of the surveillance, epidemiology, and end results program.

Marc El Beaino[1], **Rachel Baum**[1], Katherine M. Connors[1], Karim Masrouha[2], Santiago A. Lozano-Calderon[3], Patrick P. Lin[4]

[1]Department of Orthopaedic Surgery and Rehabilitation Medicine, State University of New York, Downstate Health Sciences University, Brooklyn, NY,[2]School of Public Health, State University of New York Downstate Medical Center, Brooklyn, NY,[3]Department of Orthopaedic Surgery, Harvard Medical School, Boston, MA,[4]Department of Orthopaedic Surgery, New York University Langone Health, New York, NY

In the United States, ~15000 cases of bone and soft-tissue sarcomas are diagnosed annually, representing roughly 1% of all incident cancers. While several studies have analyzed independent predictors of outcomes for these sarcomas, small samples and confounding bias have limited their ability to establish reliable conclusions. The present analysis provides a comprehensive epidemiological description of patients with any of 16 distinct bone and soft-tissue sarcomas by querying the Surveillance, Epidemiology, and End Results database between 2000 and 2020. Incidence, prevalence, incidence-based mortality, survival rates, and case-fatality ratios were computed. Using patient age, sex, race, and ethnicity, as well as tumor size, grade, and stage as covariates, multivariable survival Cox proportional hazards regression analyses were performed to model hazard ratios (HRs) and identify independent predictors of worse prognosis. Only patients with myosarcoma and fibrous histiocytoma witnessed a decrease in the prevalence of their disease over time (both, $p<0.05$). The incidence of chondrosarcoma and synovial sarcoma increased in White and Asian patients but decreased in Black individuals (both, $p<0.001$), while their case-fatality rates remained constant and increased, respectively, regardless of race and ethnicity (all, $p<0.05$). Case-fatality rates only declined significantly for White and Non-Hispanic patients with solitary fibrous tumor (both, $p<0.05$). Aside from alveolar soft-part sarcoma and clear cell sarcoma, a 10-year increase in age of patients with bone and soft-tissue sarcomas resulted in 18% to 61% higher likelihood of death (all, $p<0.05$). For most malignancies, having a tumor size greater than 5 cm yielded a 37% to 189% higher likelihood of death. While incidence trends suggest improvements in diagnostic techniques and early tumor detection, survival and case-fatality trends indicate potential for advancement in treatment for most bone and soft-tissue sarcomas.

#4845 Evaluating racial disparities in immune checkpoint inhibitor survival and autoimmunity.

K. L. Nunes, P. Llerena, P. Kaki, S. Mandloi, A. Moroco, E. Mastrolonardo, D. M. Cognetti, A. J. Luginbuhl, J. M. Curry;
Thomas Jefferson Univ. Hospital, Philadelphia, PA

Introduction: In recent years, immune checkpoint inhibitors (ICI) have revolutionized the landscape of treatment across a variety of cancers. Potential concerns regarding racial disparities in ICI access and therapeutic efficacy have been well documented. Recent studies have indicated improved ICI access and response outcomes in White patients compared to minority groups with head and neck cancer (HNC) and melanoma patients. In contrast, patients diagnosed with lung cancer have been mixed, with some research suggesting black patients may fare better with ICI therapy. Existing literature is largely limited to retrospective studies with small population sizes, and lacks comparisons of racial disparities across malignancies. We aim to describe and compare racial inequities in ICI outcomes in HNC, melanoma, and lung cancer.

Methods: The TriNetX US Collaborative Network database was queried for patients >18 years-old with a diagnosis of head and neck cancer, melanoma or lung cancer that were treated with ICIs. Malignancy cohorts were defined by race: non-Hispanic White (NHW) and Black. Race cohorts were 1:1 propensity score matched (PSM) for comorbidities, oncologic stage, and chemoradiation treatment. Demographic differences in cohorts were evaluated prior to matching. Following PSM, overall survival and rates of autoimmunity were assessed at 5 years.

Results: 19,443 NHW and 2,827 Black patients treated with ICI were identified. At a baseline, the Black patient cohorts had significantly higher rates of comorbidies ($p<0.02$). Across all malignancies, the geographic distribution of NHW patients was more equally distributed compared to Black patients (majority south). With PSM, black HNC patients had significantly lower survival rates compared to NHW [HR: 1.4 (1.2, 1.6), $p=0.0002$]. In melanoma, the same trend was present, though not significant [HR: 1.3 (0.95, 1.7), $p=0.1$]. In contrast, in lung cancer, Black patients had significantly higher survival rates compared to NHW patients [HR 0.78 (0.70, 0.86), $p<0.0001$]. In HN and lung cancer, NHW patients had significantly higher rates of autoimmune conditions after ICI therapy compared to Black [OR: 2.0 (1.4,2.8), 1.2 (1.0, 1.4), respectively].

Conclusion: This study represents the most extensive analysis of racial disparities on ICI outcomes across malignancies. This study found that black patients treated with ICIs had decreased survival rates at 5 years compared to NHW patients in HNC and melanoma, but increased survival rate in lung cancer. This disparity persisted following PSM, matching cohorts for comorbidities, oncologic stage and adjuvant therapy. Black patients also had significantly lower rates of autoimmunity in HN and lung cancer. Noted differences in survival may be a reflection of geographic practice differences, access to care and/or socioeconomic status. Further investigation is required to elucidate the underlying etiologies of these trends.

#4846 Geographic and physician-level variation in the use of hypofractionated radiotherapy for breast cancer in the U.S.: A cross-classified multilevel analysis.

Y. Sun, L. Saulsberry, C. Liao, D. Hedeker, D. Huo;
University of Chicago, Chicago, IL

Hypofractionated whole-breast irradiation (HF-WBI), a radiotherapy with a larger dose per fraction and a shorter schedule for early-stage breast cancer patients post breast-conserving surgery, shows equivalent safety and efficacy compared to conventionally fractionated whole-breast irradiation (CF-WBI) regarding local recurrence and disease-free survival. While several countries have set HF-WBI as the preferred standard of care for these patients, its uptake in the U.S. has lagged behind expectations. We used the Health Care Cost Institute (HCCI) database 2008-2017, covering a third of the U.S. employer-sponsored insurance population, to identify early-stage breast cancer patients. Patients were clustered at different geographic levels (Census region, state, core-based statistical area (CBSA), hospital referral region of Dartmouth Atlas, and zip code) and the radiation oncologist level. These two levels are cross-nested. We used a Bayesian cross-classified multilevel logistic model to simultaneously model the geographic units variability and physician-level variability in HF-WBI use across the U.S. Variation metrics included intracluster correlation coefficient (ICC) and median odds ratios (MOR). ICC with a value of 0 is equivalent to MOR of 1, indicating identical outcomes across all levels. After accounting for these variations in the cross-classified multilevel model framework, we evaluated the association between HF-WBI use and clinical and demographic factors.Our study included 79,747 women (74.0%) who underwent CF-WBI and 27,999 (26.0%) who received HF-WBI. HF-WBI adoption increased over time (2008-2017). Variability across radiation oncologists (ICC = 0.272, MOR = 2.88) was notably larger than geographic areas variability. Variability across CBSA (ICC = 0.097, MOR = 1.76) was the strongest among all the geographic levels. The variation in HF-WBI use was mainly attributed to physician-level variability (ICC=0.222, MOR=2.59) based on the cross-classified multilevel model. No substantial differences were found between young (aged 64 or younger with commercial health plans) and older patients (aged 65 or older with Medicare Advantage plans) in terms of both geographic and physician-level variations. After accounting for variability in radiation oncologists and CBSAs, older age, non-reception of chemotherapy, and several community-level factors, including longer distance from home to facility and higher community education level, were associated with a higher likelihood of HF-WBI use. These results may lend insights into potential facilitators/barriers to HF-WBI uptake. Future studies can further investigate the impact of the 2018 American Society for Radiation Oncology (ASTRO) guideline and the Covid-19 pandemic on HF-WBI use, which would illuminate potential improvements of healthcare practices.

#4847 Diverging global incidence trends of early-onset and later-onset cancers.

M. Terashima[1], H.-Y. Lee[2], Y. Tsukumo[3], S. Ugai[4], M. Song[5], N. Sasamoto[6], I. Kawachi[4], T. Ugai[6];
[1]Okayama University Medical School, Okayama, Japan, [2]Graduate School of Public Health and Healthcare Management, The Catholic University of Korea, Seoul, Korea, Republic of, [3]Boston University, Boston, MA, [4]Harvard T.H. Chan School of Public Health, Boston, MA, [5]National Institute on Aging, Baltimore, MD, [6]Brigham and Women's Hospital, Boston, MA

Background: The global increase of the incidence of early-onset cancers (defined as cancers diagnosed at 20-49 years) is a serious public health problem. However, it is understudied whether the incidence of early-onset cancers has increased in parallel with that of later-onset cancers (defined as cancers diagnosed at 50 years or above) or only the incidence of early-onset cancer has increased worldwide. We therefore evaluated the recent global trends of the incidence of early-onset cancers and later-onset cancers.
Method: We retrieved sex-stratified age-standardized incidence rates of early-onset cancer and later-onset cancer diagnosed between 2000 and 2012 in 39 countries where data was available from the GLOBOCAN database. Using joinpoint regression models, we assessed average annual percentage change (AAPC) by cancer types and countries, with statistical significance corresponding to a 95% CI that does not include zero.
Results: We observed statistically significant positive AAPCs for early-onset cancers (AAPC [95% CI], 1.9% [1.8%, 2.1%] for females, 0.7% [0.6%, 0.9%] for males in all available countries combined) in many early-onset cancer types, including colorectal, esophagus, gallbladder, kidney, liver, multiple myeloma, pancreas, prostate, stomach, testis, thyroid and uterine cancer in many parts of the world. There were variations in many later-onset cancer types depending on cancer types and countries. Notable cancer types that have significantly increased in early-onset cancers but have decreased or showed no change in later-onset cancers include colorectal (5 countries in females and 6 countries in males), uterine (4 countries), and thyroid cancers (5 countries in females and 3 countries in males). In particular, early-onset colorectal cancer has increased but later-onset colorectal cancer has decreased among both sexes in Canada (AAPC [95%CI], early-onset: 1.6% [0.9%, 2.7%], later-onset: -0.8% [-1.0%, -0.5%] for females; early-onset: 1.8% [1.0%, 2.6%], later-onset: -1.2% [-1.5%, -0.9%] for males), USA (Early-onset: 2.0% [1.5%, 2.5%], later-onset: -2.7% [-2.9%, -2.6%] for females; early-onset: 1.6% [1.1%, 2.2%], later-onset: -3.2% [-3.7%, -2.6%] for males), Australia (Early-onset: 1.8% [0.7%, 2.9%], later-onset: -1.0% [-1.5%, -0.6%] for females; early-onset: 1.4% [0.7%, 2.4%], later-onset: -1.5% [-1.9%, -0.9%] for males).
Conclusion: Our study highlights differences in cancer incidence trends between certain early-onset and later-onset cancer types in many parts of the world. Notably, early-onset colorectal, uterine, and thyroid cancers have significantly increased but corresponding later-onset cancers have decreased or showed no change in many countries. Different patterns in cancer incidence trends of early-onset and later-onset cancers in different regions should be further investigated to better understand and prevent the increase in the incidence of early-onset cancers.

#4848 An analysis of black women in the Deep South with triple negative breast cancer and the social determinants of health.

L. K. Evans, I. T. Jubilee II, K. P. Lemieux;
Xavier University of Louisiana, New Orleans, LA

Background: Triple negative breast cancer (TNBC) has a higher incidence both of diagnosis and mortality among Black women. This research aims to identify specific social determinants of health among African American women in the Deep South with breast cancer. The biological presentation of disease accounts for approximately forty percent of the Experience with the health care providers, access to greenspace, and the quality of infrastructure, such as sidewalks and streetlights evaluate environmental trends associated with the outcomes of Black women in the Deep South who have been diagnosed with TNBC.
Methods: Survey data was derived from the All of Us Research Program Database with inclusion criteria of Black women from Alabama, Georgia, Mississippi, and Louisiana who are 18 or older, born a female, and have been diagnosed with TNBC. Selected questions from the SDoH survey examined infrastructure, interactions with healthcare providers, and perceptions of community dynamics. Participants were identified via the cohort selection tool and further subdivided based on zip codes within the target states. Python was used in Jupyter Notebook to analyze the data the AoURP Workbench, responses were organized according to their corresponding survey questions. Participant responses were then extracted and quantified, facilitating the interpretation of respondents' answers on a larger scale.
Results: Three hundred and twenty women met the criteria of being born female, being black, being diagnosed with TNBC, and living in the Deep South. Of the topics examined, infrastructure was the area where participants' feedback indicated the largest socioeconomic deficit. Forty-eight and 49%, respectively. Indicated that did not have access to greenspace nor did not live within 10-15-minute walking distance of a transit stop. Thirty percent reported that their doctor or nurse does not listen to what they are saying.
Conclusion: Quality of life and interaction with members of the health care team associated with poorer health outcomes for Black women in the Deep South. These preliminary results indicate that those diagnosed with TNBC are impacted by the social determinants of health, specifically, proximity to public transportation, quality healthcare, recreational facilities, and infrastructure which suggests that basic needs are not met.

#4849 Mosaic chromosomal alterations in a prospective cohort of Mexican Americans for cancer risk and genetic insights.

Jessica Valdebenito[1], Justin Wong[1], Dahwei Chang[1], Henry Gomez[1], Kevin T Nead[1], Yasminka Jakubek[2], Paul Scheet[1]

[1]Epidemiology, University of Texas MD Anderson Cancer Center, Houston, TX,[2]Internal Medicine, College of Medicine, University of Kentucky, Lexington, KY

Introduction: In this study, we aim to explore mosaic chromosomal alterations (mCA) and their implications in cancer risk among Mexican Americans (MA) - an expanding yet historically underrepresented ethnic minority in the U.S. In addition, we propose to develop a novel method that identifies high mutant cell fraction (MCF) copy-neutral Loss of heterozygosity (cn-LOH). At sufficiently high MCF, these will look like runs of homozygosity (ROH) and may be missed by current mCA detection techniques that rely on identified germline heterozygote genotypes. Our preliminary findings revealed frequent and widespread homozygosity across the genome, predominantly in short regions (<10 Mb), although some exceeded 100 Mb. Our objective is to advance mCA detection techniques, differentiating cn-LOH from ROH, to deepen our understanding of mCA.

Methods: We analyzed SNP array data from blood and saliva samples of 1657 individuals, focusing on cancer and chronic disease risk ages, from the *Mano a Mano* Mexican American Cohort Study. We applied hapLOH and MoChA, both haplotype-based methods, to detect mCA. To identify high-MCF cn-LOH, we first scanned for observed ROH using PLINK. Separately, we develop a statistical framework through simulations to differentiate high-MCF cn-LOH from ROH. We considered multiple methods; initially, we built a statistical framework using a hypothesis-testing approach (H_0: ROH; H_1: cn-LOH), where we compared the “B allele” frequency information within observed ROH. To split this information and obtain our groups, we used population genetic principles. Secondly, we classified our events, calculating the likelihood ratio of our statistical hypotheses. Finally, we explored a haplotype-based imputation approach that leverages flanking diploid region information.

Results: We identified numerous mCA, predominantly in individuals without cancer. Simulations showed effective classification in larger homozygosity regions (>10 Mb), guiding our methodological focus on detecting shorter high-MCF regions. Not surprisingly, extremely high MCFs (0.99-1) presented challenges in accurate identification.

Conclusion and Future Directions: To improve our mCA results description, we will thoroughly characterize and study their association with cancer phenotypes and environmental exposures. We are in the process of genotyping the entire cohort, which consists of over 25,000 participants. To date, our cohort includes 909 cancer cases, of which 262 are hematological malignancies. We sought to design a unique method that differentiates high-MCF cn-LOH from observed ROH, improving current mCA discovery. Our focus is on small regions as they provide limited information to infer event types. Our next step is to characterize and validate our results, especially in pathologically normal samples, as a way of identifying potential biomarkers of interest.

#4850 Sex differences in cancer incidence: Prospective analyses in the UK Biobank.

M. Khan, K. Papier, K. Pirie, J. Atkins, T. Key, R. Travis;
Oxford Population Health, University of Oxford, Oxford, United Kingdom

Background: Exploring the underlying sex differences in cancer incidence and the potential reasons for the differences may provide insights into cancer aetiology. We aimed to examine the differences in incidence of cancer between men and women in the UK Biobank and to assess the extent to which any disparities persisted after accounting of established risk factors for those cancers.
Methods: Prospective analyses were performed in the UK Biobank to examine associations between sex and risk of 15 cancers (and 13 subtypes) common to both sexes using minimal and multivariable-adjusted Cox proportional hazards regression models.
Results: Over an average of 10.5 (SD 2.2) years of follow-up, 46,081 incident cancers were identified in 470,771 individuals (aged 37 to 73 years at recruitment); 24,634 cancers (53.5%) diagnosed in women and 21,447 (46.5%) in men. While some differences in cancer risk between the sexes were attenuated in the comprehensively multivariable-adjusted models, men compared to women remained at greater risk of cancers at eight sites. Compared to women, men had higher risks of oesophageal adenocarcinoma (hazard ratio 5.45; 95% confidence interval, 4.17-7.12), gastric cardia (3.65; 2.48-5.38), bladder (3.47; 2.85-4.24), oral (2.06; 1.69-2.51), liver (1.91; 1.48-2.47), kidney (1.77; 1.51-2.09), rectum (1.7; 1.47-1.96), and leukaemia (1.43; 1.21-1.69); while women had higher risks of cancers of the breast, thyroid (0.36; 0.26-0.49), anus (0.41; 0.26-0.64), gallbladder (0.56; 0.31-0.99), and lung adenocarcinoma (0.72; 0.62-0.84).
Conclusion: Further studies of unexplained sex differences may provide insights into cancer aetiology.

#4851 Burden and inequality of early-onset tracheal bronchus, and lung cancer in US, China, and India: A trend and comparison analysis.

Wenxuan Li, Guojin Si, Yacong Zhang, Zhangyan Lyu, **Kexin Chen**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: For tracheal, bronchus, and lung (TBL) cancer, the leading cause of cancer morbidity and mortality worldwide, guaranteeing quality health care for all populations is a critical component of achieving universal health coverage. Little is known about the burden and inequality of early-onset TBL cancer in countries with different economic development levels. This study aimed to compare the trends of TBL cancer burden among adults in the United States (US), China and India.

Methods: Early-onset TBL cancer age was defined as 15-49 years old. We used Joinpoint regression to evaluate the average annual percentage change (AAPC) and its 95% confidence intervals (CIs) to quantify trends in incidence, mortality, and disability-adjusted life years (DALY) based on the Global Burden of Disease 2019 database. We also used the Gini coefficient (GC) to measure the age-standardized DALY rate (ASDR) inequalities across three countries.

Results: The incidence, mortality, and DALY rates for early-onset TBL cancer among Americans. population from 1990 to 2019 declined from $7.81/10^5$ to $4.23/10^5$, $5.95/10^5$ to $2.96/10^5$, and $270.54/10^5$ to $133.41/10^5$, respectively. However, among the Chinese and Indian populations, the incidence (China: $5.30/10^5$ to $7.47/10^5$; India: $0.99/10^5$ to $1.38/10^5$), mortality (China: $4.73/10^5$ to $5.82/10^5$; India: $0.90/10^5$ to $1.23/10^5$) and DALY (China: $227.94/10^5$ to $270.26/10^5$; India: $42.89/10^5$ to $58.64/10^5$) rate of early-onset TBL cancer show upward trend from 1990 to 2019. The AAPC in incidence (China: 1.14, 95%CI: 0.87 to 1.40; India: 1.17, 95%CI: 0.85 to 1.49), mortality (China: 0.68, 95%CI: 0.45 to 0.91; India: 1.17, 95%CI: 0.81 to 1.52) and DALY (China: 0.50, 95%CI: 0.18 to 0.86; India: 1.11, 95%CI: 0.78 to 1.43) rates for early-onset TBL cancer from 1990 to 2019 in both Chinese and Indian populations showed an increasing trend and the increasing trend was higher than the 50-74 age group. While the AAPC in American populations presented a decreasing trend of early-onset TBL cancer (incidence: -1.76, 95%CI: -2.14 to -1.37, mortality: -2.33, 95%CI: -2.56 to -2.10, DALY: -2.35, 95%CI: -2.59 to -2.12). The AAPC in incidence mortality and DALY rates for early-onset TBL cancer from 1990 to 2019 in both the Chinese and Indian female populations showed a higher trend than the male population. The GC value of ASDR for TBL cancer showed a downward trend, from 0.32 in 1990 to 0.24 in 2019; but for early-onset TBL cancer, it showed an upward trend, from 0.28 in 1990 to 0.31 in 2019, across three countries.

Conclusions: Compared to the US, early-onset TBL cancer burden in China and India has been rising annually. The inequality in ASDR for early-onset TBL cancer remains high across all three countries. Redistributing attention and resources to help adults in low or middle socioeconomic-level countries, especially the female population, may help hold back the expanding inequality for TBL cancer.

#4852 High brain relapse rates in stage III triple negative inflammatory breast cancer are independent of systemic therapy.

Azadeh Nasrazadani, Rebecca Slack Tidwell, Megumi Kai, Rachel Layman, Vicente Valero, Sadia Saleem, Bisrat G. Debeb, Anthony Lucci, Susie X. Sun, Swetha Bopparaju, Hope E. Murphy, Angela Alexander, Angela N. Marx, Michael C. Stauder, Bora Lim, Wendy A. Woodward

MD Anderson Cancer Center, Houston, TX

Background - Inflammatory breast cancer (IBC) is an aggressive subtype of invasive breast carcinoma that confers a comparatively poorer prognosis owing to consistently observed inferior responses to systemic therapies as compared to non-IBC cases. Triple negative (TN) breast cancer which is characterized by lack of estrogen receptor (ER) and progesterone receptor (PR) expression, as well as by lack of HER2 amplification portends particularly poor outcomes including high rates of brain failure. Here we reviewed our prospective IBC registry data for contemporary TNIBC patients to assess current outcomes and brain failure risk in the context of standard neoadjuvant immunotherapy.

Methods - Given the change to the inclusion of pembrolizumab in addition to chemotherapy in the neoadjuvant setting in 2020, we reviewed records from 2016-2023 for Stage III TNIBC patients who presented to MD Anderson Cancer Center (MDACC) prior to receiving other therapy. TNIBC was defined as ER <1%, PR <1%, HER2 IHC 0/1+ or ISH-. N = 38. We examined PCR and brain mets as first failure by regimen (KN522, ACT, AC/TC) and compared using descriptive statistics. Log rank statistic was used to compare overall survival (OS) by PCR. Patients with stage III TNIBC who started the KN522 regimen achieved a pCR rate of 35% (N= 20) and pCR was less frequent in postmenopausal KN522 patients (1/7 PCRs. P = 0.016). Among this cohort, 20% of patients experienced relapse in the CNS as a site of first failure including two patients who achieved a PCR, and 25% had any brain failure at a median follow up post-surgery of 8M. Among 9 patients treated with AC/T 22% achieved pCR with 22% brain metastasis relapse rate as site of first failure and 33% overall was observed at a median follow up of 14M post-surgery. In 9 patients receiving AC/TC, the PCR was 44% and any brain relapse rate was 22%, 1/2 was a site of first failure, median follow up 38M. Despite similarities in brain relapse rates, achieving pCR nonetheless correlated with improved overall survival, P < 0.05. For comparison, among 11 stage IV TNIBC patients treated with neoadjuvant systemic therapy pre-KN522, median follow up 22M from initial diagnosis, 6/11 patients developed brain involvement, 5/6 as a site of first failure. Given small numbers it is difficult to compare PCR by regimen, however we note the PCR in KN522 is lower than expected, and the rate of brain metastases particularly as a site of first failure is consistently high across regimens regardless of PCR. It is critical to consider brain penetrance of neoadjuvant systemic therapies, brain staging and even prophylaxis of brain metastasis in patients with non-metastatic and metastatic TNIBC. Current efforts are ongoing to determine molecular signatures which may aid in prognostication and potentially study design to incorporate prophylactic therapies with the overarching goal of improving outcomes in patients with triple negative IBC.

#4853 Impact of different therapeutic strategies on survival in laryngeal squamous cell carcinoma (LSCC).

S. Alshwayyat[1], A. Erjan[2], M. Rawashdeh[3], T. Abdulsalam[1], M. Alshwayyat[1];

[1]Jordan University of Science & Technology, Irbid, Jordan, [2]King Hussein Cancer Foundation, Amman, Jordan, [3]King Abdullah University Hospital, Irbid, Jordan

Background: LSCC has seen a rise in cases and deaths over the past 30 years. Considering advancements in the treatment landscape, therapeutic options for patients with LSCC were evaluated to assess their efficacy in improving survival rates.

Methods: Data were retrieved from the Surveillance, Epidemiology, and End Results (SEER) (2000-2020) for localized/regional-stage cancer only, including the glottis (GC), supraglottic (SuGC), and subglottic (SC). Patients with a histologically confirmed diagnosis, no other malignancies, and complete data were included. Eight therapeutic groups were identified: surgery (Sx), chemotherapy (CTX), radiotherapy (RT), Sx + adjuvant radiotherapy (ART), Sx + CTX, Sx + RT, Sx + CTX + RT, and CTX + RT. T-tests and chi-square tests were used to compare variables, while Kaplan-Meier, log-rank tests, and Cox regression were used to identify prognostic factors for overall survival (OS) and cancer-specific survival (CSS).

Results: 68,282 patients were included (43,434 GC, 24,010 SuGC, and 838 SGC). 12.8% underwent Sx, 0.8% CTX, 0.3% Sx + CTX, 17.1% Sx + ART, 35.3% RT, 1.5% Sx + RT, 5.1% Sx + CTX + RT and 21.5% CTX + RT. 80.8% were males and 63.5% were over 60 years old and white (n=56,171). The median age was 64 years, and median tumor size was 3.2 cm. 36.5% underwent surgery with local tumor excision in 23.9 % and total laryngectomy in 5.7%. White race, regional stage, large tumor size, and CTX were poor prognostic factors for GC. Asian, white race, and total laryngectomy were good prognostic factors for SuGC, whereas male sex and older age were poor prognostic factors. In terms of SCG, Sx + ART was associated with a better prognosis, while regional and white race were associated with a poor prognosis.

Conclusion: This study shows survival differences among treatment groups and identifies factors for personalized treatment. It is the first study on all types of laryngeal tumors with a large sample size. Further research is necessary to validate and expand these results.

The 5-year survival rates (as a percentage of OS/CSS) for each therapeutic group

Cancer Type	Sx	CTX	Sx + CTX	RT	Sx + RT	CTX + RT	Sx + CTX + RT	Sx + ART
GC	91.9/75.5	79.8/77.3	89.2/81.8	89.8/78.1	89.5/85.3	87.8/83	79.1/90.1	90/78.1
SuGC	54.7/56.5	12.9/46.7	25.6/56.2	43.1/51.9	33.5/56.4	45.7/49.7	50.5/59.4	49.3/59.3
SGC	42.2/42.2	75/75	17.7/17.7	53/53	44.4/44.4	47.2/47.2	44.1/41.1	58.7/58.7

#4854 Breast cancer incidence trends in Ukraine 2010-2019: Rising incidence at young ages.

N. Verovkina[1], O. Sumkina[2], L. Syvak[3], W. El-Diery[1];

[1]Legorreta Cancer Center at Brown University, Providence, RI, [2]National Cancer Institute, Kyiv, Ukraine, Kyiv, Ukraine, [3]National cancer institute, Kiev, UA, Kyiv, Ukraine

Background. BC commonly affects women of older age, however, in developing countries around 20-25% cases of BC presented in young woman. Age-specific clinical characteristics or outcomes data for young women are lacking. Most of the standard treatments used in this subpopulation currently are derived from older patients. Early onset BC is often defined aggressive in nature. Several research have attributed this to a hidden unique biology. However, findings remain controversial.

Purpose: The aim of this study is to describe recent trends for BC incidence in Ukraine since 2010 by age groups and interpret them to seek clue for improvement.

Methods: We analyzed records from the NCR on 143420 BC cases (C50, International Statistical Classification of Diseases and Related Health Problems, 10th Revision (ICD-10)) diagnosed in 2010-2019 in female Ukrainian population. The data were submitted on the beginning of 2022. We calculated annual age-standardized incidence rates (ASRWs) for three age groups. The estimated annual percent change (EAPC) of the rates was calculated using the generalized linear regression. The difference of the rates with its statistical significance was determined with the standardized rate ratio.

Results: During 2010-2019, the proportion of BC in all cancers detected at the age of 20-44 increased from 21.7% to 25.9%, while the frequency of BC detection at the age of 45+ did not change and ranged 19.3-20.2%. During the study period, the BC incidence rate has increased significantly (≤0.01): the ASRW of females aged 0-85+ grew with EAPC=0.6% amounting to 42.4-45.7 per 100,000 population, the incidence rate of women aged 45+ grew with EAPC=0.3% ranging from 130.0 to 139.6 per 100,000 population, while the incidence rate of women aged 20-44 grew with EAPC=1.8% amounting to 22.8-27.8 per 100,000 population. In age group 20-44 years, EAPC of BC incidence (1.8%) significantly exceeds the EAPC of the incidence for all cancers combined (0.2%). The dynamics of stage distribution showed increasing proportion of BC cases detected in women aged 20-44 in stage 1 (by 4.1% from 2010 to 2019) and its decreasing for BC cases detected in stage 2 by 4.5%; the proportion of cases diagnosed in stage 4 decreased by 0.5% along with increase in number of cases with undefined stage by 0.6%.

Conclusions: The obtained results indicate trends for increasing the incidence of Early Onset BC in Ukraine and justify need for the further research elucidating prognosis and validating novel biomarkers for customizing therapy for this patient group .

#4855 Identifying hot spots of breast cancer and industrialized areas in Hermosillo, Sonora, Mexico.

D. E. Villa-Guillen[1], A. A. Mata-Valenzuela[2], H. Tecuanhuey-Tlahuel[2], A. M. Galvez-Arevalo[3], K. L. Garcia-Castellon[4], Y. E. Guzman-Hernandez[4], K. S. Ortega-Landa[5], F. Y. Pelayo-Rodriguez[6], J. R. Silva-Rivera[4], R. A. Urena-Acosta[7], D. O. Garcia[1], J. A. Villa-Carrillo[5];
[1]The University of Arizona, Tucson, AZ, [2]IMSS UMF No. 37, Hermosillo, Mexico, [3]Universidad Autonoma de Occidente, Los Mochis, Mexico, [4]Universidad Autonoma de Nayarit, Tepic, Mexico, [5]Universidad de Sonora, Hermosillo, Mexico, [6]Universidad de Guadalajara, Guadalajara, Mexico, [7]Universidad Autonoma de Sinaloa, Culiacan, Mexico

Background: Sonora, a state in Mexico, has the highest rates of breast cancer in the country and has a history of industrial pollution. These factors may contribute to an increased risk of breast cancer. Hermosillo, the state capital, exhibits both of these characteristics. Given these conditions, it is important to further evaluate the prevalence of breast cancer hotspots and the potential links between breast cancer and industrialized areas.
Objective: Identify breast cancer hot spots and their association to industrialized areas in Hermosillo, Sonora, Mexico.
Methods: This study collected clinical data on breast cancer cases (current, survivors, deceased) from hospital files in Hermosillo that were 10 years old. The primary unit of analysis was neighborhoods. The study estimated breast cancer prevalence by analyzing the number of females per neighborhood, based on data reported by INEGI Census 2020. The data was categorized by age groups (age group no. 1 of 18 to 59 years old, no. 2 of 60 to 64 years old, and no. 3 of 65 years old or older). The estimated prevalence was depicted on a map using ArcGIS software, version 10.8.2. Hot spot analysis was used to identify neighborhoods with high breast cancer prevalence. The study also categorized neighborhoods as industrialized areas if they contained at least six hazard-generator industries.
Results: A total of 1394 cases of breast cancer were gathered from hospitals. Location information for 3697 industries was provided by INEGI. Out of the 756 neighborhoods studied, 95 (12.6 %) were found to be industrialized areas, while 661 (87.4 %) were non-industrialized. Four neighborhoods in Hermosillo's southeast were observed to have breast cancer hot spots (unadjusted). After adjusting for age, one hot spot was found in the southeast for age group no. 1 (one neighborhood), while hot spots for group no. 2 (three neighborhoods) and no. 3 (33 neighborhoods) were in Hermosillo's northwest. The hot spots were related to industrialized areas (unadjusted OR = 6.94, 95% CI (0.94, 50.8), p-value = 0.05). After age adjustment, this association was statistically significant for group no. 3 (OR = 2.70, 95% CI (1.27, 5.72), p-value = 0.009), but not for group no. 1 (OR = 1.69, 95% CI (0.06, 41.74), p-value = 0.748) or group no. 2 (OR = 2.56, 95% CI (0.23, 28.46), p-value = 0.44).
Conclusions: Our research found a link between industrialized areas and high breast cancer rates. We also found hotspots for women aged 65+ in Hermosillo, with 33 affected neighborhoods in the city's northwest. This is the first comprehensive study examining breast cancer prevalence in Hermosillo over a ten-year period. More extensive studies are needed in other cities in Sonora, Mexico, to confirm our findings.

#4856 Sex differences in childhood leukemia genomics.

Lindsay A. Williams[1], Lauren J. Mills[2], Sofia Barragan[2], Peter M. Gordon[2], Jenny N. Poynter[2]

[1]University of Minnesota, Woodbury, MN,[2]University of Minnesota, Minneapolis, MN

Males have higher ALL and AML incidence and worse ALL survival using population-based data. Somatic genetics may play a role in ALL survival disparities and highlight potential sex specific treatment strategies for future study. Therefore, we evaluated sex differences in gene expression (RNA seq), copy number variation (CNV), and somatic mutation in ALL and AML. We stratified by cytogenomic subtypes in publicly available data from clinical cohorts using St. Jude PeCan (subtypes in Table 1). Then, we explored survival differences by sex within cytogenetic subtypes in publicly available data collected from Children's Oncology Group patients in the NCI TARGET dataset (ALL n=387, 63% male; AML n=151, 51% male). Differentially expressed genes by sex were identified for ALL adjusting for subtype (n=214) and within subtypes (Table 1). There were no sex differentially expressed genes shared across subtypes and pathways identified from sex differentially expressed genes were few. In *ETV6-RUNX1,* there was as suggestion of worse 10-year survival for males (n=44, 61% male; Log-Rank p=0.068). Differentially expressed genes by sex were identified for AML adjusting for subtype (n=537) and within subtypes (Table 1). There were no differentially expressed genes by sex shared across AML subtypes. *KMT2A* had the highest number of pathways identified from sex differentially expressed genes (Table 1). There were no sex differences in AML survival. In ALL and AML subtypes there were no sex differences in CNVs (all t-test p>0.05) or somatic mutations (all Fisher's Exact p>0.05). There were no sex differences in AML survival in TARGET, in agreement with population-based studies, and few differentially expressed genes identified in PeCan by subtypes. Sex differences in ALL survival were subtype specific and not heavily dependent on differentially expressed genes, CNVs, or somatic mutation. Sex differences in ALL survival may depend on treatment received, response to therapy, or other characteristics.

Table 1. Select characteristics from leukemia cases

PeCan ALL SubtypeTotal n=247, 58% male	N (% male)	Number of differentially expressed autosomal genes by sex (male-female expression) in PeCan	Number of biologic pathways identified from differentially expressed genes (Reactome)
BCR-ABL1	76 (68)	48	8
DUX4-IGH	54 (57)	218	0
ETV6-RUNX1	50 (52)	86	1
hyperdiploid	14 (64)	3,199	2
iAMP21	12 (50)	120	0
KMT2A	41 (51)	216	0
AML SubtypeTotal n=149, 51% male			
CBFB-MYH11	34 (55)	7	0
KMT2A	44 (50)	422	19
RUNX1-RUNX1T1	61 (46)	30	1

#4857 Contemporary hospital-based study examining demographics, treatment patterns and survival outcomes of primary effusion lymphoma in the United States, with a specific emphasis on Hispanics..

S. A. Vallejo Avila, J. Michalek, Q. Liu, A. E. Diaz Duque;
UT Health Science Center at San Antonio, San Antonio, TX

Background: Primary effusion lymphoma (PEL) is a rare and aggressive non-Hodgkin lymphoma associated with HIV and human herpesvirus 8 (HHV-8). (***Blood*** *PMID: 8695812).* Without treatment, patients typically survive only two to three months (***Oncol Res Treat*** *PMID: 28253516*) Limited research has been conducted on PEL, particularly in minorities in the United States. Limited research, especially in minority populations (***Blood*** *PMID: 30154110*), has prompted a nationwide study comparing demographics, clinical characteristics, treatment patterns, and survival outcomes between Hispanic (HI) and Non-Hispanic (NH) PEL patients.

Methods: Data on PEL patients from the National Cancer Database (NCDB) between 2004 and 2019 were analyzed in the US. Demographics and treatment characteristics were compared across ethnic groups. Kaplan-Meier and Cox regression analyses were used to compare overall survival (OS) between HI and NH populations. Multivariate analysis and propensity score matching were conducted, adjusting for age, stage, co-morbidity score, insurance status, type of facility, and great circle distance.

Results: Of 459 PEL patients, 18% were HI, and 79% were NH. Both groups had mostly male patients (87% vs. 86%). HI patients were younger at diagnosis (mean 49 years vs. 57 years, p=0.163). Diagnoses were mostly from 2014-2019, and the majority were white (87% vs. 69%). Government-sponsored insurance was more prevalent in both groups (62% vs. 66%). HI had a higher percentage of uninsured individuals (8% vs. 5% NH) (p-value=0.01). The median income bracket was over $46,000 for both cohorts, HI 34% and NH 37%. Advanced comorbidities were similar between HI 50% and NH 43% based on Charlson-Deyo Score. The survival probabilities at 2, 5, and 10 years for HI vs NH were (40% vs 40%), (34% vs 289%), and (34% vs 24%), respectively. The median survival time (MS) was 0.8 years for HI and 0.9 years for NH. There was no overall survival (OS) difference (p-value=0.51). On multivariate analysis, there were no independent variables associated with better or worse OS. The propensity-matched analysis showed no MS difference between HI and NH (0.80 vs 0.71 years).

Conclusion: This hospital-based analysis confirmed low survival rates and revealed no statistical differences in MS or OS among HI and NH individuals with PEL. Interestingly, the disease was more prevalent in high-income subjects in both cohorts, despite HI individuals having lower insurance rates. A better understanding of intrinsic disease characteristics and biological variables can offer valuable insights into how to unveil potential targets of better and hopefully meaningful therapies that could improve survival outcomes.

#4858 Examining state- and race-specific five-year prostate cancer mortality rates (2016-2020) and their association with prostate-specific antigen screening.

H. E. Guard[1], J. B. Vaselkiv[1], E. Ecsedy[1], F. Kuechen[1], N. Minassian[1], J. Dun Rappaport[1], Z. Qian[2], M. O. Sodipo[1], K. L. Penney[3], K. H. Stopsack[4], L. A. Mucci[1];

[1]Harvard T.H. Chan School of Public Health, Harvard University, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA

Background: In 2023, 34,000 US men will die from prostate cancer. The impact of prostate cancer mortality varies greatly across states. Racial differences in state populations may explain some but not all of this variability. This study examined prostate cancer mortality rates by state and race and their associations with state-level prostate-specific antigen (PSA) screening prevalence.

Methods: We obtained race-specific, state level five-year average age-standardized prostate cancer mortality rates from 2016-2020 from the NCI State Cancer Profiles. Data on race-specific, state level PSA screening prevalence in 2010 were obtained from the Behavioral Risk Factor Surveillance System. We compared mortality rate ratios (RR, 95% confidence intervals [CI]) of state level prostate cancer mortality rates of Black, Hispanic, Asian/Pacific Islander, and American Indian/Alaskan Native men to White men. We generated descriptive statistics (median and range) on state level mortality rates to quantify the variability within racial/ethnic groups. We fit univariable Poisson regression models to explore associations between prostate cancer mortality rates and PSA screening prevalence, for White, Black, and Hispanic men, but omitted Asian and American Indian men due to sparse data.

Results: Mortality data were available for 50 states and the District of Columbia (D.C.) for White, 40 states and D.C. for Black, 36 states for Hispanic, 24 states for Asian, and 11 states for American Indian men. The US average prostate cancer mortality rate was 18.8 deaths per 100,000 per year. As expected, rates were higher among Black than White men (RR 2.07; 1.90, 2.24), while rates among Hispanic (RR 0.75; 0.68, 0.84) and Asian (RR 0.48; 0.41, 0.56) men were lower. Rates among American Indian men were slightly higher than White men (RR 1.12; 0.96, 1.29). Variability of state-level mortality rates within each race was quite high, with largest ranges for Black and American Indian men. Black men had a median (range) state-level prostate cancer mortality rate of 37.9 (23.9 to 49.2), and American Indian men had a median rate of 20.4 (7.7 to 28.9). Median (range) rates were 17.7 (11.3 to 22.3) for White, 8.3 (4.3 to 17.4) for Asian, and 13.5 (8.9 to 22.5) for Hispanic men. Associations between a 5-percentage point increase in PSA screening prevalence and prostate cancer mortality rates were RR 0.92 (95% CI: 0.84, 0.99) in White, RR 0.96 (0.88, 1.05) in Black, and 0.98 (0.90, 1.07) in Hispanic men.

Conclusion: There is considerable variability in prostate cancer mortality rates across states, both between and within racial/ethnic groups, highlighting complexity of racial disparities. PSA screening may weakly contribute to this variability, but other factors such as health care access, social determinants, and lifestyle factors that vary between states should be considered in future studies.

#4859 Mental health of early-onset and late-onset cancer survivors.

J. H. Lee[1], J. An[2];
[1]Jayden Lee (Individual), South Pasadena, CA, [2]Kaiser Permanente, Pasadena, CA

Background: Psychiatric disorders such as anxiety and depression are shown to be common when diagnosed with early-onset cancer, often defined as cancers diagnosed in adults <50 years of age. We hypothesize that the mental health of early-onset cancer survivors is negatively affected compared to late-onset cancer survivors.
Methods: We identified cancer survivors in the Medical Expenditure Panel Survey 2021 Full Year Consolidated Data File. We categorized cancer survivors as early-onset (≤ 50 years of age) and late-onset (> 50 years of age). We examined the proportion of mood and anxiety disorders, and the proportion of antidepressant and antianxiety medication use among the early and late-onset cancer survivors. We conducted chi-square tests and multivariable logistic regression models by adjusting for sex and race.
Results: We identified 291 early-onset cancer survivors (mean age 41 years, 71% female) and 2556 late-onset cancer survivors (mean age 71 years, 56% female). Among the early-onset cancer survivors, 18% had mood disorders (17% took antidepressants) and 20% had anxiety disorders (6% took antianxiety medication). In comparison, 12% late-onset cancer survivors had mood disorders (21% took antidepressants) and 13% had anxiety disorders (8% took antianxiety medication). Early-onset cancer survivors were more likely to develop mood (Adjusted Odds Ratio (aOR)=1.45; 95% CI=1.06 - 1.99) and anxiety (aOR=1.42; 95% CI=1.05 - 1.92) disorders compared to late-onset cancer survivors. However, there were no differences in receiving antidepressants (aOR=0.79; 95% CI=0.57 - 1.09) or antianxiety (aOR=0.69; 95% CI=0.41 - 1.16) medication between early and late-onset cancer survivors when adjusting for sex and race.
Conclusion: Early-onset cancer survivors had an elevated risk of acquiring psychiatric disorders such as mood and anxiety disorders than late-onset cancer survivors, but treatment was suboptimal. Clinician and patient awareness can help narrow the gaps of treatment for early-onset cancer survivors.

Table 3. Odds Ratio for early-onset vs. late-onset cancer survivors (*Sex and Race adjusted)

Variables	Crude Odds Ratio	Adjusted Odds Ratio *
Mood Disorders	1.48 (1.09 - 2.00)	1.45 (1.06 - 1.99)
Anxiety Disorder	1.52 (1.13 - 2.03)	1.42 (1.05 - 1.92)
Antidepressants	0.80 (0.59 - 1.10)	0.79 (0.57 - 1.09)
Antianxiety	0.70 (0.42 - 1.17)	0.69 (0.41 - 1.16)

#4860 Recommendations for enhancing inclusion and management of esophagus cancer clinical trials: Insights on mortality of esophagus cancer as a second primary malignancy.

H. Zhou[1], J. Leng[1], H. Qiu[1], Q. Huang[1], J. Zhang[2], **Z. Jiang**[3];

[1]Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China, [2]Pingxiang People's Hospital, Pingxiang, China, [3]University of California, Berkeley, Berkeley, CA

Background: Esophagus cancer as a second primary malignancy (esophagus-2) is increasingly common, but its prognosis is poorly understood. This study aims to examine the overall, non-cancer related and cancer-specific survival of patients diagnosed with esophagus-2 compared to the first primary esophagus cancer (esophagus-1).

Methods: We included primary esophagus cancer patients diagnosed from 1975 to 2020 in the Surveillance, Epidemiology, and End Results program. Esophagus-2 was identified in patients with a previous diagnosis of non-esophageal primary malignancy. Hazard ratios of overall, esophagus cancer-specific and non-cancer related mortality were estimated among patients with esophagus-2 compared to esophagus-1, adjusting for age, sex, tumor stage and other demographic and clinical characteristics.

Results: A total of 74521 and 14820 patients were identified as esophagus-1 and esophagus-2. Esophagus-2 patients suffered lower risk of esophagus cancer-specific mortality in initial 5 years but similar risk thereafter, independent of tumor characteristics and treatment. In the first 5 years after diagnosis, patients with esophagus-2 had similar risk of overall mortality with those with esophagus-1 but increased risk thereafter. As for non-cancer related mortality, esophagus-2 patients had higher risk all along.

Conclusion: Patients diagnosed with esophagus-2 face a favorable esophagus cancer-specific survival within the early period after diagnosis. However, patients with esophagus-2 are more liable to die of non-cancer cause. A conservative approach to manage esophagus-2 solely based on malignancy history is not supported but effort should be put into surveillance, prevention and management of the comorbidities and complications for the first malignancy.

#4861 Incidence rates of bladder and kidney cancers among U.S. military servicemen: Comparison with the rates in the general U.S. population.

J. A. Bytnar[1], K. A. McGlynn[2], S. Q. Kern[1], C. D. Shriver[1], K. Zhu[1],

[1]Murtha Cancer Center Research Program, Uniformed Services University Walter Reed Surgery, Henry M. J, Bethesda, MD, [2]National Cancer Institute, Bethesda, MD

Background: The military population may differ from the general population in factors related to the incidence of bladder and kidney cancers. However, incidence rates of these cancers have not been systematically compared between the two populations. This study compared incidence rates of bladder and kidney cancers and their trends between active-duty servicemen and men in the general U.S. population.

Methods: Data were obtained from the Department of Defense's (DoD) Automated Central Tumor Registry (ACTUR) and the National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) database. Patients were active-duty servicemen in ACTUR and men in SEER who were diagnosed with malignant bladder and kidney cancers and 18-59 years at diagnosis from 1990-2013. Age-adjusted rates, incidence rate ratios (IRR), and their 95% confidence intervals (95% CI) were compared between the two populations by age, race, and cancer stage. Trends in the incidence were also compared.

Results: Incidence rates were lower in ACTUR than SEER for bladder cancer overall (IRR=0.55, 95% CI=0.48-0.62) and by age, race, or tumor stage. However, for 50-59-year-old men, the rates did not differ between the populations. Trend analysis showed bladder cancer incidence decreased more in ACTUR than SEER over the study period. Kidney cancer incidence rates were marginally lower overall (IRR=0.92, 95% CI=0.84-1.00) and significantly lower for 30-49-year-old Black men in the military than the general population. For kidney cancer, the trends were similar between the two populations with increased incidence from 1999 to 2013.

Conclusion: Lower bladder and kidney cancer incidence in ACTUR, notably in younger individuals, may be primarily associated with healthier status and better health care. The lack of differences in bladder or kidney cancer incidence among 50-59-year-old men between the populations might result from more cumulative military-related exposures in this age group, which effects were offset by healthier status and better medical care. #4862 Rural-urban disparities in early-onset breast cancer amongst US women aged 20-49, trends from 2000-2020.

K. L. Ho, A. Connor;
Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD

Purpose: To characterize rural-urban disparities of breast cancer (BC) incidence among younger women by stage and race/ethnicity.
Background: Cancer incidence in younger adults is increasing, but trends and disparity patterns in early-onset BC are not well-described for women aged <50 years. Current screening guidelines recommend against routine screening until age 40 for various perceived harms that outweigh benefits which can lead to delayed diagnosis and more aggressive stage when BC is identified among younger women. It is unclear how BC incidence patterns such as stage at diagnosis and race/ethnicity differ by rurality, as rural residents may experience geographic isolation, lower socioeconomic status (SES), higher rates of cancer risk behaviors, and limited access to healthcare, compared to urban residents.
Methods: We used incidence data from the North American Association of Central Cancer Registries to identify trends in early-onset BC among women aged 20-49 from 2000-2020, stratified by rurality (2013 USDA Rural-Urban Continuum Codes) and to explore patterns by stage and race/ethnicity. We extracted age-adjusted incidence rates (IR) [adjusted to 2000 US Standard Population] for each year and detected significant increasing or decreasing trends over time using the Joinpoint Regression Program. The annual percentage change (APC) for IR trends were calculated.
Results: Of the 854,590 patients, 88% lived in urban areas (12% rural). Cumulatively over 2000-2020, we observed similar average APCs for early-onset BC both in urban (IR = 68.8 per 100,000; avg. APC +0.37, 95% CI 0.23, 0.50) and rural areas (IR = 65.1 per 100,000; avg. APC +0.35, 95% CI 0.14, 0.57). Rural areas did not significantly trend upwards until 2010-2020 (APC +0.71, 95% CI 0.38, 1.05). Rates for localized stage increased from 2000-2020 (APC +0.69%, 95% CI 0.48, 0.89) for urban areas, but declined in rural areas between 2000-2008 (APC -0.77, 95% CI -1.33, -0.20), only to increase again from 2008-2020 (APC +1.01, 95% CI 0.68, 1.34). In rural areas, there is a corresponding dramatic increase in distant stage BC diagnosed between 2000-2007 (APC +5.99%, 95% CI 2.29, 9.93) but slowed in the period after (2007-2020 APC +1.35, 95% CI 0.22, 2.51). While the rate remained stable for Hispanics living in both urban and rural areas, Non-Hispanic Whites (2000-2020 APC +0.59, 95% CI 0.46, 0.72), Non-Hispanic Blacks (2000-2009 APC +0.85, 95% CI 0.33, 1.37), and Other Non-Hispanic racial groups (2000-2020 APC +1.27, 95% CI 1.16, 1.58) saw significant increased rates in urban areas over time.
Conclusions: Overall, early-onset BC has risen over the past 20 years in both urban and rural areas, but clear differences exist by stage at diagnosis and race/ethnicity. More research is needed to understand how SES, healthcare access, screening recommendations, and additional cancer risk factors can modulate BC incidence and disparities among younger women.

#4863 A retrospective study characterizing 1714 cases of epithelioid cell melanoma.

M. Al Kurnas, X. Wu, A. Mubin, P. T. Silberstein;
Creighton University School of Medicine, Omaha, NE

Introduction: Epithelioid cell melanoma (ECM) is a variant of cutaneous melanoma (CM) typically characterized by large malignant cells with abundant, glassy cytoplasm and large nuclei. ECMs are aggressive neoplasms and tend to have worse prognosis than other subtypes of CM with a higher risk of metastasis[1]. Few studies have explored the demographic features of ECM and their effects on outcomes. Using data from the National Cancer Database (NCDB), we hope to fill this gap.

Methods: This is a retrospective study of patients diagnosed with ECM(ICD-8771) between 2004 and 2020 in the National Cancer Database (NCDB) describing demographic features associated with and tumor characteristics of ECM (N = 1714). Descriptive statistics were collected for all patients with ECM and CM (N = 827623) and were compared using Pearson Chi-Square test. Overall survival was determined by the Kaplan-Meier test. Cox regression analysis was used to determine which factors led to decreased survival in ECM. All statistical tests were evaluated for a significance of $P < 0.05$. Exclusion criteria included missing data.

Results: The cases of ECM were composed mainly of White (96%) males (58.9%), and most had private insurance as the primary payor at diagnosis (50.1%). Greater than half of ECM cases had a primary site of skin on the trunk, upper limbs, or shoulders. Cox regression analysis revealed that patients with ECM treated at integrated network cancer programs had a HR of 0.46 when compared to community centers (95% CI 0.257 - 0.831, $P < 0.05$). Those with ECM treated at academic programs and comprehensive community cancer programs had hazard ratios of 0.41 (95% CI 0.239 - 0.701, $P < 0.05$) and 0.49 (95% CI 0.288 - 0.845, $P < 0.05$) respectively when compared to community programs. Only patients with ECM who had private insurance as primary payor at diagnosis had better outcomes when compared to non-insured with an HR of 0.40 (95% CI 0.225 - 0.714, $P < 0.05$). In addition, patients with ECM were more likely to be treated at academic centers than patients with CM (55.48% vs 46.95%, $P < 0.05$). The mean survival of patients with ECM was 12.3 months less than those with CM (141.1 months versus 153.4 months.)

Conclusion: Overall survival for patients was better at academic centers, integrated network cancer programs, and comprehensive community cancer programs when compared to community centers. In addition, only patients who had private insurance were found to have better outcomes than those who were uninsured. These findings help shed light on the effects of certain socioeconomic and factors on outcomes in ECM. We hope this study will be a launching point for further inquiry into the causal relationships these factors have on outcomes in this rare cancer.

#4864 Epidemiological characteristics and treatment strategies of gastric cancer with neuroendocrine differentiation (NED).

Z. Huang, J. Wei, Y. Shen, **J. Zhang**;
The First Affiliated Hospital of Chongqing Medical University, Chongqing, China

Background: Gastric cancer with neuroendocrine differentiation (NED) occurs in 10% to 40% of cases, a significant proportion that is under-researched. The lack of clinical guidelines for this subgroup necessitates the development of effective treatment protocols.
Methods: This study enrolled 149 gastric cancer patients, analyzing retained surgical wax blocks via immunohistochemistry for syn, CgA, and CD56 expressions. Patients were categorized into NED-positive and NED-negative groups for analysis, employing continuous variable analysis, categorical variable analysis, clustering, principal component analysis (PCA), feature importance analysis, heatmap analysis, and survival prognosis. Moreover, the clinical efficacy and safety of first-line (surufatinib + SOX + anti PD-1 antibody, n=3) and second-line (surufatinib + anti PD-1 antibody, n=3) treatments were observed in six advanced gastric cancer with NED patients, exploring the epidemiological characteristics, feasibility, and importance of clinical treatments for NED.
Results: The study revealed a 10.1% incidence of NED positivity in gastric cancer patients. NED-positive patients exhibited a rapid decline in early survival probability, with a median relapse-free survival of 32.4 months compared to 41.5 months in NED-negative patients, indicating a poorer prognosis for NED-positive patients. In-depth analysis suggested significant correlations between NED status and factors such as gender, tumor location, pathological type, and AJCC staging, with the most significant associations observed in males, stage IIIA, and gastric angle location. In the six advanced gastric cancer with NED cases, effective tumor reduction was observed in both first-line (100% tumor shrinkage rate, ORR 66.7%, DCR 100%) and second-line treatments (66.7% tumor shrinkage rate, ORR 33.3%, DCR 100%), showing sustained partial responses (PR) exceeding 10 months in two patients and 7 months in one patient, respectively. The major grade 3 or higher TEAEs being neutropenia and thrombocytopenia in the first-line, and hypertension and proteinuria in the second-line therapy.
Conclusion: This study provides pivotal epidemiological and clinical treatment evidence for gastric cancer with NED, underscoring the necessity of personalized treatment strategies for this subgroup. Future research should focus on refining treatment protocols to enhance the quality of life and overall prognosis for these patients.

#4865 Income dynamics and the risk of hepatocellular carcinoma in individuals with type 2 diabetes: A nationwide population-based cohort study.

J. Baek[1], B. Amick III[1], C. Brown[1], M. Schootman[1], M.-R. Narcisse[1], S.-H. Ko[2], P. McElfish[1], M. Thomsen[1], S.-S. Lee[2], K. Han[3], **Y.-M. M. Park[1]**; [1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]The Catholic University of Korea, Seoul, Korea, Republic of, [3]Soongsil University, Seoul, Korea, Republic of

Introduction: Type 2 diabetes (T2D) is associated with over 2 times increased risk of hepatocellular carcinoma (HCC). Low-income status is associated with a higher risk of developing HCC, more advanced stage, and mortality. Evidence is limited on whether income dynamics are associated with the risk of developing HCC in individuals with T2D who are susceptible to income changes. We examined whether income levels and income changes are associated with HCC risk.
Methods: Using representative data from the Korean National Health Insurance Service (NHIS), 2,227,893 adults with T2D (aged ≥ 20 years) without a cancer history were included between 2015-2016. Income levels were measured based on health insurance premiums and categorized into 4 levels (quartiles [Q], 1 [low income], to 4 [high income]). These quartiles excluded the very low-income individuals who qualified as Medical Aids beneficiaries (MAB), which comprised a 5th income category. To identify income change, income levels were collected annually from the baseline year backward 4 years. The incident HCC, defined based on ICD-10 codes and special reimbursement codes, was identified until December 2020. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated to assess the association between income parameters and HCC after adjusting for sociodemographic factors, comorbidities, and diabetes duration and treatment. Income parameters included 1) the baseline income status, 2) the cumulative number of years being in each income level, and 3) changes in income level between the two time points (4 years ago vs. baseline).
Results: During follow-up (median, 3.9 years), 9,887 HCC cases developed. Individuals who had experienced at least one episode of MAB during the five years showed a significantly higher HCC risk than those who had never qualified as MAB (HRs ranging from 1.52 to 2.01). In contrast, individuals who had experienced high-income status (Q4) during the five years had a lower HCC risk than those who had never experienced (HRs ranging from 0.79 to 0.92; $HR_{n=5\ years\ vs.\ n=0\ years}$ 0.79, 95% CI 0.75-0.83; *P* for trend <0.05). Individuals in the low-income status (MAB-Q1) at the first assessment (4 years ago) but experienced increased income had a reduced risk of HCC, which linearly declined with increasing income rise. Also, those who experienced a substantial increase in income up to the top quartile (Q4) had the lowest HCC risk (HR 0.73, 95% CI 0.60-0.88; P for trend<0.05) than those who maintained the low-income status.
Conclusions: Experiencing any very low- or high-income state was independently associated with increased or decreased HCC risk. Improved income levels among those in the low-income status had an inverse linear association with reduced HCC risk. Our findings underline the need for increased public policy awareness of the impact of income dynamics on HCC risk in adults with T2D.

#4866 To weight or not to weight? Studying the effect of selection bias in three EHR-linked biobanks with applications to colorectal cancer.

M. Salvatore[1], R. Kundu[1], X. Shi[1], C. R. Friese[1], S. Lee[2], L. G. Fritsche[1], A. M. Mondul[1], D. Hanauer[1], C. L. Pearce[1], B. Mukherjee[1];
[1]University of Michigan, Ann Arbor, MI, [2]Seoul National University Graduate School of Data Science, Seoul, Korea, Republic of

The use electronic health record (EHR)-linked biobanks, including All of Us (AOU), the Michigan Genomics Initiative (MGI), and the UK Biobank (UKB), has become increasingly common in cancer research. However, each has a different participant recruitment strategy resulting in non-probability samples, which can lead to selection bias. An unanswered question is whether researchers should use selections weights when analyzing these data. Using colorectal cancer as the test case, we investigate the impact of using such weights on descriptive and analytic tasks in these three biobanks.

We curated sociodemographic and clinical diagnosis data for 726,841 individuals (n = 244,071, 81,243, and 401,167, in AOU, MGI, and UKB, respectively). EHR ICD (diagnosis) code data were mapped to broader 2,042 codes, called phecodes, using the new phecode X mapping table developed by researchers at Vanderbilt University. Selection weights were constructed in AOU and MGI to make them more representative of the US adult population, using data from the 2019 National Health Interview Survey; previously described weights for the UKB were used. We estimated phenomewide prevalences, pairwise correlations, and phenome dimensionality (via principal components analysis). To investigate the role of weighting on conclusions from hypothesis testing and association estimation, we conducted a colorectal cancer phenomewide association study and estimated the sex-colorectal cancer log-odds ratio, respectively.

We found that phecode prevalences in AOU and MGI decreased following weighting (median prevalence ratio [MPR]: 0.82 and 0.61, respectively) while those in UKB increased (MPR: 1.06). MGI is enriched for phecodes compared to AOU (MPR: 1.15) and UKB (MPR: 6.28). Weighting PCA had minimal impact on phenome dimensionality (e.g., 732 PCs explaining 95% of cumulative variation in AOU vs. 711 after weighting). Weighted PheWAS for colorectal cancer identified 21 hits not identified in unweighted PheWAS, but only one was from a new disease category. Weighted estimates of the female-colorectal cancer log-odds ratio overlapped with the benchmark range in MGI and UKB though resulted in a null association in AOU.

Weighting had limited impact on dimensionality estimation and hypothesis testing but were important to consider for prevalence and association estimation. Results from untargeted analyses should be followed up with targeted analyses using curated weights. The importance of weights depends on the estimates obtained and inference
goals and can improve the representativeness of results for cancer-related outcomes based on EHR-linked biobank data. Importantly, EHR-linked biobanks should be explicit in reporting recruitment and selection mechanisms and when possible, supply selection weights to researchers for population-based inference along with a clear definition of the target population.

#4867 Longitudinal latent class analysis to further understand trajectory of density over time and risk of breast cancer.

G. A. Colditz, D. L. Bennett, S. Jiang;
Washington University School of Medicine in St. Louis, St. Louis, MO

Background: It is clinically important to refine strategies to manage women with dense breasts as they represent approximately 50% of all women screened. Change in breast density is related to risk of breast cancer.[1] We also must understand this change in density over time in women with dense and non-dense breasts. While population level data have been reported to estimate decrease in density with age, this has largely used digitized film images.[2] Expanding use of digital mammography and repeated screening generates a large library of images for each woman, offering the potential to use more of the image data.
Methods: We use longitudinal latent class analysis to cluster women and estimate their change in density over time. To evaluate the groups of women with different patterns of change in density we fit latent class models to our previously published data.[1] This includes 289 pathology confirmed cases of breast cancer and 658 controls among women followed from November 3, 2008 to October 31, 2020.
Results: Among women with dense breasts, there are 107 who developed breast cancer during follow-up and 267 control women who remained free from breast cancer. In the women without dense breasts, 173 cases and 383 controls were evaluated and showed similar age and BMI within the controls as seen in women with dense breasts. Prevalence of family history and history of benign breast biopsy did not differ between the two groups. We observe this latent class and trajectory of density phenomenal separately for dense and non-dense groups in our data. We show that the data define 2 classes, those who have decrease in density over time and those who have increase over time. The odds ratio (OR) for cancer comparing decline vs. incline is 4.9 in women with dense breasts (BI-RADS C, D) and 6.17 on women with non-dense breasts (BI-RADS A, B).
Discussion: To refine our understanding of patterns of change in breast density over time in relation to breast cancer risk we fit latent class models. Longitudinal change matters as reflected in the 2-class model. This is independent of starting density and confirms that a one-time measure of density is not enough to define level of risk for subsequent breast cancer. Further work is needed to better define the drivers and inhibitors of decline in breast density over time given this change over time as women age is a universal phenomenon.[2]

#4868 Avoiding the pitfalls in developing and validating prediction models for rare outcomes in nested case-control.

B. Rentroia-Pacheco[1], D. Bellomo[2], I. M. Lakeman[3], M. Wakkee[1], L. M. Hollestein[1], D. van Klaveren[4];
[1]Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, Netherlands, [2]SkylineDx, Rotterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Erasmus University Medical Center, Rotterdam, Netherlands

Background: Molecular-biomarker-based prediction models, whether based on statistics or artificial intelligence, are becoming increasingly popular in the medical community as an alternative or complement to more traditional prediction tools, such as staging systems. Population-based cohorts are the preferred study design for building and validating such models, but they are generally expensive and frequently unfeasible, particularly, when the outcome of interest is rare, and when the collected data include expensive or difficult-to-obtain molecular biomarkers. As such, studies often develop or validate risk models in cohorts obtained based on data availability, rather than on the representativeness of a target population. Nested case-control (NCC) is an efficient study design for building and validating such models in a rare outcome setting, but it requires a fully enumerated source population, and appropriate methodologies to accommodate the under-sampling of the controls and any matching. Unfortunately, these methodologies are not systematically described in a form easily accessible to clinicians.
Methods: We systematically characterized how to correctly develop and evaluate the performance of prediction models in NCC cohorts, by weighing the subjects based on sampling probabilities to account for the sub-cohort sampling. We illustrated the use of weighted metrics for the NCC, with a validation of a model that predicts breast cancer development - BOADICEA version 5 - in the population-based Rotterdam study. We used the C-index, threshold-based metrics, observed-to-expected events ratio (O/E ratio), calibration slope, and decision curve analysis as performance metrics. We compared the metrics obtained in the full cohort with those obtained in NCC cohorts sampled from the Rotterdam study, with and without a matched design.
Results: NCC cohorts of 326 women were derived from the full cohort of 4,377 women from the Rotterdam Study. Performance metrics without weight adjustment were biased on the NCC cohorts: the unweighted C-index of the BOADICEA model was 0.61 (0.58-0.63) for the unmatched design. However, with weight adjustment, the C-index in the NCC cohorts (0.65 (0.61-0.69)) corresponds to
the C-index in the full cohort (0.65 (0.62-0.69)), despite the NCC cohort being much smaller in size. Similarly, weighted adjustments of O/E ratio, threshold-based metrics, and net benefit for decision curves were unbiased estimates of the corresponding metrics in the full cohort, while the corresponding unweighted metrics were biased.
Conclusions: We provided a practical guide for clinicians on how to develop and validate prediction models in NCC cohorts. We showed that this study design is an efficient solution, in case of expensive or difficult-to-obtain biomarkers, and when the outcome is rare; but the performance metrics must be appropriately adjusted to the sampling procedure.

#4869 Efficient study design for the discovery of a gene expression signature predicting metastasis in cutaneous squamous cell carcinoma.

B. Rentroia-Pacheco[1], L. Pozza[2], Y. Chen[2], D. Huigh[2], C. J. Eggermont[1], O. F. Steijlen[1], S. Alex[2], J. Dwarkasing[2], D. Bellomo[2], H. J. van de Werken[1], A. L. Mooyaart[1], M. Wakkee[1], L. M. Hollestein[1];

[1]Erasmus Medical Centre, Rotterdam, Netherlands, [2]SkylineDx, Rotterdam, Netherlands

Background: The StepIdent study aims to develop a gene signature predicting metastasis in patients with cutaneous squamous cell carcinoma (cSCC) to improve risk stratification, thus enabling personalized decisions about follow-up schedules and treatment options. Here we describe the unique characteristics, challenges, and best practices for an efficient design of a discovery cohort for a rare outcome (metastasis prevalence: 2-5%); for retrieving, curating, and linking the clinical and pathological data through nationwide databases; and for measuring gene expression through sequencing of archived Formalin-Fixed Paraffin-Embedded (FFPE) primary tumor samples.

Methods: Following a predefined protocol, we identified a nested-case control cohort (NCC) of 305 cases and 305 controls from a nationwide cohort of 19,120 patients with a first cSCC in the Netherlands from 2007 to 2009, followed up until 2020. We chose an NCC design since it is an efficient study design in a rare outcome setting (weighting is needed to accommodate the under-sampling of the controls). Patients were identified from the Dutch National Cancer Registry (NCR) and the clinical information was retrieved from the NCR which is linked to the nationwide registry of histo- and cytopathology (PALGA). Tumor blocks were requested from PALGA, and pathological characteristics were assessed by dermatopathologists. We matched controls to cases, based on a risk score estimated by a clinicopathological model. Gene expression was measured using the Illumina RNA Prep with Enrichment kit combined with the whole exome panel and paired-end sequenced on the NextSeq 550.

Results: Tissue slides for 541 samples were retrieved for sequencing. 151 samples were excluded after pathology review or due to low pre-library concentration. The final cohort includes 195 case-control pairs (n=390). The median sequencing depth was 43M (Q1-Q3: 35-52M); the median Q30 was 85% (Q1-Q3: 83-87%); the median GC content was 51% (Q1-Q3: 50-52%); a median of 1.8% of base pairs (Q1-Q3: 1.4-2.1%) was trimmed prior to the mapping/alignment; a median of 69% (Q1-Q3: 65-74%) of reads were aligned as protein-coding and a median of 7% (Q1-Q3: 6-10%) as rRNA; a median of 95% (Q1-Q3: 93-96%) of reads were aligned by STAR. Two samples were excluded based on quality control.

Conclusion: We described an efficient design and implementation of a nationwide discovery study in cSCC, involving the retrieval of clinicopathological data, the collection of FFPE materials, and the execution of omics measurements. This study presents the largest cohort to date, incorporating omics measurements of primary cSCC samples, combined with simultaneous access to well-curated clinical and pathological information and follow-up data. Our findings can provide guidance for similar studies involving a rare clinical endpoint, where an efficient study design is a necessity.

#4870 Defining metabolically healthy and unhealthy obesity in relation to cancer risk: A prospective cohort study by using a machine learning approach in comparison with conventional definitions in the UK Biobank.

Z. Zhou[1], S. Parra-Soto[1], Y. Lu[2], Z. Fang[2], K. Wang[2], A. Bever[2], L. Tao[2], F. Petermann-Rocha[1], J. Boonpor[1], N. Sattar[1], C. Celis-Morales[1], J. P. Pell[1], F. K. Ho[1], M. Song[2],

[1]University of Glasgow, Glasgow, United Kingdom, [2]Harvard T.H. Chan School of Public Health, Boston, MA

Background: The definition of metabolically healthy and unhealthy obesity for cancer risk remains uncertain and controversial. This study proposed a novel classifier based on biomarkers selected using machine learning (ML) and compared its risk stratification with the conventional definition.

Methods: A prospective cohort study was conducted of 317,569 UK Biobank participants who were free of cancer and with body mass index (BMI) ≥18.5 kg/m^2 at baseline. Individuals were classified into metabolically healthy and non-obese (MHNO), metabolically unhealthy and non-obese (MUNO), metabolically healthy and obese (MHO), and metabolically unhealthy and obese (MUO), according to body mass index (BMI) and six metabolic criteria. For the ML approach, LASSO regularization was used to select a subset from seventeen metabolic biomarkers to optimize C index. Clinical cut-off value was applied to this subset to define MHO. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HRs) of total, obesity-related, type two diabetes (T2D)-related, and 23 site-specific cancers according to the conventional and ML definitions.

Findings: Of 21 biomarkers, 17 were selected using LASSO. Compared with MHNO, individuals with MHO had higher risk of obesity-related cancer ($HR_{conventional}$ 1.22, 95% CI 1.15-1.29; HR_{ML} 1.23, 95% CI 1.16-1.30) and T2D-related cancer ($HR_{conventional}$ 1.25, 95% CI 1.19-1.39; HR_{ML} 1.27, 95% CI 1.20-1.34) after adjusting for sociodemographic and lifestyle factors. ML-defined metabolic status better-stratified individuals with normal weight for risk of total cancer ($HR_{conventional}$1.02, 95% CI 0.99 -1.06; HR_{ML} 1.06, 95% CI 1.02 - 1.10) and some site-specific cancers, e.g., hepatocellular carcinoma ($HR_{conventional}$ 0.89, 95% CI, 0.53-1.48; HR_{ML} 2.52, 95% CI, 1.85-3.45).

Interpretation: Compared with the conventional definition of metabolic health, a broader array of metabolic markers may help better stratify individuals for cancer risk.

Keywords: Obesity, cancer, metabolically healthy obesity, hepatocellular carcinoma.

#4871 Colorectal cancer incidence and overall survival by race, stage, and age: A SEER database analysis, 2009-2020.

A. C. McDonald, S. Joo, J. Ma, M. M. Amonkar, C. Shao, K. Desai, A. C. Deitz;
Merck & Co., Inc., Rahway, NJ

Introduction: In the United States, colorectal cancer (CRC) is the fourth most common cancer and the second leading cause of cancer-related deaths. Although incidence rates of CRC have been decreasing overall, recent studies suggest a shift in demographics, specifically an increase in the number of new CRC cases among younger individuals and a higher incidence among those who identify as non-Hispanic Native American/Alaska Native. To examine the latest trends in incidence and overall survival (OS) among adults with CRC in the United States, we conducted an observational study using the Surveillance, Epidemiology, and End Results (SEER) Program database.

Methods: Patients aged ≥18 years with newly diagnosed CRC between January 1, 2009, and December 31, 2020 were identified in the SEER 17 database. Age-adjusted incidence rates for CRC were calculated by race/ethnicity and age groups (18-49, 50-64, and ≥65 years) from 2009 to 2020. Kaplan-Meier curves were generated to examine 5-year OS by race/ethnicity, stage, and age groups.

Results: There were 429,218 CRC cases identified with a median age of 67 years. Most were male (52.4%) with stage 0-II CRC (51.4%). Most patients identified as non-Hispanic White (66.3%), followed by non-Hispanic Black (11.5%), non-Hispanic Asian/Pacific Islander (8.9%), non-Hispanic Native American/Alaska Native (0.7%), and Hispanic of any race (12.7%). The age-adjusted incidence rate between 2009 and 2020 was 51.9 per 100,000 persons; incidence decreased from 59.5 per 100,000 persons in 2009 to 44.2 per 100,000 persons in 2020, with male patients having a higher incidence rate than female patients. By 2020, non-Hispanic Native American/Alaska Native patients had the highest incidence rate (54.5 per 100,000 persons) followed by non-Hispanic Black patients (50.6 per 100,000 persons). CRC incidence rates increased slightly for age <50 years (10.5 to 12.9 per 100,000 persons) and decreased for ages 50-64 (74.6 to 63.9 per 100,000 persons) and ≥65 years (222.4 to 136.1 per 100,000 persons). Non-Hispanic Black patients (53%), age ≥65 years (47%), and those with stage III-IV CRC (41%) had a lower 5-year OS from 2015 to 2019 compared to patients who were non-Hispanic White (57%), aged 50-64 (68%) and <50 years (70%), and with stage 0-II CRC (77%).

Conclusion: Our results confirm a slight increase in CRC incidence among younger (<50 years) individuals over the 2009-2020 time period. Patients who were non-Hispanic Native American/Alaska Native had the highest CRC incidence rate and patients who were non-Hispanic Black had the poorest OS. Targeted preventative efforts such as CRC screening programs in addition to improved access to care/treatment may be needed to reduce the number of new cases and improve outcomes among historically underserved groups.

#4872 Elevated colorectal cancer incidence among American Indian/Alaska Native persons in Alaska compared to other populations worldwide.

D. Haverkamp[1], D. Redwood[2], E. Roik[2], S. Vindigni[2];
[1]Centers for Disease Control & Prevention, Atlanta, GA, [2]Alaska Native Tribal Health Consortium, Anchorage, AK

Background: Colorectal cancer (CRC) is a leading cancer worldwide. Incidence varies greatly by country and racial group. We present recent CRC incidence and mortality rates among American Indian/Alaska Native (AI/AN) persons in Alaska and compare them to rates among other racial groups in Alaska and AI/AN persons in other regions of the United States, and to published CRC incidence rate estimates for other countries around the world.
Methods: To calculate CRC incidence in the United States, we used U.S. Cancer Statistics data, which includes cancer registry data from the Centers for Disease Control and Prevention's (CDC) National Program of Cancer Registries and the National Cancer Institute's Surveillance, Epidemiology, and End Results Program. Cancer data for AI/AN persons in Alaska came from the Alaska Cancer Registry as well as the Alaska Native Tumor Registry. Death data came from the CDC's National Death Index, which was linked with the Indian Health Service patient registry database to address race misclassification in AI/AN populations, to create the United States Cancer Statistics American Indian and Alaska Native Mortality Database. This database was used to calculate CRC mortality rates for AI/AN persons in this study. Rates were age-adjusted using the World Health Organization's World Standard Population (2000-2025), so that rates for AI/AN persons in the United States could be more comparable to rates that have been estimated for countries around the world. Estimates of worldwide CRC incidence came from the International Agency for Research on Cancer Global Cancer Observatory GLOBOCAN 2020 database.
Results: AI/AN persons in Alaska (males and females combined) had the highest CRC incidence rate (58.4 per 100,000 people) in the year 2020, when compared to AI/AN persons in every other region of the United States. Within Alaska, AI/AN persons had a higher CRC incidence rate than persons of any other racial group. When compared with published CRC incidence rates worldwide, the rate for AI/AN persons in Alaska was higher than the rates reported for any country in the world in 2020. The country with the highest recorded CRC incidence rate in 2020 was Hungary (45.3 per 100,000 people). AI/AN persons in Alaska also had the highest CRC mortality rate (27.1 per 100,000 people) in 2020. Worldwide, the country with the highest recorded CRC mortality rate in 2020 was Slovakia (21.0 per 100,000 people).
Conclusions: This review of CRC incidence and mortality rates from populations in the US and worldwide showed that AI/AN persons in Alaska had the highest documented incidence and mortality rates of CRC in the world in 2020. Health systems serving AI/AN persons in Alaska could implement policies and interventions that support colorectal cancer screening, to reduce the burden of this preventable disease.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Application of Bioinformatics to Cancer Biology 4 Poster Session

#4876 Data-driven discovery of cancer-specific targets for hepatocellular carcinoma using spatial transcriptomics.

Sungwoo Bae[1], Dongjoo Lee[2], Daeseung Lee[2], Kwon Joong Na[2], Suk Kyun Hong[3], YoungRok Choi[3], Nam-Joon Yi[3], Kwang-Woong Lee[3], Kyung-Suk Suh[3], Hongyoon Choi[2]

[1]Institute of Radiation Medicine, Medical Research Center, Seoul National University, Seoul, Korea, Republic of,[2]Portrai, Inc., 78-18, Dongsulla-gil, Jongno-gu, Seoul, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Hepatocellular carcinoma (HCC) is frequently diagnosed in advanced stages, with limited options available for systemic treatment. Given the significant investment of time, the high costs, and the notable failure rates involved in developing new drugs, it is crucial to identify appropriate cancer-specific surface targets, especially aiming at antibody drug conjugates and radioligand therapy. This study aims to propose a pipeline utilizing spatial transcriptomics (ST) to prioritize potential cancer-specific surface targets for HCC.

Methods: Visium ST samples were collected from fresh-frozen tissues of HCC patients undergoing hepatectomy. The spots with over 500 expressed genes and a mitochondrial gene percentage below 20% were selected. Counts were normalized with sctransform, and the tumor cell proportion in each spot was predicted using CellDART. Cancer region-specific genes were identified based on three criteria: high topological overlap with tumor cell distribution (using STopover), a high correlation coefficient with tumor cell proportion, or significantly higher expression in the tumor cell cluster compared to others in single-cell RNA-sequencing dataset. Genes identified through these methods were pooled and filtered based on average expression in the whole tissue using human normal cell atlas data and surface proteins. To select drug candidates with low normal organ toxcity, Tabula Sapiens datasets were used. Genes expressed in over 50% of cells and with an average expression above 1 in any critical organs were excluded.

Results: One ST sample was obtained from each of the 7 HCC patients. The topology, correlation, and single-cell-based criteria resulted in 42, 15, and 7 genes, respectively, with only 1 gene (*P4HB*) overlapping across all three methods. After filtering genes with high expression in normal organs based on Tabula Sapiens, 25 genes remained. In the GEPIA databases, *GPC3* exhibited the highest log fold change in RNA expression between HCC and normal liver (6.280), followed by *TM4SF4* (2.156), *EFNA1* (0.581), *GJB1* (0.498), and *IRS1* (0.391). To externally validate the results, 17 ST datasets from 5 patients provided by HCCDB were used. Among the selected genes, only *GPC3* and *EFNA1* had higher average expression in the tumor compared to other compartments (normal, stromal, and immune) in at least 3 out of 5 patients.

Conclusion: The proposed platform prioritizes cancer-specific surface targets for HCC, focusing primarily on spatial gene expression profiles obtained from ST and gene expression data from external databases. This analytical tool can be further utilized to identify molecular targets for developing antibody drug conjugates or radioligand therapies, which are designed to specifically deliver therapeutic agents to the tumor.

#4877 Morphological detection of chemotherapy resistance in cancer cell lines using AI-based analysis.

A. Jovic[1], M. Ray[1], R. Carelli[1], K. Saini[1], T. Pham[1], C. Corona[1], S. C. Boutet[1], C. Johnson[1], M. Salek[1], M. Masaeli[1], M. Barnes[2], C. Y. Ramathal[2]; [1]Deepcell Inc., Menlo Park, CA, [2]Abbvie, Chicago, IL

Chemoresistance can develop during the course of treatment of many cancers, which can limit the utility of standard therapeutics and lead to poor outcomes. The mechanism by which resistance arises is not well understood, and developing models to study resistance can be challenging. Resistance can spontaneously arise in cell lines, however, it is difficult to separate resistant from sensitive cells using traditional biomarkers, hampering their utility for studying mechanisms. Morphology presents another modality to examine resistance, independently of protein markers, and may solve a previously intractable problem of separating resistant from sensitive cells for further study.

Here we sought to study the mechanism of chemoresistance in cell lines using multi-parameter morphology in combination with gene expression and other standard molecular approaches. We induced resistance to specific chemotherapeutic drugs in parent cancer cell lines from lung, ovarian, and melanoma cancers. IC-50s of each drug increased by ≥1 order of magnitude in the resistant cells. Whole exome sequencing and bulk RNAseq were performed to examine differentially expressed genes and pathways between the parent and resistant cell lines.

Each cell line was analyzed using multi-dimensional morphology using the Deepcell platform, which extracts >100 morphological features from images of unlabeled single cells using artificial intelligence (AI), advanced imaging, and microfluidics. The morphology features represent both Deep Learning (DL)-derived features and human-interpretable morphometric features, such as size and shape. Unique morphotypes were observed differentiating each combination of parent and resistant cell lines, with notable changes in granularity distinguishing them. A subset of images was used to train a random forest classifier to predict the resistant state of each cell image, which performed with up to 85% accuracy on independent cell images. Strikingly, the combination of DL plus morphometric features outperformed the use of morphometric features alone, demonstrating the increased utility of combined analysis. The top gene pathways and top morphological features were examined to infer potential mechanisms underlying chemoresistance.

This work demonstrates that morphology alone can be used to distinguish drug resistant vs. parent populations without the use of markers. Morphology analysis can be applied to understanding complex phenotypes, and future platform improvements will enable sorting of these resistant populations to better identify molecular pathways in both cell lines and in primary tumor samples.

#4878 Enhancing non-invasive detection of urothelial carcinoma through combined cytology and methylation profiling of urinary cell-free DNA.

H. Zhao[1], **H. Dong**[2], H. Tang[2], Z. Zhang[1], N. Wei[3], J. Xu[3], P. Du[2], S. Jia[2], T. Xiao[4], H. Guo[1];

[1]National Cancer Center/National Clinical Research Center for Cancer /Cancer Hospital, Chinese Academy of Medical sciences and Peking Union Medical college, Beijing, China, [2]Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China, [3]the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [4]National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Detection of urothelial carcinoma (UC) faces a significant challenge in sensitivity due to the limitations of existing methodologies such as cytology. Identifying tumors through epigenetics pattern presents a promising advancement in diagnostic precision. This study aims to explore a non-invasive and more sensitive strategy by analyzing urinary cell-free DNA (ucfDNA) methylation profiles in conjunction with traditional urine cytology. The cohort for this study were collected from 20 patients with UC and 17 patients with benign or non-tumor lesions which histopathologic and cytopathologic results were reviewed by pathologist. Additional 16 cancer samples and 40 healthy donor samples were collected from independent research centers. We employed PredicineEPIC, a comprehensive whole-genome methylation assay, to investigate the DNA methylation characteristics in urine samples. The dataset was splited into 1:2 proportions for modeling and validation. The methylation signals were fed to three machine learning algorithms for determining the most effective classification model. Differentiating cancer and benign samples through urinary cytology has high specificity (1.0) but low sensitivity (0.3). Then we examined differentially methylated regions and implemented four most abnormally methylated regions as classify features. We found that the Gradient Boosting Machine (GBM) model achieved optimal performance in the validation set, with an AUC of 0.93, sensitivity of 0.81 (21/26), and specificity of 1.0 (36/36). The combination of methylation- and urine cytology-based models raised 2% prediction accuracy without reducing precision, suggesting that this assay could be applied to augment the cytology testing for UC detection. This study proposes a new and promising approach, leveraging cytology combined with epigenetic profiles of urinary cell-free DNA, for the precise diagnosis of urothelial carcinoma.

#4879 Delineating lymphocyte aggregates from tertiary lymphoid structures using spatial transcriptomics.

J. Krull, A. Byappanahalli, Y. Jiang, A. Gunderson, Q. Ma;
The Ohio State University, Columbus, OH

Tertiary Lymphoid Structures (TLSs) are ectopic lymphoid structures that form in chronically inflamed non-lymphoid tissue. The presence of TLSs in tumors is largely associated with favorable outcomes among patients and also exhibit positive associations with response to immune checkpoint blockade. Although mainly comprised of lymphocytes (B cells and T cells), they are considered a separate entity from lymphocyte aggregates within tissue. Lymphocyte aggregates are fairly routine to identify in H&E stained tissue sections, but delineating TLSs from simple lymphocyte aggregates is subjective and not clearly defined. Additionally, the definition of TLSs is only recently being elucidated, so a clear molecular definition of both TLSs and lymphocyte aggregates is needed. To address this problem, we leveraged open-source spatial transcriptomics (ST) data from 17 samples across 7 cancer types. High resolution H&E images were manually evaluated for lymphocyte aggregates by identifying dense pockets of lymphocytic-appearing nuclei. Suspected aggregates were detected in 10 of 17 samples. We then applied a visium spot-level signature scoring method for 4 well published TLS signatures. Of the spots identified, 62% had enhanced signature expression for at least 2 of the signatures, although most of the incorrect annotations came from the lone gastric cancer sample. Differential expression between a TLS-sig- suspected lymphoid aggregate and a TLS-sig+ region not identified by H&E enriched primarily for B cell identity genes, suggesting B-cell-rich TLSs may not always appear as lymphoid aggregates in histology. [AG1] Strikingly, ST revealed strongly positive enhancements in the TLS signatures, where no annotations were made, and no obvious lymphoid aggregation was present, suggesting manual annotation from H&E is inadequate for identifying TLSs. Together, these results demonstrate that literature derived TLS signatures can correctly identify lymphoid aggregates as TLSs and that cellular and molecular differences between standard lymphoid aggregates and TLSs may be smaller than is currently accepted.

#4880 Identification and clinicopathological analysis of potential p73-regulated biomarkers in colorectal cancer via integrative bioinformatics.

C. Bareja, K. Dwivedi, A. Uboveja, A. Mathur, N. Kumar, D. Saluja;
University of Delhi, New Delhi, India

This work aims to decipher p73-regulated biomarkers for a prompt diagnosis of colorectal cancer (CRC) by employing a combination of integrative bioinformatics and expression profiling technologies. Transcriptome profile of HCT116 cell line p53−/− p73+/+ and p53−/− p73 knockdown was performed to identify differentially expressed genes (DEGs) followed by cross-checking with three CRC tissue expression datasets available in Gene Expression Omnibus. KEGG and Gene ontology were performed on differentially expressed transcripts obtained via the transcriptome profile and intersected genes. The PPI network was constructed via Cytoscape to extract hub genes. KM plots assisted in investigating the prognostic significance of the hub genes. The clinicopathological relevance was explored using the GEPIA and UALCAN databases. Finally, machine/deep learning algorithms were employed to perform TNM-stage classification. Transcriptome profiling revealed 1,289 upregulated and 1,897 downregulated genes. When intersected with employed CRC datasets, 284 DEGs were obtained. The analysis of gene ontology and KEGG showed enrichment of the DEGs in metabolic process, fatty acid biosynthesis, etc. The PPI network constructed using these 284 genes assisted in identifying 20 hub genes. Kaplan Meier, GEPIA, and UALCAN analyses uncovered the prognostic and diagnostic relevance of these hub genes. Conclusively, the deep learning model achieved TNM-stage classification accuracy of 0.78 and 0.75 using 284 DEGs and 20 hub genes, respectively. This is a novel study utilizing transcriptomics, publicly available tissue datasets, and machine learning to unveil key CRC-relevant genes. These genes are found relevant regarding the patients' prognosis and diagnosis. The unveiled biomarkers are also found robust in TNM-stage prediction. This is the first study where transcriptomics, publicly available tissue datasets, and machine learning are altogether employed to reveal key genes in CRC pathogenesis. Our research highlights the robust analysis of four independent data sets to find the key hub genes, further predicting the performance of the key genes in stage-wise classification.

#4881 Detecting cancer microbiota using unmapped RNA reads on spatial transcriptomics.

Jeongbin Park[1], Seo Hye Park[1], Dongjoo Lee[1], Jae Eun Lee[1], Daeseung Lee[1], Kwon Joong Na[2], Hongyoon Choi[3], Hyung-Jun Im[4]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, Korea, Republic of,[4]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background: Recently, the study of microbiota has emerged as a novel area in cancer research. While next-generation sequencing (NGS) technologies are becoming more prevalent in the area, the acquisition of spatial information in microbiota is still challenging. Despite the possibility of detecting microbial RNAs on Visium (10X genomic, USA), methods depending on predefined host and microbial references cannot reliably capture microbial RNA reads, since Visium inherently lacks the ability to capture RNAs that are missing poly-A tails. Therefore, a reference-independent microbial RNA detection method needs to be developed for more trustworthy research on cancer microbiota on Visium.
Methods: Initially, we reconstructed Visium data from a public raw dataset (Project: PRJNA811533, European Nucleotide Archive) derived from colorectal cancer (CRC) and oral squamous cell carcinoma (OSCC). BAM files were obtained by running Space Ranger on a human reference, GRCh38. These BAM files were firstly separated according to spatial barcodes with samtools and xargs. Then, microbial scores for each barcode were obtained using PathSeq. On the other hand, barcode-wise unmapped reads were extracted from the original BAM files simply by remaining unmapped reads, sorting them by spatial barcodes, and counting the number of reads. Then, the unmapped reads originating from host RNA reads were eliminated by regression analysis, remaining the microbial RNA reads. Subsequently, we conducted a comparison of microbial RNA reads from two different techniques.
Results: By filtering out the unmapped reads associated with the host, microbial reads could be isolated. While these remaining microbial RNA reads show a significant correlation with the PathSeq scores, the unmapped reads were significantly higher than the PathSeq scores, increasing the statistical power for the downstream analysis with unmapped reads. Additionally, tissue regions with low PathSeq scores and high volumes of non-human unmapped reads were identified. These regions may indicate the presence of microbial sequences or RNA species that were not detected in the PathSeq analysis.
Conclusion: The use of unmapped reads enables us to capture a greater number of RNA transcripts compared to PathSeq to indirectly analyze cancer microbiota. This means that we can observe hard-to-identify RNA variants, such as unstable RNAs or new species originating from the interaction between microbial RNAs and host RNAs. Our methods can provide plausible explanations for the existence of microbial RNAs on Visium, and we suggest a reference-independent detection of cancer microbota reads by utilizing unmapped reads.

#4883 *NFE2L3* regulates the expression of *BHLHE40* in triple-negative breast cancer.

S. Modi, T. Andey, G. Acquaah-Mensah;
Massachusetts Col. of Pharmacy & Health Sci., Worcester, MA

Introduction: Breast Cancer (BrCA) is one of the most common cancers, causing mortality in women worldwide. Among the subtypes of breast cancer, triple-negative breast cancer (TNBC) is the most aggressive due to the absence of three major receptors: estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor-2 (HER-2). Treatment options for TNBC are limited because of the lack of these molecular targets. We hypothesized that the identification and characterization of novel transcriptional regulatory relationships in TNBC will provide etiologic insights, enhance therapeutic outcomes, and improve patient survival. Overexpression of *NFE2L3* in BrCA has inhibited cell proliferation and metastasis while overexpression of *BHLHE40* has produced an inverse effect. This study aims to characterize the relationship between *NFE2L3* and *BHLHE40* in TNBC cells.
Methods: Patient data from the two groups of our focus from the Cancer Genome Atlas BrCA RNAseq gene expression dataset were examined: triple-positive breast cancer (TPBC) and TNBC. Differentially expressed genes (DEGs) between these groups were identified using DESeq2. Pathways over-represented among the DEGs were determined using enrichR. For their impact on biological interactions, those DEGs were mapped to curate protein-protein interactions - the STRING database. Additionally, DEGs were superposed on two network inference algorithm-generated transcriptional regulatory networks (TRNs). Virtual Inference of protein activity by Enriched Regulon analysis was applied to the generated TRN to identify master regulators driving gene expression differences between TPBC and TNBC. Of the master regulators observed, the activity of NFE2L3 was explored in TNBC cells. The TRNs indicate that NFE2L3 regulates the expression of BHLHE40. This regulatory relationship was explored in TNBC cells by RNA interference, qRT-PCR, immunoblotting, and co-immunoprecipitation assays to investigate *NFE2L3* and *BHLHE40* gene and protein expression and interaction.
Results: Among 12,000 DEGs (5% FDR), over-represented pathways included "*mitotic signaling"* and *"G1/S transition*". Master regulators with higher expression in TNBC included NFE2L3, HMGA1, TP53, FOXC1, and SOX9; those with lower expression included FOXA1, BHLHE40, AR, XBP1, and ESR1. On silencing the cells of *NFE2L3* and performing qRTPCR analysis, the expression of *BHLHE40* was decreased in the TNBC cells. The protein-protein interaction between NFE2L3 and BHLHE40 was also validated.
Conclusion: DEGs up-regulated in TNBC participate in cell cycle signaling. And there is a novel transcriptional regulatory relationship between *NFE2L3* and *BHLHE40* in TNBC cells.

#4884 Evaluating the utility of *in silico* variant annotation tools for cancer driver detection.

M. Madhumita, Z. Sondka, J. Teague;
Wellcome Sanger Institute, Cambridge, United Kingdom

In cancer genomics, precise variant annotation is crucial for clinical decisions, drug development, and research. The burgeoning genomic data offers an opportunity to use data-driven approaches to generate knowledge that supports clinical decisions. Particularly machine learning (ML) and Deep learning (DL), are becoming essential, as their application is fast, scalable, simple to implement, and generates reproducible results. The methods ranging from simple sequence-based alignment scoring to advanced algorithms like Logistic regression, Support vector machine, and Recurrent neural networks, have been employed by multiple variant annotation tools. This study compares *in-silico* methods available in Ensembl's Variant Effect Predictor (VEP) using a test dataset with COSMIC annotations.

ML/DL success relies on robust training sets with comprehensive genomic variants features, including effects on transcription/translation, genomic context, annotation resources, *in silico* pathogenicity predictions, and population allele frequency. The training set, composed of known benign or pathogenic variants, serves as a reference for these algorithms to classify new and unseen variants. Our analysis reveals a limited concordance between the prediction algorithms. Despite comparable true/false positives/negatives, discrepancies persist in variant classification. Certain algorithms exhibit a propensity to over or under-call deleterious mutations. Some demonstrate a tendency to classify random variants in non-cancer genes as deleterious. Challenges include the absence of consensus on informative features, diverse training datasets, and restriction to well annotated proteins/transcripts.

Balancing the sensitivity and false positives in detecting cancer drivers is crucial. Integrating individual prediction scores with ML algorithms enhances tool performance but comes with risk of error propagation, and limited accuracy. The study emphasises the need for context-specific variant classification tools, as many variants' impacts are cancer-type specific, and some may drive disease synergistically. Existing tools, designed for a "one variant - one score approach," struggle to capture complex associations, especially those dependent on changes in the tumour microenvironment.

Highlighting areas for improvement, the study addresses the "black box" problem in decision processes. While limited interpretability might not hinder practical applications, tools should evolve to assess more complex associations guided by biology. Formal consensus, reference training datasets, and standards are deemed essential for developing next-generation tools. The envisioned context-dependent tools aim to streamline feature complexity, thereby mitigating the black box problem and advancing the accuracy and interpretability of cancer variant annotation.

#4885 Integrating mutational profiles and transcriptional data with *ASTUTE* to elucidate the key molecular functions involved in the pathogenesis of cancer.

V. Crippa, D. Fontana, I. Civettini, L. Mologni, R. Piazza, C. Gambacorti-Passerini, D. Ramazzotti;
University of Milano-Bicocca, Monza, Italy

Cancer is a highly heterogeneous disease characterized by genomic and phenotypic changes that differ among tumor subtypes. A comprehensive understanding of the molecular heterogeneity is crucial for identifying molecular biomarkers and developing targeted therapies. While recent years have seen significant progress in genomic studies and advancements in next-generation sequencing technologies, elucidate the impact of individual genomic alterations on the transcriptome landscape of cancer cells remains essential. This knowledge is crucial for developing personalized therapies. To integrate mutational profiles and transcriptional data, we have developed a novel computational framework named ASTUTE (Association of SomaTic mUtaTions to Expression). ASTUTE establishes associations between somatic mutations and gene expression profiles, quantifying the results as fold changes and comparing the effects of individual mutations. In particular, ASTUTE leverages LASSO regularized regression for feature selection, identifying the most relevant mutated genes that exhibit a strong association with expression levels. Our goal is to create a valuable resource for identifying diagnostic markers and advancing the development of targeted therapies in cancer. To this end, we applied ASTUTE to two published bulk RNA-seq datasets of adult acute myeloid leukemia (AML) patients from the Beat AML program and the TCGA study to verify the capacity of our approach to identify genes whose expression correlates with the presence of specific somatic mutations. The first dataset comprises 585 samples, while the second one includes 173 specimens, both of them contain mutations and RNA-seq data. We executed ASTUTE on the two datasets independently, considering all genes for RNA-seq data and the alterations in the top 10 most mutated genes. We considered the associations consistently discovered in both cohorts. Our analysis revealed a strong association between NPM1 mutations and the expression of HOX genes. Specifically, HOXB6, HOXB5, HOXB3, HOXA5, HOXB2, and HOXA10 exhibited a log2 fold change higher than 1.5. The upregulation of these genes has been reported in association with NPM1 mutations in AML adult patients. Additionally, ASTUTE identified HOXA6, HOXA7, HOXA4, and HOXA9, whose expression has been described to be upregulated in the presence of NPM1 mutations in AML pediatric samples. Finally, we identified a robust relationship between NPM1 mutations and the expression of PBX3, MEIS, and ITM2A. The first two genes are upregulated in the presence of NPM1 mutations, while the third one is downregulated. Our analysis showcases ASTUTE's capability to identify potential markers and underscores the possibility to apply ASTUTE to different tumors datasets, with the aim to better characterize cancer heterogeneity and develop targeted therapies.

#4886 An in-depth single-cell map of inflammatory breast cancer reveals wide-scaled restructuring associated to an immunosuppressive and inflammation-like microenvironment.

P. Schwerd-Kleine[1], T. Cheytan[1], R. Wurth[1], E. Gutjahr[2], L. Michel[3], V. Thewes[4], P. Lichter[4], A. Schneeweiss[3], A. Trumpp[1], M. Sprick[1];
[1]German Cancer Research Center (DKFZ), Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), German Cancer Consortium (DKTK), Heidelberg, Germany, [2]Institute of Pathology, University of Heidelberg, German Cancer Research Center (DKFZ), Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), German Cancer Consortium (DKTK), Heidelberg, Germany, [3]Division of Gynecological Oncology, National Center for Tumor Diseases (NCT), Heidelberg, Germany, Heidelberg, Germany, [4]Division of Molecular Genetics, German Cancer Research Center (DKFZ), National Center for Tumor Diseases (NCT) Heidelberg, Germany, Heidelberg, Germany

Inflammatory Breast Cancer (IBC) has increasingly been recognised as a distinct form of breast cancer, that is characterised by its distinctive clinical presentation, as well as its fast onset and poor prognosis. Despite previous efforts, the underlying molecular heterogeneity of IBC remains poorly understood. We used single-cell transcriptomics to dissect the transcriptional landscape of IBC at single-cell resolution, and elucidate differences to non-inflammatory breast cancer (non-IBC), of which we created and curated a subtype-matched comparison dataset. Our analysis revealed a previously underappreciated role of the microenvironment in driving the immune suppressive and angiogenic phenotype of IBC. Furthermore, we identified key transcriptional signatures associated with IBC aggressiveness, including dysregulated pathways across all major cell compartments. Within each compartment, we used a combination of approaches to assign functional roles to subsets of cells, including expression of marker genes, gene programmes and projection onto thoroughly annotated reference-spaces. We thus identify cell populations present in significantly different proportions between IBC and non-IBC. Interestingly, among the populations enriched in IBC we identified iCAFs, pro-inflammatory M1-like myeloid cells as well as regulatory T cells. In non-IBC on the other hand, enriched cell types include myCAFs, M2-like myeloid cells and cytotoxic T cells.In addition to differences in the cell composition, we also find differences in the expression of certain markers and gene programmes. A pseudo-time analysis of T cells reveals a shift towards an exhausted T cell phenotype in IBC, in line with a lower expression of HLA genes in its epithelial compartment. In agreement with the known angiogenic phenotype, we also see an enrichment in mitogenic signatures in IBC-associated endothelial cells. In summary, our data describe an immunosuppressive environment, highlighted by the presence of cell types with an inflammation-like phenotype, signs of immune evasion and exhaustion and angiogenesis. Our comprehensive and unique single-cell transcriptomic dataset of this rare form of breast cancer provides valuable insights into the complex cellular composition of IBC, offering a foundation for further functional exploration of involved pathways, and finally development of new targeted therapy approaches. Our study contributes to a deeper understanding of IBC biology and pathology, enabling future identification of direly needed biomarkers and therapeutic approaches for this hard-to-treat breast cancer type.

#4887 Unveiling the functional impact of glioma non-coding germline variants using large language models.

M. Alvarez-Torres, X. Fu, R. Sagatelian, A. Buendia, R. Rabadan;
Columbia University, New York, NY

Efforts to identify the risk for developing gliomas through Genome-Wide Association Studies (GWAS) face relevant challenges, such as accurately pinpointing the genomic positions of germline variants, primarily found in non-coding regions, with unclear functional implications in glioma development. In this context, the GET method, a large language model designed to unveil regulatory grammars across 213 human cell types, emerges as a valuable tool for elucidating the mechanisms of non-coding mutations.

Our aims include: I) Validate the efficacy of the GET method using a well-documented case and prioritize relevant variants for analysis; II) Refine the genomic positions of these variants and exploring their linkage disequilibrium (LD); III) Identify potential motifs and genes that might be influenced by these high-impact variants.

After examining published GWAS, 39 non-coding SNPs in gliomas were found. Adding 316 variants in high LD (R2 > 0.8) expanded the dataset to 355 variants for analysis. Using the GET method, we calculated impact scores (ISs) for each variant, considering changes in motif binding score (ΔBM) and motif gradient (GM) across human astrocytes. We focused on rare variants (risk allele frequency <0.25) with the higher odds ratios (OR).

The table presents GET results for a well-known case-control, showing its role in increasing glioma risk through OCT4 motif disruption and enhanced MYC expression, as previously was confirmed experimentally. Moreover, it details results concerning the 5 rare germline variants exhibiting the highest ISs, including precise genomic positions and the most affected motifs and genes that could potentially be impacted by each variant.

	Variant ID	**Genomic Position**	**Altered Motif**	**Affected Gene**	**Ref allele**	**Alt allele**
Case-control	rs55705857	Chr8:129633445	OCT4+SOX2:POU	MYC	A	G
H-I variant #1	rs78378222	Chr17:7668433	HD/18	PER1	T	G
H-I variant #2	rs518394	Chr9:22019673	KLF/SP/2	CDKN2A	G	C
H-I variant #3	rs79495512	Chr15:76199995	KLF/SP/2	LINGO1	T	C
H-I variant #4	rs78185702	Chr15:76317893	SMAD	LINGO1	C	T
H-I variant #5	rs2538067	Chr7:54907724	CTCF	EGFR	G	A

Using a large language model, this study overcomes the challenge of mere variant identification, aiming to establish a framework for uncovering the underlying mechanism of risk variants. While further validation is essential, this is a promising approach to explore the impact of germline mutations.

#4888 Multi-modal knowledge graphs enhance patient stratification & biomarker discovery.

Background: Multi-modal analysis is crucial for deeper understanding of disease subtypes and more meaningful patient selection. We developed a flexible Knowledge Graph (KG) framework that enables deep multi-omic analysis. It can be used to uncover the interrelationships between the layers of data in a population to inform patient selection or biomarker discovery. We present an application of our framework to non-small cell lung cancer (NSCLC) to identify and separate communities of patients based on their survival and identify the associated biomarkers. We identified potentially mislabeled patients that do not share all the characteristics of the cancer subtype to which they are assigned: either lung adenocarcinoma (LUAD) or lung squamous cell carcinoma (LUSC). Crucially, the community-based biomarkers for poor or long survivors were validated on the whole population.
Methods: Our KG framework was leveraged by applying supervised community detection to NSCLC data from TCGA, specifically RNA expression and DNA methylation, with overall survival (OS) as the endpoint (n=999 subjects). Biomarkers associated to each community were ranked based on their prevalence inside against their prevalence outside the community.
Results: We obtained 3 communities (391 + 229 + 379 patients) that are all significantly separated by their OS ($p<0.05$). While KG-derived communities largely overlapped with histology-labelled LUAD or LUSC (concordant LUAD (n=330) / concordant LUSC (n=342)), a small number of patients did not (discordant LUAD (n=37) / discordant LUSC (n=61)). Discordant LUAD patients had significantly lower OS than concordant LUAD ($p=0.0198$), despite being both labeled as LUAD. Many of the discordant LUSC lacked the 3q26 amplification commonly seen in LUSC and other squamous cell carcinomas. The results from our KG framework highlight its increased sensitivity in relation to existing tools (Cline, *Sci Rep* 3, 2652 (2013)) as we identified a discordant LUAD group in addition to a discordant LUSC group. Moreover, our tool can select the biomarkers most prevalent in each community, and these significantly separated long from poor survivors on the whole population ($p=3.53e-5$). Some of these KG-identified biomarkers are known regulators of progression and survival in NSCLC, whereas others are still not extensively studied. This highlights another advantage of our approach in prospective target discovery.
Conclusions: Our KG framework allowed the observation of potential misclassifications of tumor subtypes in NSCLC (TCGA). This approach is a proof-of-concept of the value KGs have in identifying signals in muti-omic data that may improve patient stratification and uncover associated biomarker signatures. Our flexible end-to-end framework can take any type of ‘omic data and can be applied to any tumor type for such findings, which represents an alternative to pre-defined KG architectures with defined relationships.

#4889 Integrative multi-omic analysis reveals novel prognostic biological entities in pediatric medulloblastoma.
